Exposure to traumatic events has been associated with increased risk for multiple health conditions such as cardiovascular disease and type 2 diabetes, and with all-cause mortality. It remains unclear if it is the exposure to trauma and/or the experience of subsequent psychological distress (e.g., post-traumatic stress disorder [PTSD], depression) that deleteriously affects physical health. US Latinos experience a high rate of cardiometabolic conditions (e.g., type 2 diabetes, hypertension) and are disproportionally affected by poor outcomes. Undocumented Latinos may be at increased risk for trauma exposure due to unique stressors (e.g., migration). This cross-sectional quantitative study evaluated the association between previous trauma exposure, current psychological distress, and self-reported cardiometabolic conditions, among a sample of undocumented Latinos (n=254) living in southern California and recruited through respondent driven sampling (69.3% female; 63% 18-40 years old; 97.6% Mexican; mean years living in US=16.4±8; 64.9% completed ≤ middle school). Structured clinical interviews were conducted to assess for exposure to potentially traumatic events relevant to immigrants and refugees (Harvard Trauma Questionnaire, adapted), current PTSD and Major Depressive Disorder (MINI International Neuropsychiatric Interview), and self-reported cardiometabolic conditions (type 2 diabetes, hypertension, hyperlipidemia, and heart disease). Approximately 27% of participants reported at least one cardiometabolic health condition. 49% had experienced confinement/robbery, 48.6% material deprivation, 44.7% a loved one injured due to violence, 45.1% a bodily injury due to violence, 39.9% war conditions, 22% had experienced a deportation, and 13.4% witnessed violence towards others. In a logistic regression model adjusting for demographic covariates (age, sex, income, years in the US), having experienced any traumatic event significantly increased the odds of reporting at least one cardiometabolic condition (OR=3.42

[1.20, 9.75]). In a final model that also accounted for PTSD and depression, trauma exposure remained significantly associated with increased likelihood of cardiometabolic conditions (OR=3.08 [1.06, 8.95]), while current PTSD and/or depression was not (OR=1.79 [0.82, 3.90]). Results suggest that trauma exposure may be associated with poor cardiometabolic health among Latinos, above and beyond the effects of psychological distress, which has important clinical implications.

CHANGE TALK, BEHAVIORAL WILLINGNESS, AND COLLEGE ALCOHOL USE: A MEDIATION ANALYSIS

Benjamin Ladd, Ph.D.[1], Kristen Anderson, Ph.D.[2]

[1]Washington State University Vancouver, Vancouver, WA; [2]Reed College, Portland, OR

Introduction: Change talk (CT), or self-motivational statements promoting health behavior, predicts subsequent behavior change and is theorized to be an important mechanism of change underlying psychotherapies, particularly motivational interviewing. However, the mechanisms by which in-session language influences health behavior change is understudied. The current study examined whether the relationship between CT and alcohol use is mediated by behavioral willingness (BW), a proximal variable in the decision-making process. **Method:** Participants (*N* = 76) were first-year college students assessed at the beginning of the academic year (*M* = 10.7, *SD* = 7.8 days in college). Participants completed the Collegiate Simulated Intoxication Digital Elicitation (C-SIDE), during which participants view five simulated drinking scenarios. After each scene, participants reported their BW to accept each offer of alcohol or food/nonalcoholic beverages (control offers) on a 5-point scale. Participants' verbal behavior was recorded using a free-response open elicitation at predetermined points throughout the C-SIDE and then transcribed and coded for occurrences of CT and its counterpart, sustain talk (ST). Percent change talk (PCT) was computed as CT/(CT + ST). Participant alcohol use was assessed at baseline and 8-month follow-up. Regression analyses were conducted using the PROCESS macro in SPSS24. **Results:** Controlling for baseline alcohol use, the total effect of PCT on alcohol use eight months later was significant, *B* = -0.99, *SE* = 0.37, 95% CI (-1.73, -0.26). This effect was mediated by alcohol BW, such that the direct effect of PCT on alcohol use was nonsignificant, *B* = 0.37, *SE* = 0.51, 95% CI (-0.64, 1.38) while the indirect effect through BW was significant, *B* = -1.37, *SE* = 0.36, 95% CI (-2.17, -0.74). **Discussion:** The effect of PCT on subsequent alcohol use was significantly mediated by BW. Greater PCT was associated with less alcohol use eight months later. This relationship is explained by BW such that greater PCT led to lower BW which in turn resulted in lower alcohol use. These results suggest the influence of client language on health behavior may work through changes in more proximal factors of the alcohol use decision-making process. This research may help researchers and clinicians begin to understand how client language in non-therapeutic settings leads to desirable health behavior change in patients' lives.

EXAMINATION OF THE HEPATITIS C VIRUS CARE CONTINUUM AMONG INDIVIDUALS WITH AN OPIOID USE DISORDER IN SUBSTANCE USE TREATMENT

Jennifer L. Brown, Ph.D., Theresa Winhusen, PhD, Nicole Gause, M.A., Daniel Lewis, BA

University of Cincinnati, Cincinnati, OH

Background: For individuals with an opioid use disorder (OUD), risk of Hepatitis C Virus (HCV) transmission and acquisition is elevated, particularly through drug use behaviors including injection drug use (IDU) or sharing needles and other injection paraphernalia. The CDC, U.S. Preventive Services Task Force, and Institute of Medicine recommend routine HCV testing for high-risk individuals, which includes those with a history of IDU. HCV antibody testing addresses the first step in the HCV treatment care cascade. Uptake and completion of HCV treatment among individuals with chronic HCV is the optimal endpoint of the care cascade; however, there is some evidence to suggest that there may be gaps in the HCV care continuum. Thus, the aim of the current study was to characterize the HCV treatment cascade including: HCV testing, acute HCV diagnosis, chronic HCV diagnosis, and receipt of HCV treatment among individuals with an OUD engaged in outpatient methadone or buprenorphine assisted substance use treatment.

Methods:Individuals receiving methadone or buprenorphine outpatient treatment (*N* = 202, 67.8% female, *M* age = 35.0, *SD* = 8.4) completed a brief, anonymous paper-and-pencil survey assessing history of HCV testing, diagnosis, and treatment.

Results: 65.1% reported either no prior HCV testing or not being tested for HCV during the past year. 42.7% of those with a lifetime HCV testing history indicated they had been told they had HCV (n=67/157), with 21% (n=14/67) of those individuals reporting that they had been told they had chronic HCV, and 71.4% (n=10/14) of those with chronic HCV having received HCV treatment.

Discussion: Results underscore gaps in the HCV care continuum among individuals with OUD engaged in outpatient substance use treatment. Interventions to increase uptake of HCV testing, linkage to HCV medical care, and uptake and adherence to HCV treatment are urgently needed, particularly among individuals with an OUD.

IMPLEMENTING AN SBIRT CURRICULUM ENHANCEMENT PROGRAM FOR SUBSTANCE USE DISORDERS AT AN HBCU TEACHING HOSPITAL

Julie A. Dunlap, MSPH[1], Heather O'Hara, MD, MSPH[2]

[1]Meharry Medical College, Antioch, TN; [2]Meharry Medical College, Nashville, TN

Background: Low-SES and racial/ethnic minority populations in the United States have a lower probability of receiving needed substance-related services and are disproportionately affected by health and social consequences of substance use disorders (SUD). Integrating Screening, Brief Intervention and Referral to Treatment (SBIRT) training and best practices for SUD has shown positive outcomes in primary care settings, particularly for low-SES populations. This paper will introduce the research design and preliminary results of a SAMHSA-funded SBIRT training program for medical students, residents and faculty at Meharry Medical College.

Methods: We have developed a graded level SBIRT training program across Family, Occupational and Preventive Medicine disciplines and primary care clinics on MMC campus. Pre and post data on SBIRT knowledge, attitudes, practices and training satisfaction are being collected and analyzed to determine the impact of SBIRT training on improving clinician skills and patient care outcomes.

Results: To date, 84 medical students and 26 residents have received a 2-hour didactic SBIRT training and 24 additional residents (four who also received the 2-hour didactic) are currently receiving more intensive 8-hour trainings. Results for 2-hour training show improved SBIRT knowledge scores, 5.39 to 6.16 ($p=0.002$). Overall, training satisfaction, attitudes towards working with patients who use drugs and alcohol, importance and confidence in using SBIRT for substance use were high. Regarding clinical behaviors, participants reported using alcohol and drug counseling interventions less than “Half-the-Time” (2.88). Preliminary results for residents receiving the more intensive 8-hour training also show significantly improved knowledge scores from 4.82 to 5.50 ($p=0.019$) and reported use of alcohol and drug counseling interventions more than “Half-the-Time" (3.41) in the clinic. The four participants who have received continuous SBIRT training have reported the highest increase in use of SBIRT practices in the clinic from “Sometimes” to “Usually” (2.17 to 4.19, $p=0.033$).

Discussion: This pilot presents a patient-centered and culturally-relevant model to integrate SBIRT training and services for clinicians in primary care settings, particularly those serving at-risk and underserved communities. Our results indicate some improvements in SBIRT knowledge and practices, and overall high training satisfaction and attitudes. Future research will analyze the effectiveness of more intensive trainings on SBIRT clinician practices and patient care outcomes, comparing outcomes based on sex and discipline, and training "champions" to sustain SBIRT practices across MMC clinics.

REDUCING DEPRESSIVE SYMPTOMS AMONG MOTHERS IN TREATMENT FOR OPIOID USE DISORDER THROUGH MINDFULNESS BASED PARENTING

Vanessa L. Short, PhD, MPH, Meghan Gannon, PhD, MSPH, Diane Abatemarco, PhD, MSW

Thomas Jefferson University, Philadelphia, PA

Introduction: Many women with substance use disorders also have co-occurring mood disorders, including depression which is associated with poor parenting outcomes and impaired maternal functioning and bonding. Finding effective approaches to decreasing depression among mothers with substance use disorders could mitigate its negative effects on infants and children. Mindfulness has been shown to positively affect a variety of psychological issues, including preventing relapse for depression, in the general population. However, no studies have examined the effectiveness of mindfulness among mothers with substance use disorder. Here we assessed whether a Mindfulness Based Parenting (MBP) intervention was successful in decreasing self-reported depressive symptoms in a population of parenting women receiving medication assisted treatment for opioid use disorder.

Methods:Data from 30 women with children less than three years of age who attended a two-hour MBP session weekly for twelve consecutive weeks were collected. The Becks Depression Inventory was administered prior to and following the MBP intervention period. Changes in the total depression score from pre- to post-MBP were investigated using mixed-effects linear regression models implemented via maximum likelihood accounting for correlations arising from the repeated-measures. Analyses were also performed to investigate differences by baseline total depression score.

Results: Among all participants, total depression scores decreased significantly from baseline to post-intervention (mean difference=-3.57, SD 6.24, p=0.04). Additionally, those with the highest baseline depression scores experienced the greatest change (mean difference=-8.3, SD 9.9, p=0.008).

Conclusions:Mindfulness Based Parenting is an innovate program with potential important application to mothers engaged in treatment for substance use disorder. Participants of an MBP intervention reported fewer depressive symptoms post-intervention compared to baseline suggesting that MBP could be used as a mental health-improving strategy for this population. Such improvements in maternal mental well-being could have significant and lasting impacts on infant and child health and development, and future MBP interventional studies are warranted.

TREATMENT MOTIVATION AMONG CAREGIVERS AND ADOLESCENTS WITH SUBSTANCE USE DISORDERS

Talea Cornelius, M.A., M.S.W.

University of Connecticut, Vernon, CT

Substance use disorders (SUDs) in adolescence have negative long-term health effects, which can be mitigated through successful treatment. Caregivers play a central role in adolescent treatment involvement; however, studies have not examined treatment motivation and pressures to enter treatment in caregiver/adolescent dyads. Research suggests that internally motivated treatment (in contrast to coerced treatment) tends to lead to better outcomes. We used Self-Determination Theory (SDT) to examine intersecting motivational narratives among caregivers and adolescents in SUD treatment. Relationships between motivation, interpretation of caregiver pressures, adolescent autonomy, and relatedness were also explored. Adolescents in SUD treatment and their caregivers (N_{Dyads}=15) were interviewed about treatment experiences. Interviews were coded for treatment motivation, including *extrinsic* (e.g., motivated by punishment), *introjected* (e.g., motivated by guilt), and *identified/integrated motivation* (e.g., seeing a behavior as integral to the self). *Internalization* of treatment motivation, *autonomy support/competence* (e.g., caregiver support for adolescent decisions), and *relatedness* (e.g., acceptance and support) were also coded. Four dyadic categories were identified: agreement that treatment was motivated by the adolescent (*intrinsic*); agreement that treatment was motivated by the caregiver (*extrinsic*); agreement that treatment was motivated by both, or a shift towards adolescent control (*mixed/transitional*); and disagreement (adolescents and caregivers each claimed they motivated treatment; *conflicting*). Autonomy support and relatedness were most prominent in intrinsic dyads, and least prominent in extrinsic dyads. The mixed/transitional group was also high in autonomy support and relatedness. The extrinsic group characterized caregiver rules as an unwelcome mechanism for behavioral control; caregivers in the other groups saw rules as a way to build adolescent competence and repair relationships, and adolescents saw rules as indicating care rather than control. Adolescents with intrinsic motivations were the most engaged in treatment. Results suggest the importance of intrinsically motivated treatment, and highlight autonomy support and relatedness as mechanisms that might facilitate treatment engagement.

USING A FAMILY SYSTEMS FRAMEWORK TO ASSESS THE IMPACT OF FAMILIAL OPIOID MISUSE ON THE OVERALL WELL-BEING OF YOUNG ADULTS

Drishti R. Shah, MS, B.Pharm, Khalid Alhussain, Pharm D, James Douglas. Thornton, PharmD, Kimberly M. Kelly, PhD, MS

West Virginia University, Morgantown, WV

Objective: Misuse of opioids has grown in epidemic proportions over the last decade in the US, particularly in the Appalachian region. Considering that misuse of opioids may significantly affect the family environment, we sought to understand overall well-being of young adults in the context of familial opioid misuse and misuse of other substances using a family systems framework (family organization, health-related beliefs, and communication within the family).
Methods: We conducted a cross-sectional, mixed-methods survey of young adults (18-30 years old) (n=194). Consistent with a family systems framework, we developed a scale assessing health-related beliefs about familial opioid misuse (Cronbach's alpha=0.72). The associations between the overall well-being of young adults and family's cohesiveness, level of coping, frequency of communication with immediate family members and knowledge about opioid misuse in Appalachia were assessed using multivariable linear regression. Quantitative data was augmented by narrative analysis of responses of familial substance abuse-related experiences by young adults (n=60).
Results: Our sample was mostly women (77%) with a mean age of 24.9 years, living in the Appalachian region (82%), who communicated with immediate family members at least weekly (84%). Nearly one fifth (17.5%) reported having familial opioid misuse, all of whom reported that opioid misuse affected familial communication, and 43.3% reported having no familial substance misuse. More than half of the study sample had heard "a lot" about opioid misuse in Appalachia (53%) and thought that their family could cope with opioid misuse (66%). Both adjusted (F (10,194) =3.7, p=.001) and unadjusted analyses showed that health-related beliefs about familial opioid misuse (β=0.31, p=0.01), familial coping (β=0.18, p=0.04), and misuse of any substance by family members (β=1.14, p=0.01) were significantly associated with overall well-being. Qualitative data also indicated the family environment was more disrupted by familial alcohol misuse rather than opioid misuse. Family members misusing opioids seem to be more isolated and disconnected from their family than those with familial alcohol misuse.
Conclusion: While familial opioid misuse did not seem to impact overall well-being, familial misuse of other substances, especially alcohol, seemed to be more disruptive for the overall well-being of young adults in our largely Appalachian sample.

A DESCRIPTIVE ANALYSIS OF UNEMPLOYED, JOB-SEEKING SMOKERS IN CALIFORNIA

Adrienne Lazaro, BS[1], Peter Soyster, BS[2], Nicole E. Anzai, BS[3], Sarah Stinson, BA[4], Anne Michalek, BA[4], Judith J. Prochaska, PhD, MPH[3]

[1]Stanford Prevention Research Center, Palo, CA; [2]Department of Psychology, University of California, Berkeley, Stanford, CA; [3]Stanford University, Stanford, CA; [4]Stanford Prevention Research Center, Stanford University, Stanford, CA

Background: Our recent research found that job-seeking smokers were half as likely as nonsmokers to be re-employed after one year. Among those who re-gained employment, smokers earned, on average, $5 less per hour than nonsmokers. These findings led to a randomized controlled trial to test a tobacco intervention in unemployment service settings. A vulnerable, impoverished group, we characterize the study sample at baseline.

Method: Participants were job-seeking smokers from the San Francisco Bay Area, working under 10 hours/week, unemployed for less than 2 years, currently smoking 1 or more cigarettes/day with an expired CO sample of at least 7 ppm and having smoked 100 or more cigarettes in one's lifetime. Intention to quit smoking was not required as the intervention was tailored to readiness to quit. Of 419 job-seeking daily smokers screened, 217 met eligibility (52%) and N=206 have enrolled into the trial (5% declined).

Results: The sample is 64% male, 28% female, and 8% transgender, with a mean age of 44 years (SD=11), identifying as 42% Black, 27% non-Hispanic White, 11% Hispanic, and 20% other. Time out of work averaged 6 months (SD=6); 19% are unhoused. Most have a high school diploma or GED (84%); 22% have a college degree; 19% have a criminal history reportable on a job application. Half (51%) interviewed for jobs they did not get in the past 12 months; the most common reported barriers to finding work were advanced age and criminal history. Tobacco use averaged 12 cigarettes/day (SD=6.2) with 44% reporting past-year use of cigars/cigarillos, 29% e-cigarettes, and 25% blunts. Most (75%) reported a 24-hr quit attempt in their lifetime and 49% in the past year. The most common quitting methods were cold turkey (57%), followed by gradual reduction of use (37%) and nicotine replacement therapy (24%). At study enrollment, 34% intended to quit in the next 30 days, 36% in the next 6 months, and 30% not in the near future.

Conclusion: With a focus on unemployed smokers, study of novel tobacco treatment outreach strategies may be especially beneficial given the group's general low intention to quit, poly-

tobacco use, and reliance on cold turkey quitting methods. Additional cessation support and pharmacotherapy may augment quit efforts and, in turn, aid re-employment.

A NOVEL MOBILE APP FOR YOUNG ADULT SMOKING CESSATION: A PILOT STUDY

Megan Jacobs, MPH, Sarah Cha, MSPH, Amanda Graham, PhD

Truth Initiative, Washington, DC

Young adult (YA) smokers are challenging to reach and less likely to engage with evidence-based cessation interventions than older adults. Mobile interventions leveraging the “stickiness” of social media may be an innovative approach to engage YA smokers. This pilot study evaluated signals of engagement with such a novel smoking cessation app.

The *This is Quitting* app was developed based on formative research with YA current and former smokers, including monitoring social media to determine how YA smokers talk about quitting; key informant interviews/focus groups; feedback on sketch concepts; beta tests; and usability testing. Main components of the app are: social media content about quitting smoking curated from multiple platforms (i.e., Tumblr, Twitter) into an aggregated feed; interactive tools (“training packs”) that list challenges to prepare users to stay smoke free in various situations; and information on evidence-based resources such as NRT and quitlines. App users were recruited via organic social media, paid online ads, and referral from YA organizations (e.g., universities). Engagement with the app was tracked via automated tracking tools and examined with descriptive statistics.

Between 12/28/15-1/17/16, 810 users installed the app. During the first 60-days after installing the app, 355 (43.8%) users opened the app more than once (M=3.3, SD=2.7 among return users). Median number of social media posts viewed was 20 (IQR=10-30). About half of the users viewed at least one training pack (360, 44.4%) and more than a quarter of the users completed at least one challenge (220, 27.2%). Fewer users accessed static content: 109 (13.5%) read about NRT and 24 (3.0%) viewed quitline information.

This pilot study demonstrated significant demand for a smoking cessation app with over 800 installations in 20 days. Engagement metrics were promising with nearly half of the users opening the app more than once (previous research showed about 1/3 repeat users for mobile health apps). Static content was accessed at lower rates than the social media-based content of the app. Future research should explore increasing adoption/engagement with mobile apps and whether this modality may promote abstinence.

DEVELOPMENT OF A SMARTPHONE-BASED MINDFULNESS INTERVENTION WITH CONTINGENCY MANAGEMENT FOR OUTPATIENT DEPRESSED SMOKERS

Haruka Minami, Ph.D.[1], Hannah R. Brinkman, B.A.[2], Shadi Nahvi, M.D.[3], Julia H. Arnsten, M.D., M.P.H.[3], Monica Rivera-Mindt, Ph.D., ABPP-CN[4], David W. Wetter, Ph.D.[5], Lawrence H. Price, M.D.[6], Lauren M. McClain, B.A.[4], Carlos Vieira, .[7], Remington E. Donnelly, .[4], Katherine A. Kennedy, B.A.[4], Erica D'Aquila, MPH[8], Jacki Hecht, R.N., M.S.N.[9], Erika Litvin Bloom, Ph.D.[10], Richard A. Brown, Ph.D.[9]

[1]Fordham Univeristy, White Plains, NY; [2]Fordham University, New City, NY; [3]Albert Einstein College of Medicine, Montefiore Medical Center, Bronx, NY; [4]Fordham University, Bronx, NY; [5]University of Utah, Salt Lake City, UT; [6]Alpert Medical School of Brown University, Butler Hospital, Providence, RI; [7]Fordham Univeristy, Bronx, NY; [8]ICAP at Columbia University, New York, NY; [9]The University of Texas at Austin, Austin, TX; [10]Alpert Medical School of Brown University, Rhode Island Hospital, Providence, RI

Smoking rates among individuals with psychiatric disorders are disproportionately higher than in the general population and in turn this group bears a large proportion of the tobacco morbidity and mortality burden. However, less than 20% of outpatient mental health treatment facilities offer smoking cessation treatments. Development and evaluation of smoking cessation interventions that could be integrated into psychiatric treatment settings is needed. In the current pilot study, we developed a smartphone-based mindfulness smoking cessation intervention with contingency management (MSI-CM) and delivered it to 8 adult daily smokers who were receiving outpatient psychiatric treatment for depression in Bronx, NY. Of the 8 participants, 100% were female and racial/ethnic minorities (50% Hispanic), 87.5% had a high school diploma/GED or less, 100% reported household incomes of less than $24,999, and 75% were on disability. Half of participants reported that they have only one or no prior serious quit attempts. Over a 38-day period (10 days before and 4 weeks after a target quit date), participants were prompted to practice mindfulness by listening to audio recordings (approx. 5 mins each) and to complete ecological momentary assessments using a smartphone 5 times per day, and to submit carbon monoxide (CO) videos twice a day for 2 weeks after a target quit date. Overall, participants practiced mindfulness an average of 3.4 times/day (≥ 3 minutes), 68% of requested CO videos were submitted, and 58% of those submitted earned cash incentives (CO ≤ 6 ppm). Participants completed 72.3% of prompted ecological momentary assessments, with 97% of reports completed within 30 minutes of the scheduled time. At each follow-up, 1 participant (12.5%) reported biochemically verified 7-day

point prevalence abstinence. All participants reported reductions in the number of cigarettes smoked per day from baseline (*M=12.5*) to 2-week, 4-week, and 3-month post-quit follow-ups (*M=2.0, 2.0, 7.2*; 84%, 84%, and 46% reduction, respectively). Participants reported that the program was helpful overall (*M=4.85*, on 5-pt scale with 1= not at all and 5= very much), daily mindfulness practice was enjoyable and helpful for both managing mood and quitting smoking (*M=4.5-4.63*), and submitting videos of CO levels aided in the cessation effort (*M=4.75*). These findings indicate high levels of acceptability and satisfaction with MSI-CM. We are currently in the preliminary randomized controlled trial phase.

DISCOVERING DIMENSIONS OF DEPENDENCY AMONG YOUNG ADULT ELECTRONIC NICOTINE DELIVERY SYSTEMS USERS

Erica R. Nahin, B.A., B.S.[1], Jordan A. Baeker Bispo, MPH[2], Maria M. Llabre, PhD[1], Alexander W. Sokolovsky, MA[3]

[1]University of Miami, Coral Gables, FL; [2]University of Miami, Miami, FL; [3]Brown University, Providence, RI

Electronic Nicotine Delivery Systems (ENDS) use is becoming increasingly common among young adults, necessitating an understanding of the salient dimensions of nicotine dependence that may underscore this novel public health phenomenon. The purpose of this study was to evaluate dimensions of dependency within the young adult ENDS user population. Data come from the second phase of an ongoing three phase study which aims to investigate ENDS use patterns and motives of continued use among young adults (ages 18-24). Participants in this sample (N = 304), were predominantly male (61.5%) and Caucasian (69.1%). Each participant self-identified as a regular ENDS user and self-reported using within a week of data collection. Participants were recruited using Amazon Mechanical Turk, an online micro-task marketplace, and were asked to self-report their demographics, smoking patterns, as well as complete a modified 14-item Wisconsin Inventory for Smoking Dependency Motives (WISDM) adapted to query ENDS dependence motives. We used confirmatory factor analysis to model six WISDM sub-scales as indicators of dependence, including automaticity, loss of control, tolerance, craving, cognitive enhancement, and affective enhancement. Subscale scores were indexed as the mean of the items composing the scales. Both a one- and two-factor solution for dependence were compared, where refinements to model specification were made as appropriate upon inspection of factor loadings, residuals, and modification indices. The two-factor model best fit the data. Automaticity, loss of control, craving, and tolerance loaded on the first factor and represent physiological ‘drive.’ Drive can be conceptualized as the desire to satisfy the urge to use ENDS. Affective and cognitive enhancement loaded onto the second factor and represent ‘positive reinforcement.’ These data demonstrate that there may be two distinct clusters of factors driving dependence among ENDS users.

EFFECTS OF ANHEDONIA ON HOOKAH USE AMONG YOUNG ADULTS

Angela Petersen, PhD, Kristin Brikmanis, BA, Neal Doran, PhD

University of California, San Diego, La Jolla, CA

Introduction: Use of hookah among young adults has increased over recent years, yet little is known about how depressive constructs, such as anhedonia, are related to hookah use. Anhedonia predicts poorer outcomes with various aspects of cigarette smoking, particularly cessation, and may similarly affect other tobacco use. The purpose of the present study was to examine the association between anhedonia and hookah use over time among young adults.

Methods: Participants (n = 392, 52% male) aged 18-24 were recruited for a longitudinal study examining cigarette and alternative nicotine and tobacco product use. Eligibility criteria included non-daily cigarette smoking for ≥ 6 months and no lifetime history of daily cigarette smoking for ≥ one month. Anhedonia was measured at baseline and participants reported hookah use at baseline, 3, 6, and 9 months. All measures were completed online or via mobile app.

Results: Anhedonia was prospectively associated with frequency of hookah use such that more anhedonic individuals reported more frequent use of hookah tobacco. Hookah use was reported by 14-32% of participants across the 4 assessments, and frequency of use significantly decreased over time.

Conclusion: Initial findings suggest that anhedonia predicts increased use of hookah among young adult non-daily smokers. More research is needed to identify mechanisms that link anhedonia and hookah use, as well as longer-term outcomes such as dependence and cessation.

GREATER SUSCEPTIBILITY TO NICOTINE PATCH TOXICITY AMONG ASIAN AMERICANS COMPARED TO CAUCASIANS

Alina M. Ostrander, B.A., Jennifer Hernandez, Julia B. Yi, B.A. , Larry D. Jamner, Ph.D.

University of California, Irvine, Irvine, CA

Smoking rates for Asian Americans is about half that shown by White Americans with those Asian American who do smoke also more likely to be light and intermittent cigarette smokers compared to Whites. A plausible explanation for the reduced consumption of cigarettes among Asians may be differences in nicotine metabolism. Benowitz et al. (2002) have shown Chinese-Americans to demonstrate substantially lower CYP2A6 liver enzyme activity than Whites or Latinos; and it is this slower nicotine metabolism that may place Asians at greater risk for nicotine toxicity. Few studies have compared nicotine toxicity sensitivity between Asians and Caucasians in response to fixed doses of nicotine under controlled conditions. In this study 21mg and 5mg nicotine patches (Nicoderm) were administered to smokers and non-smokers respectively, as well as a placebo patch, across two laboratory sessions. Participants were monitored for physical symptoms associated with nicotine toxicity and sessions were terminated as soon as participants reported becoming sick. The sample included 48 smokers and 23 non-smokers who were Asian American, and 95 smokers and 47 non-smokers who were Caucasian. Results revealed that among smokers, only 6% of Caucasian in contrast to 31% of Asian American smokers became sick from the nicotine patch (Fisher's Exact Test, *p*=.003). Among non-smokers, only 2% of Caucasians reported sickness compared to 22% of Asian Americans (Fisher's Exact Test, *p*=.013). The similarity of nicotine side-effects patterns observed in both smokers and non-smokers suggest that the findings cannot be attributed simply to increased tolerance in smokers. The greater susceptibility of Asian Americans to nicotine toxicity is consistent with models of reduced nicotine metabolism in this ethnic group and affords an explanation for the historically lower cigarette smoking prevalence rates observed in Asian Americans. An important implication of these findings relate to the relatively recent explosive popularity of electronic nicotine delivery systems (ENDS). Specifically, the greater titration control of nicotine exposure levels made possible by ENDS may pose disproportionately higher risks of these devices acting as "gateways" towards developing nicotine dependence among Asian Americans.

LIMITATIONS OF RISK PERCEPTION AND IMPLICATIONS FOR DUAL PROCESS THEORIES OF BEHAVIOUR.

Ron Borland, PhD[1], Bill King, MSc[2], Hua Yong, PhD[3]

[1]Cancer Council Victoria, Melbourne, Victoria, Australia; [2]Cancer council Victoria, Melbourne, Victoria, Australia; [3]Cance Council Victoria, Melbourne, Victoria, Australia

The limited capacity of people to make accurate quantitative estimates of risk has been known for some time. However, the extent of such limitations and their implications for making sensible behaviour choices is less well understood. CEOS theory predicts that affective factors will swamp more rational ones unless rational reasoning is supported. This raises the question of how can we strengthen capacity to make sensible choices in the context of affective forces pointing in the other direction. The aim of this study was to both quantify and use qualitative interviews to better understand the ways in which smokers understand the risks of various tobacco and nicotine products and the implications of such beliefs for making rational choices about their smoking.

Methods. Qualitative interviews and focus groups with smokers or recent quitter and a survey of two overlapping samples of smokers and young adults (under 35) resulting in approximately equal groups of young smokers, young non-smokers and older smokers (total n=1056). The quantitative survey asked for semi-quantitative estimates of risk of 4 aspects .

Results: Only 1.4% of the sample correctly identified the effects of combustion as the primary cause of harm and did not nominate multiple aspects as contributing to more than half of the harms (ie arithmetically impossible). Nearly all judgements are qualitative, so a new variable was created with thos correct plus those indicating smoke was thehighest source of harm combined giveing 4.5% of the sample. There was a a generalised negative reaction to all aspects of tobacco, and no differentiation, in particular of the lower harms of the nicotine in isolation (only 10.8% rated nicotine in the lowest category of harm . The interviews found that most smokers interviewed could talk about the harms in relatively accurate ways, but were unable to use this information in making judgements of risk. There were no clear age effects and minimal effects of smoking status, with small effects suggesting non-smokers were better informed.

Conclusions. Risk assesments are qualitatie, not empirical, so emotinal responses to risk need to be taken into account before attempting to change beliefs about extent.This confusion in

understanding may be inhibiting moves to less harmful forms of nicotine. If people are to make more rational choices about risk, communication about risk needs to focus on a separation between acceptable and unacceptable risks and educate people to have a better understand of the core determinants of health risk from various types of agent. CEOS theory provides a framework for improving communication and enhancing executive capacities to overcome the identified affective influences and allow more evidence-based judgements to influence decisions..

PARENTAL DEPRESSION IS ASSOCIATED WITH LOWER LIKELIHOOD OF SMOKING CESSATION AND POOR CHILD ASTHMA OUTCOMES: PROSPECTIVE STUDY

Romano Endrighi, PhD[1], Elizabeth L. McQuaid, PhD, ABPP[2], Kiera Bartlett, PhD[3], Ashley H. Clawson, Ph.D.[4], Belinda Borrelli, PhD[5]

[1]Boston University Henry M. Goldman School of Dental Medicine, Boston, MA; [2]Alpert Medical School, Brown University, Providence, RI; [3]The University of Manchester, Manchester, England, United Kingdom; [4]Oklahoma State University, Stillwater, OK; [5]Boston University, Henry M. Goldman School of Dental Medicine, Boston, MA

Parents of children with asthma have higher rates of depression than parents of healthy children. Given that those who are depressed are more likely to smoke and have difficulty quitting, and that secondhand smoke (SHS) triggers asthma exacerbations, we examined the effect of parental depression on smoking cessation and child asthma outcomes.

This study is a secondary analysis from a cessation trial involving Motivational Interviewing (MI) and SHS biofeedback to motivate cessation. Parents did not have to be motivated to quit to enroll. Parents (n=341, 79.8% female) of a child (Mean age=5.15±4.5 years) who had an asthma exacerbation requiring urgent care received 2 home-based asthma education visits (plus MI and SHS biomarker feedback to motivate cessation). Parents were then randomized to receive 6 counselling calls (MI plus repeated SHS feedback) or 6 control calls (brief check on asthma status) for 4 months. Depression status was defined as a score of ≥22 (Haringsma et al, 2004) on the Center for Epidemiologic Study-Depression scale. Smoking outcomes were biochemically verified 7-and 30-day point-prevalence abstinence (ppa). Child asthma outcomes were past month asthma functional limitation scores, health care utilization (≥1 urgent care or hospitalization event vs none) and asthma symptom days. Data were obtained at baseline, 2-4-and-6-months and analyzed with longitudinal generalized estimating equations models adjusting for covariates.

Depressed parents were less likely to achieve 7-day ppa (OR=.38, 95% CI=.23, .64) and 30-day ppa (OR=.27, 95%CI=.15, .47) than parents who were not depressed. Effects were consistent overtime (no group by time interaction). Parental depression predicted greater odds of health care utilization for the child's asthma exacerbation (OR=1.85, 95%CI=1.00, 3.44), and greater asthma functional limitation (B=.13, SE=.06, p=.03), even after controlling for smoking status and SHSe during the study. Depression also predicted a greater number of asthma symptom days (B=.87, SE=.44, p=.05), but became non-significant after controlling for parent smoking status (30-day ppa). Results suggest that parent depression plays a greater role that smoking in some asthma outcomes, but abstinence reduces child asthma symptom days beyond the

effect of depression.

Findings suggest that, among parents who smoke, depression as well as their smoking, should be a target for treatment aimed at improving pediatric asthma outcome.

PATTERNS AND REASONS FOR ELECTRONIC CIGARETTE USE IN PRIMARY CARE PATIENTS

Sara Kalkhoran, MD, MAS[1], Patrick Yuan, B.A.[2], Nicholas J. Alvarado, MPH[3], Jason Satterfield, PhD[4]

[1]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [2]University of California, San Francisco, San Francisco, CA; [3]Project Manager/Clinic Research Coordinator, San Francisco, CA; [4]UCSF, San Francisco, CA

Introduction: E-cigarette use is rising in both the general population and in clinical populations, including hospitalized patients and cancer patients. Little is known about e-cigarette use among patients in other clinical settings, particularly in primary care where physicians report discussing e-cigarette use with patients. We aimed to identify how and why smokers in primary care use e-cigarettes.

Methods: We used cross-sectional data from current cigarette smokers (within the past 7 days) enrolled in a randomized controlled trial of a tablet intervention to deliver the 5As for smoking cessation in primary care clinics in San Francisco, CA (N=718). We recruited patients from 3 sites: a primary care clinic at a University hospital, and a primary care clinic and HIV care clinic at a University-affiliated public safety-net hospital. We asked patients about sociodemographics, cigarette smoking, and ever and current use of e-cigarettes during the post-intervention assessment. We also asked reasons they have used or would use e-cigarettes. ICD-9 codes for comorbidities were extracted from electronic medical records.

Results: 57% (n=408) of patients reported ever using an e-cigarette and 21% (n=154) reported past 30 day use. Ever e-cigarette users were more likely to be younger, white, more educated, daily smokers, have smoked for more years, and more nicotine dependent than never users. Ever e-cigarette users had higher prevalence of mental illness than never users. The most and second most common reasons for e-cigarette use among current and former e-cigarette users were to cut down on and quit cigarette smoking, respectively. These were also the most common reasons never e-cigarette users reported for why they would use e-cigarettes. The mean number of days of e-cigarette use in the past 30 was 7, increasing with duration of e-cigarette use. Most current e-cigarette users did not know the nicotine content of their e-cigarettes.

Conclusion: Over half of smokers in primary care use e-cigarettes, with 1 in 5 reporting current use. E-cigarette use is intermittent in this population, with most reporting non-daily

use. Most patients report using e-cigarettes to cut down or quit cigarettes. Screening of patients for e-cigarette use may help identify those interested in changing their smoking habits and provides an opportunity for providing evidence-based smoking cessation treatment and counseling.

SECONDHAND SMOKE INTERVENTION IN LAKOTA FAMILY HOUSEHOLDS

Janet Thomas, PhD[1], Priscilla Nez, BS[2], Jeffrey A. Henderson, MD, MPH [2], Dedra Buchwald, professor, Elson S Floyd College of Medicine[3], Carolyn Noonan, MS[3], Patricia Nez Henderson, MD, MPH[2], Meredith Schreier, MHA[4]

[1]University of Minnesota, Mpls, MN; [2]Black Hills Center for American Indian Health, Rapid City, SD; [3]Washington State University, Seattle, WA; [4]University of Minnesota, Eden Prairie, MN

Secondhand Smoke Exposure Intervention in Lakota Family Households

Background: Nonsmokers from the Lakota tribes in South Dakota disproportionately share the burden of secondhand smoke exposure (SHS), especially in their homes. With smoking prevalence as high as 50%,the consequences of SHS include high prevalence of childhood asthma and sudden infant deaths. The expanded use of commercial tobacco products for ceremonial and cultural practices creates intervention challenges not typically seen in non-American Indian communities. Eliminating SHS in a culturally appropriate manner is fundamental to decreasing morbidity and mortality among the Lakota tribes. A novel approach to encourage the adoption of home smoking restrictions is to provide parents with objective, biomarker feedback documenting child exposure to tobacco toxins. This pilot project is the first to use biomarker feedback with American Indian adult smokers.

Methods: From 2013-2015 we recruited American Indian smokers with potty-trained children ages 2 to 8 residing in their homes into a two-arm randomized clinial trial (N=110). We randomized eligible participants to the intervention arm (n=56), consisting of biomarker feedback and counseling on their child’s exposure to NNAL and cotinine. The control group (n=54) received a brochure on SHS. An in-home survey was administered at baseline and week 12. Child urine cotinine and air nicotine were collected at both time points. Primary outcome was badge-verified (air nicotine) complete home smoking restrictions at 3-months post-randomization.

Results: All enrolled participants were American Indian, 81% female, average age 37 (SD=12) years, 62% at least high school graduates, 65% unemployed, and 81% had an annual combined family income less than $25,000. The mean number of smokers/household was 2.4

(SD=1.3) and average cigarettes smoked/day was 8.8 (SD=6.7). Median child cotinine level was 7 ng/mL (interquartile range: 3-22). At week 12, a t-test comparison indicated that the intervention and control groups had a similar reduction in air nicotine (change score in intervention = -1.02, 95% CI -1.80, -0.24; change score in control = -0.99, 95% CI -1.81, -0.17), with no changes in child urine cotinine. However, at week 12, more participants assigned to biomarker feedback than the control group self-reported implementing complete home smoking restrictions (41% vs. 20%, p=0.05).

Conclusion: Providing parents or guardians with feedback documenting their child's exposure to SHS increased the implementation of home smoking bans. Clinical, public health, policy and research implications will be discussed.

SMOKING-RELATED HEALTH BELIEFS AND SMOKING CESSATION IN THE NATIONAL LUNG SCREENING TRIAL

Annette Kaufman, PhD, MPH[1], Laura Dwyer, PhD[2], Stephanie Land, PhD[3], William Klein, PhD[4]

[1]Tobacco Control Research Branch, Behavioral Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, National Institutes of Health, Rockville, MD; [2]Cape Fox Facilities Services, Manassas, VA, Rockville, MD; [3]Tobacco Control Research Branch, Behavioral Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, Rockville, MD; [4]NCI/NIH, Rockville, MD

Lung cancer is the leading cause of cancer death in the United States and 90% of lung cancers are caused by cigarette smoking. Understanding the association between smoking-related health beliefs and smoking cessation in the screening environment is important for prevention and effective treatment. We conducted a sub-study of the National Lung Screening Trial (NLST; 2002-2006) to understand how smoking-related health beliefs may be related to smoking cessation.

Participants (N=2,761) at the time of recruitment were 55-74 years of age, current smokers with a history of 30 pack-years or more, had no history of lung cancer, and had not been treated for any cancer within the past 5 years. All trial enrollees at 8 of the 23 NLST study sites were invited to complete a questionnaire to assess beliefs: absolute risk perception, comparative risk perception, worry, perceived severity, self-efficacy to quit, perceived benefits of quitting, and perceived barriers to quitting. The outcome was cessation between the first and last assessment. Logistic regression analyses examined associations with beliefs, demographics, and all two-way interactions among beliefs, gender, and age. We applied backward elimination of terms with p-values $\geq \alpha=0.5$.

Over 37% (N=1028) of baseline smokers quit smoking at last assessment. In simple logistic regressions, the likelihood of quitting was higher among participants reporting higher perceived severity (OR=1.16, p=0.05), greater self-efficacy for quitting (OR=1.32, pp=0.05), fewer perceived barriers (B=-0.22, *p*=.01), and were older at baseline (B=0.03, *p*=0.00) were more likely to quit. Worry interacted with comparative risk perception (B=-0.19, *p*=0.04), and perceived benefits (B=0.19, *p*=0.05). Higher worry attenuated the relationship between comparative risk perception and quitting, but perceived benefits predicted increased odds of quitting at the highest level of worry.

These results suggest that, among heavy smokers undergoing lung screening, smoking-related health beliefs are associated with smoking cessation, and worry is an important moderator of these associations. Smoking cessation has an impact on lung cancer survival and smoking-related health beliefs must be considered an integral component of delivering cessation in screening settings.

SOCIAL CONTEXTS, ETHNICITY, AND ADOLESCENT SMOKING BEHAVIOR

Julia B. Yi, B.A. [1], Alina M. Ostrander, B.A.[1], Jennifer Hernandez[1], Bryan C. Mac, B.A.[2], Larry D. Jamner, Ph.D.[1]

[1]University of California, Irvine, Irvine, CA; [2]University of California, Irvine, Seal Beach, CA

Cigarette smoking in adolescence may be motivated by the desire to fit in and avoid negative evaluation from peers. Adolescents may also feel pressure to smoke if others around them are smoking. Social stimulus control over smoking has been shown to vary as a function of culture, with Korean-Americans reporting greater social determinants of cigarette use. The use of Ecological Momentary Assessment (EMA) methods to evaluate the antecedents, concomitants, and consequences of tobacco use holds great promise for the study of the cultural variations in smoking behavior. The aim of this study was to determine the impact of social environments/contexts on smoking urge and likelihood to smoke in real-time among Asian American, Latino, and White adolescents. Eighty-five female and 70 male adolescents (20% Asian American, 11% Latino, 51% White) completed two 4-day daily diary-monitoring sessions approximately 6 months apart, each year from ninth grade until twelfth grade, totaling eight monitoring periods. In each monitoring session, participants were signaled every 30 ±10 minutes to complete an e-diary entry. The diary contained 24 items tapping information about current activities, social interactions, moods, urge to smoke, and cigarette consumption on both school days and weekends. Participants' e-diary data revealed evidence of social contexts exerting differing patterns of stimulus control over smoking behavior between ethnic groups. Compared to being alone, cigarette smoking was significantly less likely while with family (OR=.20; $p < .01$) or boy/girlfriend (OR=.37; $p < .01$) among White, but not Asian-American adolescents. In contrast, Asian-American adolescents were significantly more likely to smoke across a range of social contexts including friends (OR=2.29; $p < .001$), boy/girlfriend (OR=1.97; $p < .01$), teacher/class (OR=2.45; $p < .001$) and other adults (OR=1.98; $p < .01$) compared to times they were alone. Among Whites, the only social context associated with a greater likelihood of cigarette smoking was found to be while with friends (OR=1.69; $p < .01$). Social contexts were observed to exert intermediate influences on the smoking urges and behaviors of Latino youth. The results of this study point to significant ethnic differences in the influence of social contexts/stimulus control on tobacco-use.

TRAJECTORIES OF RETURN TO SMOKING DURING THE POSTPARTUM YEAR AMONG WOMEN WHO QUIT SMOKING DURING PREGNANCY

Michele D. Levine, PhD[1], Yu Cheng, PhD[2], Rachel P. Kolko, PhD[3], Rachel H. Salk, PhD[4], Lisa J. Germeroth, phd[5], Rebecca Emery, MS[2], Rebecca Emery, MS[2]

[1]University Of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh School of Medicine, Pittsburgh, PA; [4]University of Pittsburgh Medical Center, Pittsburgh, PA; [5]University of pittsburgh, Pittsburgh, PA

Although it is well known that most women who quit smoking during pregnancy will return to smoking during the postpartum year, the time course of relapse after delivery is poorly understood. Identifying whether there are trajectories of relapse and understanding their time course may improve efforts to target treatments. Accordingly, we sought to document patterns of smoking resumption among women who quit smoking during pregnancy and to examine predictors of different relapse trajectories.

Women (*N* = 300) who recently had quit smoking participated in postpartum-specific smoking relapse prevention interventions. Participants were interviewed about smoking and provided expired air carbon monoxide samples at the end of pregnancy and 12-, 24- and 52-weeks postpartum. Overall, 39% of the sample maintained biochemically verified smoking abstinence through 52-weeks postpartum. To examine the time course of relapse, data on number of cigarettes smoked following delivery were abstracted from time line follow back interviews. Daily data on number of cigarettes were then dichotomized as any or no smoking. Trajectory analyses (PROC TRAJ) revealed four unique relapse trajectories: “sustained abstinence” (50% of the sample), “quick relapse” (21%), “slow relapse” (13%), and “inconsistent smoking” (16%). Multinomial logistic regression models identified factors related to trajectory membership. Predictors considered included demographic variables, smoking history and psychiatric disorders. Not surprisingly, the number of cigarettes smoked prior to quitting, previous quit attempt, and years of smoking predicted trajectory membership. Women with more prior quit attempts were more likely to relapse quickly than to sustain abstinence OR = 1.1, CI = [1, 1.2]), and women who had started smoking at a younger age were more likely to be inconsistent smokers than to sustain abstinence OR = 1.1, CI = [1, 1.1]).

There are four distinct courses of smoking resumption during the postpartum year. Although most women in an intervention sustained tobacco abstinence, approximately one-fifth of

women enrolled in a postpartum relapse prevention intervention resumed smoking quickly. Women who relapse quickly can be identified by their smoking history prior to pregnancy. Thus, efforts to target interventions for these women may need to be initiated prior to delivery and can be improved by readily indentifiable smoking history variables.

YOUNG ADULT MOTIVES FOR ELECTRONIC NICOTINE DELIVERY SYSTEM USE

Marie Chesaniuk, MA, Alexander Sokolovsky, MA

University of Illinois at Chicago, Chicago, IL

This study examined motives associated with ENDS use and cessation outcomes among a sample of young adults (N=304; mean age: 22.4; 38.2% female; 62.8% white). We hypothesized that motives associated with use and cessation outcomes among cigarette smokers would predict such outcomes among young adult ENDS users. We also hypothesized that previously observed gender differences (e.g., men are more motivated to smoke to increase positive affect than are women) would be replicated. Participants who self-identified as regular ENDS uses and self-reported using within a week of data collection were asked to complete a survey on the Amazon MTurk platform. Measures included an adapted version of the 14-item Wisconsin Inventory for Smoking Dependency Motives (WISDM), Smoking Consequences Questionnaire, and self-reported demographics and smoking patterns. Mean number of days smoked in the past 30 days was 21.64 with 40.5% of participants reporting daily use. 37.5% of participants reported at least one prior quit attempt with an average length of 26.55 days. Average length of non-use excluding quit attempts was 15.55 days. More men than women attempted quitting. T-tests revealed gender differences across smoking motives and outcome expectancies. Backward stepwise regression analysis was conducted, subtracting non-influential motives or outcome expectancies to achieve final models for each use and cessation outcome. Regression analyses predicting smoking use outcomes found consistent main effects of loss of control and tolerance. Paradoxically, less loss of control predicted higher levels of ENDS use. Greater tolerance predicted more use across all use outcomes. For cessation outcomes, only loss of control predicted quit attempts. Less loss of control increased odds of attempting to quit. Lower levels of craving and higher levels of affective enhancement increased length of quit attempts. Only tolerance predicted non-use days: lower levels of tolerance predicted more non-use days. No gender interactions were found in any regression analyses. Results suggest an escalation is most associated with tolerance among young adult ENDS users. One possible explanation for the negative effect of loss of control on ENDS use is that more frequent use prevents withdrawal symptoms and a sense of losing control, whereas intermittent use allows gaps in which these symptoms might appear. While a number of gender differences were expressed, none of them affect use or non-use outcomes.

YOUNG ADULT'S PARTICIPATION AND BELIEFS ABOUT THE IMPORTANCE OF GENETIC MARKERS ON SMOKING BEHAVIOR

Kathleen Diviak, PhD[1], Adriana Perez, BS[1], Emily Anderson, PhD[2], Robin Mermelstein, PhD[1]

[1]University of Illinois at Chicago, Chicago, IL; [2]Loyola University, Maywood, IL

This poster will examine the consent process and participation in a genetic study of tobacco dependence as well as participant beliefs about the important and influence of genetic markers on smoking behavior. Participants were part of the Social and Emotional Contexts of Adolescent Smoking Patterns longitudinal study (cohort N = 1,263). The cohort was recruited when they were approximately 14-15 years old and is quite diverse in terms of race and ethnicity with 56% Non-Hispanic White, 17% non-Hispanic African American, 13% Hispanic White, and 14% all other categories. During the 5- and 6-year follow-up assessments when participants were between 19 and 23 years old, they were recruited to participate in a genetic sub-study. Of the 1,112 participants approached, 1,019 provided a saliva sample for genotyping for a participation rate of 91.6%. Participation did not vary by gender, race/ethnicity, or current smoking status. Participants who declined to participate in the genetics sub-study were slightly older (M=21.9, SD=0.95) than participants who provided a sample (M=21.3, SD=0.79); t(963)=-2.79, p=0.005. Everyone who asked to participate completed a semi-structured interview about their understanding of the genetic project, reasons for participation, and their beliefs about genetic influences on smoking behavior. Reasons for participation were primarily to help the overall project (25.5%), the $20 cash incentive (23.0%), and interest/curiosity about the overall results (16.6%). Most participants could correctly and clearly describe the purpose of the genetic study (68.5%), but some (17.6%) were not able to correctly describe the purpose of the study after the informed consent process was completed. Female participants rated the influence of genetics on smoking behavior higher than male participants, but there were no differences between the other demographic or smoking status variables. Current smokers reported that they would smoke less if they were to find out that they had a genetic risk for tobacco dependence compared to no risk; t(536)=-13.92, p=0.000. In addition, current smokers also reported that they would be more interested in quitting if they were to learn that they had a genetic risk factor compared to no risk; t(534)=--9.86, p=0.000. The implications for participation in genetic studies and understanding young adult beliefs about genetic testing for complex behavior like cigarette smoking will be discussed.

SEDENTARY BEHAVIOR IN THE WORKPLACE: UNDERSTANDING AND INTERVENING

Mark A. Pereira, PhD[1], Meynard Toledo, B.S., M.S.[2], Sarah Mullane, Ph.D.[2], Charlotte Brakenridge, BPsySc[3], Nirjhar Dutta, M.S., D.O.[1]

[1]University of Minnesota, Minneapolis, MN; [2]Arizona State University, Phoenix, AZ; [3]The University of Queensland, Brisbane, Queensland, Australia

The health benefits of moderate-vigorous physical activity are well-established across the lifespan. However, guidelines also state the need to “minimize the amount of time spent being sedentary.” Adults spend an average of 7.5h/day sedentary, yet recent studies suggest reallocating just 30 min/day from sedentary to light activity may significantly improve health risk factors. In recent years a paradigm shift has emerged in the area of physical activity and health stemming from: 1) emergence of new technologies to accurately assess sedentary time and very light intensity physical activity, 2) accumulation of scientific evidence supporting sedentary time (adverse) and light activity (protective) having important impacts on chronic disease risk independent of moderate and vigorous activity, and 3) emergence of new, innovative ways to modify posture and behavior through capitalizing on various layers of the socioecological framework. This symposium focuses on the worksite of adult populations in the U.S. and Australia. The worksite is a logical intervention target for sedentary behavior, as adult workers spend 70-80% of their time at work sitting. We will present observational and experimental studies aimed at understanding the correlates of sedentary time in the workforce, and evaluating approaches to intervening on sedentary time using novel experimental strategies. Unique aspects of this collection of scientific endeavors towards understanding and intervening on sedentary behavior include 1) modern technologies in objective assessment of sedentary time, posture (sitting v. standing), and light activity, 2) ecological momentary assessments in 271 adults with 673 EMA data points, 3) parsing correlates of sedentary behavior into environmental and individual-level factors in 279 adults, 4) efficacy of wearable tracking devices in a worksite intervention of 153 adults in a cluster-randomized trial, and 5) examination of long-term sustained changes in follow-up to a within-person cross-over randomized trial of sit-stand workstations. These collective research studies significantly add to the accumulating body of rigorous studies to date on the efficacy of workplace interventions to increase light activity, reduce sitting, and improve health. Findings will inform the potential health benefits of sit-stand workstations and other approaches that are becoming increasingly popular, but for which rigorous science is needed. The findings also stand to be generalizable to much of the sedentary workforce, and will help lead towards more informed health practitioner and employer preventive plans and decisions.

Symposium 70A

ECOLOGICAL MOMENTARY CORRELATES OF WORKPLACE SEDENTARY BEHAVIOR

Mr. Meynard Toledo, B.S., M.S.

PURPOSE: To examine the bi-directional relationship between momentary perceptions and affective states and objectively-measured workplace SB. **METHODS:** Participants were recruited from 13 worksites in the greater Minneapolis and Phoenix regions. Participants completed an ecological momentary assessment (EMA) survey (delivered via smartphone or e-mail) on three random days during work hours on a 7-day assessment period. Participants also wore an activPAL3c accelerometer. The EMA survey assessed momentary perceptions and affective states (i.e., feeling hungry, tired, relaxed, and happy). SB outcomes were sitting time, sit-stand transitions, long sitting bouts (sitting bouts that are >30 mins), and light physical activity (LPA) (standing or stepping< 3.0 metabolic equivalents), one hour preceding and proceeding each EMA response. Multilevel models were used to examine bi-directional associations of between- and within-person SB and physical feeling and affective states. All models were adjusted for age, gender, BMI, and job type. **RESULTS:** A total of 673 EMA responses were collected from 271 participants (73% female; age = 42.7 ± 11.3 yrs; BMI= 28.5 ± 6.8 kg/m^2). At the between-person level, more happiness was associated with less time in long sitting bouts during the next hour *(b*[SE]= -3.3 [1.58], ρ=0.04). No other between-person relationships were significant. At the within-subject level, participants reported more hunger following periods of higher than usual LPA (*b*[SE]= 0.06[0.02], b[SE]= -0.03[0.02], b[SE]= -0.03[0.02], b[SE]= 0.04 [0.02], ρ=0.02). **CONCLUSION:** Sedentary behavior was bi-directionally associated with subsequent physical feeling states; conversely, feelings of happiness were associated with subsequent SB. Within-person relationships may have been attenuated due to a limited number of observations per person. Nevertheless, these results can inform future studies aimed at reducing workplace sedentary behavior through contextually-aware interventions.

ENVIRONMENTAL AND INDIVIDUAL LEVEL CORRELATES OF SEDENTARY BEHAVIOR IN THE WORKPLACE

Dr. Sarah Mullane, Ph.D.

PURPOSE: To identify environmental and individual level correlates of objectively measured sedentary behavior in the workplace. **METHODS:** Participants were recruited from thirteen worksites in the greater Minneapolis and Phoenix regions. Participants wore an activPAL3c accelerometer continuously for seven consecutive days. Work time was identified and extracted using daily logs. Workplace sedentary behavior outcomes were sit time, stand time, light-intensity physical activity (LPA, stepping < 3.0 metabolic equivalents), number of sit-stand transitions per hour, and time in long bouts of sitting (≥30 min). Outcomes were standardized to an 8h work day. An electronic survey was completed to assess environmental factors (i.e., desk-based vs. centralized amenities, private vs. public office, floor level) and individual factors (i.e., perceptions of work engagement [UWES], work satisfaction and performance). Mixed model analyses (worksite-level clustering) were performed to examine relationships between sedentary behavior and environmental and individual factors. All models were adjusted for work sector (academic, state, industry), job type, age, gender and BMI. **RESULTS:** Participants (N = 297; 70% female; age: 42.3 ± 11.3 yrs) wore the activPAL3c for 90.2 ± 15.5% of the workday. Presence of a centralized recycling area was associated with less sitting time (b[SE] = -54.2[17.2], *P* = 0.002), less prolonged sitting (b[SE] = -64.4[21.5], *P* = 0.034) and more standing time (b[SE] = 48.7[16.6], *P* = 0.004), sit-stand transitions (b[SE] = 2.0[0.9], *P* = 0.02) and LPA (b[SE] = 2.2[0.9], *P* = 0.01). Conversely, perceived job performance was associated with more sitting time (b[SE] = 11.7[5.8], *P* = 0.047) and less standing time (b[SE] = -13.5[5.6], *P* = 0.02). Private office use was marginally associated with more prolonged sitting (b[SE] = 31.0[17.4], *P* = 0.08). **CONCLUSIONS:** Environmental factors such as centralized amenities and office type may influence workplace sedentary behavior. Surprisingly, high perceived job performance may be a barrier to workplace sedentary behavior reduction strategies. These findings may inform future longitudinal examinations and interventions targeting reductions in workplace sedentary behavior.

Symposium 70C

EVALUATION OF A PILOT 12-MONTH ORGANISATIONAL INTERVENTION TO REDUCE SITTING TIME WITH OR WITHOUT AN ACTIVITY TRACKER.

Ms. Charlotte Brakenridge, BPsySc

Introduction: Effective, worksite-driven strategies are needed for sustainable ways to reduce sitting time. This study evaluated the efficacy of reducing sitting time of minimally intensive organisational-support strategies alone or combined with a novel activity tracker. Methods: A pilot 12-month cluster-randomised trial was conducted in 153 Australian office workers (18 teams) in 2014-2015. Nine teams received an organisational-support intervention (e.g., emails, manager support; n=87), and nine teams (n=66) also received a waist-worn LUMOback activity tracker. Data were collected (baseline, 3 months, 12 months) by activPAL3 monitors (work and overall sitting), other objective assessments (anthropometrics, activity tracker), and questionnaire. Data were analysed by linear mixed models (n=102-112). Results: After 12 months, both groups significantly ($p<0.05$) reduced sitting time at work and overall (by 32.1±12.8 to 40.5±10.4 min/day [mean±SE]) with no significant difference between interventions, adjusting for confounders. Baseline sitting, back problems, higher job performance and manager support significantly predicted greater sitting reductions at work. Work satisfaction and uptake of other activity apps or trackers significantly predicted greater overall sitting reductions. Longer LUMOback usage tended towards reductions in work and overall sitting ($p<0.10$). Conclusions: The findings demonstrate that organisational-support strategies may effectively reduce office workers' sitting time over 12 months. Management support and addressing performance issues, for example, may facilitate sitting reductions. The LUMOback may require longer usage to be effective; uptake of other apps and trackers were associated with improvements and merit investigation.

Symposium 70D

ONE YEAR FOLLOW-UP OF A RANDOMIZED TRIAL ON THE EFFICACY OF SIT-STAND WORKSTATIONS TO DECREASE SEDENTARY TIME AT WORK

Dr. Nirjhar Dutta, M.S., D.O.

Background: We previously reported on a four week within-person randomized cross-over trial using a sit-stand desk (SSD) intervention that resulted in decreased sedentary time at work by 3.2 hour per week. Purpose: The purpose of this study was to measure the long term effect of the SSD intervention on sitting time and activity level 14 months after the original trial was completed. Methods: A pre-post design was used where the control period from the original study was regarded as "pre" and the measurements made in the follow-up study were "post" . The intervention SSDs were left with the participants at the end of the original study in April 2012. The follow-up study was conducted in the same participants over a two week period in June 2013. The primary outcome for the study was objectively measured physical activity with the Gruve accelerometer. Results: 15 out of the 23 eligible participants took part in the follow-up study. Self-reported sitting time (OSPAQ survey) during work-hours was decreased by 22% (95% CI: 15% to 29%; p<0.001), replaced almost entirely by standing. Activity measured by accelerometer during work-hours was significantly higher at follow-up compared to baseline (+24748 AU/hr; 95% CI: 7150 to 42347; p<0.05). There was also a trend towards lower sedentary time during work-hours at follow-up compared to baseline (p=0.17). As suggested in the original trial, perceived hunger assessed by ecological momentary assessment was lower at follow-up compared to baseline. Conclusion: These findings suggest that sit-stand workstations use may be sustained over the long-term and they may be an effective tool not only decreasing sitting but also for increasing light physical activity at work.

Symposium 71 8:30 AM-9:45 AM

ETHICAL CONSIDERATIONS FOR USING ONLINE STRATEGIES FOR RECRUITING AND INFORMING PARTICIPANTS IN GENOMIC SEQUENCING STUDIES

Christine Rini, PhD[1], Jennifer Hay, PhD[2], Megan Lewis, PhD[3], Gail E. Henderson, PhD[4], Kimberly Kaphingst, ScD[5]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]RTI International, Research Triangle Park, NC; [4]UNC School of Medicine at Chapel Hill, Chapel Hill, NC; [5]University of Utah and Huntsman Cancer Institute, Salt Lake City, UT

Genomic sequencing is rapidly becoming the technology of choice in many clinical fields for screening and diagnostic testing. Using genomic sequencing for these purposes creates ethical considerations for researchers due to potential disparities in uptake of this technology across groups characterized by age, education, race/ethnicity, family composition or family history. In this symposium we will explore the ethical and social issues raised by genomic sequencing studies that use online strategies to recruit, educate or inform participants about genomic risk. First, we will describe a randomized controlled trial examining uptake and outcomes (screening, sun protection) of skin cancer genetic testing, which involved an on-line *MC1R* test offer. Racial/ethnic disparities in test interest, as well as potential explanations for these disparities in test interest, will be explored. Second, we will present ongoing work describing a randomized trial in which genomic sequencing is offered to two family cohorts: those with a newborn or those with a young child that has a previously diagnosed disorder. All families can opt to learn about medically actionable childhood conditions and then they are randomized to learn about other categories of information that vary by age of onset and medical actionability. Early recruitment data suggest differences in interest between the two cohorts of parents, and that family conflict may play a role in whether to participate. Third, we will describe clinic-based recruitment of adults for genomic screening that targets rare, medically actionable conditions. Education and consent materials are provided online. Those who join take a survey about decision making and understanding. Preliminary recruitment data reveal differential uptake by age, gender, and race/ethnicity. Individuals often make the decision to join before reading the online consent materials, and two-thirds did not open additional items on the consent summary page. The only predictor of knowledge of the study objectives was income. Our discussant, an expert in the communication of genomic information, will discuss common themes across presentations and health communication best practices for increasing diversity and access for genomic sequencing studies that use online strategies. This

Symposium will highlight important issues that need to be considered as the field moves toward the recruitment of large population-based studies.

Symposium 71A

ONLINE SKIN CANCER GENETIC TESTING IN DIVERSE PRIMARY CARE

Jennifer Hay, PhD

Translational research in genomics has disproportionately engaged highly-educated and Caucasian populations, but must broaden reach to fully realize the public health potential. Rates of melanoma are on the rise. Germline variants in the *MC1R* gene are common in the general population and confer moderate melanoma risk in those with varied skin types. In a randomized controlled trial examining uptake and outcomes (screening, sun protection) of *MC1R* testing in Albuquerque primary care clinics, 1,339 patients (English or Spanish speakers) have been approached; 25% have agreed to participate. Participants (N=325; 45% Hispanic, 49% non-Hispanic White, 74% female, mean age=56) were randomized 1:6 to a usual care condition (NCI skin cancer brochure for diverse skin types) or an online *MC1R* test offer. Of the 285 patients randomized to the test offer to date, 42% (n=119) elected to learn about *MC1R* testing by logging onto the study website; most (91%) that log on request testing (via saliva test kit). Those who log onto the website were more likely to be non-Hispanic, have lower cancer fatalism, report lower family influence on health information seeking, and report fewer misconceptions about skin cancer (*p*sps>.05). In a logistic regression including all significant predictors of logging on and participant education level and income, only ethnicity was significant (*p*MC1R testing). Level of comprehension of *MC1R* risk feedback (average *versus* higher risk) and three-month sun protection and screening outcomes (target N=885) will ultimately be examined, as well.

We acknowledge the funding support of NIH R01 CA181241 to Jennifer Hay and Marianne Berwick (MPIs)

Symposium 71B

PARENTAL DECISION MAKING ABOUT GENOMIC SEQUENCING FOR THEIR CHILDREN: ETHICAL AND PRACTICAL CONSIDERATIONS

Megan Lewis, PhD

Genomic sequencing is becoming the screening technology of choice in many clinical fields. Using genomic sequencing for screening creates ethical considerations for researchers. These issues are compounded when parents make screening decisions for their child or newborn. Negotiating whether to have a child's genome sequenced and what types of information to learn can increase conflict between parents during decision making. The NC NEXUS study is offering genomic sequencing to two cohorts of parents: those with seemingly healthy newborns or with children previously diagnosed with a disorder. Online decision aids (DA) are being used at different points in the study along with clinical consultation to support decision making. We will report on enrollment data between the two cohorts and describe differences between those who enroll and accept sequencing and those who decline on demographic variables, reported barriers and psychosocial factors. To date, the response rate is high in both cohorts (74% in the healthy newborn cohort; 50% in the previously diagnosed cohort). Of parents who complete the DA, most choose to have sequencing for their child (56% in the healthy newborn cohort; 83% in the previously diagnosed cohort) suggesting potential differences in interest between the cohorts. Early reports on barriers to participation between spouses include the need for both to consent. Dual consent is a regulatory requirement for participation. In some cases, one parent wants to participate, but the other does not. In two families, so far, custody battles have made participation impossible. Several families discontinued participation because one parent completed part of the study procedures, but the other did not, indicating passive withdrawal from the study. Another barrier to participation is that all questionnaires and DAs are online. So far, 10 families report lack of Internet access or not having a device that can display both the DA and questionnaires as challenges for participation. We will discuss ethical issues raised by differences in participation and lessons learned about how to recruit parents into studies focused on genomic sequencing for their children.

Symposium 71C

REPORT FROM GENESCREEN: ONLINE RECRUITMENT FOR PREVENTIVE GENOMIC SCREENING AMONG HEALTHY ADULTS

Dr. Gail E. Henderson, PhD

Programs that screen adults for rare, medically actionable conditions will likely use web-based education and consent. Yet, there is little evidence for the effectiveness of e-consent to convey study information. In *GeneScreen*, we investigate issues raised by such screening, focusing on 11 medically actionable conditions. We piloted recruitment at a hospital-based primary care practice (*n*=436) and a research biobank (*n*=650), attempting to recruit equal numbers by gender, race/ethnicity, and age. Individuals were mailed a brochure and letter directing them to the *GeneScreen* website. It provided a summary of 14 study features relevant for informed consent, which could be expanded to display more information. *GeneScreen* "joiners"were surveyed about decision making and understanding, and a subset were interviewed in more detail. Here we describe recruitment results, joiners' decision making processes and characteristics, and factors related to understanding the study. 1,086 individuals were approached, 275 (25.3%) joined. Among those approached, women and whites were more likely to join; age was related to joining, but in opposite ways at the two sites. 68% of joiners were female, 79% non-Hispanic white, 9.6% Hispanic; and average age was 59 (range 24-95). Joiners had generally high literacy and SES, typical of early adopters of new technology. Median Income was $75,000-99,999; two-thirds had at least a college degree. 87.9% reported being very or extremely confident with medical information. Genetic self-efficacy was high: mean on scale of 1-6 was 5.01. Compliance with doctors' advice was high: mean on scale of 1-5 was 4.74. The only significant difference between white and African American joiners was age: 58.16 vs 47.27 (t=2.43, p= .018). Data on website behavior revealed that of 14 consent summary items, the mean number opened was 1.67. Two-thirds did not open any item; 20% opened 1-3 items. On a 6-item scale measuring understanding study objectives, mean score was 4.51 (sd=1.19). In multivariate analysis, study knowledge was not associated with expanding more consent summary items; nor was it related to study site, education, health literacy, race (white vs. AA), or self-efficacy. Higher study knowledge was only statistically significantly associated with higher income. Most found the decision to join extremely or very easy. Telephone interviews (n=50) found that over two-thirds made the decision to join after reading the printed recruitment materials, before going online. We discuss implications of these findings in the context of e-consent for genomic screening.

Symposium 72 8:30 AM-9:45 AM

NEW FINDINGS ON UNDERSTANDING AND TREATING BINGE EATING IN OBESITY

Niloofar Afari, PhD[1], Kathryn Godfrey, MS[2], Gina Evans-Hudnall, PhD[3], Jessica Gundy Cuneo, Ph.D. [4], Shira Maguen, PhD[5]

[1]University of CA, San Diego & VA San Diego Healthcare System, La Jolla, CA; [2]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, La Jolla, CA; [3]Michael E. Debakey VA Medical Center, Humble, TX; [4]University of California, San Diego, Sonoma, CA; [5]San Francisco VA Medical Center and UCSF, San Francisco, CA

Two-thirds of Americans are overweight or obese and the prevalence is even higher among veterans. Binge eating disorder is characterized by persistent and frequent episodes of consuming large quantities of food in addition to other symptoms. Regardless of meeting diagnostic criteria, binge eating is a behavioral problem that can interfere with attempts to lose weight and contributes to obesity. Additionally, binge eating alone or in the context of obesity is linked to substantial morbidity and undesirable physical and mental health consequences. Therefore, it is important to better understand the physiological and behavioral markers of binge eating as well as to develop and test interventions that address the underlying mechanisms that may maintain binge eating in obesity and the associated health-related functioning. The goal of this symposium is to highlight several new findings that may shed light on the processes involved in the maintenance of binge eating and its amelioration. The first presentation will describe findings from a novel study of the stress and binge eating link in obesity by examining associations between lab-based heart rate variability (HRV) and binge eating behaviors. Presenter 2 will explore the relationships between binge eating and patient activation and social support in a sample of participants recruited from the VA's MOVE! Program. Presenter 3 will discuss findings from mediation analyses to examine the links between psychological flexibility, binge eating, and quality of life in obese or overweight veterans receiving psychological treatment for binge eating. Finally, the discussant will critically discuss the presented findings, implications for clinical care, and potential future research directions.

Symposium 72A

BINGE EATING AND HEART RATE VARIABILITY: IDENTIFYING PHYSIOLOGICAL MARKERS OF RETROSPECTIVE AND NATURALISTIC EATING BEHAVIOR

Kathryn Godfrey, MS

Advancing prevention and treatment of obesity requires developing interdisciplinary paradigms spanning physiological, psychological, and behavioral bases and designs that explain eating behaviors within real world settings. This study examined the stress and binge eating link by modeling associations between lab-based heart rate variability (HRV) and binge eating behaviors measured through retrospective diagnostic interview and ecological momentary assessment (EMA). A community-recruited sample of 32 male and female participants with obesity completed a lab visit to measure HRV and assess binge eating in the past month. HRV was measured through a lab protocol containing baseline and stressed conditions. A subsample (n=16) of participants completed a 7 day at-home EMA protocol to assess binge eating using a smartphone. Multiple linear regressions modeled the relationships between HRV variables at baseline and when stressed with the frequency of retrospective binge eating and during the at-home EMA protocol. At baseline, participants with higher SDNN reported fewer retrospective episodes of overeating ($p = 0.03$). Similarly, participants with higher sympathetic activation measured by LFn at baseline had more retrospective episodes of loss of control over eating ($p = 0.04$). During the at-home protocol, overeating, loss of control over eating, consumption of non-nutritious, high calorie foods and breaking dietary rules were non-statistically significantly associated with time and frequency-domain HRV variables and heart rate with small to medium effect sizes (semi-partial $r^2 = 0.10$ to 0.35), which can be detected in larger samples. Lower autonomic flexibility at baseline is related to binge eating severity in individuals with obesity. Further elucidating the link between HRV and eating behaviors and examining the clinical potential of integrating physiological, psychological, and behavioral assessment will inform the theoretical models for weight management and the development of individualized, real-time intervention.

CORRESPONDING AUTHOR: Niloofar Afari, PhD, University of CA, San Diego; nafari@ucsd.edu

Symposium 72B

EXAMINING RELATIONSHIPS BETWEEN PATIENT ACTIVATION, SOCIAL SUPPORT, & MENTAL ILLNESS AMONG VETERANS WITH BINGE EATING IN MOVE!

Dr. Gina Evans-Hudnall, PhD

Nearly 78% of Veterans are estimated to be overweight or obese and those poor patient activation (taking an inactive role in managing health conditions) and limited social support have difficulties with weight loss. Binge eating (BE) is associated with obesity in Veterans. Veterans with BE often have co-occurring depression, anxiety and PTSD, which creates barriers to weight loss. The VA developed an evidenced based weight management program (MOVE!) that targets change in obesity related health behaviors but does not target patient activation or social support. The HELP program is a pilot study of a mental health treatment effectiveness trial designed to be adjunctive to MOVE!. Participants were recruited during the first MOVE! session. At baseline, participants completed the MOVE 11 and validated measures of patient activation, depression, anxiety and PTSD symptom severity, and social support for healthy eating. The MOVE 11 is an assessment of medical, psychological, and behavioral contributors to obesity. BE was assessed by a positive response to a single item on the MOVE 11.Correlational analysis was used to assess the relationships between patient activation, social support, and mental health variables with BE at baseline. Fifty-four participants met the criteria for BE. BE was significantly associated with low baseline scores for patient activation (p=.031) and social support for healthy eating (p=.030). BE was also significantly associated with high scores for anxiety symptom severity (p=.039). Thus, BE among Veterans is associated with heightened symptoms and anxiety, suboptimal personal activation for effectively managing health conditions and perceived deficits in support for making healthy dietary practices. Future investigation of the direct and mediating relationship between BE, psychological symptoms, patient activation and social support is needed.

Symposium 72C

CHANGES IN PSYCHOLOGICAL FLEXIBILITY, BINGE EATING, AND QUALITY OF LIFE IN VETERANS: EXAMINING MEDIATED TREATMENT EFFECTS

Dr. Jessica Gundy Cuneo, Ph.D.

Weight-related avoidance and inflexibility play a central role in problematic health behaviors, such as binge eating. Binge eating in obese individuals is also associated with a greater degree of morbidity and impairment in quality of life (QOL) than in obesity alone. Psychological treatments targeting psychological flexibility (PF) improve openness and awareness of thoughts and feelings related to weight and may improve binge eating behavior and, in turn, increase QOL. The current study explored the binge eating mediation pathway linking weight-related PF and QOL in obese/overweight veterans receiving psychological treatment for binge eating. 90 veterans with an average BMI of 38.9 kg/m^2 (*SD* = 7.6) who reported binge eating after completing a standard 8-week weight management program (MOVE!) were randomized to either Acceptance and Commitment Therapy (ACT) or active control. Measured included the Binge Eating Scale, Acceptance and Action Questionnaire for Weight-Related Difficulties, and Obesity Related Well-Being questionnaire. As both groups demonstrated comparable changes in PF during treatment, groups were combined for mediation analyses. Change scores on the measures were used from baseline to 6-month post treatment follow-up (*n* = 82). Higher levels of PF were positively related to improvements in binge eating (*b* = .2150, *SE* = .055, *p* = .0002), and improved binge eating was positively related to increased QOL (*b* = .8468, *SE* = .305, *p* = .007). A statistically significant indirect effect of increased PF via decreased binge eating was found on improvements in QOL (*b* = .182, *SE* = .083, 95% *CI* = .052,

.090). Thus, the relationship between increased weight-related PF and increased QOL could be a function of improved binge eating for Veterans receiving psychological treatment after completing a weight management program. Future studies can further examine the efficacy of weight-related psychological treatments that focus on increasing PF.

Symposium 73 8:30 AM-9:45 AM

A STRENGTH-BASED APPROACH TO UNDERSTANDING HEALTH DISPARITIES: EXAMINING RISK AND RESILIENCE IN MOTHERS LIVING WITH SYNDEMICS

Idia B. Thurston, PhD[1], Kathryn Howell, PhD[1], Rebecca C. Kamody, M.S.[2], Courtney Peasant, PhD[3]

[1]University of Memphis, Memphis, TN; [2]The University of Memphis, Memphis, TN; [3]RTI International, Raleigh, NC

Physical and emotional adversities in mothers have rippling effects across the family system. Consistent with syndemic theory, violence, HIV, and substance use are adversities that frequently co-occur among racial/ethnic minorities and the urban poor. This health disparity may unfairly create an excess burden of poor health and functioning among vulnerable populations. To date, there is a gap in our understanding of how syndemics affects the functioning of mothers and their children, as well as a dearth of information on factors that protect these women from poor health outcomes. Thus, this symposium utilizes a strength-based framework to examine risk and resilience in mothers living with syndemics. Such an approach recognizes healthy adaptation in the midst of adversity, which is critically needed to improve maternal and child health equity. We will begin this symposium with an overview of syndemic theory and provide context for the examination of both risk and resilience factors among mothers. The first presentation will assess how mothers' historical and current experiences of partner violence impact communication with their children about violence, HIV, and substance use. The second presentation will evaluate how resilience serves as a protective factor against depressive symptoms in mothers living with HIV. The third presentation will explore the relationship between poverty and gender-based violence as perpetrated by a partner among high-risk South African mothers using substances. The fourth presentation will examine the protective role of support from family and friends on the relationship between syndemics and posttraumatic stress among high-risk U.S. mothers. This panel will highlight the impact of cumulative adversity among mothers exposed to violence, HIV, and substance use. It will also underscore the many strengths these women utilize in the midst of experiencing syndemics. Consistent with the 2017 SBM conference theme to expand horizons in behavioral health, this innovative symposium will advance knowledge about the social context of syndemics, offer novel ways to decrease maternal and child health disparities, and inform future strength-based treatments.

Symposium 73A

THE MEDIATING ROLE OF RESILIENCE ON THE RELATIONSHIP BETWEEN SYNDEMICS AND DEPRESSIVE SYMPTOMS AMONG MOTHERS LIVING WITH HIV

Dr. Idia B. Thurston, PhD

Background: According to syndemic theory, people living with HIV experience other adversities, including substance use and violence, with risk elevated among the urban poor. The consequences of syndemics are pronounced in mothers, given their central role as caretakers in the family. While women experiencing syndemics endure poor mental health, many show resilience (ability to bounce back from adversity). We examined the mediating role of resilience on the relation between syndemics and depression in mothers living with HIV.

Method: Participants were 55 mothers living with HIV, aged 25-62 (*M*=41.2, *SD*=9.0; 81% Black). 85% of mothers had a yearly income of ≤ $20,000. Women were recruited via HIV/AIDS service organizations in the U.S. MidSouth and reported time since HIV diagnosis. Syndemics were assessed via report of illicit drug use and physical/sexual violence with an intimate partner (both in the past 6 months). Women completed measures of depression, resilience, and life stress. Women living with HIV (1 syndemic) were compared to those with HIV plus substance use and/or partner violence (2 or 3 syndemics).

Results: Mediation analyses were conducted using SPSS PROCESS to generate 5000 bootstrap samples with 95% CI. Controlling for lifetime stressors and time since HIV diagnosis, the mediation model was significant, R^2=.23, *F*(4, 50)=3.78, *p*=.009. Being in the syndemic group had a direct effect on depression, *B*=6.19, *SE*=2.89, *p*B=-.039, *SE*=0.15, *p*=.01. When resilience was included, the direct effect of syndemic group membership on depression was no longer significant, *B*=3.50, *SE*=2.91, *p*=0.24, indicating full mediation. Thus, resilience had an indirect effect on the association between syndemic group membership and depression, *B*=2.70, *SE*=1.64, 95% *CI*=0.43, 6.91.

Conclusions: Findings suggest that while mothers who experience syndemics are at greater risk for psychopathology, they are protected by the ability to bounce back following adversity, even after accounting for other stressors. Interventions aimed at improving the wellbeing of mothers living with HIV should move beyond assessing risk and instead consider positive factors that protect women from poor health outcomes.

Symposium 73B

SOCIAL SUPPORT AS A MEDIATOR OF THE RELATIONSHIP BETWEEN SYNDEMICS AND POSTTRAUMATIC STRESS

Dr. Kathryn Howell, PhD

Background: Syndemics (co-occurrence of multiple adversities including intimate partner violence (IPV), HIV, and substance abuse) in mothers has a rippling effect across the family system. An understanding of factors that might protect against the negative impact of syndemics, such as social support is lacking. This study explored the mediating role of social support from friends and family on the relation between syndemics and posttraumatic stress.

Method: Participants were 178 mothers who experienced physical or emotional adversities (i.e., living with HIV, experiencing IPV, or using substances). Mothers were aged 22-62 (*M*=35.2*, SD*=8.4; 71% Black) who were recruited from community organizations in the U.S. MidSouth. Syndemics were examined based on report of being HIV positive, illicit drug use, and physical/sexual IPV (both in the past 6 months). Mothers completed measures of posttraumatic stress, social support, and life stress. Women with one syndemic were compared to those with two or three.

Results: Mediation analyses were conducted in SPSS PROCESS to examine the indirect effects of social support (family vs friends) on syndemics and posttraumatic stress. Controlling for other stressors, the family support model was significant, R^2=.04, *F*(2, 175)=3.27, *p*=.04. Syndemic group membership had a direct effect on posttraumatic stress, *B*=.41, *SE*=.16, *p*=.01 and family support, *B*=-2.70, *SE*=1.09, *p*=.01. When family support was added as a mediator, the effect of syndemics on posttraumatic stress was weakened, *B*=.35, *SE*=.16, *p*=.03, indicating partial mediation. Family support had an indirect effect on the association between syndemic group membership and posttraumatic stress, *B*=-.02, *SE*=.01, 95% *CI*=-0.436, -.0001. The model examining social support from friends was not significant.

Discussion: Results show the protective role of social support on mitigating the negative impact of syndemics on traumatic stress. The finding that social support from family has a stronger protective role highlights the importance of examining social support from multiple sources. Researchers and clinicians working with mothers should examine the unique role family support plays, as this could be a target for resilience-focused interventions.

Symposium 73C

THE RELATIONSHIP BETWEEN INTIMATE PARTNER VIOLENCE AND MOTHER-CHILD COMMUNICATION ABOUT SYNDEMICS.

Ms. Rebecca C. Kamody, M.S.

Background. Syndemic theory suggests a clustering of substance abuse, violence, and HIV/AIDS (i.e., SAVA) among racial/ethnic minorities and the urban poor. Parent-child communication about syndemics may protect against the intergenerational risks related to substance use, violence, and HIV/AIDS. Among children, open communication may enhance their resilience (i.e., ability to bounce back) to combat adversities in their high risk environment. As such, we aimed to identify variables that may influence mothers' willingness to communicate with their children about SAVA.

Method. Participants were 174 mothers (70% Black, M_{age} = 34.7) of children ages 6-14 (51% female, M_{age} = 10.3), recruited from community centers. Mothers completed measures of parent-child communication about SAVA, history of violence perpetration, and the Revised Conflict Tactics Scale. Path analysis was used to evaluate a hypothesized model, in which mothers' current IPV was related to willingness to communicate about SAVA, as mediated by violence perpetration.

Results. An excellent model fit was found (Comparative Fit Index = .99; Root Mean Square Error of Approximation = .02; Standardized Root Mean Square Residual = .02). IPV had a direct path to violence perpetration (est.=.29, $p < .01$), which had a direct path to willingness to communicate about SAVA (est. = -.60, $p < .01$). Further, Maternal IPV had both a direct (est. = -.41, $p < .01$) and indirect (est. = -.17, $p < .01$) path to communication about SAVA via the mediator of violence perpetration. Child's age was a moderator of the relationship between violence perpetration and communication about SAVA (est.=.56, p

Discussion. Findings highlight the negative consequences of bidirectional violence, such that mothers who are both victims and perpetrators of violence are less willing to communicate with their children about SAVA. Given that parent-child communication is a protective factor for positive health and well-being, this lack of communication may place children on a problematic health trajectory. Accordingly, researchers should develop parenting interventions that target the family system and promote open communication, which may enhance resilience in children.

Symposium 73D

CONTROL IS KEY: POVERTY, VIOLENCE, AND ALCOHOL ABUSE AMONG HIGH-RISK SOUTH AFRICAN MOTHERS.

Dr. Courtney Peasant, PhD

Background: Interconnected epidemics such as poverty, gender-based violence (GBV), and substance abuse contribute to the disproportionately high rates of HIV among South African women, particularly among mothers who must provide for their children. Th e current study takes a resilience approach to explore how sexual control, a factor that is associated with lower HIV risk, may moderate the relation between poverty, GBV – specifically, intimate partner violence (IPV), and alcohol abuse among most-at-risk mothers in Pretoria, South Africa.

Method: Data for this study are derived from a subset of participants of a larger trial examining the efficacy of a women-focused HIV prevention interventions. Participants were 416 Black/African mothers who were 15 years or older and reported use of at least two substances on ≥ 13 of the past 90 days, had unprotected vaginal sex with a male partner in the last six months, and had a boyfriend. Women completed computer-assisted interviews that assessed the frequency of going to bed hungry in the past year (proxy for poverty); physical, emotional, or sexual IPV by their boyfriend in the past 90 days; problems with alcohol use in the past year; and sexual control (i.e., ability to refuse unwanted sex from their boyfriend).

Results: Analyses indicated that sexual control moderated the associations between poverty and physical IPV including being attacked with a weapon (CI = -.11, -.02), and being struck or beaten (CI = -.09, -.009). Tests of simple slopes revealed that there was a positive association between poverty and being attacked or struck/beaten among women with sexual control scores of 14.42 and 14.20 (Range = 6-30) or less, respectively. However, the associations between poverty and IPV were not significant for mothers with higher levels of sexual control.

Discussion: These findings indicate that empowering mothers to have sexual control with their partners and educating couples about the importance of respecting sexual control may lessen the impact of poverty on gender-based violence. Given that sexual control is amenable to change, this construct could be a key target for future strength-based interventions.

Symposium 74 8:30 AM-9:45 AM

SYSTEMATIC REVIEWS IN CANCER: LEARNING FROM COCHRANE METHODS AND NEW FINDINGS

Joanna Buscemi, Ph.D.[1], Sherri Sheinfeld Gorin, PhD, FSBM[2], Dorothy McLeod, N/A[3], Heather L. McGinty, PhD[4], Kristen Wells, Ph.D., MPH[5], Paul B. Jacobsen, PhD[6]

[1]DePaul University, Chicago, IL; [2]New York Physicians Against Cancer, http://nypac.center/, New York, NY; [3]Loyola University Chicago, Chicago, IL; [4]The Ohio State University & James Cancer Hospital and Solove Research Institute, Columbus, OH; [5]San Diego State University, San Diego, CA; [6]National Cancer Institute, Bethesda, MD

There are more than 15 million citations in MEDLINE, with 10,000 to 20,000 new citations added each week, many in cancer, and more than researchers, clinicians, and policy makers can regularly review, parse, and apply to practice and policy. According to the Cochrane Collaboration, a 20-year old organization that publishes the *Cochrane Database of Systematic Reviews*, internationally-recognized as the highest standard in evidence-based healthcare resources, systematic reviews attempt to identify, appraise, and synthesize all of the empirical evidence that meet pre-specified eligibility criteria to reduce bias and answer a given research question. Using Cochrane criteria produces reliable findings that can be used to inform decision-making. Our symposium will focus on lessons learned from systematic reviews and meta-analyses across the cancer continuum, using Cochrane Collaboration and non-Cochrane approaches. Dr. McGinty will examine the processes and findings from two recent systematic reviews of multiple cognitive outcomes following cancer treatment in two distinct populations, men with androgen deprivation therapy (ADT) and individuals receiving hematopoietic cell transplant (HCT). Ms. McLeod will describe a recent systematic review exploring the effects of acculturation on weight among Latino children in the US. Drs. Kumar and Wells, novice and experienced Cochrane reviewers, will discuss their experiences conducting Cochrane systematic reviews in the fields of medicine and behavioral medicine across the cancer continuum. They will highlight the differences between Cochrane and other systematic reviews, as well as the supports and barriers to conducting them. The symposium aims to increase the implementation of systematic reviews and meta-analyses, particularly using Cochrane Collaboration processes.

Symposium 74A

A SYSTEMATIC REVIEW OF ACCULTURATION AND WEIGHT AMONG LATINO CHILDREN

Dorothy McLeod, MA

We propose to describe a recent systematic review, which examined the effects of acculturation on weight among Latino children in the US. Using this review as a case example, we also propose to highlight methods and lessons learned over the course of the process.

In the systematic review “Becoming American, Becoming Obese?” findings across studies on the relations between acculturation and obesity in Latino children were explored. Previous research has found that there is a positive relationship between US acculturation and obesity, a known risk factor for cancer development, among Latino adults (Oza-Frank & Cunningham, 2010); however, less is known about how the process of acculturation may affect children’s weight. The identification of potential factors associated with obesity in children and adults is critical to inform future interventions that may reduce obesity and obesity-related cancers. Using search terms referring to “children,” “acculturation,” and “obesity” to search PsychInfo, ERIC, Cochrane, PubMed, and CINAHL, the authors located 381 records. The first two authors independently assessed 59 of these articles in their full-text form, and 29 of these were included in the qualitative synthesis. The authors concluded that there was heterogeneity across studies of acculturation and weight, likely stemming from the variability in the measurement and definition of acculturation across the studies. However, overall, relations between US acculturation and weight were more likely to be positive among adolescents and toddlers, whereas they were more likely to be negative among school-aged children.

Throughout conducting the systematic review, the authors recognized three important lessons: (1) carefully consider the definition and measurement of your variables of interest, (2) keep detailed records of every step of the process, and (3) examine findings through as many lenses as possible in order to determine best next steps for the field. In addition to these three lessons for preparing a review, the authors also recognized a lesson for authors of empirical (non-review) manuscripts: define your methods and findings with enough detail that they may be incorporated into a review. We propose to present these lessons, contextualized by real-world examples from our own review, in order to inform and empower early career researchers with the tools to conduct their own reviews.

Symposium 74B

CONDUCTING SYSTEMATIC REVIEWS AND META-ANALYSES OF MULTIDIMENSIONAL OUTCOMES WITH MULTIPLE COMPARISON GROUPS

Dr. Heather L. McGinty, PhD

Two recent systematic reviews of cognitive outcomes following cancer treatment in two distinct populations are described and used to illustrate special considerations for conducting complex systematic reviews and meta-analyses.

The first systematic review and meta-analysis examined cognitive outcomes for men treated with androgen deprivation therapy (ADT) across 7 cognitive domains and 3 types of control comparisons (cancer patient controls, non-cancer controls, and pre-ADT baselines). A total 157 abstracts were reviewed for inclusion by independent pairs of raters, with 14 studies with unique samples (n = 417 ADT patients) included in the meta-analysis. Separate meta-analyses were conducted for each identified cognitive domain. For the random effects model, ADT patients performed significantly worse than controls on visuomotor tasks (g = -0.67, p = .008).

The second systematic review and meta-analysis evaluated cognitive functioning before and after hematopoietic cell transplant (HCT) across 8 cognitive domains. 732 abstracts were pulled and a total of 17 studies were included in a systematic review; of those, 11 studies had sufficient data for meta-analysis (n = 404 HCT patients). Again, separate meta-analyses were conducted for each domain and several possible study characteristics were evaluated including moderators and meta-regression. No significant cognitive changes were observed across studies (ps > .05).

Specific recommendations are offered for 1) defining multidimensional outcomes a priori, 2) developing and honing literature search strategies, 3) designing and conducting detailed data abstraction procedures, and 4) conducting analyses for complex outcomes. Guidance for graduate students interested in conducting meta-analyses is also discussed.

Symposium 74C

LESSONS LEARNED IN CONDUCTING COCHRANE SYSTEMATIC REVIEWS

Dr. Kristen Wells, Ph.D., MPH

The goal of a systematic review is to identify, evaluate, synthesize, and summarize the findings from all relevant studies on a specific question related to a specific question domain (e.g., treatment). Systematic reviews provide decision makers with the best possible evidence to make informed decisions. As a global independent network of researchers, professionals, patients, carers, and people interested in health, Cochrane has a mission to promote evidence-informed health decision-making by producing high-quality, relevant, accessible systematic reviews and other synthesized research evidence. Historically, most Cochrane systematic reviews have been conducted in the field of medicine, with relatively few behavioral medicine systematic reviews having been completed. As more behavioral medicine researchers become interested in conducting Cochrane systematic reviews, it is clear that these researchers will need to become familiar with the steps required to complete a review. We will share our experiences with conducting Cochrane systematic reviews in the fields of medicine and behavioral medicine by incorporating the perspectives of both a novice Cochrane review author and an experienced Cochrane author and reviewer. First, we will summarize major differences between Cochrane and non-Cochrane systematic reviews. Then, we will provide an overview of the supports and barriers to conducting a Cochrane review, with a focus on the following topics: understanding and following Cochrane procedures, adhering to Cochrane timelines, funding for the conduct of systematic reviews, determining a specific research question, assembling a team with content and methodological expertise, developing a systematic review protocol, collaborating with a librarian, training of data abstractors, and evaluating publication venues. We will conclude with lessons learned from our experiences conducting Cochrane systematic reviews on a wide range of behavioral medicine and medical topics.

Symposium 75 8:30 AM-9:45 AM

EXPANDING BEHAVIORAL MEDICINE'S IMPACT ON THE PREVENTION AND TREATMENT OF SUBSTANCE USE IN THE CONTEXT OF INFECTIOUS DISEASE

Amy Starosta, PhD[1], Andrea L. Hobkirk, PhD[2], Sarah M. Wilson, Ph.D.[3], Sara N. Edmond, PhD[4], Courtney Peasant, PhD[5]

[1]Denver VA Medical Center, Denver, CO; [2]Duke University School of Medicine, Durham, NC; [3]Department of Veterans Affairs, Durham, NC; [4]VA Connecticut Healthcare System, West Haven, CT; [5]RTI International, Research Triangle Park, NC

For those living with chronic infectious diseases in the United States, substance use contributes to deteriorating health and poor treatment adherence. Substance use-related health disparities exist despite significant advances in HIV and Hepatitis C pharmacological treatment and prevention. More than ever before, infectious disease clinical practice and research can be informed by behavioral medicine with regard to reducing health risk behavior and increasing health promotion.

This symposium, conducted by behavioral health investigators from research institutions across the country, focuses on the intersection of non-intravenous substance use and infectious disease and will elaborate on empirical research and clinical models from a variety of perspectives. Sessions will discuss the prevention and treatment of substance use and infectious disease risk reduction in the context of clinical care, address health behaviors in complex social contexts that include stigma and addiction, and highlight the translational potential of the research findings.

Each session will review a non-intravenous substance of abuse that impacts infectious disease transmission and/or clinical care. The use of alcohol and crack cocaine continue to drive HIV transmission risk in the US through risky sex behaviors. For those living with infectious diseases like HIV, smoking now accounts for more morbidity and mortality than HIV itself. In addition, prescription opioid abuse is a rapidly growing epidemic that affects medical populations at disproportionately high rates.

The symposium will begin with a discussion of research findings from two studies assessing neurobehavioral and individual factors that contribute to sex risk behavior among cocaine users in the community and college-aged women who use alcohol. The implications for incorporating these substance use factors into prevention interventions in primary care settings will be discussed. The second half of the symposium will focus on substance use among those with infectious diseases. This will include findings from the first nationally representative study to examine the prevalence of smoking among veterans living with HIV and problematic opiate use among OIF/OEF veterans. A discussion of the implications for behavioral health treatment within multidisciplinary teams in the VA system will follow.

Our discussant will synthesize the findings by reviewing the over-arching impact of substance use on sexual risk and infectious disease care. This review will highlight the importance of interventions that address the social context of substance users. Given the expanding role of behavioral medicine in the prevention and treatment of substance use and infectious disease, we believe this symposium will be of interest to the attendees at the Society of Behavioral Medicine 38th Annual Meeting and Scientific Sessions.

Symposium 75A

ALCOHOL AND CONDOMS: IT’S COMPLICATED.

Dr. Amy Starosta, PhD

Although it has frequently been assumed that alcohol use negatively impacts condom use, the research on this topic has been mixed. Some studies find no difference between condom use following drinking, while others find a negative association between number of drinks and condom use. While actual alcohol consumption is an important factor to consider, there may also be attitudes and expectancies associated with drinking that may be important mechanisms in the mixed association between drinking and risky sexual behavior. The current study examines the relationship between condom attitudes and intentions with drinking behaviors.

Participants (318 single college women M_{age}=18.84 years, *SD*=1.78) completed demographic, sexual, and condom attitudes, condom and drinking intentions questionnaires as well as a Timeline Followback Interview to assess their drinking and condom use for the previous three months.

Drinking more times per week and more drinks during each drinking event were both associated with more sexual partners (frequency of drinking r=.278, p<.0001; number of drinks r=.281; p<.0001), and poorer attitudes toward condoms (frequency of drinking r= -.208, p<.0001; number of drinks r= -.150; p<.0001). Drinking behavior, as measured by frequencies of events, number of drinks, or binge drinking over the previous 90 days, was not associated with condom use over the previous 90 days or during the most recent sex act. Intentions to use condoms were negatively associated with the frequency of drinking (r=-.115, p=.041), but not with number of drinks or binge drinking over the previous 90 days. Condom attitudes were positively associated with actual condom use over the previous 90 days (r=.376, p<.0001) and during the last act sex act (F=10.11, p<.0001).

Overall, drinking behavior was not related condom use. However, increased drinking was associated with poorer attitudes toward condoms, lower intentions to use condoms, and more sexual partners. These findings further highlight the complex relationship between alcohol use and risky sexual behavior. The implications of these findings on behavioral interventions to reduce risky sexual behavior will be discussed.

Symposium 75B

NEUROBEHAVIORAL CHARACTERISTICS AND HIV SEX RISK BEHAVIOR: A COMPARISON OF COCAINE USERS WITH AND WITHOUT HIV TO NON-DRUG USERS

Dr. Andrea L. Hobkirk, PhD

Background: Infectious disease is the second leading cause of death among high risk substance users in primary care settings. While there are well-known neurobehavioral characteristics that differentiate substance users from non-drug users (e.g., impairments in neurocognitive function, altered decision-making, trait impulsivity), few behavioral HIV risk reduction interventions are designed with these in mind.

Method: The current study sought to identify neurobehavioral characteristics that differ between HIV+ cocaine users (n=19), HIV- cocaine users (n=22), and a control sample of HIV- non-drug users (n=21), and how these neurobehavioral factors relate to sex risk behavior. Participants completed a clinical interview, computerized survey and decision-making tasks, and a neuropsychological battery.

Results: Cocaine users had significantly higher rates of sex risk behavior than non-drug users. Specifically, HIV- cocaine users had the highest scores on the Risk Assessment Battery (RAB) followed by HIV+ cocaine users and HIV- non-drug users (*F*[2,59]=7.12, *p*=.002). Neurobehavioral function was also altered among cocaine users compared to non-drug users. The HIV+ cocaine users had the highest number of errors on the Wisconsin Card Sorting Task (WCST) (*F*[2,59]=4.13, *p*=.021) and the worst deficits in attention (*F*[2,59]=3.62, *p*=.033), while the HIV- cocaine users had the highest trait impulsivity (*F*[2,59]=13.31, *p*=.001).

Controlling for group status, several neurobehavioral characteristics were associated with sex risk. Higher deficits in memory and motor function were associated with unprotected intercourse (*r*=.280, *p*= .029 and *r*=.473, *p*= .001) and total number of sex partners in the past year (r=.296, p=.020 and r=.457, p=.001). Having multiple partners in the past 3 months was associated with higher deficits in verbal fluency (F[1,59]=7.079, p=.010). Less impairment in executive function was associated with higher RAB scores (*r*=-.295, *p*=.021) and sex with a prostitute (*F*[1,59]=5.268, *p*=.025). Finally, higher sensation seeking was associated with higher RAB scores (*r*=.298, *p*=.020), unprotected intercourse (*F*[1,59]=11.710, *p*=.001), and sex while high or drunk in the past year (F[1,59]=5.020, p=.029).

Using multiple regression, the effect of group status on RAB scores was moderated by sensation seeking (*B*=-0.11, *p*=.038) and the effect on total number of sex partners in the past year was moderated by deficits in attention (*B*=-0.81, *p*=.025). Sex risk increased with higher sensation seeking and worse deficits in attention for the HIV+ cocaine users, but not for the other groups.

Implications: The findings highlight the important role of neurobehavioral function in the risk for contracting and transmitting infectious diseases like HIV among cocaine users. The implication of these findings for behavioral interventions in primary care settings will be discussed.

Symposium 75C

VETERANS LIVING WITH HIV: A PARTICULARLY HIGH-RISK GROUP FOR CIGARETTE SMOKING

Dr. Sarah M. Wilson, Ph.D.

The Department of Veterans Affairs (VA) is the largest provider of medical care to persons living with human immunodeficiency virus (HIV) in the United States. Although HIV status and veteran status are known risk factors for smoking, there is no population-level evidence of smoking prevalence among veterans with HIV. Data from the National Survey on Drug Use and Health (NSDUH) were examined to characterize smoking as a function of veteran and HIV status. Results indicated that 51% of veterans living with HIV were daily smokers, as compared to 25% of veterans without HIV and 31% of non-veterans living with HIV. Additionally, veterans living with HIV were more likely than HIV-negative veterans to endorse past-month smoking. This study provides preliminary evidence that veterans living with HIV may be a particularly high-risk group for daily tobacco smoking, with consequent poor health. Findings are discussed in the context of multiple ecological levels of health risk and behavior change for this at-risk population, including public policy, institutional policies, interpersonal models, and intrapersonal behavior change.

Symposium 75D

CHRONIC PAIN MANAGEMENT IN THE CONTEXT OF OPIOID USE AND INFECTIOUS DISEASES

Sara N. Edmond, PhD

In the context of the national opioid crisis, both prescribed and unprescribed opioid use is fueling opioid misuse and adverse events including overdose and death. Chronic pain, the most common indication for opioid therapy, is common among patients with infectious diseases such as Hepatitis C (HCV), and data suggest patients with chronic pain frequently use alcohol and illicit substances to manage pain. Among veterans of recent conflicts with HCV (n=2942), 51% endorse moderate to severe pain. Given high rates of chronic pain, unhealthy alcohol use (46%), and tobacco use (58%) in this at-risk population, innovative models of care are needed for veterans with HCV. The Opioid Reassessment Clinic (ORC) is a multidisciplinary care team staffed by an internist, addiction psychiatrist, APRN, and health psychologist to work with patients with problems with safety, efficacy, or misuse of opioids. Within the ORC, patients receive care from a multidisciplinary team with attention to safer pain management including non-opioid pain medications and non-pharmacological pain management approaches. Although the ORC is not explicitly designed for patients with infectious diseases, ORC patients are often medically complex. Of 87 consecutively referred patients over a two-year period, 33% had a diagnosis of HCV and 1% had HIV. At time of referral, average morphine equivalent daily dose (MEDD) was 121.4; average pain score was 6.8/10. Over half (57%) had an aberrant urine toxicology screen prior to their ORC referral. The majority had a history of substance use disorder (84%); 54% had opioid use disorder at initial assessment. Two-thirds met criteria for alcohol use disorder and 47% met criteria for cocaine use disorder, yet only 36% were seen for addiction treatment in the prior year. Mental health co-morbidities were common with diagnosis rates of 56% for depression, 39% for PTSD, 24% for an anxiety disorder, and 19% for bipolar disorder. Integrated clinics such as the ORC may be useful in managing complex patients such as those with HCV and co-morbid pain, substance use, and mental health concerns.

Symposium 76 8:30 AM-9:45 AM

EXERCISE AS A NON-PHARMACOLOGICAL APPROACH TO THE MANAGEMENT OF CHRONIC PAIN

E. Amy Janke, PhD[1], Erin Dannecker, PhD, ATC[2], Francis Keefe, PhD.[3], Linda C. Li, PT, PhD[4]

[1]University of the Sciences, Philadelphia, PA; [2]University of Missouri, Columbia, MO; [3]Duke University, Durham, NC; [4]University of British Columbia, Richmond, BC, Canada

Exercise is Medicine® (EIM) is a global initiative started by the American Medical Association and the American College of Sports Medicine (ACSM) to make physical activity (PA) a first-line behavioral medicine strategy to prevent and treat many forms of disease and disability. Approximately 1/3 of all Americans experience persistent pain, and such pain is associated with significant distress, disability, and economic cost. An estimated 41% of adults with chronic, non-cancer pain report their pain symptoms are not controlled. Furthermore, the growing opioid addiction crisis demands exploration and support of non-pharmacological approaches to pain management. The aims of this jointly sponsored symposium by ACSM and the Society of Behavioral Medicine are to discuss exercise as a non-pharmacological approach to aid in the management of chronic pain. Specifically, this symposium will review: 1) the relationship between chronic pain and physical activity, and specifically the role of exercise in the treatment of chronic pain; 2) clinic-based brief intervention approaches delivered alongside allied health professionals to increase activity in individuals with pain; and 3) community-based approaches to safely increase exercise in individuals with pain. The first panelist will review current prevalence and trends in pain and physical activity, shared risk factors for chronic pain and insufficient physical activity, and provide an overview of the relationship between pain and exercise within the larger context of EIM. The second panelist will discuss brief intervention approaches with physical therapists and other health professionals to increase exercise in individuals with osteoarthritis and discuss some of the challenges faced when implementing these approaches. The third panelist will discuss community based approaches for remotely counseling individuals with arthritis to increase daily activity and exercise, linking these approaches to the EIM model of engaging patients in community resources. Finally, the discussant will comment on the presented approaches for increasing physical activity in individuals with pain and discuss current opportunities and challenges implementing exercise as a non-pharmacological approach to pain management.

Symposium 76A

THE RELATIONSHIP BETWEEN EXERCISE AND PAIN

Erin Dannecker, PhD, ATC

Improving the management of chronic pain and increasing physical activity are both current public health priorities. The purpose of this presentation is to review the prevalence of chronic pain and physical activity, shared risk factors for chronic pain and insufficient physical activity, and the complex relationship between pain and exercise. Based on best estimates, chronic pain conditions are highly prevalent and represent an increasing burden on the U.S. healthcare system as the population ages. Current pharmacologic practices to address these conditions have proven inadequate while inadvertently contributing to an epidemic of opioid abuse and deaths from overdose. In comparison, exercise can be an effective pain-management approach, which is why recent guidelines from the Centers for Disease Control and Prevention prioritize non-pharmacological treatments before initiating opioid therapy in some patients. Actually, many clinical practice guidelines for various painful diagnoses have recommended exercise. Systematic reviews support these guidelines, but the relationship between exercise and pain is complex. For example, the exercise parameters and/or the condition of the exerciser can affect the magnitude and direction of change in pain. Also, the mechanisms of exercise’s effects on pain vary depending upon the exercise parameters. Moreover, pain is a barrier to exercise behavior and, in the U.S., physical activity levels are inadequate. Inadequate physical activity is a leading cause of death worldwide. These issues and the shared risk factors for chronic pain and inadequate physical activity must be considered by efforts to use exercise as an intervention for chronic pain.

Symposium 76B

PAIN COPING SKILLS TRAINING & PHYSICAL EXERCISE TRAINING FOR PATIENTS WITH OSTEOARTHRITIC PAIN: OPPORTUNITIES AND CHALLENGES

Dr. Francis Keefe, PhD.

Many patients with osteoarthritis (OA) pain report that difficulties coping with pain are important factor limiting their ability to follow recommendations about remaining active and engaging in physical exercise. This presentation highlights a program of research that has examined the separate and combined effects of physical exercise training and training in pain coping skills. Three randomized studies (collaborator: Kim Bennell, U. of Melbourne) are presented. In the first 201 OA knee pain patients were randomized to physical exercise alone, pain coping skills training (PCST), or a combined physical exercise training/PCST protocol. Though no significant between-group differences in pain were found, the combined physical exercise training/PCST condition had greater improvements in function compared to each intervention alone. One limitation is that the PCST protocol involved ongoing training and supervision of physical therapists. Two more recent studies tested an internet-based interactive PCST program that did not require therapist training/supervision. In a study of 148 individuals with OA knee pain we found that a protocol that combined an online interactive PCST program with a physiotherapist home exercise program delivered via videoconferencing was effective in reducing walking pain and improving physical function. A third study of 144 OA hip pain patients found the online PCST program produced immediate improvements in pain coping and physical function but did not confer any additional benefits to a subsequent exercise program, though it did produce sustained long-term improvements in pain coping. The presentation concludes with a discussion of lessons learned and challenges and opportunities in this emerging research area.

Symposium 76C

CAN PHYSICAL ACTIVITY MONITORING TOOLS SUPPORT PEOPLE WITH CHRONIC PAIN TO BE PHYSICALLY ACTIVE?

Dr. Linda C. Li, PT, PhD

The evidence supporting a physically active lifestyle among people with chronic diseases is compelling. Many patients, however, do not meet the minimum recommended amount of physical activity, and evidence suggests individuals with persistent pain may be particularly vulnerable to inactivity. For example, in people with arthritis, pain and fatigue are the major barriers. It is known that people with arthritis were less active during their leisure time compared to the general population. A recent study also found 42% of rheumatoid arthritis patients accumulated 0 minute of bouted moderate/vigorous physical activity, performed in bouts of 10 minutes or more, in a week. Commercially available self-monitoring tools, such as pedometers and accelerometers, are popular to support an active lifestyle. The purpose of this presentation is to examine opportunities and challenges of using self-monitoring tools to promote a physically active lifestyle in patients with chronic pain. Using arthritis as an example, the feasibility of a remote counselling intervention by a physical therapist with the use of a popular wearable device will be presented. Findings of a subsequent ongoing randomized controlled trial in patients with knee osteoarthritis will be discussed. The presentation will end with findings from a qualitative study in three Canadian provinces on the views and experiences of patients and health professionals on the use of physical activity monitoring technologies in arthritis care. A key finding was the discrepancy in how the two groups perceived the ability of monitoring tools to motivate users, the sustainability of these tools, and how they were changing patient-health professional interactions. Potential opportunities in the use of self-monitoring tools to support the Exercise is Medicine (EIM) initiative in the community will be discussed.

Symposium 77 8:30 AM-9:45 AM

PREVALENCE AND PREDICTORS OF DEPRESSION AND STRESS IN DIVERSE SAMPLES OF PREGNANT WOMEN

Karen L. Weis, PhD, RNC-OB, FAAN[1], Patricia Kinser, PhD, WHNP-BC, RN, FNAP[2], Jeni Matthews, MS[3], Jenn Leiferman, PhD[4]

Karen L. Weis, PhD, RNC[1], Patricia Anne Kinser, PhD, WHNP, RN[2], Jennifer Matthews, MS[3] and Jenn Leiferman[4]

[1]University of the Incarnate Word, San Antonio, TX; [2]Virginia Commonwealth University, Richmond, VA; [3]Arizona State University, Phoenix, AZ; [4]Colorado School of Public Health University of Colorado, Denver, CO

Prenatal maternal stress and depression are associated with pregnancy complications, negative birth outcomes, poor maternal-infant attachment and infant neurodevelopmental disorders. Research is just beginning to uncover the etiology of fetal programming to adult cardiovascular, metabolic and neuroendocrine disorders. Prenatal maternal stress and depression increase the likelihood of tobacco and substance use, poor dietary habits and late or inadequate prenatal care. All of these risk factors are modifiable but the development of well-designed effective interventions requires a clear understanding of population characteristics and the influence on the outcome variables.

This symposium will address predictors and correlates of prenatal maternal stress and depression in three diverse populations. The first presentation will focus on demographic predictors of prenatal maternal anxiety, depression, self-esteem and resilience within a military sample. The second presentation will concentrate on pre-conception and early prenatal predictors of depression within an urban sample of black and white women. The final presenter will compare various stressors and coping mechanisms reported in a sample of pregnant women with low to severe stress levels (Perceived Stress Scale) - . Lastly, the Chair will comment on how these identified predictors and correlates of prenatal depression/stress differ across populations and how these findings may inform future intervention approaches.

Symposium 77A

PREDICTORS OF INCREASED PRENATAL MATERNAL ANXIETY, SELF-ESTEEM AND RESILIENCE IN A SAMPLE OF MILITARY WOMEN

Dr. Karen L. Weis, PhD, RNC-OB, FAAN

Background: A relationship exists between prenatal maternal anxiety and depression to pregnancy complications, poor birth outcomes and infant/childhood cognitive delays. Traditionally, high-risk groups of young, unmarried, undereducated primigravidas have been the focus of prenatal assessment and interventions. Less understood is anxiety and depression in differing samples. **Purpose/Methods:** Two hundred and forty-six military women were consented and randomized to either a prenatal support program or regular prenatal care starting in the first trimester. All participants completed the PSEQ, EPDS, RSE and BRIEF in each trimester. Women in the intervention attended 8, 1-hr mentored sessions aimed at decreasing prenatal pregnancy-specific anxiety and depression. The efficacy of the intervention across pregnancy was examined for prenatal anxiety, self-esteem, depression and resilience using linear mixed models with autoregressive correlation. Demographic covariates were: age, employment, parity, marital status, education, deployment history, military branch, race, and active duty status. **Results:** Compared to multigravidas, primigravidas had lower anxiety for accepting pregnancy and concerns related to partner relationships, but a five-fold increase in anxiety related to preparation for labor and higher fears of helplessness in labor. Marital status afforded a five-fold decrease in anxiety for accepting pregnancy, a two-fold decrease in fears of well-being but non-married women had resilience scores two times higher. Those having a high school degree had two times greater anxiety for accepting pregnancy than those with some or a college degree, unrelated to age. College graduates had greater fears related to well-being. Age was only predictive of increased anxiety for relationship with mother. Deployment significantly effected maternal identification and self-esteem was two-times greater for women of color. **Conclusion:** This military sample experienced lower overall anxiety and depression scores compared to previous studies in military and civilian samples. The results reflect a different picture than generally anticipated in that women with higher education and parity had increased anxiety for certain dimensions and age was not a significant factor. The military environment promotes opportunities to gain increased self-esteem and resilience regardless of sex or race, and the study bears this out. The impact of the father's absence on a women's identification as a mother is extremely important, particularly within a military population. The findings provide relevant information indicating the unique differences that exist for women regarding pregnancy anxiety and the need for appropriate assessments and interventions for the particular population.

Symposium 77B

DEPRESSIVE SYMPTOM PREVALENCE AND PREDICTORS IN THE FIRST HALF OF PREGNANCY

Dr. Patricia Kinser, PhD, WHNP-BC, RN, FNAP

Background/ Purpose/Methods: Despite recent guidance about screening for depression by the US Preventive Services Task Force, depressive symptoms continue to be under-identified and under-treated in pregnant women. The purpose of this IRB-approved study is to examine the predictors of depression in white and black women in early second trimester of pregnancy as part of a larger study designed to explore how environmental and social exposures contribute to inter-individual differences in the timing of birth. A sample of 230 black and white women receiving prenatal care in obstetric clinics in Richmond, VA were recruited for the study from 2013 to 2016.

Results: Univariate logistic regression indicated that multiple variables were associated with CIDI-SF depression, such as demographic (race, relationship status, employment status and education), preconception health (having visited a healthcare worker for depression/ anxiety in the past 12 months, lifetime history of depression), coping strategies, the prenatal social environment, and other symptoms (perceived stress, pregnancy-related anxiety). These variables were then entered into a multivariable logistic regression model with a backwards elimination procedure to arrive at two parsimonious models: the first included a single covariate of a lifetime history of a depression episode (AUC=0.87; 95% CI 0.82-0.90; sensitivity 97%; specificity 76%) and the second eliminated lifetime history and included race, employment status, having visited a healthcare worker for depression/anxiety in the past 12 months, and the Prenatal Social Environment Inventory scale (AUC=0.74; 95% CI 0.64-0.82; sensitivity 49%; specificity 88%).

Conclusions: This study contributes to the body of knowledge predictors of depressive symptoms with onset during in preconception and early pregnancy. Future research is warranted to explore differences in clinical presentation and underlying biological patterns because, in clinical settings, the use of predictive variables in combination with identifiable biomarkers related to depressive symptoms may allow for earlier diagnosis and/or differentiate appropriate treatment modalities.

Symposium 77C

DIFFERENCES IN STRESSORS AND COPING STRATEGIES OF PREGNANT WOMEN WITH LOW-MODERATE AND HIGH-SEVERE PERCEIVED STRESS SCORES

Jeni Matthews, MS

Background: Up to 78% of women experience elevated levels of stress during pregnancy. Elevated levels of stress have been linked to negative birth outcomes such as preterm birth (
Methods: We conducted a national survey in women ≥8 weeks pregnant, ≥18 years old, and residing in the US (N=971). Descriptive statistics, frequencies, and percentages were calculated. The Perceived Stress Scale (PSS) was used to determine levels of stress. Data was split into quartiles to determine PSS cut points within the 25th, 50th, and 75th percentiles.

Results: Fifty-one percent of women scored within the low-moderate range (0-15) and 49% scored within the high-severe range (≥16). Women with low-moderate levels of stress reported financial burden (N=190, 38%), work (N=164, 33%), and time (N=152, 30%) as the top three stressors. Women with high-severe levels of stress reported financial burden (N=271, 58%), work (N=187, 40%), and pregnancy (N=170, 36%) as the top three stressors. Women with low-moderate levels of stress reported reading (N=232, 46%), exercising (N=179, 36%), and eating (N=127, 25%) as the most frequently used coping strategies. Women with high-severe levels of stress reported reading (N=145, 31%), eating (N=135, 29%), and nothing (N=126, 27%) as the most frequently used coping strategies.

Conclusion: Our data suggest that pregnant women with high-severe levels of stress frequently do nothing to manage their stress and women in both groups eat as a response to stress. This is important, as researchers may want to consider focusing on limiting these types of negative coping strategies when designing interventions to decrease stress during pregnancy. Future studies may want to consider providing specific resources for healthy coping strategies in women with high-severe stress (e.g., exercise, meditation).

Symposium 78 8:30 AM-9:45 AM

OPTIMIZATION OF ONLINE SUBSTANCE USE INTERVENTIONS TARGETING COLLEGE STUDENTS

Kari C. Kugler, PhD, MPH[1], Emily Grekin, PhD[2], Kari C. Kugler, PhD, MPH[1], David Wyrick, PhD[3], Gary G. Bennett, PhD[4]

[1]The Pennsylvania State University, University Park, PA; [2]Wayne State University, Detroit, MI; [3]University of NC - Greensboro, Greensboro, NC; [4]Duke University, Durham, NC

The multiphase optimization strategy (MOST) is an engineering-inspired framework for building more efficacious, effective, cost-effective, and scalable behavioral interventions. This phased approach (preparation, optimization, and evaluation phases) often uses factorial experimentation to identify which components to include in an optimized intervention. Online interventions are useful platforms for taking advantage the efficiency of a factorial experiment. The talks in this symposium showcase three studies at different stages of MOST, each interested in optimizing an online intervention targeting substance use among college students.

The first talk presents the results from a pilot study examining elements of a brief computer-delivered intervention targeting heavy alcohol use. This talk highlights the importance of pilot testing intervention components prior to experimentation during the optimization phase. The second talk presents the results from the first (of two) screening experiments during the optimization phase. This talk demonstrates how the conceptual model of alcohol use and sexual risk behaviors was used to identify the intervention components for the factorial experiment. The third talk presents the results evaluating the effectiveness of an optimized substance use intervention during the evaluation phase. This study shows how repeated experimentation during the optimization phase engineered a potent intervention.

Collectively, these talks demonstrate how the phases of MOST are currently being used to optimize online behavioral interventions among college students. Following the principles and phases of MOST increases the likelihood that a behavioral intervention will achieve its desired outcome. The discussant for this symposium has extensive expertise in technology-delivered behavioral interventions and will review the benefits of using MOST to improve the public health impact of behavioral interventions.

Symposium 78A

OPTIMIZING E-INTERVENTIONS FOR ALCOHOL USE

Dr. Emily Grekin, PhD

The flexibility and modularity of computer-delivered brief interventions (CDBIs) makes them an ideal platform for (a) isolating the active ingredients that are associated with positive outcomes; and thereby (b) continually optimizing CDBIs to achieve cumulative increases in efficacy. The current study seeks to systematically manipulate four CDBI elements – presence versus absence of (1) empathy/positive regard, (2) voice, (3) animated narrator, and (4) use of techniques adapted from Motivational Interviewing (MI) – to determine which combination of elements is most associated with reductions in drinking. The current project will recruit 352 university students meeting NIAAA criteria for heavy drinking and randomly assign them to 1 of 16 different conditions representing all combinations of the four intervention elements noted above (2 X 2 X 2 X 2). Outcomes include state motivation immediately following baseline participation and alcohol use at 1- and 3-months post-baseline. As a critical first step, we pilot tested content for three specific cells (high empathy only, high positive regard only, and education-only control) to evaluate discriminability. Pilot participants viewed the content for these cells in counterbalanced order and ranked them for preferability, understanding, and supportiveness. A total of 63.6% of participants preferred the high empathy content, compared to 18.2% for both the high positive regard and education-only CDBIs ($z = 3.01$, $p < .01$). Participants also found the high empathy CDBI to be the most supportive ($z = 3.01$, $p < .01$), understanding ($z = 3.47$, $p < .01$), and affirming ($z = 2.56$, $p = .01$). Interestingly, participant ratings for the control and positive regard conditions did not differ. These results suggest that either more work is needed on the positive regard content, or that expressions of positive regard have no impact on participant preferences or perceptions. These results also support the Nass et al. Media Equation Theory, which suggests that interactions with even minimally lifelike technology leads to social responses that are indistinguishable from those with human beings.

Symposium 78B

OPTIMIZATION OF AN ONLINE STI PREVENTIVE INTERVENTION TARGETING COLLEGE STUDENTS

Dr. Kari C. Kugler, PhD, MPH

Drinking alcohol is often implicated in the sexual behaviors that increase college students STI risk. Most existing interventions target alcohol and sex separately, rather than focus on the alcohol-sex intersection. The current study will present results from an ongoing factorial experiment of itMatters, an online intervention focused at the alcohol-sex intersection (completion fall 2016). The experiment is designed to identify which intervention components (i.e., descriptive norms, injunctive norms, expectancies, perceived benefits of protective behavioral strategies, and self-efficacy to use strategies) are effective at changing the corresponding primary outcomes. All first-year students from four universities were recruited and randomized to one of 32 experimental conditions that included a combination of the aforementioned components. The 3439 students who completed the baseline survey were mostly female (61%), White (52%), heterosexual (94%), and lived on campus (74%). Baseline results provide behavioral context for the intervention. Most students reported past alcohol use (63%) and sex (oral, anal, and/or vaginal; 58%). Among those who had had sex, 9% reported using alcohol (33% reported being drunk) and 38% did not use a condom at their most recent vaginal sex. Among the 35% of students who reported a hookup, 20% used alcohol (42% which reported being drunk) and 31% did not use a condom for vaginal sex. There were no statistically significant baseline differences in outcomes based on randomization levels. The results from this experiment will be used to guide decisions about which intervention components to revise and reexamine in a subsequent factorial experiment. Complete results from the first screening experiment, the rationale for conducting two screening experiments to optimize the STI preventive intervention, and overall study design and goals will be discussed.

Symposium 78C

ENGINEERING AN EFFECTIVE SUBSTANCE USE PREVENTION PROGRAM FOR COLLEGE STUDENT-ATHLETES

David Wyrick, PhD

College student-athletes are at increased risk of substance use compared to non-athletes. We developed *myPlaybook*, an online substance use intervention tailored to college student-athletes using the Multiphase Optimization Strategy (MOST), to optimize its impact. As part of optimization phase, we tested whether a set of intervention components (i.e., lessons) met specific optimization criteria in a series of three component screening experiments. The results from 3 factorial experiments (ranging from 8 to 16 conditions) identified the optimized *myPlaybook* intervention, which was then evaluated using a randomized control trial to test effectiveness. The optimized intervention package consisted of 4 components: (1) knowledge lesson, (2) normative perceptions lesson, (3) expectations lesson, and (4) harm prevention lesson. Schools (n=73) were randomly assigned to receive the packaged intervention or just the introductory lesson. First-year and transfer student athletes (n=5,860) completed a baseline survey, a 30-day follow-up survey, and a 4-month follow-up survey. There was a significant and sustained effect on descriptive and injuctive norms for drug use, and positive expectancies for alcohol use; however, there was no significant effect on harm prevention behaviors or intentions. In terms of drug use behavior, there was a significant effect on frequency of alcohol use and marijuana frequency at 30-day follow-up, but no effect for binge drinking, heavy drinking, or tobacco use frequency. Finally, there was a significant effect on non-alcohol and other drug related consequences (e.g., missing class) for in-season (but not off-season) student-athletes at 30 day follow-up. These results suggest that the optimized *myPlaybook* intervention was successful in changing short-term behaviors. Detail about the process of using MOST and next steps will be discussed.

Symposium 79 8:30 AM-9:45 AM

INTIMATE PARTNER VIOLENCE AND TRAUMA-INFORMED CARE: PRIORITY ISSUES FOR BEHAVIORAL MEDICINE

Emily F. Rothman, ScD[1], Sheela Raja, PhD[2], Ivy Ho, PhD[3], Rose Constantino, PhD, JD, RN, FAAN, FACFE, Fulbright Scholar[4]

[1]Boston University School of Public Health, Boston, MA; [2]University of Illinois at Chicago, Chicago, IL; [3]University of Massachusetts Lowell, Lowell, MA; [4]University of Pittsburgh School of Nursing, Pittsburgh, PA

Increasingly behavioral medicine experts are recognizing the importance of addressing patients' history of trauma and violence victimization in order to optimize all kinds of health-promoting interventions and to improve individuals' overall well-being. However, precisely how individual physicians and other healthcare providers, or healthcare organizations, should tackle the complicated problem of "addressing trauma" is still emerging. "Trauma-informed care" is now a somewhat commonly-used phrase (or buzzword), but not everyone understands what is meant by "trauma-informed care" in the same way. Further, we lack a broad and deep body of evidence about the most effective ways to approach certain victims of trauma, such as survivors of intimate partner violence. In this session we bring together three nationally-recognized experts in addressing trauma in the healthcare setting in order to accomplish three aims. First, we will provide attendees with a neurophysiological explanation for why and how trauma can influence somatic health in the short- and long-term. Second, we will provide attendees with evidence that intimate partner violence, specifically, is associated with physical health outcomes in Southest Asian American women, and finally we will present data that explores the ways in which caring for survivors of interpersonal violence can cause compassion fatigue in medical care providers and discuss how compassion fatigue can be prevented or treated. Understanding and addressing experiences of interpersonal violence and traumatic experiences so that patients have positive healthcare and health-promoting experiences is a critically important priority for behavioral medicine, and this session will provide an ideal forum for anyone with an interest in these topics to engage with other thought-leaders and experts in the field.

Symposium 79A

TRAUMA INFORMED CARE FOR INTERPERSONAL VIOLENCE SURVIVORS: UNDERSTANDING NEUROPHYSIOLOGY AND BEHAVIORAL COPING

Sheela Raja, PhD

The World Health Organization defines interpersonal violence (IPV) as physical, sexual, and emotional abuse, as well as controlling behaviors that take place in an intimate relationship. A sizable portion of the US population have experienced IPV, and many children witness IPV on a daily basis. This session will provide an overview of the health effects of IPV, with a particular emphasis on the neurophysiological changes resulting from chronic IPV exposure. Children who witness IPV on a regular basis may be particularly vulnerable to toxic stress, which results in long-term neurophysiological disruption. The Hypothalamic-Pituitary-Adrenal (HPA) axis may become chronically over-activated in some individuals. We will focus on how these physiological changes may encourage maladaptive coping methods later in life, including overeating, smoking, drinking, and high risk sexual behavior. In addition, trauma history is likely to influence healthcare utilization patterns, including underutilization of preventive care and more emergency and sick visits, resulting in a higher disease burden. The session will explore how trauma-informed approaches can help survivors break intergenerational patterns of violence. These approaches include psychological interventions that alleviate neurophysiological disruption and community-based supports that can decrease the prevalence of IPV.

Symposium 79B

INTIMATE PARTNER VIOLENCE AND PHYSICAL HEALTH OUTCOMES AMONG SOUTHEAST ASIAN AMERICAN WOMEN

Dr. Ivy Ho, PhD

Although intimate partner violence (IPV) is prevalent among Southeast Asian (SEA) American women, little is known about the associations between the experience of IPV and negative health outcomes in this population. Resnick, Acierno and Kilpatrick (1997) proposed a model explaining the development of health problems following violent assault, which includes three direct outcomes (acute physical injury, increased stress, and increased risk of mental health problems) that in turn precipitate a second layer of mediating factors (chronic physical injury, impaired immune system functioning, increased health risk behavior, and ineffective health care utilization). The present paper assesses the applicability of Resnick et al.'s model to SEA American women who have experienced IPV by reviewing cultural, historical, and social factors in this population. Our review indicates that the applicability of Resnick et al's (1997) model to SEA American women is mixed. Some components of the model – such as factors that pertain to physical injury, both acute and chronic – fit well with this population. Other components – such as factors pertaining to increased stress, increased risk for mental health problems, and increased health risk behavior – require a more nuanced and complex perspective. This presentation will conclude with a discussion on the research and clinical implications of with regard to IPV among SEA American women.

Symposium 79C

EXPLORING TRAUMA-INFORMED CARE AND COMPASSION FATIGUE IN HEALTHCARE PROVIDERS

Dr. Rose Constantino, PhD, JD, RN, FAAN, FACFE, Fulbright Scholar

Purpose: The purpose of this presentation is to inform the attendees of the signs, symptoms, and consequences of Compassion Fatigue (CF), the various ways it is displayed and the healing effects of trauma-informed care. The signs and symptoms of CF are not readily seen by the untrained eye especially by the sufferer; it is an insidious and gradual lessening of compassion over time to the observant, trauma-informed, and compassionate co-worker, supervisor or partner.

Literature Review: We present applicable evidence based literature, examine protective factors and trauma-informed care in both the healthcare provider and the CF sufferer. For example, Berg and others (2016) studied CF in a trauma team and found that team members were not as managing work stresses as well as they perceived themselves to be. Raja and others (2016) developed a program on educating healthcare providers on trauma-informed care: the trauma-informed medicine eCases (TIMe) where every part of the institution (from staff, administrators, supervisors, to healthcare providers) understand the consequences of traumatic events, sensitively interact trauma supervisors, avoid re-traumatization, and engage in trauma screening and prevention.

Case Study: An extreme case of tension and preoccupation with the suffering of those being helped to the degree that it traumatizes the helper. Gentry suggests that we enter into the healthcare giving field already with CF. CF differs from burnout as burnout is exhaustion from the chronic tedium of the job (Tabor 2011). The healthcare provider in the case study will perform her duties and provide compassionate care to the patient devoid of CF. We will have an interactive session with the audience what if the healthcare provider in this case was suffering from CF.

Implications: Whether we like it or not, believe or not, realize it or not, healthcare providers are in the ministry of compassionate and trauma-informed care because we "help" and "care" for the sick and traumatized; dedicated to caring for the displaced, traumatized and relief of human suffering. Trauma-informed care prods us to suffer with the others, to enter the dark places where it hurts and be able to leave those dark, bloody and chaotic places after we put them in some order.

Conclusions: No one is immune to job-related trauma and stress. We need to care for each other. We are indeed our brothers'/sisters' keeper. Being a trauma-informed healthcare professional is not expensive nor does it remove anything from us in fact it adds something to the vast knowledge, information and evidence-based practice we already possess.

Symposium 80 8:30 AM-9:45 AM

PERSONALITY PREDICTS HEALTH COGNITIONS, EXPERIENCES, AND BEHAVIORS: FINDINGS FROM DIVERSE PERSPECTIVES

Jennifer Howell, PhD[1], Jennifer M. Taber, PhD[2], Jenna R. Cummings, M.A.[3], Kate Sweeny, PhD[4], Jennifer Howell, PhD[1]

[1]Ohio University, Athens, OH; [2]Kent State University, Kent, OH; [3]University of California, Los Angeles, Los Angeles, CA; [4]University of California, Riverside, Riverside, CA

The field of behavioral medicine has long recognized the influence of demographic characteristics on health cognitions and behaviors. Recently, emerging technologies have made individually-tailored health communications and interventions possible. However, many of these endeavors have focused exclusively on demographic differences and ignored the role of personality. In this symposium, we attempt to extend knowledge about how individual differences can affect health cognitions and behaviors to include the domain of personality. In four talks, we offer evidence that personality can affect health cognitions, experiences, and behaviors across a diverse set of domains. First, Taber will discuss research suggesting that personality predicts perceptions of risk in a sample of adults undergoing genomic sequencing. Taber will highlight how personality factors like optimism, spontaneous self-affirmation, and big-five personality traits predict the discrepancy between people's understanding of their absolute risk and their feelings about their risk. Next, Sweeny will discuss how personality affects physical health and psychological well-being as people wait for uncertain news. Specifically, she examines the health of law school graduates during four months as they waited to learn whether they passed the bar exam. Sweeny's results demonstrate that personality traits associated with handling stressors (e.g., spontaneous self-affirmation, trait mindfulness) are associated with better health trajectories during the waiting period. Third, Cummings will discuss the role of personality and demographics in determining the social aspects of drinking and eating. Specifically, her data suggest that bonding over food and drink is moderated by both gender and the trait emotional eating. Finally, Howell will discuss evidence that personality traits predict the likelihood that people will avoid health information. Data from several studies suggests that traits that indicate dispositional openness to information (e.g., curiosity, openness to experience) and emotional coping resources (e.g., low neuroticism, high spontaneous self-affirmation, and high optimism) predict less avoidance of health information and feedback. Together, these four talks provide evidence of the nuanced and important role of personality in health cognitions, experiences, and behavior.

Symposium 80A

THINKING ONE WAY ABOUT RISK BUT FEELING ANOTHER: PERSONALITY CORRELATES OF HAVING MISMATCHED RISK PERCEPTIONS

Dr. Jennifer M. Taber, PhD

People think about personal disease risk in diverse and nuanced ways, and conceptualizations of risk may depend on personality factors, including individual differences in psychological resources (i.e., characteristics that help individuals to bolster against emotional, social, or physical threats). Characteristics of people with discrepancies between what they “think” and “feel” about their risk are relatively unexplored. We examined the prevalence and correlates (personality/sociodemographic) of mismatches between deliberative (i.e., cognitions) and experiential (i.e., intuitions) risk perceptions among adults enrolled in an NIH genome sequencing trial (*n*=536). Participants completed a survey of their risk perceptions before learning sequencing results, reporting the extent to which they believed their results would confer personal risk for a common disease (deliberative) and the extent to which they felt their genes put them at risk for a common disease (experiential). Participants were categorized into four groups based on responses to these questions. Excepting those who selected the midpoint of “unsure” for both risk items (9.3%) and were removed from analyses, responses of “unsure” were categorized as estimates of low risk. Nearly one-quarter (24.3%) perceived high deliberative but low experiential risk. Fewer (14.7%) reported low deliberative but high experiential risk. Slightly over half did *not* have risk mismatches: 28.2% perceived high deliberative and experiential risk and 23.5% perceived low deliberative and experiential risk. Compared to all other participants, those in the group whose experiential beliefs were greater than their deliberative beliefs reported lower optimism (*F*(1,475)=11.80, *p*=.001), greater worry (*F*(1,478)=16.54, *p*F(1,450)=5.37, *p*=.021), somewhat lower extraversion (*F*(1,450)=3.58, *p*=.059), and greater education (*F*(1,468)=8.06, *p*=.005). Those whose deliberative risk beliefs were higher than their experiential risk beliefs were older (*F*(1,482)=9.52, *p*=.002). There were no differences in education, gender, race, resilience, spontaneous self-affirmation, conscientiousness, openness to experience, or agreeableness across groups. These data suggest that people with lower levels of trait-level psychological resources but higher education might “feel” that they are at risk for disease but acknowledge low risk or be unsure of their actual objective risk. This is consequential, as deliberative measures (most commonly used in health behavior research) may not adequately capture how such individuals engage with risk. Future research may examine whether these individuals distribute resources (e.g., protective actions) to threats that “feel” risky rather than targeting resources to threats that are perceived as objectively risky.

Symposium 80B

TRAIT AND DEMOGRAPHIC PREDICTORS OF BONDING OVER ALCOHOL AND UNHEALTHY FOOD CONSUMPTION

Ms. Jenna R. Cummings, M.A.

Excessive consumption of alcohol and unhealthy food is a modifiable risk factor for multiple chronic illnesses. However, positive social experiences that coincide with eating and drinking, such as improved social connection, may reinforce consumption of alcohol and unhealthy food. This may be especially pertinent for individuals with certain traits and demographic profiles. The objective of the current study was to experimentally examine how individual differences in sex, emotional eating, and endorsement of alcohol expectancies may moderate social experiences that reinforce eating and drinking. Participants (N = 200) completed demographic and personality questionnaires online. Then, participants were randomly assigned to consume milkshakes, placebo beer, or water (control) with a stranger in a laboratory space similar to real-world settings where people eat and drink with others. Research assistants coded how often participants talked, smiled, and laughed. Participants self-reported how close they felt with, and chose how close to sit to, the stranger. Results indicated several effects moderated by individual differences: (1) Men, but not women, laughed ($p = .032$) and smiled more ($p = .082$), and reported feeling closer with the stranger if they consumed placebo beer but not milkshakes or water ($p < .001$). (2) Individuals scoring higher in trait emotional eating laughed ($p = .007$), smiled ($p = .007$), and talked more ($p = .063$), and reported feeling closer with the stranger ($p = .062$), if they consumed milkshakes but not placebo beer or water. (3) Individuals with stronger expectancies that alcohol reduces tension or promotes social assertiveness reported feeling closer with the stranger if they consumed placebo beer but not milkshakes or water ($p = .037$ and $p = .032$, respectively). Challenging positive social experiences that coincide with eating and drinking may prevent excess consumption of alcohol and unhealthy food, particularly if targeted at individuals with certain traits and demographic profiles: men, individuals that emotionally eat, and individuals with strong alcohol expectancies.

Symposium 80C

PERSONALITY AS A HEALTH BUFFER DURING STRESSFUL WAITING PERIODS

Kate Sweeny, PhD

Research suggests that waiting for uncertain news can be both emotionally and physically taxing. As the news approaches, people typically experience increasing levels of anxiety, rumination, sleep disruption, and poor health. In the present study we examined whether a variety of personality traits moderate these trends in psychological and physical well-being. Specifically, we examined whether dispositional optimism, trait mindfulness, tolerance of uncertainty, and the tendency to spontaneously self-affirm (i.e., to think about one's values and strengths) might moderate these trends in well-being. To do so we investigated the subjective health, sleep disruption, well-being, and personality profiles of a sample of law school graduates awaiting their bar exam results. The results showed that those high in spontaneous self-affirmation, trait mindfulness, dispositional optimism, and tolerance of uncertainty generally reported better physical and psychological well-being during the waiting period. Moreover, participants high in these traits also showed different longitudinal trajectories in anxiety, rumination, subjective health, and sleep disruption. Specifically, participants high in these traits tended to show less deterioration in their well-being as the news approached and "flatter" trajectories generally, suggesting that the waiting period was not as unhealthy for them. Taken together, these results suggest that at least personality is associated with greater well-being during a stressful waiting period and that personality may buffer people from the escalations in anxiety, rumination, sleep disruption, and poor health associated with forthcoming news.

Symposium 80D

THE PERSONALITY PROFILE OF HEALTH INFORMATION AVOIDERS

Jennifer Howell, PhD

Although knowing health information can be critical for disease prevention, people sometimes intentionally avoid learning information about their health. Indeed, research suggests that up to 39% of Americans would avoid learning their cancer risk (Emanuel et al., 2015). In this talk, we examine who avoids information about their health. That is, using evidence from four distinct studies, we examine what personality traits predict information avoidance. Broadly, these studies reveal two categories of dispositional predictors of avoidance: orientation toward information and coping resources. First, we offer evidence that people who are dispositionally open to information display less health information avoidance. Using evidence from a longitudinal study and a nationally representative sample, we demonstrate that personality traits associated with an open orientation toward the world (e.g., dispositional curiosity, openness to experience) predict less information avoidance. Next, we discuss two studies that demonstrate that personality traits associated with better internal coping resources (e.g., optimism, self-esteem, emotional stability) are associated with less health information avoidance. Throughout the talk, we will also highlight personality predictors that do not predict health information avoidance (e.g., extraversion, agreeableness, and intolerance of uncertainty). Discussion centers around identifying people whose personality profiles indicate they are particularly prone to health information avoidance, and on possible tailored interventions to reduce problematic health information avoidance.

Symposium 81 8:30 AM-9:45 AM

NON-PHARMACOLOGICAL APPROACHES TO MANAGEMENT OF CHRONIC MUSCULOSKELETAL PAIN AMONG VETERANS

Robert D. Kerns, PhD[1], Eve E. Reider, Ph.D.[2], Erin E. Krebs, MD, MPH[3], Rollin Mac. Gallagher, MD, MPH[4], Ranjana Banerjea, PhD[5]

[1]Yale University, West Haven, CT; [2]National Center for Complementary and Integrative Health, National Institutes of Health, Bethesda, MD; [3]Minneapolis VA Health Care System, Minneapolis, MN; [4]University of Pennsylvania, Gladwyne, PA; [5]Veterans Health Administration, Princeton, NJ

Chronic pain and prescription opioid abuse and harms have been recognized by the Department of Health and Human Services (HHS) and the Centers for Disease Control and Prevention (CDC) as public health crises. Both HHS and CDC have encouraged greater access to evidence-based non-pharmacological approaches to chronic pain management as alternatives to long term opioid therapy, The Department of Veterans Affairs (VA) in collaboration with the Department of Defense (DOD) and the National Institutes of Health (NIH) have established a partnership that includes funding research to develop and test as well as adapt efficacious interventions for military and veteran populations who have problems with pain and comorbid conditions. Objectives are to promote equitable and timely access to these approaches that have existing evidence to support their effectiveness and to promote research to address gaps in scientific knowledge. Dr. Robert Kerns, health services investigator and advocate for improved pain care for veterans, will introduce the symposium and provide a brief background as context for three presentations and discussion. Dr. Eve Reider, a Health Scientist Administrator at the National Center for Complementary and Integrative Health, National Institutes of Health (NIH), will describe a joint 2014 NIH-VA funding initiative and provide a brief overview of early findings from 13 funded projects addressing this topic. Dr. Erin Krebs, a VA health services investigator will review the recommendations from a VA sponsored State-Of-The-Art Conference on this topic held in November 2016. Recommendations related to four categories of non-pharmacological approaches will be presented: Behavioral/psychological/ mind-body, exercise/movement, manual therapies, and model of care. Dr. Rollin Gallagher, VA National Director for Pain Management, will describe ongoing practice and policy initiatives designed to promote evidence-based, integrated, multimodal and interdisciplinary chronic pain management for military service members and veterans. VA's Opioid Safety Initiative, Joint Pain Education Project, and Acupuncture Training Across Clinical Settings initiatives will be highlighted. Dr. Ranjana Banerjea, Scientific Program Manager for VA's Health Services Research and

Development Service, will discuss the implications of these initiatives and describe opportunities for continued research in this area.

Symposium 81A

A JOINT NIH-VA COLLABORATION ON NON-PHARMACOLOGICAL APPROACHES TO PAIN MANAGEMENT N U.S. MILITARY AND VETERAN POPULATIONS

Dr. Eve E. Reider, Ph.D.

Since 2001, more than 2.5 million U.S. troops have been deployed for Operation New Dawn, Operations Enduring Freedom (OEF) in Afghanistan, and Iraqi Freedom (OIF) in Iraq. Many service members returning from these operations experienced pain and related comorbidities (e.g., mental health, substance abuse, sleep, etc.). Studies report approximately 45-50% of soldiers and veterans experience pain on a regular basis and there is significant overlap between chronic pain and co-morbid conditions. In addition, there is an incomplete evidence base for effective pain management. Opioid medications are often prescribed for the treatment of chronic pain, but chronic use is associated with the potential for misuse, abuse, and dependence and sometimes fails to adequately control pain. As a result, there is a need for non-pharmacological approaches, which may complement pharmacological strategies, for pain management and to reduce the needs and hazards of excessive reliance on opioids.

The National Institutes of Health (NIH), Department of Defense (DoD), and Veterans Administration (VA) have been working individually and collaboratively to develop and improve pain management approaches for military personnel, veterans and their families by adopting changes in clinical protocols and implementing research initiatives. In 2014 a joint NIH-VA funding initiative took place that included the National Center for Complementary and Integrative Health (NCCIH), the National Institute on Drug Abuse (NIDA) and the VA Health Services Research and Development (HSR&D) Division. Thirteen research projects totaling approximately $21.7 million over five years were funded to enhance non-pharmacological approaches to managing pain and co-morbid conditions in U.S. military personnel, veterans and their Families. Projects funded included pilot/feasibility, efficacy/effectiveness, and health care services studies. This presentation will provide an overview of the studies funded from this initiative as well some early findings that are available from this initiative.

Symposium 81B

VA STATE OF THE ART (SOTA) CONFERENCE ON NON-PHARMACOLOGICAL APPROACHES TO CHRONIC MUSCULOSKELETAL PAIN MANAGEMENT

Dr. Erin E. Krebs, MD, MPH

Chronic pain is an important public health problem that has long been a major cause of disability in the US. In recent years, an emerging epidemic of opioid-related harms—triggered by decades of increased opioid analgesic prescribing—has added substantially to the public health burden of chronic pain. To address these dual challenges, a transformation in the approach to chronic pain care is needed. The National Pain Strategy envisions this transformed approach as involving integrated, multimodal care that meets patients' biopsychosocial needs. Achieving this new standard of pain care will require greater access to evidence-based non-pharmacological therapies.

At an October 2015 White House summit on the opioid epidemic, the Department of Veterans Affairs (VA) committed to lead a research initiative evaluating non-opioid alternative approaches to pain management. Toward this end, the VA Health Services Research and Development service is organizing a State of the Art (SOTA) conference focused on non-pharmacological approaches to chronic musculoskeletal pain management, including complementary, conventional, and integrative therapies. The SOTA conference will be held in November 2016 and will generate both consensus recommendations and peer-reviewed publications. The three main goals are as follow: 1) to synthesize existing evidence and evidence gaps related to non-pharmacological approaches, including psychological/behavioral therapies, exercise/movement therapies, manual therapies, and models for delivery of multi-modal pain care; 2) to identify promising non-pharmacological approaches that may be ready for wider dissemination and implementation in VA and non-VA settings; and 3) to identify a research agenda that can lead to increasing use of evidence-based non-pharmacological approaches for the benefit of chronic musculoskeletal pain management. This presentation will include a discussion of SOTA processes and products, including recommendations for implementation and research priorities related to non-pharmacological pain care approaches.

Symposium 81C

IMPLEMENTING NON-PHARMACOLOGIC PAIN CARE IN THE STEPPED CARE MODEL IN THE DEPARTMENTS OF VETERAN AFFAIRS AND DEFENSE

Dr. Rollin Mac. Gallagher, MD, MPH

The large number of older Veterans (>50%) with disabling chonic pain conditions and pain-related co-morbidities and the even higher rates in Veterans from recent wars (>60%), has prompted the Department of Veteran Affairs, working closely with the Department of Defense, to engage in an almost decade-long multi-pronged population-based program to implement a multi-modal Stepped Care Model of pain management across our health systems. The urgency of this transformational effort is heightened by data demonstrating the dangers of over-reliance on opioid analgesics for pain care, and has encouraged the development of team-based, multi-modal care with a specific focus on engaging the Veteran in a developing self-management as a foundation of effective Stepped Care. This presentation will outline five core domains in our strategic approach to implementing system-wide access to evidence-based stepped integrative, physical, and psychological therapies for pain and measuring the quality of that care. First, system-wide training programs for clinical teams and specific professionals on those teams, including cased-based virtual SCAN ECHO training, the Mini-residency, the Joint Pain Education Project(JPEP) for training primary care teams and providers, the Tiered Acupuncture Training Across Clinical Settings (ATACS) program, the Pain Psychology Training program, and the Nurse Resource Program. Second, comprehensive patient/family education programs to empower Veterans in learning pain self-management, including pain schools and education websites with interactive learning programs and videos . Third communication tools and resources to support the pain management strategy in both training and clinical care, including those that directly address the need for safe opioid prescribing such as the academic detailing approach(measure, monitor, feedback, train) in the Opioid Safety Initiative to changing practice, the use of electronic medical tools such as OTRR and STORM to support safe prescribing, and the use of process improvement tools such as the Patient Aligned Clinical Team (PACT) Pain Roadmap. Fourth, strengthened communication amongst pain leadership in VHA's Central Office (VHACO), Veterans Integrated Service Networks (VISN), and Veterans Affairs Medical Centers (VAMC) to assure dissemination of strong practices and implementation of strategies to standardize and measure care quality. Fifth, implementation of standardize pain care between the Department of Defense (DoD) and VHA health systems and facilitation of effective transitions of care from DoD to VHA. The presenter will discuss challenges in implementation and in measuring outcomes to foster change.

Symposium 82 8:30 AM-9:45 AM

THE ROLE OF FATHERS IN SUPPORTING CHILD HEALTH BEHAVIORS

Deirdre Dlugonski, PhD[1], Kirsten Davison, PhD[2], Elena Jansen, PhD[3], Emily L. Mailey, PhD[4]

[1]East Carolina University, Greenville, NC; [2]Harvard TH Chan School of Public Health, Boston, MA; [3]Centre for Children's Health Research - Queensland University of Technology, South Brisbane, Queensland, Australia; [4]Kansas State University, Manhattan, KS

This symposium addresses the role of fathers in supporting physical activity, healthy eating, and obesity prevention among children. It is well-established that parents play an important role in the uptake of health behaviors among children. Yet, the majority of research studies focus primarily on the behaviors and beliefs of mothers, rather than fathers, for understanding and promoting child health behaviors. Thus, the overall goals of this symposium are to: quantify the inclusion of fathers compared to mothers in childhood obesity prevention interventions; provide evidence for the shared behavioral patterns of fathers and young children; and describe opportunities and challenges related to engaging fathers in health behavior research. The first presenter will describe results of a systematic literature review and quantitative content analysis of the representation of fathers in family based interventions targeting childhood obesity prevention. The second presenter will describe the physical activity patterns of father-young child dyads. The final presenter will share data from multiple studies on factors associated with recruitment and engagement of fathers within childhood nutrition research. After this symposium, attendees will have a better understanding of the role of fathers in the promotion of child health behaviors.

Symposium 82A

PHYSICAL ACTIVITY PATTERNS AMONG FATHER-YOUNG CHILD DYADS

Dr. Deirdre Dlugonski, PhD

Approximately 50% of preschool aged children are not meeting physical activity guidelines. Parents can serve as role models for child health behaviors, but evidence for the relationship between parent and child physical activity is mixed. Role modeling is most effective when the parent and child engage in the behavior together (shared physical activity). As such, shared physical activity might be more strongly associated with child physical activity than parental physical activity. No previous studies have examined shared physical activity among parent-young child dyads using an objective measure of physical activity and most studies have focused on mothers rather than fathers.

The aims of this study were to: describe patterns of shared physical activity among father-child dyads and examine the associations among shared physical activity, father physical activity, and child physical activity. Participants (*N* = 52; 26 father-child dyads) in this cross-sectional study made two visits to a research lab. Visit 1 included a demographic survey, height and weight measurement, and instructions for wearing a Bluetooth enabled accelerometer. Fathers and children were asked to wear the accelerometer on their right hip during waking hours for 8 days. The accelerometers produced individual physical activity data and a proximity file with a minute-by-minute analysis of whether or not the parent and child were in proximity. Individual data files were overlaid with proximity data and processed to yield shared physical activity. During visit 2, fathers returned the accelerometers.

Fathers and children engaged in an average of 40.5 ± 24.3 and 56.7 ± 21.2 minutes of daily moderate to vigorous physical activity (MVPA), respectively. Father-child dyads spent 107.1 ± 51.8 minutes in daily shared time. Shared minutes were primarily spent in shared sedentary activities (36%) and shared light activities (25%). Less than 1% of shared minutes were spent in shared MVPA. The relationships between child physical activity with shared and father physical activity were not statistically significant. The magnitude of the relationship between shared physical activity and child MVPA ($r = .28$, $p = .19$) was stronger than the relationship between father MVPA and child MVPA ($r = -.16$, $p = .47$). This suggests that child physical activity might be more strongly associated with father-child shared physical activity participation rather than a father's physical activity level.

These data provide an initial description of shared patterns of physical activity between father-young child dyads using a novel application of accelerometers that will inform future efforts to understand and promote physical activity within family contexts..

Symposium 82B

THE FORGOTTEN PARENT: FATHERS MAKE UP ONLY 6% OF PARENT PARTICIPANTS IN FAMILY-BASED CHILDHOOD OBESITY INTERVENTIONS SINCE 2008

Kirsten Davison, PhD

It has been suggested that child health research disproportionately focuses on mothers which may hinder the design of family-based interventions. In this study, we used rigorous, systematic methods to quantify the inclusion of fathers, relative to mothers, in family-based childhood obesity interventions published since 2008. We conducted a systematic review and quantitative content analysis of the literature using methods consistent with PRISMA (Preferred Reporting Items for Systems Reviews and Meta-Analyses) guidelines. Eligible articles included original studies reporting the results of family-based interventions for childhood obesity control and prevention published in English between January 1st, 2008 and July 31st, 2015. “Family-based” was defined as active and repeated involvement by parents or legal caregivers. Articles were excluded where parent/caregiver involvement was passive (eg. educational brochure sent home to parents) and only children were included as research participants. Two trained coders used a standardized coding scheme to record parent (e.g., number of fathers and mothers, parent race/ethnicity) and intervention (eg. setting, intervention length, attrition rate, child age) characteristics for all eligible interventions. Differences in parent and intervention characteristics for studies that did and did not include fathers were tested using chi-square analysis. Seventy nine eligible interventions were identified. Twenty nine (37%) interventions included only mothers, 27 (34%) included mothers and fathers, and 1 included only fathers (1%); parent gender was not reported for 22 (28%) interventions. Of the interventions that included fathers (N=28), the majority (N=14, 52%) included 10 or fewer fathers. The estimated number of participating fathers across all interventions was 880; the comparable figure for mothers was 12,980. There is no evidence that interventions that included fathers varied systematically in intervention design or participant demographics (beyond gender) compared to interventions that did not include fathers. In summary, only 6% of all parent participants in family-based childhood obesity interventions published since 2008 were fathers. This study is a call to action for increased inclusion of fathers in childhood obesity interventions.

Symposium 82C

ENGAGING FATHERS IN CHILD NUTRITION RESEARCH

Dr. Elena Jansen, PhD

Parents’ feeding practices influence development of children’s eating behaviour and growth trajectory. The nature and impact of feeding practices may differ between mothers and fathers. Studies examining the role of fathers in child feeding are relatively scarce, however, and recruitment to and engagement of fathers in child feeding research is a challenge.

This presentation draws on evidence from three Australian early childhood nutrition research projects related to identifying factors associated with recruitment and engagement of fathers. First, 436 fathers of 2-5 year old children were recruited via a university email list and two community-based family research cohorts. Fathers reported their confidence and knowledge of healthy eating, willingness to participate in healthy eating programs, with focus on type and mode of delivery. Second, 28 fathers of 0-12 year old children participated in focus groups conducted at their workplace and, amongst other themes, discussed their view on using their workplace as point of contact for nutrition interventions. Third, 195 mother-father pairs of 2-5 year old children were recruited in a socioeconomically disadvantaged community. A variety of engagement methods and choice of incentives were examined to determine uptake and identify the most successful strategies for engagement and recruitment of hard-to-reach families and pairs in particular.

Analyses examined five key issues in engagement of fathers in nutrition research: 1) fathers' interest in research and intervention participation, 2) fathers' preferences for recruitment strategies, 3) feasibility and acceptability for recruitment at the workplace, 4) role of incentives, and 5) recruitment of mother-father pairs.

Our results indicate that recruitment and engagement of fathers in child nutrition research may require modification to methodologies applied in “mother only” samples. Experience from these three research projects will inform father-focused recruitment strategies and intervention delivery which will help delineate and foster the father-specific impact on child health.

Symposium 83 8:30 AM-9:45 AM

YOUTH IN FOSTER CARE: UNDERSTANDING AND INTERVENING UPON EARLY LIFE ADVERSITY

Rebeccah L. Sokol, B.S. [1], Kym Ahrens, MD/MPH[2], Jennifer Blakeslee, PhD, MSW[3], Susan Spieker, PhD[4], William D. Tynan, Jr., PhD, ABPP[5]

[1]Gillings School of Public Health, UNC Chapel Hill, Carrboro, NC; [2]Seattle Children's Hospital/University of Washington, Seattle, WA; [3]Portland State University, Portland, OR; [4]University of Washington, Seattle, WA; [5]American Psychological Association, Washington, DC

In the United States, over a half-million youth are in foster care. A myriad of circumstances cause youth to enter state care, but these situations broadly entail exposure to maltreatment and family instability. Such early life exposures are risk factors for negative outcomes across multiple domains, including poor mental and physical health. Experiences of abuse, neglect, or household disruption increase the risks of future alcoholism, drug abuse, depression, sexually transmitted diseases, severe obesity, and other negative health consequences by as much as twelve-fold—yet youth in foster care remain underserved by health promotion programs.

This symposium provides an overview of the relationships between adverse experiences and subsequent health for youth in or transitioning out of foster care, and it also details specific intervention strategies that have exhibited success in improving health in this population. The format of the symposium follows the early life course, starting with infancy and concluding with young adults transitioning out of care. Dr. Susan Spieker begins with describing an intervention program (and its associated randomized controlled trials) that teaches caregivers how to be responsive to the unique needs of toddlers with child welfare involvement in order to alleviate the burden that early maltreatment has on physical and mental health problems. This transitions to Dr. Jennifer Blakeslee's presentation, where she details various intervention models that are aimed at improving psychosocial and socio-emotional development for youth both in and transitioning out of foster care. The symposium concludes with Dr. Kym Ahrens providing an evaluation of the health risks that youth in foster care face, with an emphasis on reproductive health. Dr. Ahrens closes with discussing specific strategies that could be employed by practitioners and policymakers to disrupt these risks.

Symposium 83A

UNDERSTANDING AND REDUCING PHYSICAL AND REPRODUCTIVE HEALTH RISKS AMONG TRANSITION AGE YOUTH IN FOSTER CARE

Kym Ahrens, MD/MPH

Foster youth are an understudied population with high rates of chronic/untreated health conditions both upon entrance into and while in foster care. Consequently, in 2009 the Institute of Medicine highlighted them as a priority population for federally funded research.

There are many reasons to expect that former foster youth may be vulnerable to similarly increased rates of chronic health problems once they transition to adulthood. They are frequently exposed to poverty as well as many other adverse childhood experiences including abuse, neglect, domestic violence, parental substance use, and many undergo frequent placement and school changes while in foster care. Several theories exist regarding the effects of chronic and early exposures to adversity, all of which suggest that the more stressors to which one is exposed, the higher the likelihood of a chronic physical or mental health condition later in life. However, few studies have focused on understanding health risks in young adulthood for this group. One exception to this is reproductive health. We know that, compared with youth in the general population, youth who have been in foster care have 2-4 times the risk of teen pregnancy as well as 2-14 times the risk of several sexually transmitted infections (STIs).

In my presentation, I will review findings from several studies in which my collaborators and I and other investigators have evaluated physical and reproductive health risks during the transition to adulthood for youth who emancipate from foster care. I will also review research my collaborators and I have conducted to better understand the cumulative effects of historical and current risk and protective factors influencing these outcomes. My presentation will include data on a variety of health conditions, with an emphasis on reproductive health outcomes. Finally, I will discuss potential strategies relevant to practitioners and policymakers, which could be used to disrupt negative health trajectories and mitigate health risks for youth in foster care.

Symposium 83B

DEVELOPING INTERVENTION MODELS TO BETTER ADDRESS FOSTER YOUTH WELL-BEING NEEDS

Jennifer Blakeslee, PhD, MSW

Research shows that many young people who age out of the child welfare system experience poor outcomes during the transition from foster care, and multiple studies identify a large subgroup characterized by limited service engagement and/or minimal social support who experience higher rates of mental health challenges, delinquency, and substance abuse. Accordingly, there is growing interest in developing services that better address aspects of foster youth well-being in a system where policy and funding are geared towards child protection. In general, existing approaches do not adequately attend to socio-emotional development for youth in care which likely contributes to poor outcomes in early adulthood.

I will discuss intervention models that demonstrate effectiveness in improving foster youth wellbeing by focusing on psychosocial skills and socio-emotional development. One approach uses weekly curriculum-based coaching to increase youth self-determination, and this model has been adapted and tested with foster youth in high school, foster youth experiencing a disability (physical, emotional/behavioral, or intellectual), and undergraduate foster youth experiencing mental health challenges. This model improves transition readiness, increases college enrollment and retention, and reduces criminal justice involvement in young adulthood, all of which are broadly associated with better-functioning subgroups of foster youth.

Additionally, I am currently developing an intervention model to enhance foster youth support networks. This model uses practice strategies identified as acceptable and feasible by youth and service providers to increase service engagement and mobilize informal networks and natural supports. This approach is grounded in systematic support network assessment methods that are linked to practice strategies intended to counter the impact of ongoing social network disruption related to child welfare system involvement. I will discuss how these two intervention approaches—relationship-based curriculum delivery and strategic network enhancement—may be combined to improve youth psychosocial and socio-emotional development in preparation for the transition from foster care.

Symposium 83C

PROMOTING FIRST RELATIONSHIPS®: INTERVENING WITH CAREGIVERS OF INFANTS AND TODDLERS IN FOSTER CARE OR AT RISK OF REMOVAL

Susan Spieker, PhD

Infants and toddlers are a growing population in child welfare and foster care. The obvious vulnerability of infants and toddlers, and the fact that critical aspects of brain development occur in the contexts of attachment relationships in the first 3 years of life, necessitate a preventative approach that supports caregiving relationships. This is the primary aim of the *Promoting First Relationships® (PFR)* program. PFR is a manualized, relationship-based, strengths-based, 10-week home visiting program with video feedback techniques.

PFR helps caregivers be sensitive and responsive to the unique needs and challenges of caring for toddlers and young children with child welfare involvement. Infants in foster care must develop a new attachment relationship with each placement. Children grieve when attachment relationships are disrupted, even when they receive excellent care in their new home. Infants younger than 12 months tend to seek comfort and closeness from new attachment figures within a week of placement, but toddlers do not readily seek out new attachment figures, and may be inconsolable or push them away. The process of attachment formation in toddlers and older children is complicated by these difficult child behaviors, which may be further exacerbated if there are serial placements resulting in multiple caregiver changes. These events can compound the effects of early maltreatment and lead to physical and mental health problems. However, caregiver sensitivity and understanding of the meaning of the child's behavior is associated with child attachment security, even for older toddlers and preschoolers with a child welfare history.

This presentation has two parts. The first part includes descriptions of the active elements of PFR, methods that have been effective for training and ensuring fidelity by community service providers, and current adaptations of PFR for primary care providers during the first 3 years of life. The second part presents an overview of results from two randomized control trials of *PFR* involving about 450 toddlers in child welfare and their caregivers. The studies address the need for parenting services that are suitable for community delivery systems, have a training mechanism accessible to service providers, are brief enough to keep families engaged, and are effective.

Symposium 84 8:30 AM-9:45 AM

PASSIVE SENSING OF EATING BEHAVIORS: CURRENT STATE OF THE ART AND IMPLICATIONS FOR BEHAVIORAL MEDICINE RESEARCH

Nabil Alshurafa, PhD[1], Angela Fidler Pfammatter, PhD[2], Edward Sazonov, PhD[3], Bonnie Spring, PhD[1]

[1]Northwestern University, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]The University of Alabama, Tuscaloosa, AL

Eating behaviors contribute to a variety of health outcomes such as cardiovascular disease, diabetes, obesity, and cancer. To date, the vast majority of behavioral medicine research has relied on measurements of eating that are inherently flawed. Daily self-monitoring is often burdensome, incomplete, and inaccurate. 24 hour recalls, considered the gold standard in dietary intake assessment, is burdensome, often limited in accuracy, and only captures a snapshot in time of what was consumed. Further, using today’s technology, behavioral scientists are increasingly able to intervene on individuals just-in-time, when the person most needs or would most benefit from support. However, with both popular methods of dietary intake, the measures are retrospective and not assessed while eating is occurring, limiting the potential of using just in time interventions. Other behaviors such as physical activity have benefitted from passive sensing technologies to overcome this barrier. Passive sensing, detection, and prediction of eating has the potential to decrease biased reports of eating, gather real time information about eating, and predict problematic eating behaviors. In this symposium, we seek to review the state of the science of passive sensing of eating in the first presentation. We will then move on to discuss the “guts” of how detection and prediction of eating works along with privacy, stigma, and user-comfort of wearable sensors. In our third presentation, we will illustrate a package of real time sensing and the potential for intervention. Finally, we will review the implications of moving this aspect of science forward as it pertains to prevention and treatment of problematic eating.

Symposium 84A

FROM LAB TO FIELD: EATING DETECTION MACHINE LEARNING MODELS, PRIVACY, STIGMA AND USER-COMFORT OF WEARABLES

Prof. Nabil Alshurafa, PhD

Wearable sensors combined with computer science machine learning methods have given rise to passive sensing, making it feasible to validly infer in real time physical features of psychological states, such as stress, and appetitive behaviors, such as overeating. The advantage of these real time passive sensing capabilities is their ability to use machine learning models to measure objectively (minimizing self-report bias), precisely (with high sensitivity and specificity), passively (without burden or disruption), and dynamically (detecting rapidly changing states). However, to succeed in passively sensing, people must be willing to wear them, and sensing algorithms must be able to sense eating in the real world. Despite the continuous growth in the wearable market, adherence continues to be impacted by concerns of user privacy, social stigma associated with wearing eating-detection based sensors, and user-comfort. Understanding these concerns will help the wearable community and researchers ultimately improve our ability to design wearables that mitigate these effects, increasing adherence to passive sensing and ultimately paving the way towards personalized behavioral medicine. This talk will present the process of building machine learning models to detect eating both in-lab and in the field. A study will also be presented aimed at understanding the factors that influence adherence to wearing sensors used to detect eating-habits including a wrist-worn, neck-worn sensor and a camera to validate ground truth in different environments and situations.

Symposium 84B

LEVERAGING PASSIVE SENSING FOR JUST IN TIME ADAPTIVE INTERVENTIONS ON EATING

Dr. Angela Fidler Pfammatter, PhD

Current technologies are moving closer to realizing passive sensing of eating. Leveraging these technologies will be a new frontier for behavioral medicine and could be used to deploy just in time adaptive interventions (JITAIs). However, computer and behavioral scientists must work in tandem to actualize the potential. Specifically, types of eating and temporality must be specified when sensing, particularly in real time, as part of an intervention decision rule. An ongoing trial, Sense2Stop, will be presented as a case study in developing a JITAI using passive sensing to intervene on smoking behaviors given sensing of stress. Elements of the project such as the sensing capabilities, algorithm development, and decision rules for intervention will be presented. Lessons learned will be highlighted and a proposal for moving forward and generalizing to other sensing technologies elucidated. Paramount to this work, a strategy for working alongside computer scientists will be discussed. Primary questions around eating sensing including discovery of context and factors that contribute to typical and problematic eating behaviors must be explored prior to intervention development. Once these factors and contexts are identified, they may be used within decision rules to deploy JITAIs. Finally, examples of microrandomized trials to optimize JITAIs in eating behaviors will be presented.

Symposium 84C

WEARABLE SENSORS FOR DETECTION AND CHARACTERIZATION OF FOOD INTAKE

Dr. Edward Sazonov, PhD

Food intake provides energy and nutrients to sustain human life. Studying the ingestive behavior of individuals is of particular interest for understanding and treatment of medical conditions strongly associated with food intake, such as obesity and eating disorders. Traditionally, ingestive behavior in humans has been assessed through self-monitoring of food intake. However, this approach is time-consuming and suffers from the observation and misreporting effects. Wearable sensors present a compelling alternative to overcome the limitations of self-reporting methods. These sensors can potentially provide more objective measurements of food intake by monitoring behavioral and physiological phenomena related to one or more stages of the food consumption process: hand-to-mouth gestures, bites, chewing or swallowing. Specialized signal processing and pattern recognition methodologies applied to the sensor signals are used to automatically detect and characterize each intake episode. Timing, duration of the meals, the mass and volume, caloric and nutritional content of ingested food, and the rate of ingestion could potentially be estimated from sensor data. Furthermore, the sensor-derived measurements of ingestive behavior may inform tailored, real-time interventions aimed at modification of food intake. This talk presents an overview of the wearable sensors and accompanying methodologies that have been proposed for monitoring and modifying ingestive behavior in humans.

HEALTH LITERACY AND DISEASE SELF-MANAGEMENT IN OLDER COPD PATIENTS: WHEN SOCIAL SUPPORT IS NOT SUFFICIENT

Kimberly Muellers, MPH, Li Chen, MPH, Juan Wisnivesky, MD, DrPH

Icahn School of Medicine at Mount Sinai, New York, NY

Background

Although the importance of social support to health outcomes is well established, its role as a moderator of the effect of health literacy (HL) on medication adherence in patients with chronic disease has yet to be explored. An investigation of this pathway would further understanding of the mechanisms through which social support modifies health behaviors among patients with chronic illness. We predicted that the negative effect of inadequate HL on self-management in a population with Chronic Obstructive Pulmonary Disease (COPD) would be mitigated by caregiver support. Moreover, we expected that caregivers with adequate HL would have greater impact on patient medication adherence than those whose caregiver had inadequate HL.

Methods

We enrolled 400 community-dwelling individuals who were ≥55 years of age, had a diagnosis of moderate to severe COPD made by a health care provider, and spoke English or Spanish over a 2-year period. We excluded patients with asthma or other chronic respiratory illness, dementia, or other neurological and psychological conditions. Participant HL was assessed through the Short Test of Health Literacy in Adults (S-TOFHLA), and caregiver presence was based on patient self-report. STOFHLA scores (scale 0-36) were dichotomized as adequate (≥23) or inadequate/marginal (< 23). Adherence to COPD medications was measured with the Medication Adherence Reporting Scale (MARS) and categorized as low (< 4.5) vs. adequate (≥4.5). We used logistic regression to test the relationship between HL and adherence; the model included an interaction term between HL and caregiver presence to test for moderation. We also examined a subset of patients with caregivers (N=97 dyads).

Results

Our sample included 342 patients, 47% of whom reported having an informal or formal caregiver. Of the patients, 61% had inadequate HL, and 17% of caregivers had inadequate HL. Patients with inadequate HL had significantly higher odds of poor medication adherence (OR=2.48, CI: 1.47-4.19). Contrary to our hypothesis, the presence of an informal caregiver did not attenuate the negative impact of low HL (p>.05). Among patients with caregivers, inadequate HL was again associated with higher odds of poor medication adherence (OR:3.5, 95%CI: 1.4-8.8). This relationship remained significant with the inclusion of caregiver HL, however the interaction term of caregiver HL did not significantly contribute to medication adherence.

Conclusions

Low HL among patients with moderate with severe COPD is associated with lower medication adherence. However, social support from caregivers does not appear to attenuate the negative impact of low HL on patient’s self-management, regardless of the caregivers’ HL level. These findings suggest that interventions to improve adherence to COPD medications are specially needed for low literacy patients, even those with adequate caregiver support.

DOES SELF-WEIGHING AFFECT MOOD? FOR WHOM?

Carly R. Pacanowski, Phd, RD[1], Jonathan Miller, MURP[2], Jennifer A. Linde, PhD[2], Dianne Neumark-Sztainer, PhD MPH RD[2], Marla Eisenberg, Sc.D. M.P.H.[2]

[1]University of Delaware, Newark, DE; [2]University of Minnesota, Minneapolis, MN

Abstract

Frequent self-weighing may prevent weight gain in young adults, but concerning psychological correlates of self-weighing have been documented. Self-weighing may impact mood, which may mediate relationships with adverse psychological outcomes (e.g. self-esteem, depressive symptoms). Individuals more likely to be concerned with shape and weight (e.g. females; those who are overweight or obese; those having experienced an eating disorder (ED)) may be at heightened risk for self-weighing impacting their mood. This study assesses whether the frequency of self-weighing is related to mood and if this relationship differs by gender and lifetime presence/absence of an ED.

Methods

Young adult (ages 25-36) respondents to Project EAT-IV (n = 1830) reported self-weighing frequency and whether viewing their weight affects their mood. Mean weekly self-weighing frequencies and proportions of participants reporting an effect on mood were compared across gender, overweight status, and presence/absence of lifetime ED diagnosis. The association of self-weighing frequency with likelihood of effect on mood was assessed using linear regression adjusting for gender, report of eating disorder, BMI, age, race, education and income, and including interactions of weighing frequency with gender and ED.

Results

Respondents reporting ED reported higher self-weighing frequency (3.1 times/week) than respondents who had recovered from an ED (2.0 times/week) or never had an ED (1.5 times/week, $p = 0.03$). Female and overweight respondents and respondents who reported ED were more likely to report that self-weighing affected their mood compared to male, non-overweight participants, and those who never had an ED (all $p < 0.001$). Frequency of self-weighing was associated with higher likelihood of reporting that self-weighing affects mood ($p < 0.0001$).

Conclusions

These data suggest that female participants, those who are overweight, and those with history of an ED may be more emotionally impacted by self-weighing. The probability of self-weighing affecting mood significantly increased with each additional self-weighing occurrence per week. Given the rates of overweight and obesity in young adults, and the promise of self-weighing to facilitate weight control, but potential effects on mental health, it is imperative to consider individual characteristics and exercise caution when recommending self-weighing as a weight control strategy.

EXAMINING FAITH AS A MEDIATOR OF MOTIVATION FOR DIET AND PHYSICAL ACTIVITY AMONG AFRICAN AMERICAN WOMEN

Leilani Dodgen, MPH[1], Sumihiro Suzuki, PhD[2], Heather Kitzman-Ulrich, PhD[3]

[1]University of North Texas Health Science Center, Fort Worth, TX; [2]UNT Health Science Center, Fort Worth, TX; [3]Baylor Scott & White Health, Dallas, TX

African American (AA) women have the highest prevalence of overweight and obesity in the U.S. and suffer disproportionately from chronic diseases. These conditions are primarily preventable through behavioral lifestyle changes, however interventions with AA women have been less effective than in other populations. Due to the importance of faith among AA women, a popular way to address obesity has been through faith-adapted or faith-based interventions. However, little is known about *how* these adaptations influence outcomes. In this study, possible mediating effects of motivation on the relationship between religiosity (measured by spiritual health locus of control (SHLOC)) and weight loss behaviors were examined.

Baseline data from AA female participants in the NIH-funded Better Me Within program (N= 158) were collected through surveys from January 2014 to March 2015. Mean age was 48.9 years (SD 11.7) and participants were overweight or obese with mean body mass index (BMI) of 38.2 (SD 9.7), and waist circumference of 43.0 inches (SD 5.9). Two linear regression models were run to examine motivation for diet and motivation for physical activity. Since motivation for diet and physical activity were closely correlated ($r = 0.67$, $p < 0.0001$) both variables were included in each model and stratified to examine participants with high motivation versus low motivation. In the diet model, among women with low motivation for physical activity, active SHLOC (e.g., belief that God is a partner in health empowering a person to take care of him/herself) was the primary predictor of motivation for diet ($p < .05$); while in women with high motivation for physical activity, self-efficacy predicted motivation for diet ($p < 0.001$). In the physical activity model, among women with both high and low motivation for diet, self-efficacy for exercise, not SHLOC, was the primary predictor of motivation for physical activity ($p = 0.01$).

By incorporating scripture and other faith elements that support an active SHLOC, faith may serve as a change agent to increase motivation to eat healthy. Faith-based programs may need to focus faith elements on the connections between faith, health and food in addition to self-efficacy to enhance motivation for diet. Research focused on defining and measuring specific constructs within faith-based programs is needed to understand their impact on obesity-related outcomes.

EXERCISE INTENTIONS MODERATE THE EFFECTS OF IMPLEMENTATION INTENTION INTERVENTIONS FOR PHYSICAL ACTIVITY

Scout M. Kelly, M.A., John A. Updegraff, PhD

Kent State University, Kent, OH

Background: Implementation intentions (IIs) are plans made in the form of “if-then” contingencies and have been shown to be effective in promoting physical activity (Gollwitzer & Sheeran, 2006). However, IIs are not equally effective for all people. Recent research indicates that exercise intentions and plan quality may moderate II effectiveness. The present study examined whether pairing II interventions with a novel online plan quality training module promotes greater physical activity than a traditional II intervention or control activity, and whether the intervention effects are moderated by baseline exercise intentions. Method: 166 undergraduates (69.5% female, 69.3% non-Hispanic white, mean age = 19.9) completed baseline questionnaires and were randomly assigned to complete a traditional II intervention, a training-enhanced II intervention, or an information-only control activity at the end of the lab session. Participants self-reported physical activity one- and two- weeks later. Results: Controlling for baseline physical activity, intentions, and time, a bootstrapped generalized estimating equation revealed no main effect of either intervention on subsequent physical activity compared to the control condition (p’s > .10). However, there was a significant interaction between exercise intentions and conditions (II: b = .34, p = .006; II+T: b = .42, p = .001), such that both II interventions led to significantly greater physical activity than the control condition among participants with high intentions, but led to significantly less physical activity than the control condition among participants with low intentions. There were no significant differences in the simple slopes of intentions and physical activity between the two intervention conditions. Conclusions: Both II interventions were effective for individuals with high exercise intentions, but backfired for those with low intentions. Additionally, the enhanced II intervention had no effect beyond the traditional II intervention on self-reported physical activity. Potential explanatory factors, such as changes in plan quality, and memory for plans will be discussed. While implementation intentions offer great promise as time-and cost-effective interventions for physical activity, providers should account for existing exercise intention levels of II intervention recipients.

FACTORS ASSOCIATED WITH DIETARY DECISION MAKING IN PATIENTS WITH TYPE 2 DIABETES AND CHRONIC KIDNEY DISEASE IN A BEHAVIORAL TRIAL

Lu Hu, PhD[1], Huilin Li, PhD[2], Kathleen Woolf, PhD, RD[3], David St-Jules, RD, PhD[1], Ram Jagannathan, PhD[4], David S. Goldfarb, MD[5], Stuart Katz, MD[5], Aditya Mattoo, MD[6], Stephen Williams, MD[7], Lisa Ganguzza, MS, RD, CDN[8], Mary Lou Pompeii, RDN, CSR, CDN, CDE[4], Alex Sierra, MS[9], Zhi Li, MPH[7], Mary Ann Sevick, ScD, RN[10]

[1]Center for Healthful Behavior Change, NYU School of Medicine, New York, NY; [2]New York University, New York, NY; [3]NYU Steinhardt, New York, NY; [4]Center for Healthful Behavior Change Department of Population Health New York University School of Medicine, New York, NY; [5]NYU Langone Medical Center, New York, NY; [6]NYU Langone Medical Center, NEW YORK, NY; [7]New York University Langone Medical Center, new york, NY; [8]NYU School of Medicine, New York, NY; [9]Center for Healthful Behavior Change Department of Population Health New York University School of Medicine, NEW YORK, NY; [10]Center for Healthful Behavior Change Department of Population Health New York University School of Medicine, new york, NY

Purpose

Patients with type 2 diabetes (T2D) often are encouraged to make dietary changes. Yet, little is known about the extent to which they make autonomous dietary decisions or associated factors. In this report, we 1) describe participants' involvement in dietary decisions regarding food purchase and preparation, and 2) examine associations of dietary decision making autonomy with sociodemographics and self-efficacy.

Methods

Participants were asked to describe their involvement in: 1) choosing or buying food brought to their homes, and 2) making their meals and snacks. Scores for each question ranged from 0% (none) to 100% (all of the time), and were averaged to yield an autonomy score. The Weight Efficacy Lifestyle survey was used to assess self-efficacy to lose weight. Linear regression modeling was used to examine each factor separately and only those significant in univariate models were entered in the multivariate model to examine joint effect.

Results

The sample (N=76) was mostly white (80.3%), male (60.5%), currently or living as married (56.6%) with a mean age of 66.1 (SD=8.0) and BMI of 32.5 (SD=4.2) kg/m^2. Participants reported a mean autonomy score of 77.2% (SD=27.8%). In the univariate models, there were no differences due to age, race, education, income, number of comorbidities, employment status, and self-efficacy, except gender, marital status and BMI. When entering these 3 factors into a multivariate model, only marital status ($p < .001$) and BMI ($p=.048$) remained significant. More specifically, decision-making autonomy decreased by 1.4% for each unit decrease in BMI and those who were or living as married scored 22.1% lower than those who were not.

Conclusions

Participants who had a lower BMI, and were or living as married, had less dietary decision-making autonomy. Engaging those with low dietary decision-making autonomy may be important for lifestyle interventions involving dietary behavior change, but requires further study.

HOW ASSESSMENT MODALITIES AFFECT THE ENDORSEMENT RATE OF SKIN SELF-EXAMINATION FOR EARLY SIGNS OF MELANOMA

Annett Körner, PhD, Adina Coriou, MA, Chelsea Moran, BSc, Beatrice Wang, MD CM, FRCP, CSPQ, FAAD

McGill University, Montreal, PQ, Canada

Background: E*arly detection* and melanoma removal are the *most effective methods to decrease melanoma-related mortality and* the majority of melanomas are self-detected. Regular skin self-examination (SSE) for early signs of subsequent melanomas is recommended worldwide by clinical guidelines as essential part of melanoma follow-up care. A systematic review in preparation (Coroiu et al., also submitted for presentation at SBM meeting) identified 14 randomized controlled trials testing psycho-educational interventions to improve SSE practice in individuals at increased risk for melanoma. It was found that the operationalization of SSE varies widely across studies. As a follow up, the current study examines how different assessment modalities may result in different endorsement rates of SSE behaviors among melanoma survivors. Further, our study examines how predictors of SSE behavior may change depending on the operationalization of SSE.

Methods: Our longitudinal study enrolled 242 melanoma survivors (M_{age} 59 years, 49% female). SSE was assessed with a 1-item measure commonly used in melanoma research and by inquiring about the frequency of SSE for 5 body areas (head, front upper and lower body, back upper and lower body). SSE behavior data were collected at baseline and at 3 and 12 months after a dermatological education about SSE. Analyses included descriptive statistics for the different SSE assessment modalities and linear regressions using medical and socio-demographic data, as well as psychosocial variables (assessed at 3 months post intervention) to predict SSE (assessed at 12 months post intervention)

Results: When we asked “How often did you carefully and purposefully examine your own skin for suspicious changes?”, 3% of melanoma survivors indicated that they had not self-examined their skin over the past 3 months whereas 97 % reported checking their skin at least once. When we inquired about the frequency of SSE for each of the 5 body parts: monthly whole-body SSE was endorsed by 46% and 80% reported at least 1 whole-body SSE over the past 3 months.

In regression analyses, psychosocial variables such as tumor fear, social support seeking, physician support, SSE attitude and SSE self-efficacy explained between 12% and 31% of the SSE outcome – depending on which operationalization of SSE practice was used; while melanoma stage and time since diagnosis explained between 1% and 6% of the variance.

Conclusions: Our study illustrates that findings differ depending on the way SSE behavioral practice is operationalized. This stresses the need for the development and validation of a measure that could be used across studies in order to allow for the synthesis of findings of different research teams. We hope the current study will stimulate a lively discussion about the most promising ways to operationalize SSE and to test the psychometric properties of this measure.

SIMULATION AND COMPARISON OF SUN PROTECTION INTERVENTIONS UTILIZING THE THEORY OF PLANNED BEHAVIOR: AN AGENT-BASED APPROACH

W. Kyle Hamilton, BA, Linda D. Cameron, Ph. D.

University of California, Merced, Merced, CA

One of the most common forms of cancer is melanoma. Cancer treatment costs directly attributable to melanoma are about $3.3 billion per year in the U.S. Sun protection behaviors such as sunscreen use and minimizing sun exposure are advertised as ways to prevent skin cancers. Yet despite the costs and dangers of sun exposure, protective sun behaviors such as sun screen use remains low. Influencing people to adopt these behaviors remains a challenging public health issue. According to the Theory of Planned Behavior, intentions and behaviors are shaped by attitudes, subjective norms, and perceived behavioral control. These psychological factors could therefore be key targets of health communications aimed at promoting sun protection behaviors. This study tests an agent-based model that compares sun protection interventions aimed at young adults. This model is based on previous interventions which have targeted all three facets of the Theory of Planned Behavior as well as recent evidence that norms are the strongest predictors of intentions to engage in sun protective behavior.

Using simulations of this agent-based model, we observed the transmission and spread of a behavioral intervention within a social network that included users who have not previously adopted the intervention. We used effect sizes from a recent meta-analysis on sun protection interventions on reported subjective norms for our model's initial conditions. For our network size, we designed the model to have 375 nodes (users), which is the average number of Facebook friends for a college undergraduate. By identifying the diffusion of norms and intentions to engage in sun protection behaviors within the simulated social network, we identified the factors which best influence change or maintain behavioral adherence on a larger scale and thus represent key targets for interventions.

SINGLE AND MULTIPLE HEALTH BEHAVIOR CHANGE INTERVENTIONS IN CANCER SURVIVORS: A SYSTEMATIC REVIEW

Ellen M. Kinner, MA, Anne I. Roche, BS, Alan J. Christensen, PhD

University of Iowa, Iowa City, IA

Single and Multiple Health Behavior Change Interventions in Cancer Survivors: A Systematic Review

Health behavior change has become an important addition to cancer survivorship care. Favorable changes in physical activity, diet, and weight management behaviors promote long-term health and improve quality of life while simultaneously reducing the risk of additional health and treatment-related problems in cancer survivors. Although there is a large and growing literature on health behavior change interventions in cancer survivors, it is currently not known if these interventions differ in effectiveness when addressing more than one behavior or what factors may influence such changes when more than one behavior is targeted. This review examined the effects of single health behavior change interventions (SHBC) and multiple health behavior change (MHBC) interventions in cancer survivors that targeted physical activity (PA), diet quality (DQ), and weight management (WM). The specific aims of this review are to 1) assess and compare the effectiveness of SHBC and MHBC behavior change interventions; and 2) identify and compare the sample and intervention characteristics that may impact observed effects. A systematic search strategy yielded 31 randomized controlled trials that met inclusion criteria with nine identified as SHBC and 22 identified as MHBC. Generally, MHBC interventions in comparison to SHBC appear to be more effective in promoting behavior change in the physical activity and diet quality trials, while no discernable differences were seen in weight management trials. Due to the substantial variability observed in sample and intervention characteristics within the MHBC and SHBC domains, few notable comparisons between the domains emerged. Overall, randomized controlled trials of health behavior change interventions in cancer survivors have shown interventions to be effective in facilitating behavior change in comparison to control groups. , Additionally, MHBC interventions appear to be superior to SBHC interventions when targeting physical activity and dietary quality behaviors. This difference in effectiveness was not observed when examining weight management behaviors. Given the amount of variability seen across these studies, a great deal of work is still needed to clarify what aspects of these

interventions are most effective in facilitating and maintaining health behavior change in cancer survivors.

STAGES OF CHANGE AND FRUIT AND VEGETABLE CONSUMPTION IN MINORITY POPULATIONS

Elizabeth M. Orsega-Smith, PhD, Shannon Robson, PhD, Katie Greenawalt, BS

University of Delaware, Newark, DE

Data from 2007-2010 show 75.5% of adults were below recommendations for fruit and 87.3% were below for vegetables. Diet-related disparities exist among minority populations with Black and Hispanic populations often consuming less fruits and vegetables compared to Caucasian populations in the United States. Due to the disparities in health behaviors and outcomes between populations, nutrition education programs such as those offered through Cooperative Extension Services often target the most vulnerable communities. We investigated the stage of change along with other factors that influence fruit and vegetable consumption in these diverse populations.

Methods:

A total of 126 adults (≥18 years-old) from two communities in Delaware were enrolled in a seven-month community-based participatory research study through the University's Cooperative Extension Agency, which formed the basis of the educational programs that were part of the challenge. Participants who agreed to participate in the research study completed a comprehensive baseline questionnaire that assessed demographics, health-related status, fruit and vegetable staging, fruit and vegetable self-efficacy, and self-reported intake of fruits and vegetables. Bivariate correlations were conducted to determine what demographic and health variables were associated with fruit and vegetable intake and were included as covariates in subsequent analyses. A block linear regression examined the relationship between fruit and vegetable staging, fruit and vegetable self-efficacy and fruit and vegetable intake.

Results:

Of the 126 participants, 64 identified as Hispanic and 62 as African American, corresponding to the community of residence. The mean age for was 46.7 ± 15.3 years and 77.9% of participants were female. Most participants reported being in the contemplation (39.2%) or preparation stage (48.5%).Fruit and vegetable staging was significantly associated with fruit and vegetable consumption (F (7,69) = 7.49). The total variance explained by the model was 37.1%, $p < 0.001$.

Conclusion:

These findings suggest stages of change is strongly related to fruit and vegetable consumption in these diverse minority populations. Utilizing this information may be advantageous when developing programs focused on increasing the behavior of fruit and vegetable intake of ethnic minorities by developing programs to move participants along the stages of change continuum toward action.

THE EFFECT OF A PEER MODELING WORKPLACE PHYSICAL ACTIVITY INTERVENTION FOR WOMEN

Sheri Rowland, MSN, APRN-BC[1], Bernice Yates, PhD, RN[2], Marlene Cohen, PhD, RN, FAAN[2], Kris Berg, PhD[3], Carol Pullen, EdD, RN[2], Kevin A. Kupzyk, PhD[2]

[1]University of Nebraska Medical Center, Gretna, NE; [2]University of Nebraska Medical Center, Omaha, NE; [3]University of Nebraska Omaha, Omaha, NE

Purpose

People compare themselves to others for self-evaluation, practical information, and motivation for health behavior change. Peers models have been used effectively in health behavior interventions to recruit, educate, and motivate but not specifically to provide vicarious experience for healthy physical activity (PA). The purpose of this study was to evaluate the effect of a 12-week peer-modeling intervention on self-efficacy, motivation, and social comparison for PA.

Theoretical Framework

Social cognitive theory and social comparison theory support the intervention. Peer-models in this study provided vicarious experience and were a focus of comparison for an active lifestyle.

Methods

Inactive women 19 to 65 years old were recruited from a Midwestern health system. Participants were randomized to either the attention control group (ACG) (n = 24) or the intervention group (IG) (n = 26). Both groups met every other week for six sessions for a lunch and learn presentation. The ACG received general health information. The IG received specific information on PA and observed a different active peer each session who presented their personal story for being active. Both groups completed pre- and post-intervention measures of: self-efficacy and motivation for PA, social comparison orientation (abilities and opinions), and motives for making social comparisons (distancing, similarity, enhancement, modeling, future self). Hierarchical linear modeling was used for data analysis.

Results

Forty-three women (ACG n = 22; IG n = 21) completed both pre and post testing. There were no significant group X time interaction effects. There were trends favoring the IG in a majority of social comparison measures. The IG increased comparison on abilities (pre/post M = 15.1 to 15.5), opinions (pre/post M = 18.3 to 19.1), modeling (pre/post M = 8.6 to 9.9), and future self (pre/post M = 18.5 to 20.2) The ACG decreased comparison on abilities (pre/post M = 15.6 to 15.0), opinions (pre/post M = 20.0 to 18.8), modeling (pre/post M = 8.46 to 8.41), and future self (pre/post M = 18.7 to 18.4).

Conclusions

Active peer-models may be a viable source of vicarious experience to increase PA through social comparison processes. A fully powered study is needed to evaluate intervention effects on self-efficacy and motivation for PA.

THE EFFECT OF COGNITIVE-BEHAVIORAL WEIGHT LOSS INTERVENTIONS ON PSYCHOLOGICAL OUTCOMES: A META-ANALYSIS

Ariane Jacob, Ph.D student[1], Simon L. Bacon, PhD[2], Gregory Moullec, PhD[3], Catherine Laurin, PhD[4], Tovah Cowan, BSc.[5], Christina Kazazian, BA[2], Candace Raddatz, BSc[6], Kim L. Lavoie, PhD[7]

[1]Université du Québec à Montréal, Montréal, PQ, Canada; [2]Concordia University, Montreal, PQ, Canada; [3]Public Health School, University of Montreal, Montreal, PQ, Canada; [4]hôpital du sacré-Coeur de Montréal, Montreal, PQ, Canada; [5]Concordia University, Beaconsfield, PQ, Canada; [6]Concordia University, Haley Station, ON, Canada; [7]University du Quebec a Montreal, Montreal, PQ, Canada

Objectives: To examine the effects of cognitive behavioral therapy weight loss (CBTWL) interventions on psychological outcomes (eating behaviors [cognitive restraint, emotional/binge eating], and depressive/anxiety symptoms) and on weight reduction in adults with overweight or obesity.

Methods: Selection criteria: 1) randomised controlled clinical trials of CBTWL intervention versus a comparison intervention, 2) study that included weight loss and psychological outcomes, 3) patients who were overweight/obese.

Results: Twelve studies (6805 participants) were included. The average weight loss difference between each arms was -1.70 kg (95%CI, -2.52 to -0.86, p

Conclusions: Beyond weight reduction, literature provides evidence suggesting that CBTWL is an efficacious therapy for increasing cognitive restraint and reducing emotional eating. However, CBTWL does not seem to be superior to other interventions for decreasing depressive symptoms. Future studies should focus on psychological outcomes to better understand the mechanistic role of these factors.

THE EFFECT OF IN-SESSION CHANGE LANGUAGE ON ALCOHOL OUTCOMES AMONG EMERGENCY DEPARTMENT PATIENTS.

Reyna Puentes, BS[1], Jon Houck, PhD[2], Miriam Alvarez, MA[1], Sandra Oviedo-Ramirez, BA[1], Craig Field, PhD, MPH[1]

[1]Latino Alcohol and Health Disparities Research (LAHDR) Center, Department of Psychology, The University of Texas at El Paso, El Paso, TX; [2]Center on Alcoholism, Substance Abuse, and Addictions, University of New Mexico, Albuquerque, NM

Motivational Interviewing (MI) is a clinical approach that focuses on enhancing a patient's readiness to change by exploring ambivalence while evoking and strengthening the patient's own verbalized reasons and motivations for change. The technical component of MI is based on an implicit causal chain hypothesis, in which increased patient in-session verbalized arguments for change (i.e. change talk) and decreased language in favor of maintaining the status quo (i.e. sustain talk) predict behavior change. Researchers have found that frequency of patient in-session change and sustain talk independently predict drinking outcomes. Efforts to enhance the efficacy of brief interventions in reducing risky drinking among patients has led to the adoption of the theoretical approach of MI. The present study tests this causal chain hypothesis by investigating the relationship between in-session client language and drinking reported at 3-month follow-up.

Emergency department patients were screened for heavy drinking and were randomly assigned to one of three treatment conditions: brief advice, brief motivational intervention, and BMI+Booster. Participants (n = 162, M_{age} = 36.6, SD = 12.4) were 75% male and 45% non-Hispanic White. Interview audio recordings were coded using the Motivational Interviewing Skill Code 2.5 and analyzed using the CASAA Application for Coding Treatment Interactions software to assess clinician and client in-session behaviors. Patient maximum number of drinks per week was regressed on sustain talk and change talk, covarying for baseline drinking. Patient sustain talk was significantly related to maximum drinks per week at the 3-month follow-up, accounting for approximately 3.1% of the variance in the outcome (b = 4.24, SE = 1.79, t = 2.38, p = .019). Change talk was not significantly related to drinks reported at 3-months, however the relationship was in the expected direction.

Our results provide support for the causal chain mechanism proposed by MI theory, given the significant effect of patient in-session sustain talk on drinking outcomes at 3-months. More specifically, our findings suggest higher levels of sustain talk (i.e. patient language against change, in favor of maintaining the status quo) is related to higher maximum number of drinks per week at 3-month follow-up, highlighting the influence sustain talk can have on predicting behavior change. Future studies should pay particular attention to how to properly address in-session sustain talk and could investigate how to enhance the effectiveness of change talk on future behavior change.

TRANSLATING AN INTENSIVE BEHAVIORAL INTERVENTION FOR DELIVERY BY CHWS

April Idalski Carcone, PhD[1], Deborah Ellis, PhD[1], Gloria Palmisano, na[2]

[1]Wayne State University, Detroit, MI; [2]CHASS Center, Inc., Detroit, MI

We previously demonstrated the efficacy of Multisystemic Therapy (MST), an intensive, home-basedpsychotherapy, to improve diabetes management and metabolic control and reduce diabetes-related hospital admissions among urban, minority youth with poorly controlled type 1 diabetes (T1D). The goal of this study was to test an adapted version of MST – Fit Families (FF) – for delivery by community health workers (CHWs).FF was developed and pilot tested in collaboration with a federally qualified health center in Detroit that provides primary health care and support services to underserved minority families. Forty-eight youth with poorly controlled T1D (HbA1c≤9 %) and their primary caregivers were randomized to either FF plus treatment as usual (TAU) (N=24) or TAU alone (N=24). Adolescents were 14.2 years old (*SD*=2.4), 37% male, and 78% African American. Mean HbA1c was 11.5% (*SD*=1.9%) at study entry. Caregivers were 88% biological mothers, 47% were single parents, and the median income was $20-29K (*IQR*= $10-19K, $50-59K). Families randomized to FF received 6 months (*M*=12.3, *SD*=9.5) of home-based cognitive-behavioral treatment delivered by a CHW, and included disease education and skills training, but also parenting skills, family communication skills, and skills for communicating effectively with medical care providers and school personnel regarding diabetes care. Treatment began with a functional assessment to assess areas of strengths and needs and an individualized treatment plan was developed to address the specific barriers to illness management for each family. Data were collected at baseline and six-month follow-up (treatment completion). FF adolescents demonstrated improvements in HbA1c (-0.78%) and frequency of blood glucose monitoring (+0.27 tests/day). TAU adolescents had worsening HbA1c (+0.13) and decreased frequency of blood glucose monitoring (-0.45) [$t_{\mathrm{HbA1c}}(41)=1.48$, $p=.073$ and $t_{\mathrm{BGM}}(42)=-1.80$, $p=.040$]. In per protocol analysis, treatment completers demonstrated an even greater improvement in their HbA1c (-1.12%) versus TAU (+0.15) [$t(37)=2.02$, $p=.026$]. BGM results were similar ($M_{\mathrm{FF}}=+0.24$ versus $M_{\mathrm{TAU}}=-0.54$, $t(38)=-1.81$, $p=.039$. These outcomes are comparable to those observed in our previous trials where MST was delivered by masters-level mental health professionals. Results suggest that an evidence-based intervention to improve illness management in youth with poorly controlled diabetes can be delivered by CHWs. Delivery by paraprofessionals could increase real-world utility of the intervention.

USE OF STATE SPACE GRIDS TO CHARACTERIZE DYADIC INTERACTIONS IN SMOKING CESSATION COUNSELLING SESSIONS: A FEASIBILITY STUDY

Heather Gainforth, PhD[1], Fabiana Lorencatto, PhD[2], Karl Erickson, PhD[3], Kristy L. Baxter, Human Kinetics[4], Kailey Owens, Bachelor of Human Kinetics[5], Susan Michie, BA, MPhil, DPhil[6], Robert West, BSc PhD[7]

[1]University of British Columbia, Kelowna, BC, Canada; [2]City University London, London, N/A, United Kingdom; [3]Michigan State University, East Lansing, MI; [4]University of British Columbia Okanagan, Kelowna, BC, Canada; [5]UBC Okanagan, Edmonton, AB, Canada; [6]University College London, London, N/A, United Kingdom; [7]University College London, London, England, United Kingdom

Background: The content of behavior change counselling sessions is typically characterized in terms of the presence (or absence) behavior change techniques (BCTs) used by practitioners. However, understanding how BCTs operate in practice requires a method for characterizing the reciprocal, dynamic and real-time nature of interactions between practitioners and clients. State-space grids (SSGs) are an observational, dynamic systems methodology used to map the trajectory of dyadic interactions in real time. By mapping the flow of events in terms of practitioner and client actions, SSGs seem potentially well suited to characterize behavior change counselling sessions. Smoking cessation counselling sessions can be reliably and usefully characterized in terms of practitioner-delivered and client-received BCTs and so this domain provides a useful starting point for assessing the feasibility of using the SSG methodology. **Aim:** To examine the feasibility of using the SSG methodology for characterizing practitioners' delivery of and clients' response to BCTs in smoking cessation behavioral counselling sessions. **Methods:** Six smoking cessation counselling sessions were video recorded, transcribed and divided into single speech acts by either the practitioner or the client (n = 3404 speech acts). All speech acts were coded for both content and duration using published frameworks for specifying practitioner-delivered and client-received BCTs in stop cessation interactions. This coding scheme was used independently by two researchers and inter-rater reliability was assessed. Indices of practitioner-client interaction dynamics were derived: 1) reciprocity (i.e. attractor states, content congruence, conditional pairing) and 2) temporal patterning (i.e. variability, inter-grid distance, lagged phase plots, sessional macro-patterning). The ability of the indices to differentiate between sessions involving different practitioners and clients was assessed. **Results:** Inter-rater reliability was moderate to high with 72% initial agreement which was resolved through discussion. Indices of reciprocity and temporal patterning were able to differentiate between sessions involving different practitioners and clients. **Discussion:** State space grids provide a useful method for characterizing the dynamics of practitioner-delivered and client-received BCTs in smoking cessation counselling sessions.

USING BETWEEN-SESSION TELEPHONE CALLS TO OVERCOME BARRIERS TO PHYSICAL ACTIVITY IN A GROUP-BASED INTERVENTION

JoEllen Wilbur, PhD, RN, FAAN[1], Michael Schoeny, PhD[1], Susan Buchholz, PhD, APN[2], Arlene Miller, PhD, RN, FAAN[2]

[1]Rush University, Chicago, IL; [2]College of Nursing Rush University, Chicago, IL

Introduction: The efficacy of interventions to increase physical activity (PA) may vary as a function of participants' barriers to PA. Prior research has been limited and considered primarily demographic moderators of intervention efficacy. The aim of this presentation is to determine whether individual barriers (demographic, physical health, psychological health, neighborhood factors, perceived barriers to PA, social support for PA) moderate treatment effects on increases in PA. **Methods**: Three treatment conditions tested the relative efficacy of a group-based PA intervention alone or supplemented by either personal or automated phone calls made between group meetings. From 2010 to 2012, 284 African American women (ages 40-65) living in the Chicago, IL, area were randomized to one of the three treatment conditions. Data collection occurred at baseline as well as 24 and 48 weeks after baseline. Moderation of intervention effects by barriers to PA were tested across four outcome measures (self-reported moderate-vigorous PA, self-reported walking, accelerometer steps, and aerobic fitness) using multilevel mixed-effects analyses. **Results**:Significant condition by barrier interaction effects for the accelerometer steps outcome were found for economic hardships, F(2, 171)=3.37, *p*=.037; depressive symptoms, F(2, 173)=4.96, *p*=.008; neighborhood crime rate, F(2, 172)=2.46, *p*=.088; and perceived barriers to PA, F(2, 171)=2.65, *p*=.073. For aerobic fitness, intervention effects were moderated by economic hardships, F(2, 218)=4.00, *p*=.020; and perceived pain, F(2, 217)=3.50, *p*=.032. Increases in the outcome variables were greater for the conditions in which group sessions were supplemented with personal and/or automated calls. **Conclusion**: Among participants with greater barriers to PA, supplementing the intervention group meetings with between-session personal and/or automated phone calls may be an effective way to strengthen intervention effects. Future research should examine the use of between-session phone calls as treatment supplements for non-responders in the context of adaptive interventions.

USING MACHINE LEARNING TO REFINE BEHAVIOR CHANGE THEORY: THE CASE OF PARTICIPANT ENGAGEMENT IN MHEALTH INTERVENTION

Angela Fidler Pfammatter, PhD[1], Nabil Alshurafa, PhD[1], Bonnie Spring, PhD[2]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University, Chicago, IL

Current technology allows for logging of specific actions within an app to track engagement, thus an opportunity to use strategies like machine learning emerges. Leveraging this depth of information enables refinement of our behavioral theories and constructs as it relates to mHealth interventions. Participant engagement is one construct that is assumed to lead to change in behavior during mHealth interventions. Engagement refers to a myriad of concepts within behavioral medicine research and generally refers to any action done to achieve the best health outcome from available services. Though many researchers propose engagement as an outcome or mediator, there is not a standardized operational definition for engagement when evaluating interventions. Despite mHealth apps requiring various types of engagement, little to no work has been done to conceptualize these types or their differential contribution to outcomes. At worst, trials do not report how often or to what extent an app is used when evaluating the effect on health outcomes. At best, few report how many days a participant opens the app, wears a device, or logs into an mHealth system. Machine learning was used in an ongoing mHealth multiple behavior change trial in college students over 6 months to identify actions that comprehensively define engagement such that specific actions or profiles may be linked to better health outcomes. Aligned with intended use of mHealth apps, engagement was divided into two primary categories: reviewing feedback and self-monitoring. We applied a head-tail classification to classify sub-types of engagement. Five sub-types of feedback engagement emerged: glances (< 7 seconds), check (7 – 17 seconds), brief review (17-38 seconds), detailed review (38-68 seconds), and deep review (> 68 seconds). For self-monitoring, three subtypes emerged: brief interact (3 - 29 sec), detailed interact (29-51 sec), and deep interact (> 52 seconds). This new operationalization enables identification of profiles that can be used to label participants and to predict outcomes. Future work will determine what type or combination of types of engagement predict important mechanisms and clinical outcomes in health behavior change research.

USING PSYCHOPHYSIOLOGICAL METHODS TO UNDERSTAND THE EFFECTS OF DIFFERENT POSITIVE FACIAL EXPRESSION MANIPULATIONS

Diana Dominguez Ortega, Undergraduate[1], Tina Singh, Undergraduate [2], Shuo Zhang, Undergraduate[3], Susan E. Koh, Bachelor of Arts in Psychology[4], Aline Carcano, Bachelor of Arts in Psychology & Social Behavior[5], Liana Gheorma, BA[6], Marie P. Cross, M.A.[1], Sarah D. Pressman, PhD[7]

[1]University of California, Irvine, Irvine, CA; [2]University of California, Irvine, Newport Beach, CA; [3]University of California Irvine, Newport Beach, CA; [4]University of California, Irvine, Foothill Ranch, CA; [5]University of California, Irvine, Los Angeles, CA; [6]University of North Carolina, Chapel Hill, Chapel Hill, NC; [7]University of California- Irvine, Irvine, CA

Differences in positive facial expressions have long been implicated in psychological disorders, physiological activity, and even health outcomes. Despite this, little work has objectively validated experimental methods of positive expression manipulation. The current study tested the differences between three methods of inducing smiles: a newly developed commercial device (“the Smile Stick”), chopsticks held in the mouth (used in past studies), and natural smiling. Participants (N = 32, data collection underway) performed three different tasks while electromyography (EMG) recorded orbicularis oculi (eye) and zygomaticus major (cheek) muscle activation in the face while participants demonstrated their assigned conditions. An analysis of variance revealed that natural smiling was associated with higher zygomaticus major muscle activation compared to the other conditions, F(1.302, 36.46)=10.629, p=.001. Paired contrasts of smile stick versus natural or chopsticks versus natural also revealed significantly higher zygomaticus activity in the natural condition (F(1,28)=10.960, p=.003 and F(1.28)=12.356, p=.002, respectively). There was no significant difference in orbicularis oculi muscle activation between groups, F(2,56)=1.689, p=.194. Participants self-reported feeling less tired after naturally smiling or holding chopsticks as compared to the smile stick, F(1.587,44.441)=7.206, p=.004. Of note, while all conditions activated both muscle groups above baseline, cheek muscles were 52.8% more activated from natural smiles. When using the Smile Stick, there was a 1,478.2% increase in the zygomaticus major (cheek) muscle activity and a 277.2% increase in the orbicularis oculi (eye) muscle activity compared to baseline. Thus, while future studies can continue to use oral device methodologies with confidence, for the largest zygomaticus major effects in future health and psychology research, new methods should be developed where natural smiles could be encouraged covertly via other non oral device methods.

VACCINE HESITANCY AMONG MILLENNIALS: CONCERNS, BELIEFS AND ATTITUDES

Julie E. Volkman, PhD, Kirsten L. Hokeness, PhD, Alyce Viens, MA, Alexandra Dickie, N/A

Bryant University, Smithfield, RI

Background: Vaccines have proven to be the most effective mechanism available to prevent disease; yet an increase in vaccine hesitancy has led to a subsequent increase in vaccine refusal. It is suggested that the largest population of vaccine-hesitant individuals are young adults ranging from 18-29 years of age.

Objective: To assess vaccine hesitancy in the millennial generation using the WHO Vaccine Hesitancy conceptual items (Larsen et al., 2015) and understand if uncertainties exist related to vaccines among millennials.

Method: Participants (N=180) from two northeastern universities answered the WHO Vaccine Hesitancy items and additional questions related to uncertainty about vaccines. Questions assessed contextual, individual and group influences, and vaccine specific issues related to vaccine hesitancy along a Likert scale (1=Strongly Disagree to 5=Strongly Agree). Frequencies were assessed using SPSS 21.0.

Results: Most participants were female (n=114; 63.3%), White/Caucasian (n=123; 68.3%) and business majors (n=104; 57.8%). Respondents agreed on mandatory vaccines (M=3.34; SD=.85) and agreed vaccines are a socially accepted norm (M= 3.71; SD=.62), but expressed uncertainty and a desire to know more about vaccines (M=3.46; SD=.77). They believed vaccines are safe (M=3.47; SD=.72), yet reported concern with getting new vaccines (M=2.93; SD=.47) and the motives of the pharmaceutical industry in designing vaccines (M=2.61; SD=1.05). For vaccine related information, participants trusted healthcare providers (M=4.10; SD=.85) and parents (M=3.83; SD=.94), and less trust from the government (M=3.00; SD=1.01), friends (M=2.92; SD=1.03), news media (M=2.71; SD=1.02) and social media (M=2.20; SD=1.01).

Conclusion: Findings suggest young adults believe vaccines should be mandatory and are safe, but have concerns with vaccine processes. Healthcare providers and parents are the best sources of information for decision-making among this age group. Interventions to decrease vaccine refusal may want to encourage more communication between healthcare providers, parents and young adults about vaccines and their processes. Future research can begin to examine uncertainties related to specific vaccines and the vaccine process.

VALIDATING STAGES OF CHANGE FOR OBESOGENIC BEHAVIORS ACROSS ADOLESCENT MINORITIES

Sasha A. Fleary, PhD[1], Michelle Tagorda, MPH[2], Sophia Kim, Phd[3], Michelle Thompson, N/A[3], Claudio R. Nigg, PhD, FSBM[3]

[1]Tufts University, Medford, MA; [2]University of Hawaii at Manoa, Honolulu, HI; [3]University of Hawaii, Honolulu, HI

Background: Filipino adolescents are underrepresented in obesity research although Filipinos are the second largest Asian American and Pacific Islander subpopulation in the US. Given that increasing obesity rates, and inadequate physical activity (PA) and fruit and vegetables (FV) consumption are characteristic of US adolescents with minority adolescents being more likely to experience obesity-related chronic illnesses into adulthood, an understanding of how well the theories of behavior change apply to Filipino adolescents is critical to addressing obesogenic behaviors in this group. This study aimed to validate the Transtheoretical Model of behavior change (TTM) for PA and FV among a majority Filipino adolescent population. The convergent validity hypothesis was that adolescents grouped in the precontemplation, contemplation and preparation stages would report less PA and FV compared to those in action and maintenance stages.

Methods: Adolescents in grades 9-11 (N=164, 82% female, 70% Filipino) who were part of the Health Action and Research Training project completed measures of PA (minutes/week) and FV (times/day) in the past seven days, and PA and FV stages of change. To assess the validity of the PA and FV stages of change with the respective behaviors, one-way ANOVAs and Tukey HSD post-hoc tests were computed.

Results: There was a significant effect for fruits (action [M=1.53, SD=1.26] > contemplation [M=.74, SD=.76], preparation [M=.79, SD=.90]) and vegetables (maintenance [M=1.39, SD=1.24], action [M=1.30, SD=1.13] > contemplation [M=.45, SD=.31]) intake across the FV stages of change. There was a significant effect of strenuous PA (contemplation [M=25.8, SD=30.4], preparation [M=45.2, SD=52.4] < action [M=141.7, SD=111.4] < maintenance [M=214.8, SD=114.4]) and moderate PA (contemplation [M=63.2, SD=74.9] < action [M=134, SD=112.3], maintenance [M=139.6, SD=98.3]) across the PA stages of change.

Discussion: This study provides validity evidence for the TTM stages of change for FV and PA among minority (predominantly Filipino) adolescents. This validation, in turn, extends the generalizability of the stages of change construct across health behaviors, replicating other adolescent studies and in other age groups.

WELLNESS SELF-COACHING AS A BOOSTER INTERVENTION FOR THE STANFORD SMALL GROUP SELF-MANAGEMENT PROGRAMS

Thelma J. Mielenz, PT, PhD, OCS, Laura Durbin, MPH, MPH, Haomiao Jia, PhD

Columbia University Mailman School of Public Health, New York, NY

The enormous burden of multiple chronic diseases is clear in older adults, especially among low-income and underserved minority populations. We evaluated the Stanford Small Group Self-Management Programs (SSGSMP) plus wellness coaching as a booster intervention. We conducted a pragmatic randomized controlled trial (RCT) with complete block design using two intervention arms: 1) SSGSMP and 2) SSGSMP plus a wellness self-coaching program initiated as a booster after SSGSMP completion. In addition to completion of a SSGSMP course, inclusion criteria for the 125 participants were: 1) 55 or greater years old, 2) resident of one of the five South Bronx New York City Housing Authority communities, 3) self-report of two or more chronic diseases, 4) cognitively competent, 5) ambulatory (independently or walker/canes), and 6) English- or Spanish-speaking. Participants (n=125) were enrolled from. Certified wellness coaches led three groups (two in Spanish) for 24 one-hour weekly wellness self-coaching phone sessions. Physical activity was the primary outcome, measured by the Community Health Activities Model Program for Seniors. Secondary outcomes included the following PROMIS v1.0 measures health domains: depression, fatigue, pain, physical function, and sleep disturbance. Participant surveys were completed at baseline, 3-months, and 6-months time points. We evaluated the outcomes of 121 participants in the RCT using appropriate general linear models to test directly the joint effects of SSGSMP and the wellness self-coaching as a booster. Data collectors and analyzers were blinded to group allocation, and intent-to-treat analyses were conducted. Participants in the wellness coaching intervention did not differ significantly from control participants on an improvement in physical activity but did differ on self-reported physical functioning (1.3 units higher, p=0.03 on the Physical Function SF 20a). Wellness coaching post-SSGSMP was a booster to physical function, a plausible upstream outcome for physical activity.

WHO BENEFITS FROM A DIETARY ONLINE INTERVENTION? EVIDENCE FROM ITALY, SPAIN, AND GREECE

Ralf Schwarzer, Dr.[1], Lena Fleig, PhD[2], Lisa Warner, PhD[3], Maryam Gholami, PhD[4]

[1]Freie Universität, Berlin, Berlin, Germany; [2]Freie Universität Berlin, Berlin, Berlin, Germany; [3]Freie Universiät Berlin, Berlin, Berlin, Germany; [4]University of California San diego, Berlin, Berlin, Germany

Objective: The traditional Mediterranean diet includes high consumption of fruits, vegetables, olive oil, legumes, cereals, nuts, moderate to high intake of fish and dairy products, and low consumption of meat products. Intervention effects to improve adoption of this diet may vary in terms of individuals' motivational or volitional prerequisites. In the context of a three-country research collaboration, intervention effects on these psychological constructs for increasing adoption of the Mediterranean diet were examined.

Design: An intervention was conducted to improve Mediterranean diet consumption with a two-month follow-up. Linear multiple level models examined which psychological constructs (outcome expectancies, planning, action control, stage of change) were associated with changes in diet scores. Setting: Web-based intervention in Italy, Spain, and Greece. Subjects: N=454 adults; age range=18 to 65 years; M_{age}=42.2, SD_{age}=10.4; n=112 at follow-up. Results: Analyses yielded an overall increase in the Mediterranean diet scores. Moreover, there were interactions between time and all four psychological constructs on these changes. Participants with lower levels of baseline outcome expectancies, planning, action control, and stage of change were found to show steeper slopes, thus greater behavioral adoption, than those who started out with higher levels.

Conclusion: The intervention produced overall improvements in Mediterranean diet consumption, with outcome expectancies, planning, action control, and stage of change operating as moderators, indicating that those with lower motivational or volitional prerequisites gained more from the online intervention. Individual differences in participants' readiness for change need to be taken into account to gauge who would benefit most from the given treatment.

“A TOOL, NOT A CRUTCH': PATIENTS WITH BREAST CANCERS’ PERCEPTIONS OF THE IBM WATSON FOR ONCOLOGY CLINICAL DECISION SUPPORT SYSTEM

Jada G. Hamilton, Ph.D., M.P.H., Elyse Shuk, M.A., Joy S. Westerman, B.A., Margaux C. Genoff, B.S., Rachel S. Werk, B.S., Val Pocus, B.S., Jennifer L. Hay, Ph.D., Chasity Walters, Ph.D., R.N., Elena Elkin, Ph.D., Ayca Gucalp, M.D., Andrew D. Seidman, M.D., Marjorie G. Zauderer, M.D., Andrew S. Epstein, M.D., Mark G. Kris, M.D.

Memorial Sloan Kettering Cancer Center, New York, NY

Background: IBM Watson for Oncology (WFO) is a cognitive, cloud-based clinical decision support system designed to inform oncologists’ choices about personalized, evidence-based treatments and clinical trials for their patients. Although substantial technical and clinical expertise has been devoted to the development of WFO, patients’ perspectives of this emerging technology have yet to be examined. Clarifying and addressing patients’ preferences about WFO could increase patient satisfaction and contribute to greater physician adoption of this technology.

Methods: To understand patients’ perspectives about the acceptability of WFO, we are conducting nine focus groups with patients who received therapies at our institution. Here, we report preliminary findings from the first three focus groups conducted with patients with breast cancers who received either neoadjuvant/adjuvant chemotherapy (*n*=6; in-person group), chemotherapy for metastatic disease (*n*=3; in-person group), or chemotherapy through a clinical trial (*n*=4; virtual group). Focus groups were audio-recorded, transcribed, and analyzed through inductive thematic text analysis to identify common thematic findings.

Results: Across all groups, participants felt comfortable with the prospect of their oncologists using WFO, as long as it was used as a supplementary tool to inform their treatment decision-making. Participants strongly believed that their oncologists were the best providers of personalized care, and questioned whether a computer could replicate this highly valued facet of patient care. Participants raised concerns about potential physician over-reliance on the decision support tool, which could undermine their trust in the physician. Participants perceived the ability to expand the body of up-to-date medical knowledge available to physicians at the point of care as a primary advantage of WFO; however, concerns about data quality and accuracy were common. Participants also expressed information needs regarding issues such as cost and confidentiality that, if unaddressed, would undermine their acceptance of this decision support tool.

Conclusion: Participants generally reacted favorably to WFO, but with serious caveats regarding the quality of content and clinical implementation of this technology. Results suggest a need for transparency to ensure that patients are comfortable with their physicians integrating this tool into the treatment decision-making process.

CORRELATES OF TANNING DEPENDENCE AMONGST SEXUAL MINORITY MALES

Kelsey A. Nogg, B.A.[1], Benjamin M. Rooney, B.A.[1], Kalina M. Lamb, B.A.[2], Aaron J. Blashill, Ph.D. [1]

[1]San Diego State University, San Diego, CA; [2]San Diego State University, San Deigo, CA

Background: Sexual minority males are an at-risk population for developing skin cancer. Disparities in skin cancer diagnoses among sexual minority males are likely the result of increased skin cancer risk behaviors. Indoor and outdoor tanning have been linked to increased likelihood of developing skin cancer, and sexual minority males tan at rates comparable to or greater than heterosexual females. One construct that may underlie frequent tanning is tanning dependence: compulsive tanning behaviors associated with tolerance, withdrawal, and craving of UV exposure. To date, preliminary research has shown tanning dependence to be associated with increased skin cancer risk behaviors; however, no known studies have examined tanning dependence among sexual minority males. Thus, the current study aimed to explore the correlates of tanning dependence among a sample of young, sexual minority males.

Methods: This study employed Facebook to recruit 238 sexual minority males ages 15 to 35 years (M = 24.56, SD = 5.44) living in San Diego County. Participants completed an online self-report questionnaire, which included items assessing skin cancer risk behaviors (e.g., indoor and outdoor tanning behavior, use of sunscreen). Tanning dependence was measured via the Behavioral Addiction Indoor Tanning Screener (BAITS).

Results: Elevated tanning dependence was significantly and positively associated with intention to indoor tan within the next three months*,* (r = .31, p < .001), frequency of indoor tanning over the past three months (r = .44, p < .001), and frequency of outdoor tanning over the past three months (r = .20, p = .002). Elevated tanning dependence was also significantly and negatively associated with frequency of sunscreen use (r = -.15, p = .026).

Conclusion: The current study is the first known to explore tanning dependence among sexual minority males—a population at risk for developing skin cancer. Elevated tanning dependence was associated with several established skin cancer risk behaviors, suggesting that tanning dependence may play a role in skin cancer disparities seen among sexual minority males. Thus, future skin cancer prevention efforts aimed at this population may benefit from exploring strategies to reduce tanning dependence in order to prevent the development of skin cancer.

DISGUST AS A PREDICTOR OF COLONOSCOPY SCREENING INTENTIONS

Maria M. Keller, BS

University at Buffalo, SUNY, Buffalo, NY

BACKGROUND: Colorectal cancer (CRC) is responsible for nearly 50,000 deaths each year and though screening is an effective way to reduce deaths, screen compliance is only 50-60% (American Cancer Society, 2016). An underlying factor in failure to screen or to comply with screening preparation procedures may be disgust elicitation. Disgust causes the urge to withdraw from potential contaminants. Fecal matter and violations of the bodily envelope are two known elicitors of disgust (Curtis & Biran, 2001). Both are central features of colonoscopy screening, making it plausible that disgust reactions result in failure to screen. However, this has not been well tested and the affective mechanisms through which disgust impacts screening are not known. METHODS: We conducted an online survey of US adults (N = 298) using Amazon mTurk. We examined affective associations with colonoscopy, including disgust associations, current feelings of disgust, dispositional disgust sensitivity, and three components of intentions to be screened (intent to screen, intent to complete preparation regimen, and intent to discuss screening with provider). RESULTS: Both overall negative affective associations and specific associations with disgust significantly predicted intent to screen, intent to complete preparation regimen, and intent to discuss screening with provider ($\beta = -.15$, $p < .001$, $\beta = -.10$, $p < .05$, and $\beta = -.12$, $p < .01$, respectively). By contrast, neither current disgust nor disgust sensitivity were significant predictors, nor did either moderate the relation of affective associations to screening. DISCUSSION: Affective associations of disgust (that is, associated feelings of disgust with the colonoscopy screening procedure) was a significant predictor of intentions to be screened—the more disgust associated with screening, the lower the screening intentions. This effect of disgust on screening seems to be through the behavioral affective associations pathway (Kiviniemi, Voss-Humke, and Seifert, 2007)—neither experienced disgust when thinking about screening nor dispositional sensitivity to disgust were related to screening intentions. Interventions to encourage screening colonoscopy should address the impact of disgust on noncompliance.

INDOOR TANNING PREDICTS SOME SKIN CANCER COGNITIONS AMONG FEMALE COLLEGE STUDENTS

Jennifer Bowers, B.A.[1], Anne Moyer, Ph.D.[2]

[1]Stony Brook University, Port Jefferson, NY; [2]Stony Brook University, Stony Brook, NY

Introduction

Skin cancer, a behaviorally influenced disease, which increasingly and adversely affects college age individuals, is the most common cancer in the United States. One of the most potent risk factors for developing skin cancer is the use of indoor tanning. This study aimed to understand if self-reported indoor tanning predicts cognitions about skin cancer, specifically, risk perceptions, attitudes, and behavioral intentions.

Method

Participants were 158 female students attending a Northeastern US university who indicated that they were or were not indoor tanners.

In addition to demographic questions, measures were administered to assess previous tanning behavior, attitudes about skin cancer, behavioral intentions, and risk perceptions.

Results

Ages ranged from 18 to 47, with a mean of 20.88 (*SD* 4.107). Sixty percent were White, 22.8% Asian, and 4.4% Black. Forty-one percent self-reported tanning indoors at least once.

Three two-stage hierarchical multiple regressions were conducted with behavioral Intentions, risk perceptions, and attitudes as dependent variables. Age, ethnicity, and skin type were entered at stage one of each regression to control for these demographic factors. Tanner status was entered at stage two.

For behavioral Intentions, the demographic variables contributed significantly to the regression model, $F\ (4,150) = 4.85$, $p < .001$, and accounted for 11.5% of the variance. Introducing the indoor tanning variable explained an additional 12.7% of the variance and this change in R^2 was significant, $F\ (1,149) = 24.97$, $p < .001$.

For risk perceptions, the demographic variables contributed significantly to the regression model, F (4,152) = 7.25, $p < .001$ and accounted for 16.0% of the variance. Introducing the indoor tanning variable explained an additional 3.0% of variation and this change in R^2 was significant, F (1,151) = 5.56, $p < .03$.

Multiple regression results were not significant for the Attitudes variable.

Discussion

These results demonstrate that indoor tanning may contribute to various cognitions about skin cancer, which may negatively impact future health behavior. Indoor tanners were more likely to view themselves as at-risk for skin cancer, but were less likely to intend to participate in skin protective behaviors. In order to facilitate behavior change, future studies and interventions should consider these differences to create tailored messages for those who have used indoor tanning.

LIMITED EFFECTS OF USING MASS MEDIA TO COMMUNICATE GENOMIC RISK INFORMATION TO DEMOGRAPHICALLY DIVERSE ADULT SMOKERS

Erika A. Waters, PhD, MPH

Washington University in St. Louis, St. Louis, MO

Background: Past research suggests that using the mass media to communicate information about the genetic basis for nicotine addiction may discourage smoking cessation. Yet, most prior research has involved primarily white, highly educated samples.

Objective: To examine how alerting demographically diverse adult smokers about the discovery of a genetic variant that confers a high risk of severe nicotine dependence and lung cancer affects key smoking-related health cognitions and quitting behavior.

Methods: Adult smokers (n=343) were recruited from community locations (e.g., laundromats, bingo halls). Participants read either a real news article describing a pharmacy's decision to stop selling tobacco products or a real article describing the discovery of a gene for nicotine addiction and lung cancer. Next, they completed measures of the following outcomes: message acceptance, quit intentions, lung cancer-related cognitive and affective perceived risk, worry, and perceived severity, and quitting self-efficacy and response efficacy. Quit behaviors were assessed at 90-day follow-up (n=212). Data were analyzed using ANCOVAs and logistic regressions, as appropriate. Race, sex, health literacy, numeracy, perceived genetic knowledge, and nicotine dependence were covariates. The covariates were explored as potential moderators.

Results: 51.0% of participants were racial minorities, 51.0% had no college experience, 63.3% were women, and 42.0% were 50+ years old. The genetic article elicited more personal reflection than the control article ($p=.03$, $\text{Mean}_{\text{diff}}=0.26$), but there were no other main effects on the remaining Time 1 outcomes (ps>.05). However, race moderated the effect of article type on self-efficacy ($p=.03$) and quit intentions ($p=.002$). White smokers reported lower self-efficacy ($p=.002$, $\text{Mean}_{\text{diff}}=0.53$) and intentions ($p=.01$, $\text{Mean}_{\text{diff}}=0.61$) in the genetic condition but not in the control condition (ps>.05). This effect was not present among minority smokers. Type of article did not affect quit behaviors at follow up (ps>.05).

Conclusion: Reading about the discovery of a genetic basis for nicotine addiction may produce unfavorable changes in some health cognitions in white smokers, but not in minorities.

Furthermore, there are no effects on actual quitting behavior. Mass media-based genomic communication likely neither helps nor hinders smoking cessation campaigns.

MOBILE DISSEMINATION OF AN EFFICACIOUS DYSPHAGIA PREVENTION PROGRAM FOR HEAD AND NECK CANCER PATIENTS DURING RADIATION

Shinn Shinn, Ph.D.

University of Texas M. D. Anderson Cancer Center, Houston, TX

Introduction: While cancer of the throat is highly curable, 39% of survivors experience serious permanent swallowing problems. To prevent dysphagia, targeted swallowing exercises performed during radiation have been shown to be effective in preventing radiation-induced fibrosis of the swallowing musculature. Thirty-nine pharyngeal/ laryngeal cancer patients at a community clinic in North Texas have been enrolled thus far on a mobile application pilot study reinforcing adherence to swallowing exercises. The mobile app is based on a successful 10-session, in-person intervention program called PREPARE, which resulted in significantly increased adherence to swallowing exercises in nonrecurrent pharyngeal/ laryngeal cancer patients during radiation compared to randomized controls. **Methods:** All pilot participants were provided with a pilot version of the mobile app, which includes video of exercises, recipes, patient stories, didactic information and hyperlinks to over-the-counter products for radiation-induced mucositis, dry mouth, skin burn and opioid-related constipation. Practical skills to promote communication with caregivers and physicians during this stressful time are also included. In-person speech pathology services are provided pre-radiation and 3 months post-radiation. Participants were asked for feedback regarding the mobile system content and delivery platforms both during radiation and 1 month post-intervention. **Results**: Feedback from participants has been somewhat difficult to obtain remotely, but post-radiation survey results indicate that patients are satisfied with the breadth and reading level of the program content and valued the videos and patient stories most highly. Average time spent per week was 40 minutes, with more time being spent in the first few weeks of radiation and decreasing in the latter weeks as side effects worsened. Most participants preferred to view the mobile app on their desktop computers rather than their phones (average age of the sample was 57 years). While participants endorsed the importance of having caregiver components in the mobile app, very few caregivers used the program. The mobile application was delivered via secured email link but the full-scale study will be delivered via a secure interactive website. **Conclusion:** This program has the potential to significantly decrease the likelihood of long-term dysphagia in head and neck cancer survivors being treated in rural, community-based clinics.

RELATIONSHIPS BETWEEN SALIVARY DIURNAL CORTISOL AND CANCER SURVIVORSHIP OUTCOMES: A SYSTEMATIC REVIEW

Jennifer Hulett, PhD, APRN, FNP-BC[1], Kristen Fessele, PhD, RN[2], Margaret F. Clayton, PhD[1], Linda Eaton, PhD, RN, AOCN[3]

[1]University of Utah, Salt Lake City, UT; [2]University of Utah, Salt Lake City, UT, Bridgewater, NJ; [3]University of Utah, Mill Creek, WA

Background
Relationships between altered salivary diurnal cortisol (SDC) rhythms and clinical outcomes are unclear, possibly due to variances in cortisol sampling. This systematic review examined studies that assessed for SDC using a minimum of 2 collection times in 24 hours, including awakening, in order to examine relationships between SDC and outcomes within cancer patient populations.

Methods
Electronic database searching was conducted for the past 10 years using keywords: salivary cortisol, cancer, and SDC assessment with combinations of subcategories for studies of adults diagnosed with cancer in which salivary cortisol was an outcome measure. Main exclusion criteria included endocrine-related disorders, exogenous glucocorticoids, and studies that did not assess for SDC.

Results
The initial search yielded 13,913 articles, reduced to 165 after screening for inclusion and exclusion criteria. An additional 135 studies did not meet SDC sampling criteria of interest, resulting in a final sample of 30 articles. The majority of studies reported outcomes among breast cancer survivors (n=20). Cortisol sampling across studies ranged from 1 to 4 days, with a majority reporting 4 to 5 collection times per day (n=21) for 2 days (n=12). Few studies (23%) reported objective monitoring of collection times (e.g., electronic bottle caps). Most common SDC parameters reported were diurnal slope (n=19) and cortisol awakening response (CAR) (n=12). Flattened cortisol slopes reported by 8 studies were associated with poorer psychosocial outcomes and poorer cancer prognosis; however, 5 studies reported no change in cortisol slope associated with yoga, sleep, stress, or psychosocial outcomes. CAR findings were mixed, with higher CAR amplitude associated with tumor progression in 2 studies, while a sharper dynamic rise in CAR was associated with less fatigue. A blunted CAR was associated with poorer sleep, fatigue, and depression.

Discussion

Despite our inclusion criteria focusing on recommended SDC sampling, directional relationships between cancer outcomes and SDC across studies remain varied. Cortisol variability within and between persons may account for differences across study findings. Further, 2 to 3 days of SDC assessment may not consistently portray or detect measureable changes in SDC. Further study is needed to inform rigor of SDC sampling with respect to number of collection times per day and number of consecutive days. Finally, electronic device monitoring of collection times would increase rigor and reproducibility of SDC sampling in cancer research.

Learning Objectives

After attending this talk, participants should be able to:

1. Understand how the rigor of salivary diurnal cortisol sampling may affect the conclusions regarding clinical outcomes.
2. Know the common SDC reporting parameters and potential relationships between these parameters and survivorship outcomes.

SELF-COMPASSION, INSECURE ATTACHMENT, AND RELATIONSHIP FORMATION DIFFICULTIES IN WOMEN POST-BREAST CANCER

Laura-Kate Shaw, BA Psych Hons[1], Kerry Sherman, PhD[1], Julie Fitness, PhD[1], Elisabeth Elder, PhD[2], Breast Cancer Network Australia ., NA[3]

[1]Macquarie University, Sydney, New South Wales, Australia; [2]Westmead Breast Cancer Institute, Sydney, New South Wales, Australia; [3]BCNA, Camberwell, Victoria, Australia

Introduction: Many un-partnered women experience difficulty forming romantic relationships after breast cancer, characterized by low interpersonal competence and dating anxiety. An individual's insecure attachment style has been linked with these difficulties. Emerging evidence suggests that self-compassion, a kind manner of treating oneself during suffering, may underlie the relationship between attachment style and difficulties in forming romantic relationships.

Aim: This study investigated whether self-compassion underlies the association between insecure attachment style and relationship formation difficulties in women post-breast cancer.

Methods: Women (N=156) diagnosed with breast cancer, who were either currently un-partnered and desired a romantic relationship or had commenced a relationship post-diagnosis, completed an online survey. Measures included attachment style (ECR-M36), interpersonal competence (Interpersonal Competence Questionnaire), dating-related anxiety (Dating Anxiety Scale), and self-compassion (Self-compassion Scale).

Results: Bootstrap mediation analyses revealed higher attachment anxiety and attachment avoidance indirectly predicted lower interpersonal competence through lower self-compassion. Higher attachment anxiety and attachment avoidance were also found to indirectly predict greater dating anxiety through lower self-compassion.

Conclusions: Women with insecure attachment styles are at risk of experiencing difficulties in forming new romantic relationships post-breast cancer. As attachment style can be somewhat difficult to change, self-compassion may be a more appropriate target for interventions to help facilitate romantic relationship formation in insecurely-attached breast cancer survivors.

SLEEP DURATION AND QUALITY OF LIFE IN KIDNEY CANCER SURVIVORS: INTERACTIONS WITH SEDENTARY BEHAVIOR

Jaime Wong, B. A.[1], Kerry S. Courneya, PhD[2], Linda Trinh, PhD[1]

[1]University of Illinois at Urbana Champaign, Urbana, IL; [2]University of Alberta, Edmonton, AB, Canada

Background: Sleep duration and sedentary behavior (SED) have been individually linked to lower quality of life (QoL). As cancer survivors are more likely to report higher SED than healthy individuals, they are at higher risk for lower QoL, negative mental health effects and lower physical functioning, independent from the benefits of physical activity (PA). Furthermore, cancer survivors have been shown to have shorter sleep duration that may contribute to depression, fatigue and lower QoL. An understanding of how sleep duration affects the relationship between SED and QoL in KCS is needed.

Purpose: To examine the associations between sleep duration and QoL in KCS, and the interactive associations between SED and sleep duration on QoL for a work day (WD) and a non-work day (NWD).

Methods: All 1985 KCS diagnosed between 1996 and 2010 were identified through a Canadian Provincial Registry and mailed a survey including the Godin Leisure Time Exercise Questionnaire, the modified domain-specific sitting time questionnaire (including sleep duration), and several Functional Assessment of Cancer Therapy scales. Self-reported demographic and medical variables were collected.

Results: Completed surveys were received from 481 KCS with Mage = 64.0±10.4 years, 64% male, and 84% having localized kidney cancer**.** In the main hierarchical analysis, the interaction effect of sleep duration by SED was significantly associated with physical well-being (PWB) (p=.04), functional well-being (FWB) (p=.01), emotional well-being (EWB) (p=.05), general QoL (p=.009) and fatigue, (p=.05) on a WD only. Follow-up simple slope analyses demonstrated that among KCS with higher levels of sleep, higher levels of SED significantly predicted lower levels of PWB (B=-.002; p=.09), lower levels of FWB (B=-.003; p=.08), and higher levels of fatigue (B=-.009; p=.06). However, among KCS with lower levels of sleep, higher levels of SED significantly predicted higher levels of general QoL (B=.006; p=.04) and higher levels of EWB (B=.003; p=.00). There were no associations between SED and sleep duration on QoL for a NWD.

Conclusions: Sleep duration appears to play a role in moderating the relationship between SED and QoL on a WD only. Higher levels of sleep duration coupled with higher levels of SED may be detrimental to some aspects to the functional aspects of QoL (i.e. PWB, FWB, fatigue), However, lower levels of sleep duration appear to positively influence general QoL and EWB in the presence of higher SED. Having optimal levels of sleep and SED are likely to result in better symptom management.

SOCIAL CONSTRAINT, SOCIAL SUPPORT, AND PERCEIVED BURDEN AMONG CHINESE CANCER SURVIVORS: A MEDIATION MODEL

Kelly Yu-Hsin Liao, Ph.D.[1], Qian Lu, Ph.D.[2], Jennie Ho, Bachlor of Art[3], Celia C.Y. Wong, MPhil[2]

[1]Cleveland State University, Cleveland, OH; [2]University of Houston, Houston, TX; [3]University of Houston, Sugar Land, TX

Although cancer has now become the leading cause of death among urban and rural residents (Wang, Wei, Liu, Li, & Wang, 2012), very limited research has focused on Chinese cancer survivors. The current study aimed to increase our understanding of this population by examining a mediation model to determine what factors predict perceived burden, which in turn contributes to fatigue and physical symptoms. Chwalisz's (1996) Perceived Stress Model of Burden describes that coping and social support are both associated with perceived burden, which can influence metal and health outcomes. Based on this model, the current study hypothesized that social constraint or difficulty cancer survivors experience in talking with others about cancer-related issues, would predict increased perceived burden, in turn, influencing cancer survivors' health outcomes. It was also hypothesized that social support would be associated with decreased perceived burden, which would in turn predict health outcomes (i.e., fatigue and physical symptoms). Data were collected from 136 Chinese cancer survivors from cancer associations in the United States. The hypothesized model was tested using path analysis in Mplus Version 6.1 program (Muthén & Muthén, 2010). The results supported the hypotheses that social constraint and social support were associated with perceived burden, which in turn predicted increased fatigue and greater number of physical symptoms. Thus, perceived burden was the mediator or the mechanism through which social constraint and social support were associated with health outcomes among Chinese cancer survivors. Detailed findings and research/clinical implications will be presented.

SOCIAL CONSTRAINTS AND CARINGGUIDANCE PROGRAM EFFECTS ON PSYCHOLOGICAL ADJUSTMENT IN MONTHS AFTER BREAST CANCER DIAGNOSIS

Robin M. Lally, PhD, MS, BA, RN, AOCN[1], Kevin A. Kupzyk, PhD[1], Steven M. Gallo, MS[2], Karen Meneses, PhD, RN, FAAN[3]

[1]University of Nebraska Medical Center, Omaha, NE; [2]University at Buffalo, Buffalo, NY; [3]University of Alabama at Birmingham, Birmingham, AL

Social constraints are negative human interactions that prevent cognitive processing of a life-altering event. Avoidance, minimizing and preventing a person with cancer from expressing concerns, exemplify social constraints. Breast cancer diagnosis alters one's life-view and requires cognitive processing to reduce distress and depressive-symptoms toward achieving psychological adjustment. C*aringGuidance™ After Breast Cancer Diagnosis* is a new, Internet-based, self-guided, psychoeducational program developed to support psychological adjustment in the initial months after diagnosis. Learning modules include content on diagnosis disclosure, strategies for coping with social constraints and spouse/partner relationship changes.

Method: 100 women diagnosed within 0 - 3 months with their first, stage 0 – 2 breast cancer, randomized to self-guided use of the *CaringGuidance™* Internet-program or usual care for 3 months completed psychosocial measures including the Distress Thermometer (DT), CES-D, Impact of Event Scale (IES), and Social Constraints Scale (SCS) (once for spouse/partner (S/P) behavior and again for family/friend (F/F) behavior) at baseline and monthly. A custom data analysis system monitored program use.

Results: Subjects' mean age was 54.2 years (SD= 9.9). The majority was married; college educated, employed, with no prior mental health diagnosis. Groups did not differ significantly at baseline on demographic or psychosocial variables. The Intervention Group used the program a median 4.4 hours. The SCS was highly reliable at each time point for S/P -focused and F/F-focused responses (Cronbach's alpha >.90). Mean SCS scores ranged from 1.4 – 1.7. Higher scores (significant only at month 1) were noted for F/F-focused scale responses versus S/P. S/P and F/F-focused responses were highly correlated (r=.57 - .71). Significant positive correlations were also found between SCS responses and DT, CES-D and IES scores. A non-significant decrease in scores for both S/P and F/F-focused SCS responses occurred over the 3 months. However, a significant time by group interaction indicated that the Intervention group significantly decreased in their reports of social constraints over time.

Conclusion: Greater social constraints correlated as predicted with greater reported distress and depressive-symptoms among women newly diagnosed with breast cancer. Access to *CaringGuidance™* resulted in significantly fewer reports of constraints compared to usual care.

STUCK IN THE SPIN CYCLE: AVOIDANCE AND INTRUSIONS FOLLOWING BREAST CANCER DIAGNOSIS

Margaret Bauer, M.A., C.Phil.[1], Joshua F. Wiley, PhD[2], Karen Weihs..., MD[3], Annette L. Stanton, Ph.D.[4]

[1]University of California, Los Angeles, Los Angeles, CA; [2]Monash Institute for Cognitive and Clinical Neurosciences and School of Psychological Sciences at Monash University, Melbourne, Victoria, Australia; [3]University of Arizona, cancer center, Tucsn, AZ; [4]UCLA, Los Angeles, CA

Cognitive processing theories of adjustment to chronic stress suggest that individuals alternate between periods of intrusive thoughts and feelings and periods of avoidance. Theoretically, phases of intrusions are characterized by stressor-related ideas and emotions that are brought to mind for eventual integration. These phases of intrusions alternate with periods of avoidance, which prevent individuals from becoming overwhelmed by intrusions. However, most relevant studies assess avoidance as a predictor of intrusions or vice versa rather than examining the theorized bidirectional process. The current study presents a longitudinal empirical investigation of the reciprocal relationship between intrusions and avoidance coping through the six to ten months following breast cancer diagnosis. Breast cancer patients (N = 460) completed measures of cancer-related intrusions (Impact of Event Scale) and avoidance (COPE Avoidance-oriented Coping composite) at study entry (i.e., zero - four months after diagnosis), three-, and six-month follow-ups.

Cross-lagged panel analyses tested a series of nested models that contrasted a hypothesized cross-lagged model demonstrating mutual influence between predictors with unidirectional models (intrusions predicting avoidance, avoidance predicting intrusions). Wald tests revealed that a model with bidirectional cross-lagged paths between avoidance and intrusions fit the data better than a model with only avoidance (X^2 =8.55 (2), p = .02) or intrusions (X^2 =11.87 (2), p =.003) as a predictor. In the best-fitting model, intrusions at study entry predicted greater avoidance three months later (b = .06, p < .001), and avoidance coping at study entry predicted more intrusions three months later (b = .34, p = .01), controlling for the stability of intrusions and avoidance as well as time since diagnosis. There was no significant relationship between avoidance and intrusions at the three-month to the six-month assessment (ps > .05).

These findings provide empirical support for theories of cognitive processing following stressful events in revealing a bidirectional relationship between avoidance and intrusions in approximately the first six months after breast cancer diagnosis, which appears to diminish in the next three months. Whether this process can be accelerated via psychosocial intervention is worthy of investigation.

SUN SAFETY, SKIN CANCER, AND SOCIODEMOGRAPHIC CHARACTERISTICS AMONG APPALACHIAN ADULTS COMPARED TO NON-APPALACHIAN ADULTS

Minal Patel, PhD, MPH[1], Katrina J. Serrano, PhD[2], Elise L. Rice, PhD[3], Chan Thai, PhD, MPH[4], Kelly D. Blake, ScD[5], Robin Vanderpool, BS, MPH, DrPH[6]

[1]National Cancer Institute, Rockville, MD; [2]National Cancer Institute/Behavioral Research Program, Bethesda, MD; [3]National Cancer Institute, Bethesda, MD; [4]Santa Clara University, Santa Clara, CA; [5]Behavioral Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, National Institutes of Health, Bethesda, MD; [6]University of Kentucky College of Public Health, Lexington, KY

Background: Individuals living in the US Appalachian region experience greater cancer disparities compared to their non-Appalachian counterparts. Although melanoma incidence is comparable among Appalachians and non-Appalachians, melanoma mortality rates are 23% higher in Appalachia compared to the national average. Protective behaviors related to limiting UV exposure, such as sunscreen use and tanning bed avoidance, can help reduce skin cancer mortality among Appalachians. Previous research examined sunscreen use among Appalachian Ohio residents, but little is known about the entire 13 state region.

Objective: This study examines skin cancer and associated behaviors among Appalachian adults vs. non-Appalachian adults, along with related sociodemographic characteristics in a nationally representative US sample.

Methods: Data from four waves of the Health Information National Trends Survey, a nationally representative population-based survey collected from 2011-2014, were combined (N = 14,451). Descriptive analyses examined sunscreen use, tanning bed use, and history of melanoma and non-melanoma skin cancers among Appalachian respondents vs. non-Appalachians. Weighted multivariable analyses were conducted to examine sunscreen use, controlling for sociodemographic characteristics.

Results: Approximately 8% of the sample resided in Appalachia (n=1,015). Melanoma rates among Appalachians were low (0.5%). Non-melanoma skin cancer (2.6%) also did not differ statistically between Appalachian and non-Appalachian adults. Only 1.7% of Appalachian respondents reported using sunscreen often or always when going outside for more than 1 hour on a warm, sunny day, compared to 25.2% among non-Appalachians. Only 0.5% of Appalachian adults reported tanning bed use and residents appeared to be no more or less likely to use a tanning bed than non-Appalachians in multivariable models. In a multivariable logistic regression, individuals residing in Appalachia reported a lower odds of sunscreen use often or always compared to non-Appalachian residents (OR=0.73, $p < 0.05$), controlling for sociodemographics and general health status. Women were more likely than men to report sunscreen use often or always (OR=2.18, $p < 0.05$), as were individuals with a college degree or higher (OR=1.99, $p < 0.05$), compared with individuals with less than a high school degree.

Conclusions: Consistent with national surveillance data, Appalachian respondents were no more or less likely to report being diagnosed with melanoma or non-melanoma skin cancer, but were less likely to report sunscreen use than non-Appalachian residents. No differences in tanning bed use were seen, indicating that interventions should focus on increasing regular sunscreen use among Appalachian residents. Communication efforts in both occupational and recreational settings are needed to increase sun safety behaviors.

SURVIVORSHIP CARE PLANNING AND ADHERENCE TO GUIDELINE-RECOMMENDED CANCER SCREENING

L. Aubree Shay, PhD, MSSW[1], Shayda I. Dioun, MPH Student[2]

[1]UT School of Public Health, San Antonio Regional Campus, San Antonio, TX; [2]University of Texas School of Public Health, San Antonio, TX

Introduction: With improvements to cancer screening and treatment, the number of cancer survivors living in the United States is increasing. Cancer survivors are at high risk of chronic health conditions and additional cancer diagnoses. To aid in long-term follow-up care, the National Cancer Institute recommends that all cancer survivors receive a written treatment summary and plan for follow-up care, jointly called a survivorship care plan. However, survivorship care planning is underutilized and there little evidence yet linking its use to positive patient outcomes.

Purpose: Thus, for this study we used data from the 2014 Behavioral Risk Factor Surveillance System (BRFSS) survey to look at the association between survivorship care planning and adherence to guideline-recommended cancer screening.

Methods: We used 3 multivariable logistic regression models to test whether receipt of a written treatment summary and receipt of instructions for follow-up care were associated with being up-to-date on mammography, cervical cancer screening, and colorectal cancer screening while controlling for patient demographic and cancer history related variables.

Results: In total, 4264 off-treatment cancer survivors completed the 2014 BRFSS cancer survivorship module and were included in our analysis. Most survivors were female (63%), white (93%) and 65 years old or older at the time of the survey (63%). Breast cancer was the most common cancer diagnosis (22%) followed by melanoma (18%), and prostate cancer (11%). In total, 40% of survivors reported receiving a treatment summary and 71% reported receiving instructions for follow-up care. Additionally, 79% of eligible survivors were up-to-date on mammography, 83% on cervical cancer screening, and 78% on colorectal cancer screening. In our adjusted models we found that receipt of a plan for follow-up care was significantly associated with adherence to guideline-recommended mammography (OR=2.2, 95% CI (1.6-2.9), cervical cancer screening (OR=1.9 (1.1-3.1)) and colorectal cancer screening (OR=1.7 (1.4-2.2). Receipt of a written treatment summary was not associated any of the cancer screening behaviors.

Conclusion: Timely cancer screening can be life-saving and is particularly important among cancers survivors who have higher odds of subsequent cancer diagnoses. Our study shows initial evidence for the impact of survivorship care planning on adherence to guideline-recommended cancer screening.

SYMPTOM CLUSTERS IN METASTATIC BREAST CANCER PATIENTS

Danielle Tometich, M.S.[1], Catherine E. Mosher, Ph.D.[1], Kevin L. Rand, Ph.D.[2], Adam T. Hirsh, PhD[1]

[1]Indiana University-Purdue University Indianapolis, Indianapolis, IN; [2]IUPUI, Indianapolis, IN

Co-occurring symptoms, or symptom clusters, have a negative, compounding effect on functional status and quality of life in cancer patients. Symptom clusters are also significant because they point to common mechanisms—both biological and psychological—that may underlie various symptoms. Psychoneurological symptom clusters consisting of mood disturbances, cognitive dysfunction, fatigue, sleep disturbance, and pain have been found in patients with early-stage breast cancer and other cancer types. Symptom cluster research in breast cancer patients has largely focused on patients with early-stage disease or survivors in remission, and little is known about symptom clusters in metastatic breast cancer patients despite their increasing longevity and high symptom burden. In order to address this gap, this study aimed to identify physical and psychological symptom clusters in metastatic breast cancer patients. Eighty women with metastatic breast cancer (91% Caucasian, average age = 55 years, SD = 11 years) were recruited from the Indiana University Simon Cancer Center to participate in this cross-sectional telephone interview study. The interview included valid measures of the severity of 10 common symptoms (i.e., pain, fatigue, anxiety, depressive symptoms, neuropathy, edema of arms or legs, nausea, hot flashes, sleep disturbance, and cognitive concerns). An exploratory cluster analysis was performed on measures of all 10 symptoms. Anxiety, depressive symptoms, fatigue, sleep disturbance, and cognitive concerns were found to cluster. A separate cluster consisted of pain, neuropathy, and nausea. Hot flashes and swelling did not cluster. The first cluster is consistent with a psychoneurological symptom cluster, which has been found in patients with non-metastatic breast cancer and other cancer types. The co-occurrence of pain and neuropathy may reflect neuropathic pain, which, along with nausea, is a common side effect of chemotherapy. Further research is needed to replicate these clusters and elucidate common mechanisms underlying co-occurring symptoms to inform intervention development.

[3]Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL;
[4]University of Texas at Austin, Austin, TX

Background: Adolescent and young adult (AYA) cancer survivors are an understudied and underserved patient population. This study aimed to better understand AYAs' perceptions of cancer survivorship research in order to identify barriers and inform research approach and methodology to ultimately improve evidence-based supportive care.

Methods: Individual interviews and small focus groups were conducted with AYA cancer survivors (N=17) attending an oncology conference and social networking event. Analyses were guided by grounded theory using an inductive data-driven approach to thematic content analysis.

Results: Participants averaged 33 years old (SD=5.5), were 10 years post-diagnosis (SD=2.3), and primarily female (79%); most common diagnoses were leukemia/lymphoma (37%) and sarcoma (11%). Major themes included: perceptions of cancer research (2 subthemes) and recommendations for improving research methodology and approach (3 subthemes). All participants reported uncertainty as to what "cancer survivorship research" encompassed, but drew from their clinical experiences and prior participation in clinical trials to inform their opinions. Perceptions of research were both positive and negative. Positive feelings included optimism about the potential to improve the cancer survivorship experience and wanting to give back to the AYA community through research participation. Negative perceptions included seeing research as inaccessible, overwhelming, and frustrating; participation as inconvenient and burdensome; and viewing researchers with skepticism and mistrust. Recommendations centered on: 1) making study materials age-appropriate and patient-focused; 2) increasing AYAs' control over participation requirements and the flexibility and convenience of procedures; and 3) creating a back-and-forth dialogue between researchers and the AYA community to improve study-specific communication (dissemination of findings), stay up-to-date on medical information specific to one's disease, and to have a voice in determining research priorities.

Conclusion: Specific strategies are needed to address AYAs' negative perceptions and perceived barriers to research participation. Future work should determine how to best improve communication with the AYA community including dissemination of research findings, providing opportunities to participate in age-appropriate research advisory roles, and building trust.

THE BEHAVIORAL MEASUREMENT AND INTERVENTION SHARED RESOURCE (BMISR) SUPPORTS RESEARCHERS CONDUCTING BEHAVIORAL STUDIES

Loescher J. Lois, PhD, FAAN[1], Angela Yung, RDN[1], Cynthia Thomson, PhD, RD[2]

[1]The University of Arizona, Tucson, AZ; [2]University of Arizona, Tucson, AZ

Background: The University of Arizona Cancer Center (UACC) BMISR provides support and services to UACC members and other University and national researchers studying human lifestyle behavior (diet, physical activity, sun safety, sexual practices, tobacco use) and quality of life (sleep, symptom management) related to cancer prevention and control. The BMISR supports the design and implementation of highly innovative behavioral measurement and interventions research within diverse populations. Specifically, the BMISR provides consultation for theory and research design, offers a repository of data collection tools and measurement equipment, facilitates development and use of ehealth and mHealth measurement and intervention strategies, and provides training for data collection, measurement, and multimodal lifestyle behavior coaching.

Purpose: To describe the structure of the BMISR and its effectiveness as a mechanism to promote behavioral health research in multiple populations, organizations and settings.

Methods: We evaluated BMISR recruitment techniques, usage from 2014 to 2016 by UACC members and nonmembers with and without peer-reviewed support, types of activities requested by researchers, implementation in diverse populations, and cost.

Results: The BMISR has successfully recruited users using strategies of local and national person-person networking, formal presentations to UACC and University faculty, and publication in newsletters. Innovative partnerships with a smoker's quitline program and mHealth development program has increased usage. The BMISR provided services to over 35 researchers nationally, including those in 9 comprehensive cancer centers. Of those researchers, 35% were UACC members with peer-reviewed support and 65% were nonmembers. Researchers requested support for questionnaire development (n=8 researchers) dietary measurement (n=21), health coaching (n=2), mHealth studies (n=4). These researchers were conducting studies in populations of adolescents, American Indians, Hispanics, healthcare providers, and cancer survivors. Fees for BMISR services such as survey analysis, dietary recalls, coaching calls, and accelerometer use were at least 50% less than charges from outside vendors.

Conclusions: The BMISR is an effective and economical means of supporting researchers who conduct behavioral research in diverse populations and settings.

THE BOTTOM LINE: WHY MENTAL HEALTH PROVIDERS NEED TO PARTICIPATE IN THE CARE OF NON-ELDERLY ADULTS WITH CANCER

Diana D. Jeffery, PhD[1], C. Allison Russo, PhD[2], Laura Hopkins, M.P.A.[2], Harry B. Burke, MD, PhD[3]

[1]Department of Defense, Defense Health Agency, Falls Church, VA; [2]Kennell and Associates, Inc., Falls Church, VA; [3]Department of Defense, USUHS, Bethesda, MD

Background: This study examines the relationship of mental health comorbidities and cost in non-elderly cancer patients.

Methods: A cross-sectional analysis of Military Health System data was conducted on all beneficiaries (9.5 million) to select patients ages 18-64 with a primary diagnosis of cancer for fiscal years 2007 – 2014. General linear models were used to examine the relationship between mental health comorbidities and annual costs, the number of ambulatory visits, the number of hospitalizations, and the number of admission days. Predictors included demographic characteristics, type and location of enrollment, types of treatment modalities, number of chronic disease comorbidities, presence and type of mental health comorbidities, and tobacco use.

Results: On average, 92,318 patients had a primary cancer diagnosis each year of observation. The Department of Defense paid an average of $20,357 (adjusted to U.S. 2014 dollars) per patient per fiscal year. The mean number of annual visits per patient was 26.44; the mean number of annual hospitalizations was 1.62; and the mean number of admission days was 16.13. The majority of patients were ages 45 - 64, female, and military retired or a family member of a retiree. After controlling for other predictors, concurrent diagnosis of depression, anxiety, or adjustment disorder (DAA) was significantly related to annual cost ($p < 0.0001$), with only the receipt of chemotherapy being a stronger predictor. A concurrent diagnosis of DAA, or of a serious, persistent mental illness, were significant predictors of annual number of ambulatory visits ($p < 0.0001$).DAA comorbidity was highly related to annual number of hospital readmissions ($p < 0.0001$), as well as annual number of admission days ($p < 0.0001$). A comorbidity of alcohol and drug use disorder was statistically significant ($p < 0.0001$) in all regression models, though not as strong a predictor as DAA. Additionally, tobacco use was significantly related to annual cost ($p < 0.0001$), ambulatory visits ($p < 0.0001$), and hospital readmissions ($p < 0.0001$), but not to the annual number of admission days.

Conclusions: This study found that cancer patients had high levels of depression, anxiety, and adjustment disorder and that these patients generated increased annual costs, including costs

related to ambulatory visits, hospital readmissions, and admission days. These findings suggest that the increased involvement of mental and behavioral health professionals may be beneficial in improving patient care and reducing costs.

THE BREAST CANCER ONLINE REHABILITATION PROGRAM – FEASIBILITY OF A MUNICIPALITY-BASED UPPER-BODY REHABILITATION PROGRAM

Bolette Skjødt. Rafn, PT. MSc, PhD student[1], Carina Nees, PT[2], Jette Vibe-Petersen, MD[3], Julie Midtgaard, PhD[4], Pat Rafn, PhD[5], Kristin Campbell, PhD[6]

[1]University of British Columbia, Vancouver, BC, Canada; [2]Copenhagen Center for Cancer and Health, Copenhagen, Hovedstaden, Denmark; [3]Copenhagen Centre for Cancer and Health, Copenhagen, Hovedstaden, Denmark; [4]Section of Social Medicine, Department for Public Health, University of Copenhagen and The University Hospitals' Centre for Health Research, Copenhagen University Hospital, Copenhagen, Hovedstaden, Denmark; [5]St. Paul's Hospital and University of British Columbia, Vancouver, BC, Canada; [6]University of British Columbia, Department of Physical Therapy, Vancouver, BC, Canada

Background Following treatment for breast cancer, a considerable amount of women experience persistent upper-body issues. Innovative interventions for early post-surgery rehabilitation are needed. An online resource offers the opportunity to deliver homogenous, high-quality breast cancer rehabilitation that may reduce the prevalence or severity of persistent upper-body issues. We developed the Breast Cancer Online Rehabilitation (BRECOR) program through an iterative process (usability testing, discussion panels, and focus group interviews with women with breast cancer and physiotherapists). The program consists of a clinical assessment tool for physiotherapists to prescribe individualized exercises, and a website and education pamphlet to support the home-based rehabilitation prescriptions.

Objective To test the feasibility of integrating the BRECOR program into clinical practice to support upper-body rehabilitation for women after breast cancer surgery.

Design and setting Single-group, feasibility study in 11 municipalities in the Capital Region of Denmark.

Subjects Women age 18-80 years with 1) a surgery for breast cancer within the past 8 weeks, 2) access and ability to use internet, and 3) ability to read and understand Danish.

Methods All participants underwent an in-person assessment with a physiotherapist using the BRECOR clinical assessment tool, which then formed the therapist's decision-making for the prescription of specific exercises for a 12-week home-based upper-body rehabilitation program tailored to each participant's needs. Each participant received in-person instruction

by the physiotherapist for the specific exercises at that visit. To support this program, participants were asked to use the BRECOR education pamphlet and the BRECOR website to complete 5 to 7 exercise sessions weekly. At 12-weeks, the in-person assessment with a physiotherapist was repeated and used as a measure of retention. Primary outcomes were recruitment and retention rate, adherence, participant satisfaction, capacity/resources and secondly, self-reported shoulder function (QuickDASH).

Results From 49 women, who were eligible, 39 (79.6%) participated and 29 (74.6%) completed the 12-week follow-up assessment. 72% (21 of 29) adhered to the BRECOR program. 90% (26 of 29) reported to have benefitted “much” or “very much” from the BRECOR program. Capacity (total time spent by the physiotherapist in delivering the program) was 1.5 hour ±27 min at baseline and 54±13 min at follow-up. Self-reported shoulder function improved from baseline (mean 18.60±12.5) to 12-weeks (mean 13.97±16.1) but was not significant (p=0.08).

Conclusion The BRECOR program can reach and retain the majority of women in the early phase after surgery for breast cancer. Participants are satisfied with and adhered to the program.

THE DEVELOPMENT, IMPLEMENTATION, AND EVALUATION OF A COMMUNICATION SKILLS TRAINING PROGRAM FOR ONCOLOGY NURSES

Smita Banerjee, Ph.D.[1], Ruth Manna, MPH[2], Nessa M. Coyle, PhD, RN[1], Stacey Penn, BSN, RN, OCN[3], Tess Gallegos, MPH[4], Talia Zaider, PhD[1], Carol Krueger, LCSW-R[5], Philip Bialer, MD[1], Carma Bylund, PhD[6], Patricia A. Parker, PhD[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Memorial Sloan Kettering Cancer Center, new york, NY; [3]Memorial Sloan Kettering Cancer Center, Riverdale, NY; [4]Memorial Sloan Kettering Cancer Center, Montclair, NJ; [5]Memorial Sloan-Kettering Cancer Center, New York, NY; [6]Hamad Medical Corporation, Houston, TX

Many nurses express difficulty in communicating with their patients, especially in oncology settings where there are numerous challenges and high stakes decisions during the course of diagnosis and treatment. Providing specific training in communication skills is one way to enhance the communication between nurses and their patients. We developed and implemented a communication skills training program for nurses, consisting of three teaching modules: Responding Empathically to Patients, Discussing Death, Dying, and End-of-Life Goals of Care, and Responding to Challenging Interactions with Families. Training included didactic and experiential small group role plays. This paper presents results on program evaluation, self efficacy and behavioral demonstration of learned communication skills. Three hundred and forty two in-patient oncology nurses participated in a one-day communication skills training program, and completed course evaluations, self-reports, and pre- and post-Standardized Patient Assessments. Overall nurse participants rated the training favorably. Specifically, more than 90% of nurse participants indicated that they agreed or strongly agreed with 5 of the 6 evaluation items (with one item receiving endorsement by more than 80% but less than 90% of participants). As well, a majority of nurse participants (>80%) rated each individual module component as aiding in learning (as indicated by ratings of “somewhat aided my learning” to “aided my learning a lot”). Participants reported significant gains in self efficacy in their ability to communicate with patients in various contexts. Overall, nurses’ self-efficacy significantly improved [$t(1016) = 31.17$, $p < .001$] from pre- ($M = 3.31$, $SD = .88$) to post-training ($M = 4.05$, $SD = .65$). In addition, there was a significant increase in overall skill use from pre- to post-training. The biggest gain was observed in empathic skills. In particular, 4 out of 5 empathic skills (encourage expression of feelings, acknowledge, normalize, and praise patient efforts) significantly increased from pre- to post-training. Additionally, significant increase was observed in 1 out of 5 questioning skills (clarify) and 1 out of 4

information organization skills (summarize). This work demonstrates that implementation of a nurse communication skills training program at a major cancer center is feasible, acceptable, and has a significant impact on participants' self-efficacy and uptake of communication skills. A key practical implication of this work is that communication skills training for oncology nurses (as well as for other health providers) is an effective way of improving communication between nurse and patient/families, with putative improvements in patient-related outcomes. Future research should examine the impact of communication skills training on relevant patient outcomes.

THE EFFECT OF ACCEPTANCE AND COMMITMENT THERAPY ON COGNITIVE FUSION, DISTRESS, AND MOOD DISORDERS: A PILOT STUDY

Symone McKinnon, Bachelors of Arts in Psychology[1], Maya Santoro D'Eon, Ph.D.[2], April May, Masters of Arts in Psychology[3], Terry A. Cronan, Ph.D.[4]

[1]San Diego State University, La Mesa, CA; [2]University of California, San Diego, San Diego, CA; [3]University of California San Diego/San Diego State University Joint Doctoral Program, San Diego, CA; [4]San Diego State University, San Diego, CA

Acceptance and Commitment Therapy (ACT) is designed to promote psychological flexibility through various cognitive and behavioral processes, including cognitive defusion—the act of detaching from one’s thoughts and emotions. Defusion promotes greater flexibility in coping with difficult thoughts and emotions, which may help newly diagnosed breast cancer patients who experience psychological distress and mood disorders. A pilot study was conducted to examine whether ACT would reduce cognitive fusion, psychological distress, depression, and anxiety in a sample of 22 women diagnosed with breast cancer (stages 0 to 3) within the past year, who reported experiencing significant levels of distress. Participants were randomly assigned to an 8-week ACT intervention group or an attention-control group and were administered the Brief Symptom Inventory-18, the Cognitive Fusion Questionnaire-13, and the Hospital Anxiety and Depression Scale pre- and post-intervention. The small sample size limited power to detect interactions between the intervention groups and time points; thus, effect sizes were calculated to compare the two groups on change for each of the variables of interest. The results showed a reduction in cognitive fusion in both groups; however, the effect size was moderate for the ACT group ($d = 0.614$) and small for the attention-control group ($d = 0.246$). The attention-control group reported a greater reduction in psychological distress ($d = 1.615$) than the ACT group ($d = 1.475$), with both groups having large effect sizes. A large effect was detected in the ACT group for reduction of depressive symptoms ($d = 1.740$), with only a moderate effect size for those in the attention-control group ($d = 0.773$). Lastly, moderate effect sizes were obtained for both groups in the reduction of anxiety symptoms (ACT: $d = 0.765$; Attention-control: $d = 0.644$). A large randomized controlled trial is warranted to determine whether the promising effects of ACT found in this pilot study will be sustained among newly diagnosed breast cancer patients.

THE IMPACT OF CANCER ON THE SEXUAL FUNCTION OF ADOLESCENTS AND YOUNG ADULTS: A SYSTEMATIC REVIEW

Amelia Stanton, BA, Ariel Handy, BA, Cindy Meston, PhD

University of Texas at Austin, Austin, TX

Background: Adolescence and young adulthood (ages 15-39) is a critical period for sexual development, and a diagnosis of cancer during this time may have negative implications for sexual health (Nathan, Hayes-Lattin, Sisler, & Hudson, 2011). To date, no review has examined the effect of cancer on the sexual function of either men or women within this age range.

Objective: To identify, with supporting evidence, the effect cancer and its various treatments on the sexual function of adolescent and young adult men and women.

Data sources: A systematic review of articles published in English using PsycINFO, PubMed, and CINAHL was conducted. Additional studies were identified through reference lists. A total of 1,465 articles were retrieved after duplicates were removed. Search terms included: cancer, adolescents, young adults, sexual function, sexual satisfaction, sexual desire, sexual arousal, sexual pain, orgasm.

Study selection: Studies were eligible for inclusion if they a) were published in peer-reviewed journals; b) presented original findings; c) used validated measures; and d) included men and/or women who were diagnosed with cancer between the ages of 15 and 39.

Data extraction: Quality assessments and data extraction were performed independently by the first two authors using The Strengthening the Reporting of Observational Studies in Epidemiology Statement (STROBE; von Elm et al., 2008).

Results: In the 14 final studies, there was a total of 2,265 participants (849 females), with sample sizes ranging from 9 to 793. The results showed that a diagnosis of cancer during the adolescent and young adult period affects the following domains of sexual function: desire, arousal, lubrication/erection, orgasm/ejaculation, pain, enjoyment/satisfaction, and frequency of sexual activity. For both women and men, a diagnosis of cancer during this time significantly impacted sexual satisfaction. In women specifically, the domain of sexual function that was most impacted was desire, whereas for men erectile function was most compromised.

Conclusion: Adolescents and young adults have been identified as particularly vulnerable to the negative impact of cancer and its treatments. Increased awareness of the potential consequences of cancer on sexual function in this population is essential to developing targeted interventions.

THE IMPACT OF MATCHING TO PSYCHOTHERAPY TREATMENT PREFERENCE ON THERAPEUTIC ALLIANCE IN PATIENTS WITH ADVANCED CANCER

Allison Marziliano, MA[1], Allison Applebaum, PhD[2], Anne Moyer, Ph.D.[3], Barry Rosenfeld, PhD[4], William Breitbart, MD[2], Hayley Pessin

[1]Memorial Sloan-Kettering Cancer Center, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Stony Brook University, Stony Brook, NY; [4]Fordham University, Bronx, NY

Background: A common challenge in randomized controlled trials (RCTs) is that participants may inherently prefer one treatment over another, which may impact attrition, outcomes, and therapeutic alliance. The purpose of these analyses is to examine whether matching patients with advanced cancer to their preferred psychotherapy treatment will positively impact their alliance with their therapist during treatment.

Method: Data were drawn from an RCT comparing the efficacy of Individual Meaning-Centered Psychotherapy (IMCP), Individual Supportive Psychotherapy (ISP), and Enhanced Usual Care (EUC) in a sample of patients with advanced cancer. Patients' preference for treatment was assessed with a categorical question, "if you were able to choose, which arm would you prefer?". Therapeutic alliance was measured before the fourth session by a member of the study team other than the therapist using the Working Alliance Inventory-Short Form.

Results: For the purposes of these analyses, only participants (N = 168) who prefer and are randomized to one of the two psychotherapy treatments (either IMCP or ISP) will be included. Eighty-six (51%) participants were matched to their preferred type of psychotherapy treatment. Of those 86, 49 participants preferred and received IMCP, and 37 participants preferred and received ISP. Eighty-two (49%) participants were categorized as having been mismatched to their preferred type of psychotherapy treatment. Of those 82 participants, 46 preferred IMCP but received ISP, and 36 preferred ISP but received IMCP. Results demonstrated that patients who matched to their preferred psychotherapy treatment had a significantly stronger therapeutic alliance than those who did not, (t = -3.10, p =.003). Further breaking down the mismatched group, those who preferred IMCP and received ISP, compared to other mismatched patients, demonstrated a significantly weaker therapeutic alliance, (t = 2.93, p = .005). By contrast, there was no significant difference in therapeutic alliance between those who preferred ISP but received IMCP and other mismatched patients, (t =

0.76, p = .451).

Conclusions: Matching to treatment preference appears to impact the therapeutic alliance between the therapist and patient, as reported by the patient, in a RCT comparing psychotherapeutic treatments for patients with advanced cancer. Mismatch seems to differentially impact therapeutic alliance, and might be less relevant for people who prefer ISP than those who prefer IMCP.

THE PSYCHO-PHYSIOLOGICAL IMPACTS OF SELF-COMPASSION TRAINING FOR CANCER SURVIVORS: A RANDOMIZED-CONTROLLED PILOT STUDY

Adrian H.Y. Wan, MSW[1], Tiffany Hon, BSc(Psy)[2], Rainbow T. H. Ho, PhD[1]

[1]Centre on Behavioral Health, Hong Kong, N/A, Hong Kong; [2]The University of Hong Kong, Hong Kong, N/A, Hong Kong

Background: Being self-compassionate is to treat yourself with kindness at times of adversity. Although self-compassion training was found to be associated with domains of positive mental health outcomes among non-clinical population, few studies examined the effectiveness of compassion training among people with chronic medical conditions. Utilizing both subjective self-report and the biomarkers Heart Rate Variability, this pilot study explored the benefits of mindfulness-based self-compassion training among cancer patients.

Methods: This pioneer study adopted a 2-arm randomized-controlled study design. A total of 37 Chinese cancer survivors were surveyed once at baseline and at post-training. They were surveyed on a self-report inventory of self-compassion, symptoms of anxiety and depression, positive and negative affect, and non-reactivity; they were also invited to participate in a stress task to capture clinical data heart rate variability.

Results: On subjective measures, co-varying age,participants of the Self-Compassion Training showed significant *Time x Group* effects on self-compassion, positive affect, non-reactivity, and depressive symptoms. However, no significant *Time x Group* effect was reported for negative affect. In terms of mood regulation, participants also showed significant improvements in heart rate variability as reflected on the measures of RMSSD, HF, and LF during a stress test at post-intervention.

Conclusions: Results of the pilot study revealed the potential effectiveness of cultivating self-compassion among cancer survivors through mindfulness practice. Participants showed improvements in self-compassion, non-reactivity, positive affect, depressive symptoms after the program, and they reported better emotional resilience during a stress task. Further study with a discrete sample of larger size is recommended to yield further evidence on effectiveness of self-compassion training.

THE ROLE OF SELF-EFFICACY IN INTENTIONS TO RECEIVE HPV VACCINATION AMONG FEMALE COLLEGE STUDENTS

Shannon M. Christy, PhD[1], Joseph Winger, M.S.[2], Catherine E. Mosher, Ph.D.[3]

[1]Moffitt Cancer Center, Tampa, FL; [2]Indiana University-Purdue University Indianapolis, Durham, NC; [3]Indiana University-Purdue University Indianapolis, Indianapolis, IN

College women are at high risk for contracting human papillomavirus (HPV), and yet, up to 70% of young women do not complete the three-shot HPV vaccination series. Drawing upon the Health Belief Model (HBM), prior studies have identified cognitions (e.g., perceived risk of disease, perceived barriers) associated with young women's intentions to receive the HPV vaccine. Self-efficacy, a common target for intervention, may be a factor underlying the relationship between HBM variables and young women's vaccine intentions. The current study tested the hypothesis that self-efficacy for HPV vaccination would mediate relationships between five HBM variables (i.e., perceived risk, perceived benefits, perceived barriers, perceived severity, cues to action) and intentions to receive the vaccine among unvaccinated college women. Data were collected via an anonymous, web-based survey from 115 unvaccinated women aged 18-26 who were attending a Midwestern university. Five separate mediation analyses were conducted to examine whether self-efficacy mediated relationships between the five HBM variables and intentions while controlling for the other four unexamined HBM variables and prior knowledge of the HPV vaccine. As hypothesized, there were significant indirect effects of perceived risk on intentions through self-efficacy (indirect effect=.16, SE=.09, 95% CI=.02-.37) and perceived barriers on intentions through self-efficacy (indirect effect=-.16, SE=.06, 95% CI=-.31--.06). Specifically, perceived risk of developing an HPV-related condition was positively associated with self-efficacy for HPV vaccination which, in turn, was positively associated with vaccine intentions. In addition, perceived barriers to HPV vaccination were negatively associated with self-efficacy for vaccination which, in turn, was positively associated with vaccine intentions. Self-efficacy did not mediate the effects of the other HBM variables on intentions. Future intervention research might examine whether increasing self-efficacy for HPV vaccination by providing risk information and reducing perceived barriers promotes vaccination among college women.

TRUENTH LIFESTYLE MANAGEMENT: FEASIBILITY AND BENEFITS OF PHYSICAL ACTIVITY AND YOGA PROGRAMS FOR PROSTATE CANCER SURVIVORS

Nicole Culos-Reed, PhD[1], Ashley Zahavich, MSc, RN[2], Kathryn Wytsma-Fisher, MKin, CSEP CEP[3], Michael Dew, MSc, CSEP CEP[4], Bronte Viznaugh, N/A[4], Christine MacSween, BA[5], Daniel Santa Mina, PhD[6]

[1]University of Calgary, Calgary, AB, Canada; [2]Kinesic Sport Lab, Halifax, NS, Canada; [3]Faculty of Kinesiology, calgary, AB, Canada; [4]Faculty of Kinesiology, University of Calgary, calgary, AB, Canada; [5]Faculty of Kinesiology, University of Calgary, Calgary, AB, Canada; [6]Faculty of Kinesiology and Physical Education, University of Toronto, Toronto, ON, Canada

TrueNTH Lifestyle Management (LM) aims to improve the quality of life for prostate cancer survivors through community-based physical activity and yoga programs. The LM physical activity program is a 12-week, evidence-based program with weekly group fitness and yoga classes, as well as education on key behaviour change skills that will help facilitate physical activity adoption and adherence. Instructors with specialized training followed a manual of operations that included (a) class plans that could be modified to the unique needs of participants based on baseline assessments, and (b) education topics to be delivered on a bi-weekly basis during the weekly classes. Assessments at baseline and 12-weeks included quality of life (Functional Assessment of Cancer Therapy-Prostate and PORPUS), weekly activity levels (Godin Leisure Time Exercise Questionnaire), body composition measures, and fitness assessments (functional aerobic capacity, flexibility, balance, muscular strength and endurance). Participants (n=69) mean age was 66 years, with 18% on active surveillance, 15% on active treatment, and 68% completed treatment. Treatments included surgery (60%), radiation (24%), ADT (26%), and chemotherapy (3%). Significant pre to post intervention improvements were seen in quality of life (FACT-P, *p=.046;* PORPUS, *p=.03*), total moderate/strenuous exercise (GLTEQ, *p=.018*), body composition (waist-to-hip ratio, *p=.012*), functional aerobic capacity (6-minute walk test, *p=.003*), flexibility (sit and reach, *p=.002*), dynamic balance (8-foot timed-up-and-go, *p=.000*), and muscular endurance (push-ups, *p=.042*; 30-second sit-to-stand, *p=.01*). Previously sedentary participants also reached ACSM physical activity guidelines at 12-weeks (GLTEQ, *p=.012*). Ongoing program implementation in additional sites (n=8) includes quality improvement cycles to update programming based on feedback from both participants and instructors, as well as on current evidence. The in-class programming is supplemented by a dedicated website that provides program participants as well as those men who may not have access to the programs (i.e., in rural locations) with the (a) educational resources for physical activity behaviour change as well as key nutrition and

stress-reduction topics, and (b) connection with experts online to aid in physical activity screening and prescription.

'ULTIMATELY, MOM HAS THE CALL:' VIEWING CANCER PATIENTS' CLINICAL TRIAL DECISION MAKING THROUGH THE LENS OF RELATIONAL AUTONOMY

Gladys Asiedu, PhD[1], Jennifer L. Ridgeway, MPP[2], Aminah Jatoi, MD[3], Katherine Carroll, PhD[4], Carmen Radecki Breitkopf, PhD[1]

[1]Mayo Clinic, Rochester, MN; [2]Robert D. and Patricia E. Kern Center for the Science of Health Care Delivery, Rochester, MN; [3]Mayo Clinic Rochester, Rochester, MN; [4]The Australian National University, Wandin North, Victoria, Australia

Rational decision models and shared decision making processes offer principles regarding how cancer patients should approach clinical trial (CT) decisions, but actual social circumstances may influence patients’ self-determination, resulting in departures from these decision processes. This study aimed to understand the social and familial contexts that may impact CT decisions. In-depth interviews were conducted with 33 ovarian cancer patients who had been offered a CT and 39 of their family members (FM). Data were analyzed thematically using constructs derived from the theory of relational autonomy (RA), which argues that social and structural contexts can support or undermine self-determination. Findings suggest that knowledge and self-reliance are important to patients as they actively seek the opinion of FM regarding participation and yet create boundaries around who to include, how, and when. Some patients exhibited strong self-agency by informing FM of their CT participation only after the decision had been made. While RA is focused on the self-determination of patients, this study also offered unique insights into how FM view patients’ autonomous decision making. FM largely confirmed that the decision ultimately rests with the patient (“ultimately, mom has the call”), as the patient is the one who will bear the risks and burdens of trial participation. Although most FM appear to be passive in this process there was evidence of deep relational engagement as FM sometimes sought clarification on the patient’s position and said they would influence a shift in perspective or intervene if they felt patients did not make the right decision. Similar to patients, FM were cautious and created boundaries around what to say and how to present their views to patients. Other influential social and contextual factors present in the data included altruism, provider recommendations, past CT experience, structural and logistic factors. Our study provides a comprehensive understanding of how social circumstances, significant relationships, and contextual factors may influence cancer patients’ autonomy when making CT decisions. It also provides novel insight into how FM view their role in supporting patient autonomy. CT presentations emphasize patient autonomy but also should call attention to the relational aspects that influence decision

making. Tools are needed to guide cancer patients and their FM through complex social factors during CT decision making.

UNDERSTANDING BARRIERS AND FACILITATORS TO COLORECTAL CANCER SCREENING AMONG LATINOS IN A BORDER REGION:FOCUS GROUP FINDINGS

Jessica Haughton, MPH, MA[1], Jesse Nodora, DR. PH[2], Carolina Lopez, MPH[1], Kristen Wells, Ph.D., MPH[3], Rebeca Espinoza Giacinto, MA/MPH, PhD[4], Balambal Bharti, Staff Res Assoc[2], Samir Gupta, MD[2], Christian Ramers, MD[5], Elva M. Arredondo, PhD[3]

[1]San Diego State University/UC San Diego Moores Cancer Center Partnership Institute for Behavioral and Community Health, San Diego, CA; [2]University of California, San Diego, La Jolla, CA; [3]San Diego State University, San Diego, CA; [4]San Diego State University/UC San Diego, Auburn, CA; [5]Family Health Centers of San Diego, San Diego, CA

Title: Understanding barriers and facilitators to colorectal cancer screening among Latinos living in a border region: Focus group findings

Background. Latinos with colorectal cancer (CRC) are diagnosed at late stages and experience disproportionately higher rates of related mortality. CRC screening has been found to be an effective tool for management and prevention of this type of cancer, yet screening continues to be underutilized by Latinos.

Methods. As part of the formative research for developing an intervention to increase colorectal cancer screening in Latino men and women aged 50 and older, five focus groups were conducted with Latino males (n=8) and females (n=31); n=11 were not up-to-date with CRC screening. These focus groups aimed to further understand knowledge and attitudes about colorectal cancer, perceived barriers to participate in CRC screening as well as to inform the development of a related community-health care intervention. All focus groups were conducted in Spanish, audio recorded and transcribed verbatim. Transcripts were analyzed using inductive content analysis and thematic coding.

Results. Primary themes included: 1) poor access to care and low knowledge of resources for CRC as barriers to cancer screening; 2) among uninsured participants, fear of incurring economic costs/debt as a barrier to engaging in preventive health services; 3) significant influence of primary care provider recommendations to be screened. Overall, participants equated cancer and cancer treatment with negative outcomes (i.e. death) and were poorly informed about CRC and types of screening.

Conclusions. Study findings suggest that efforts to increase knowledge of CRC and screening are needed among Latinos. Further, low or no-cost CRC screening resources as well as culturally relevant health education is needed to increase CRC participation by individuals who are economically disadvantaged and underserved. As seen in prior work, provider recommendations may have a significant impact on CRC screening. Findings from this qualitative research will be used to further inform the development of an intervention in a culturally appropriate CRC prevention study.

Keywords. Colorectal cancer; Screening; Qualitative research; Latinos

UNDERSTANDING BARRIERS TO CERVICAL CANCER SCREENING USING PHOTOVOICE AMONG RURAL INDIAN WOMEN

Prajakta Adsul, MBBS, MPH, PhD[1], Purnima Madhivanan, MBBS, M.P.H., Ph.D[2]

[1]National Cancer Institute, Bethesda, MD; [2]Florida International University, Miami, FL

Objectives:

Cervical cancer is the second most common cancer diagnosed among women in India and current estimated indicate that coverage of cervical cancer screening in developing countries is on average 19% compared to 63% in developed countries. The goal of the present study was to explore perceptions and beliefs that can increase cervical cancer screening uptake among women using a community-based participatory approach called photovoice.

Methods

A total of 14 women between 30-60 years, residing in rural villages around Mysore, Karnataka, India participated in the project. Each participant was provided with a digital camera and asked to photo document their everyday realities which reflected the perceived barriers towards cervical cancer screening. During the 3 weeks of photo collection, participants met individually with the researchers to discuss the meaning of the clicked photographs. Group discussions were conducted to discuss the action steps required to address these barriers.

Results

Seven themes emerged from the data: lack of knowledge regarding cervical cancer, methods and the concept of screening for cancer; socioeconomic factors such as poverty and childcare that affect participation in cancer screening initiatives; lack of family support from husbands and mothers-in-law for participating in health care related activities including cancer screening and further treatment; personal religious beliefs that are not aligned with health care seeking behaviors in the present health systems for participating in cancer screening; misconceptions about screening test methodology and the role of physicians and health care workers in the cancer care continuum; fear of a positive screening test, embarrassment associated with a pelvic exam, and stigma surrounding a cancer diagnosis that is prevalent in the community; and lack of appropriate health care services including lack of privacy for physical examination in primary care clinics and access to a female doctor. Action steps were

identified for each of these themes in group discussions.

Conclusions

Study findings helped identify elements of the social and cultural context of rural communities thereby providing a rich understanding of the barriers of cervical cancer screening which can be integrated into pre-intervention capacity development in the future.

UNDERSTANDING MOTIVATION TO CHANGE THROUGH THE LENS OF A MOTIVATIONAL INTERVIEWING FRAMEWORK

Heatherlun Uphold, PHD[1], Felicity Harper, PhD[1], Terrance L. Albrecht, PhD[2], Louis A. Penner, PhD[2]

[1]Karmanos Cancer Institute/Wayne State University, Detroit, MI; [2]Wayne State University/Karmanos Cancer Institute, Detroit, MI

Introduction

Previous research indicates that for parents of pediatric cancer patients, their level of self-efficacy influences their child's level of distress and cooperation during cancer-related treatment procedures. Understanding factors that motivate parents to engage in Motivational Interviewing (MI) interventions to increase their self-efficacy is essential to improving parent and child coping and emotional well-being. The purpose of this study was to develop a typology, based on MI principles of importance and self-confidence, to characterize parents' motivation to change.

Methods

Participants were 19 parents of pediatric cancer patients receiving treatment in a Midwestern urban children's hospital. Data were compromised of audio-recorded treatment sessions between parents and a trained MI interventionist. Using qualitative methods, audio-recordings were analyzed to develop an exhaustive list of parent cognitions and behaviors that reflected reasons or motivation to change (or not change).

Results

A typology was developed consisting of four categories based on the MI dimensions of confidence and importance. Parents who were low importance/low confidence were characterized as unaware or cynical about the need for change and believing it was not their job to calm their child. Parents in the low importance/high confidence category were skeptical of the need for change, guarded in admitting weakness, and not open to suggestions for helping their child. Parents in the high importance/low confidence category were characterized as wanting to help their child but lacking confidence in their ability to help. Finally, parents in the high importance/high confidence category were characterized as optimistic about their ability to help and always “having a Plan B.”

Conclusions/Implications

This typology provides a framework for assessing parental levels of importance and self-confidence with respect to increasing their caregiving self-efficacy. This framework furthers our ability to identify parent’s motivation to change and ultimately will guide future MI interventions designed to improve coping and emotional well-being.

USE OF EHEALTH/MHEALTH TECHNOLOGIES FOR SELF-MANAGEMENT AMONG CANCER SURVIVORS

Yun Jiang, PhD, MS, RN, Brady T. West, PhD, Marcelline Harris, PhD, RN, Debra L. Barton, PhD, AOCN, FAAN

University of Michigan, Ann Arbor, MI

Background and Purpose: Cancer survivors' use of eHealth/mHealth technologies for self-management needs is not well understood. The purpose of this study was to examine survivors' use of the Internet and mHealth apps for four self-management processes, including resource utilization, partnerships with healthcare providers, treatment decision-making, and taking action, and to explore correlates of technology use for each process.

Methods: Secondary analysis utilized data from the Health Information National Trends Survey 4 (HINTS 4) Cycle 4, a national health information collection program administered by the National Cancer Institute. Variables examined were chosen based on the Individual and Family Self-Management theory. All analyses accounted for the complex sampling features, including weights and stratification. Descriptive statistics were used to characterize the cancer survivor subpopulation in terms of self-management behaviors, and bivariate associations between the correlates and indicators of engaging in each process were tested.

Results: Just under 1/3 of cancer survivors had used technologies for seeking online cancer information (32%), accessing the patient portal (29%), and exchanging medical information electronically with healthcare professionals (30%). Forty one percent of cancer survivors did not have a smartphone or tablet, and 36% of those who had a smartphone or tablet did not have mHealth apps. Among cancer survivors having mHealth apps, 56.3% used the apps for achieving health-related goals, and 32.9% used the apps to help treatment decision making. Cancer survivors who were younger, married, employed, and had higher income had higher odds of using technologies for self-management. In addition, new diagnosis, receiving treatment, and the belief that everything causes cancer were correlates of online information seeking or exchanging information with healthcare professionals. BMI and rural residence were correlates of the use of mHealth apps.

Conclusion: Less than one-third of cancer survivors used eHealth/mHealth technologies for self-management. Their use may be limited by the availability of technologies and health-related applications, and was associated with their socio-demographic characteristics, as well as certain cancer-specific factors and beliefs. Findings from the study may aid the

development of appropriate technology-supported self-management programs for cancer survivors.

USING THE COMMON SENSE MODEL TO UNDERSTAND BRCA PREVIVORS' CONCEPTUALIZATION OF THEIR INCREASED RISK FOR CANCER

Courtney L. Scherr, PhD[1], Marleah Dean, PhD[2], Amy A. Ross, Ph.D. Student[3], Charlotte G. Marshall-Fricker, N/A[3], Renee Jacoby, N/A[1], Meredith L. Clements, BA, MA[2]

[1]Northwestern University, Chicago, IL; [2]University of South Florida, Tampa, FL; [3]Northwestern University, Evanston, IL

Background: Women who have not had cancer, but test positive for a *BRCA* mutation (previvors) are at significantly increased risk for developing breast and ovarian cancer. Little is known about how *BRCA* previvors conceptualize their increased cancer risk, and subsequently, make risk management decisions. The Common Sense Model (CSM) provides a cognitive framework for exploring individual's risk perceptions and management decisions. Using this framework, we explored how *BRCA* previvors conceptualize and manage their cancer risk.

Methods: Female *BRCA* previvors over 18 years were recruited through social network sites to participate in a semi-structured telephone interview. Demographic information was collected during the interview. Interviews were audio recorded and transcribed verbatim. Two coders conducted content analysis based on an a priori code list including four CSM constructs: cause, timeline, control, consequence, and emotional response. Inter-coder reliability was established using Krippendorf's alpha.

Results: Twenty-five *BRCA* previvors participated. Coders were reliable at $\alpha = 0.73$. Most previvors obtained genetic testing due to a family history of cancer and/or *BRCA* mutation. They described their increased risk as something they always had, but became aware of through testing. Many identified a certain age at which they were most concerned about developing cancer, an age that often aligned with the age of the first cancer diagnosis in their family. This age became a self-imposed deadline for prophylactic surgery decisions, Knowledge of their *BRCA* mutation impacted family planning, and in some cases, personal relationships. Emotions were higher immediately after receiving genetic test results, but lessened over time, especially after completing prophylactic surgeries.

Conclusion: *BRCA* previvors conceptualized cancer risk as something they have always had, and managed their risk by engaging in surveillance prior to undergoing surgery at a self-imposed age based on family history. Prophylactic surgeries provided a return to normalcy

and eliminated negative outcomes. Understanding how *BRCA* previvors conceptualize their risk can inform intervention development.

WHAT GOOD IS SELF-COMPASSION? BRIDGING MINDFULNESS PRACTICE AND POSITIVE PSYCHOLOGICAL OUTCOMES AMONG CANCER SURVIVORS

Adrian H.Y. Wan, MSW[1], Tiffany Hon, BSc(Psy)[2], Rainbow T. H. Ho, PhD[1]

[1]Centre on Behavioral Health, Hong Kong, N/A, Hong Kong; [2]The University of Hong Kong, Hong Kong, N/A, Hong Kong

Background: The practice of mindfulness teaches one to respond to stress in non-reactive manner. Ample of evidence suggested the benefit of mindfulness in improving psychosocial well-being of cancer patients. However, little is known about how such transformations took place. With reference to the Buddhist root of mindfulness practice, this present study explored the role of self-compassion in mindfulness training for cancer patients.

Methods: 47 Chinese adult cancer survivors attending an 8-week mindfulness-based self-compassion training program were surveyed on a self-report questionnaire on their level of reactivity, self-compassion, positive and negative affect, as well as anxiety and depression symptoms.

Findings: Participants reported significant improvement in non-reactivity, self-compassion, as well as symptoms of anxiety and depression after attending the 8-week program. Regression analyses showed that non-reactivity was positive associated with self-compassion and positive affect; but association was not found either between non-reactivity and negative affect or anxiety symptoms. Further analyses showed that self-compassion completely mediated the relationship between non-reactivity and positive affect as well as depression.

Conclusions: Mindfulness practice emphasizes the non-reactive way in responding to daily life stress; the present study suggested that the association between non-reactivity and positive coping outcomes were mediated by the presence of self-compassion. Cancer survivors who are less reactive reported more positive affect and fewer depressive symptoms by means of becoming more self-compassionate. The cultivation of self-compassion could be one of the ways to cancer survivors to alleviate mood and nurture positive affect for cancer survivors.

WHEN CANCER STIGMA GETS UNDER THE SKIN: ASSOCIATIONS OF CANCER STIGMA WITH COGNITIONS AND QUALITY OF LIFE

Celia C.Y. Wong, MPhil, Qian Lu, Ph.D.

University of Houston, Houston, TX

Objective:

The “pink ribbon” culture presents breast cancer as a disease of innocence, which results in much less public stigma against women with breast cancer. While surviving breast cancer is less stigmatized and even honored in the American culture, stigma remains a significant stressor among Asian breast cancer survivors. Therefore, the present study aimed to examine the association between internalized stigma and quality of life among Chinese American breast cancer survivors, and how impeded cognitive processing (i.e., reduced posttraumatic growth and more intrusive thoughts) may mediate this association

Methods:

One hundred and thirty-five Chinese breast cancer survivors aged between 33 and 82 (M = 54.55, SD = 9.37) were recruited from Chinese community organizations in Southern California. Interested and eligible individuals were invited to complete a questionnaire package assessing their levels of internalized stigma, posttraumatic growth, intrusive thoughts, and quality of life.

Results:

Results of correlation analysis showed internalized stigma was significantly associated with increased intrusive thoughts (*r* = .67) but reduced posttraumatic growth (*r* = -.28) and quality of life (*r* = -.48). Results of path analysis indicated the data fit well to the proposed mediation model, $\chi^2(1) = 0.45$, p = .50, CFI = 1.00, TLI = 1.02, RMSEA < .001, SRMR = .01. The indirect effects of internalized stigma on quality life through posttraumatic growth (standardized indirect effect = -0.09, *p* < .05, 95% CI: -.72 to -.07) and intrusive thoughts (standardized indirect effect = -0.39, *p* < .01, 95% CI: -1.79 to -.87) were significant, whereas the direct effect of internalized stigma on quality of life was not significant (standardized indirect effect = 0.00, *p* = .93, 95% CI: -.66 to .63).

Discussion:

Findings suggested internalized stigma was associated with poorer quality of life among Chinese American breast cancer survivors, and impeded cognitive processing may be the underlying mechanism. To attenuate the negative associates of internalized stigma and promote quality of life among Asian breast cancer survivors, cognition-focused interventions should be developed to foster posttraumatic growth and reduce intrusive thoughts.

YOUNG BREAST CANCER SURVIVORS' SPECTRUM OF REPRODUCTIVE AND SEXUAL HEALTH NEEDS FROM DIAGNOSIS TO SURVIVORSHIP

Kristin Z. Black, PhD, MPH[1], Eugenia Eng, DrPH[1], Jennifer C. Schaal, MD[2], La-Shell Johnson, MA[3], Hazel B. Nichols, PhD[1], Diane L. Rowley, MD, MPH[1]

[1]University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Chapel Hill, NC; [2]The Partnership Project, Greensboro, NC; [3]UNC Center for Health Promotion and Disease Prevention, Chapel Hill, NC

Background: The long-term reproductive health impact of cancer treatments is a legitimate concern for premenopausal women with a breast cancer (BC) history, particularly since it is recommended that women delay childbearing for 2-3 years after diagnosis. Whether or not they desire to conceive after treatment completion, all young women with a BC history may experience treatment-induced reproductive/sexual health issues that potentially affect their quality of life in survivorship. This study aimed to determine the unmet reproductive healthcare needs of premenopausal BC survivors. **Methods:** We recruited women with a BC history, ages 18-45 at diagnosis, and living in North Carolina to participate in an in-person 2-part semi-structured interview that inquired about reproductive health history, BC experience, and reproductive/sexual health concerns around the time of diagnosis. To analyze the data, we used ResearchTalk's *Sort and Sift, Think and Shift©* Method, a multidimensional qualitative analysis approach. This approach along with member checking with a community advisory committee and interview participants allowed us to identify the most salient themes from the data. **Findings:** Seventeen women with a BC history completed the interview. The mean age at first BC diagnosis was 38.6 years. Of the 17 women, 12 delivered all of their children prior to diagnosis, 1 delivered her children after her diagnosis, 2 delivered children before and after their diagnoses, and 2 did not have any children. Ten of the women were white and 7 were women of color (e.g., black, Latina, and Asian). The 5 overarching themes were that women with a BC history: 1) received limited reproductive health information; 2) desired realistic expectations of conceiving post-cancer; 3) made lifestyle choices based on family history of BC; 4) struggled with adjusting to their altered physical appearance; and 5) had menopausal symptoms that led to sexual health and quality of life issues. Despite many commonalities in these women's experiences, there were subtle differences between women who did and did not have a child after their BC diagnosis, as well as between women of color and white women. **Conclusions:** Women with a BC history are in need of and desire more education and resources to address their reproductive and sexual health concerns. Young BC

survivors would greatly benefit from receiving reproductive health counseling to address their concerns during the BC treatment phase and beyond.

METABOLIC SYNDROME, INFLAMMATION, AND COGNITIVE FUNCTIONING IN A COMMUNITY SAMPLE OF AFRICAN AMERICANS

Kanesha Simmons, B.A. [1], Olga Herren, M.S. [2], Denee Mwendwa, Ph.D.[2], Clive Callendar, M.D.[3], Alfonso Campbell, Ph.D.[2]

[1]Howard University, Acccoke, MD; [2]Howard University, Washington, D.C., DC; [3]Howard University, Washington, D.C>, DC

Research has shown that Metabolic Syndrome (MetS) has adverse effects on cognitive functioning. Studies have illustrated that pro-inflammatory cytokines such as interleukin-1a (IL-1a), interleukin-6 (IL-6), and C-Reactive protein (CRP) mediate this relationship. African Americans are disproportionately affected by MetS and at greater risk for earlier onset and accelerated decline in cognitive functioning. Few studies have examined this relationship in African Americans. The current study investigated the relationship between MetS and cognitive functioning in an African-American community sample. The study also determined if the association between MetS and cognitive functioning is mediated by IL-1a, IL-6, and CRP and whether it is moderated by gender and socioeconomic status (SES). The study consisted of 214 African Americans in the Washington, D.C. metropolitan area. Participants underwent a medical examination conducted at the General Clinical Research Center at Howard University Hospital. Blood serum was collected using venipuncture procedure to determine cholesterol, triglyceride, IL-1a, IL-6, and CRP levels. Weight, height, and blood pressure were also taken. Participants completed a full health history, as well as a battery of psychosocial and neurocognitive measures, which included the Stroop, Trail-making A, and Trail-making B. Results showed no significant main effects of MetS on cognitive functioning. However, the relationship between MetS and cognitive functioning was mediated by Il-6 and CRP. This relationship was not moderated by gender or SES. Results emphasize the important role of inflammation as a mechanism by which MetS impacts cognitive functioning. Future research should consider the role of inflammation when determining risk for cognitive impairment in individuals with MetS. The central role of inflammatory processes associated with other chronic conditions and their impact on cognitive decline should be further investigated.

MILD COGNITIVE DEFICITS IN MEN AND WOMEN WITH AND WITHOUT CORONARY ARTERY DISEASE: PERSONALITY MATTERS

Bianca D'Antono, PhD

Montreal Heart Institute/Université de Montréal, Montreal, PQ, Canada

BACKGROUND: Mild cognitive deficits and dementias are more prevalent with aging. Pro-inflammatory and vascular processes likely play a significant role in their pathophysiology. However, personality traits and affective states that drive much of how individuals interact with their world, and that have been shown to increase the risk of coronary artery disease (CAD) morbidity and mortality, may also be of importance. To examine the presence and correlates of mild cognitive deficits in men and women with and without CAD and no known cognitive disorder.

METHODS: Five hundred and eighteen men and 212 women with and without CAD (N = 478 and 252, respectively; Age=65.7 ± 6.7 years), and no known cognitive disorder, were administered the Montreal Cognitive Assessment (MoCA) as well as various psychological and health questionnaires. Blood was drawn in fasting state and anthropomorphic and BP data obtained to ascertain metabolic syndrome (MS), as well as CRP and Il-6 levels. Presence of mild cognitive deficits was determined on the basis of MoCA scores **RESULTS:** Patients with CAD showed significantly more mild cognitive deficits compared with similarly aged individuals with no CAD (41.4% vs 26.6%; $p < 0.001$). Differences were maintained after controlling for age, lifestyle, personality, depressive state, and Il-6 ($p < 0.007$). A forward logistic regression to predict presence of cognitive deficits led to the following stepwise inclusions: age (OR=1.071), Il-6 (OR=4.165), hostility (OR=1.044), CAD status (OR=1.634), social desirability (OR=1.082), and alcohol frequency (OR=0.907) (all $p < 0.001$, except for alcohol; Nagelkerke R^2=0.132, $p < 0.007$).

CONCLUSION: Prevalence of mild cognitive deficits among our participants without known cognitive disorders was high. We found a pro-inflammatory state, vascular impairment, as well as higher hostility and social desirability traits to predict concurrent cognitive deficits. Whether interventions targeting these physiological and psychological dimensions could delay conversion to dementia requires further study.

OPTIMISM INCREASES THE ODDS THAT ADULTS WITH CARDIOVASCULAR DISEASE ENGAGE IN EXERCISE

Jacob Julian, B.A.[1], Rachel Monane, B.A.[1], Laura Meli, M.S.[1], Carmela Alcantara, PhD[2], Keith M. Diaz, PhD[1]

[1]Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; [2]Columbia University, New York, NY

Background: Exercise following a myocardial infarction (MI) is a critical part of care for cardiac patients. However, few cardiac patients regularly exercise. One key factor associated with adherence to recommended cardiovascular health regiments in the general population is optimism. To examine a potential factor that influences exercise participation among cardiac patients, we tested the association of dispositional optimism with exercise in a representative U.S. sample of adults with a history of MI. **Methods:** Data were collected from a national sample of 1485 adults with a history of MI (64% male; mean age: 68 ± 11 years). Participants completed an online survey that queried health beliefs and behaviors. Physical activity was self-reported by the item, “In the past week, on how many days have you done a total of 30 minutes or more of physical activity, which was enough to raise your breathing rate?” A regular exerciser was defined as those who reported >1 day of physical activity of 30 minutes or more. A revised version of the Life Orientation Test was used to assess optimism. Participants were stratified into low, moderate, and high optimism groups in accordance with previous publications. **Results:** Among the 1485 participants, 178 (11.9%), 736 (49.6%), and 571 (38.5 %) participants reported low, moderate, and high levels optimism, respectively. In a multivariable adjusted model that included age, gender, race, education, number of heart attacks, years since last MI, and depressive symptoms, the odds of being a regular exerciser were significantly higher with greater levels of optimism. Compared to participants with low optimism, participants with moderate and high optimism were 1.94 (95% Confidence Interval (CI): 1.35-2.79) and 2.26 (95% CI: 1.51.-3.40) times more likely to be regular exercisers, respectively (P-trend < 0.001). **Conclusion:** In this nationally representative sample of adults with a history of MI, our findings show that optimism is associated with a greater likelihood of exercising. Future studies should examine whether psychological interventions to improve positive affect improve adherence to health behaviors among adults with cardiovascular disease.

PHYSICAL ACTIVITY BUFFERS DETRIMENTAL INFLUENCE OF STRESS ON DEPRESSION AND ANXIETY AMONG PATIENTS WITH CORONARY HEART DISEASE

Biing-Jiun Shen, PhD[1], Ester Pei Xuan Lee, N/A[2], Hung Yong Tay, MS[3], Cindy KS Lim, N/A[3]

[1]Nanyang Technological University, Saratoga, CA; [2]Nanyang Technological University, Singapore, N/A, Singapore; [3]Singapore Heart Foundation, Singapore, N/A, Singapore

Background: For patients with coronary heart disease (CHD), promotion of physical activity is an essential task in behavioral intervention to encourage comprehensive healthy lifestyle changes. Research has shown that stress, depression, and anxiety are prevalent and detrimental to CHD patients. This study investigated whether physical activity would buffer the negative effect of stress on depressive and anxiety symptoms among CHD patients.
Methodology: Participants were 161 CHD patients (84% men), with a mean age of 63.7 (SD=9.1), who participated in a community-based cardiac rehabilitation program. Physical activity was assessed with the International Physical Activity Questionnaire, stress by Perceived Stress Scale, depression by the Center for Epidemiologic Studies Depression Scale, and anxiety by the Hospital Anxiety and Depression Scale. Hierarchical multiple regression was conducted to examine (1) whether higher stress and lower physical activity were associated with elevated depression and anxiety symptoms, and (2) whether physical activity interacted with stress to buffer its negative impact on depression and anxiety. All models were adjusted for age, gender, and ethnicity as standard covariates.
Results: In the model to predict depressive symptom severity, both higher stress ($\beta = .55$, $p < .001$) and lower physical activity ($\beta = -.15$, $p = .03$) were significantly associated with higher depressive symptoms, and there was also a significant stress by physical activity interaction ($\beta = -.20$, $p = .004$), indicating that physical activity buffered the negative impact of stress on depression. The simple slope analysis showed that for patients with higher stress levels (1 SD above the mean), higher physical activity was strongly associated with lower depressive symptoms ($\beta = -.36$, $p = .002$), whereas for those with lower stress (1 SD below mean), physical activity ($\beta =.07$, $p = .47$) was not associated with depression. In predicting anxiety, higher stress ($\beta = .44$, $p < .001$) and lower physical activity ($\beta = -.16$, $p = .03$) were both significantly associated with more elevated anxiety, and there was a significant stress by physical activity interaction ($\beta = -.32$, $p < .001$) indicating a buffering effect. The simple slope analysis demonstrated that for patients with higher stress, higher physical activity ($\beta = -.51$, $p < .001$) was strongly associated with lower anxiety; in contrast, for those with lower stress, physical activity was related to higher anxiety ($\beta =.20$, $p = .03$).
Conclusion: The findings suggest that physical activity appears to be an effective stress buffer

among CHD patients. Promoting physical activity may be associated with lower depression and anxiety, especially for patients with higher stress levels.

POST-TRAUMATIC STRESS DISORDER SYMPTOMS AND AVERSIVE COGNITIONS ABOUT PHYSICAL ACTIVITY IN ACUTE CORONARY SYNDROME PATIENTS

Rachel Monane, B.A.[1], Brendan Swan, B.S.[1], Othanya Garcia, B.A.[1], Ian Kronish, MD, MPH[2], Keith M. Diaz, PhD[1]

[1]Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; [2]Columbia University Medical Center, Center for Behavioral Cardiovascular Health, New York, NY

Background: ~1 out of 8 patients who survive an acute coronary syndrome (ACS) event develop post-traumatic stress disorder (PTSD). Patients with ACS-induced PTSD have twice the risk of recurrent cardiac events; however the contributing mechanisms have not been elucidated. The purpose of this study was to test our hypothesis that patients with ACS-induced PTSD symptoms avoid physical activity due to fear of trauma-related bodily sensations (e.g. increased heart rate, shortness of breath). **Methods:** We studied 133 patients who presented to the emergency room of a university hospital with ACS symptoms. PTSD symptoms were evaluated 1-month post-hospitalization using the 17 item PTSD checklist (PCL-5), tailored to those who incurred a cardiac-related event. Aversive cognitions about physical activity were also measured with the following items: 1) “It scares me when my heart beats rapidly during physical activity;” 2) “When I notice my heart beating rapidly during physical activity, it reminds me of my heart event;” 3) “When I become short of breath during physical activity, it reminds me I’m at risk of having another heart event;” 4) “I sometimes avoid physical activity because I’m afraid it will cause me to have a heart event.” **Results:** In multivariable adjusted analyses, a 5 point increase in PTSD symptoms was associated with a 1.55 (95% CI 1.23-2.04; $p < 0.001$) odds of feeling scared when the heart beats rapidly during physical activity, a 2.21 (95% CI 1.58-3.57; $p < 0.001$) odds of a rapid heartbeat during physical activity triggering reminders of the cardiac event, a 1.77 (95% CI 1.39-2.40; $p < 0.001$) odds of shortness of breath during physical activity triggering worry about future risk of another cardiac event, and a 1.30 (95% CI 1.10-1.58; $p=0.004$) odds of avoiding physical activity due to fear that it could trigger another cardiac event. **Conclusion:** ACS-induced PTSD is associated with aversive cognitions about physical activity, a critical secondary prevention behavior. Interventions that promote positive associations with physical activity may have potential to reduce the incidence of recurrent events in the high-risk group of ACS-survivors who develop PTSD symptoms.

PSYCHOLOGICAL DISTRESS IN FEMALE PATIENTS WITH SPONTANEOUS CORONARY ARTERY DISSECTION

Kelsey Clemson, M.S.[1], Katharine Sears Edwards, Ph.D.[2], Jennifer Tremmel, M.D.[2]

[1]PGSP-Stanford Psy.D. Consortium, Mountain View, CA; [2]Stanford University School of Medicine, Stanford, CA

Symptoms of psychological distress often occur in patients after myocardial infarction (MI) and may be more common when MI is caused by Spontaneous Coronary Artery Dissection (SCAD) (Starovoytov et al., 2016). SCAD is an atypical vascular condition that occurs in patients who are often young (mean age = 42), female (>80%), and do not have traditional cardiac risk factors (Hayes, 2014; Giacoppo et al., 2014). Women with SCAD may be particularly susceptible to emotional distress due to the suddenness and severity of the condition, its lack of warning signs, and its relative untreatability. Three studies have described high rates of anxiety and depression in SCAD patients (Liang et al., 2013; Silber et al., 2015; Chou et al., 2016). As the condition is rare, most published studies include a small *n.* The goal of this study was to further characterize female SCAD patients' psychosocial distress. Female participants, identified by Stanford physicians as having had a SCAD event, were invited to participate in a psychosocial support group. Data was collected in two waves, first in October 2015 for group participants and second in April 2016 for women who had declined to participate in the group. Fourteen women (mean age = 51) returned self-report measures of physical and mental health and quality of life. Demographic information showed that, of 11 women reporting a history of mental health treatment, 8 indicated their treatment was related to having SCAD. Scores on self-report questionnaires suggest that most participants were experiencing clinically significant levels of anxiety and depression or PTSD warranting clinical concern or diagnosis. Nearly all participants reported high stress levels and many suffered from clinical levels of insomnia. Descriptive statistics revealed ongoing physical impairment, mostly high levels of social support, and beliefs that Doctors and Chance had the strongest influence on their condition. Findings are consistent with earlier studies documenting high rates of anxiety and depression; this study extends prior research by including other indicators of psychological distress and as the first known study to investigate PTSD symptoms in SCAD patients.

PSYCHOMETRIC PROPERTIES OF THE CONSULTATION AND RELATIONAL EMPATHY (CARE) MEASURE IN A CARDIOLOGY SETTING

Robert Scales, Ph.D.[1], Stewart Mercer, M.D.[2], Douglas Murphy, M.D.[3], Cengiz Akalan, Ph.D.[4], Farouk Mookadam, M.D.[1], Elise Storey, B.S.[5], Loreley Hall, B.S.[1], Wilansky Susan, M.D.[1]

[1]Mayo Clinic-Arizona, Scottsdale, AZ; [2]University of Glasgow, Glasgow, Scotland, United Kingdom; [3]University of Dundee, Dundee, Scotland, United Kingdom; [4]Ankara University, Ankara, Ankara, Turkey; [5]Mayo Clinic-Arizona, Sottsdale, AZ

The Consultation and Relational Empathy (CARE) Measure is a 10-item questionnaire that rates the patient experience and the interpersonal quality of a medical visit. The measure has been validated in primary care and some sub-speciality disciplines, but it has not been assessed in cardiology. This was a preliminary study of the utility of the CARE Measure to assess physicians in cardiology fellowship training. Adult patients completed the CARE Measure after a medical visit. Face validity was estimated by the number of ‘not applicable’ responses. Statistical analysis included principal component analysis (construct validity), Cronbach’s alpha (internal consistency), and Generalisability theory (inter-rater reliability).Twenty-two cardiology trainees were assessed after 1372 total visits. The level of ‘not applicable’ responses was low, ranging from 0.2% to 5.3% per item (average 1.4% across all 10 items). Missing values were rare (0.2% overall). The measure showed high internal consistency (Cronbach’s alpha coefficient=0.97) and the removal of any of the items reduced reliability. Factor analysis revealed a single factor with high factor loading for each item. The mean CARE Measure score at the patient level (n=1372) was 48.3 (SD=4.00), with mean scores ranging from 23-50. The skew was -2.721 and the kurtosis 7.743 with 48% of patients reporting a maximum CARE score of 50. The mean CARE Measure score at the physician level (n=22) was 48.2 (SD=0.85), with an essentially normal distribution (skew -0.314, kurtosis -0.594). Although mean CARE scores did vary significantly between physicians, the variation was limited (range 46.5-49.5, $p < 0.005$) and thus the ability of the measure to discriminate between individuals in this sample was correspondigly low (G=0.36-0.48). Higher reliability, suitable for formative feedback (G=>0.5) would require $\geq$60 completed questionnaires per physician. Preliminary findings suggest that the CARE Measure has face and construct validity with internal reliability in cardiology fellowship training and it may provide a practical measure of interpersonal communication. Further investigation is needed with a larger number of physicians and patients in different cardiology settings to determine if the CARE Measure can differentiate between individuals within this sub-speciality.

RACIAL/ETHNIC DIFFERENCES IN PROGRESSION OF SUBCLINICAL ATHEROSCLEROSIS IN THE NORTH TEXAS HEART STUDY

John M. Ruiz, Ph.D.[1], James Garcia, M.S.[2], Melissa Flores, MS[3], Chul Ahn, PhD[4], Matthew Allison, MD, MPH, FAHA[5], Timothy Smith, PhD[6], Joshua Smyth, Ph.D[7], Daniel J. Taylor, Ph.D.[8], Bert N. Uchino, PhD[9]

[1]University of Arizona, Tucson, AZ; [2]Southern Arizona VA Health Care System, Tucson, AZ; [3]The University of Arizona, Tucson, AZ; [4]UT Southwestern Medical Center, Dallas, TX; [5]University of California San Diego, La Jolla, CA; [6]University of Utah, Park City, UT; [7]The Pennsylvania State University, University Park, PA; [8]University of North Texas, Denton, TX; [9]University of Utah, Salt Lake City, UT

Compared to Whites, Blacks/African Americans experience a disproportionate burden of cardiovascular disease including higher prevalence, incidence, morbidity, and mortality. In contrast, Hispanics experience similar or relatively better outcomes compared to non-Hispanic (NH) Whites despite a significantly worse risk profile. One hypothesis is that atherosclerotic disease progresses more slowly among Hispanics contributing to lower early mortality. The aim of this study was to examine racial/ethnic differences in progression of carotid intima-media-thickness (cIMT) as a marker of preclinical atherosclerosis.

Participants were a community sample of 300 healthy adults (150 men, 150 women) ages 21 to 70 years (M=42.44 yrs), stratified by age within gender and race/ethnicity. The sample included 60% NH Whites, 15% NH Blacks, and 19% Hispanic/Latino. Participants completed a physical and underwent a bilateral ultrasound imaging of the extracranial carotid vasculature as part of a larger study. A returning sample of 239 participants (80% retention) repeated all procedures at a 2-year follow-up. Procedures were used to optimize test-retest over time. Images were scored by two blinded raters using Vascular Research Tools (V 5.0). Consistent with field standards, mean of the maximum scores was derived for the common carotid artery (CCA), bifurcation (BIF), and internal carotid artery (ICA) and difference scores (time 2 – time 1) were calculated.

Analyses of Covariance adjusting for demographics (gender, age), socioeconomic status (household income, education), BMI, and time 1 values of the matched cIMT variable revealed main effects for both the CCA and BIF, all $Fs(2,145) > 3.515$, $p < .05$, $np^2 > .045$. Progression was greater for NH Blacks than NH Whites with no difference between NH Whites and

Hispanics. A marginal interaction between race/ethnicity and gender was observed for ICA with the effect driven by differences among men, $F(2,46) = 5.237$, $p = .009$, $np^2 = .185$. Progression was significantly greater for NH Blacks compared to Hispanics.

These findings document important racial/ethnic differences in atherosclerotic progression and suggest that the rate of progression among Hispanics is similar to that of NH Whites despite a greater risk profile.

RACIAL/ETHNIC DIFFERENCES IN SUBCLINICAL ATHEROSCLEROSIS IN THE NORTH TEXAS HEART STUDY

John M. Ruiz, Ph.D.[1], Chul Ahn, PhD[2], Matthew Allison, M.D., MPH[3], Timothy Smith, PhD[4], Joshua Smyth, Ph.D[5], Daniel J. Taylor, Ph.D.[6], Bert N. Uchino, PhD[7], James Garcia, M.S.[8]

[1]University of Arizona, Tucson, AZ; [2]UT Southwestern Medical Center, Dallas, TX; [3]University of California at San Diego, San Diego, CA; [4]University of Utah, Park City, UT; [5]The Pennsylvania State University, University Park, PA; [6]University of North Texas, Denton, TX; [7]University of Utah, Salt Lake City, UT; [8]Southern Arizona VA Health Care System, Tucson, AZ

Evidence documents significant racial/ethnic differences in heart disease prevalence, incidence, morbidity, and mortality (Mozzafarian et al., 2015). Data also document black-white disparities with more recent data characterizing Hispanics as having rates similar to or better than non-Hispanic (NH) Whites; a paradox given their elevated risk factor profile. Diagnosis and outcomes can be influenced by access to care. Less known is whether racial/ethnic groups differ in the undiagnosed or objective measures of subclinical atherosclerosis. Therefore, the aim of this study is to examine differences in carotid intima-media-thickness (cIMT) as an objective marker of preclinical disease.

Participants were a community sample of 300 healthy adults (150 men, 150 women) ages 21 to 70 years (M=42.44 yrs), stratified by age within gender and race/ethnicity. The sample included 60% NH Whites, 15% NH Blacks, and 19% Hispanic/Latino. Participants completed a physical and underwent a bilateral ultrasound imaging of the extracranial carotid vasculature as part of a larger study. Images were scored by two raters using Vascular Research Tools (V 5.0). Consistent with field standards, mean of the maximum scores was derived for the common carotid artery (CCA), bifurcation (BIF), and internal carotid artery (ICA).

Racial/ethnic differences in each segment of cIMT were cross-sectionally evaluated with a series of Analyses of Covariance adjusting for gender, age, and BMI. No differences were observed for either the CCA or BIF. However, a main effect of Race/Ethnicity was found at the ICA, $F(2,223) = 6.261$, $p = .013$, $np^2 = .03$. Follow-up revealed that Hispanics had greater cIMT at the ICA than NH Whites (.777 vs. .719), $F(1, 185) = 4.833$, $p = .029$, $np^2 = .025$. Importantly, inclusion of household income rendered the main effect non-significant, $F(2,213) = 0.357$, $p = .70$, np^2 = ns.

Contrary to expectations, Hispanics in this study were found to have somewhat greater subclinical atherosclerosis in one segment of the carotid vasculature. However, these differences were accounted for by disparities in SES indicators.

RELATIONSHIP BETWEEN MINDFULNESS AND HEART RATE VARIABILITY IN PATIENTS WITH CHF

Brandon Khuu, BS, Paul Mills, Ph.D, Meredith A. Pung, Ph.D, Kathy Wilson, MS, Brook Henry, Ph.D., Srikanth Kalluri, BS, Laura Redwine, Ph.D

University of California, San Diego, La Jolla, CA

Relationship between mindfulness and heart rate variability in patients with CHF

Chronic heart failure (CHF) is a growing concern, with over 5.1 million cases in the United States alone and a 5-year mortality rate. Reduced heart rate variability (HRV) is associated with increased morbidity and mortality. Research shows that psychological factors can impact HRV, which presents a possible mechanism influencing cardiac health. While mindfulness is associated with increased HRV in healthy individuals, it is unknown whether this relationship occurs in patients with serious heart conditions. **Methods:** Forty-three stage B and C heart failure patients (mean age = 65.69 +/- 8.23 and left ventricular ejection fraction (LVEF%) = 60.03% +/- 11.48%) from two separate studies were examined for HRV and components of mindfulness. Components of mindfulness were accessed through the Five Facets Mindfulness Questionnaire (FFMQ) in both groups. The resting HRV was collected using the Equivital EQ-01 heart rate sensor, while the participants sat quietly in an upright position for 10 minutes. **Results:** Regression analyses adjusted for LVEF% revealed a positive association between HRV and combined awareness and nonjudging facets of mindfulness (change R^2 = .125, t = 2.252, p = .034). Also, combined mindfulness facets, awareness and nonreactivity showed a positive association with HRV (change R^2 = .101, t = 2.204, p = .035). However, total mindfulness scores were not related to HRV. **Conclusions:** These results indicate that there are aspects of mindfulness that may promote increased HRV in CHF patients. Through the understanding of the various interactions of the facets of mindfulness, this can help lead to the development of interventions that may improve physiological responses and potentially improve CHF prognosis.

RISK FACTORS FOR HYPERTENSION IN EARLY TO MID-LIFE KENYANS: THE KENYA DEMOGRAPHIC AND HEALTH SURVEY

Muhammad Abdul Baker Chowdhury, MPH, MPS, M.Sc[1], Rahma S. Mkuu, MPH, CPH[2], Katrina Epnere, MPHc, BS[3], Nafissatou Cisse-Egbuonye, PhD[4], Idethia Harvey, DrPH[5], Md Aminul Haque, PhD[6], Gerald Yonga, MBChB, MMed, MD, FRCP (Edin), MBA(healthcare), FESC, FACC[7]

[1]Department of Data Science, The University of Mississippi Medical Center, Jackson MS 39216, Dhaka, Dhaka, Bangladesh; [2]Texas A&M University, College Station, TX; [3]Florida International University/Robert Stempel College of Public Health and Social Work, Miami, FL; [4]Black Hawk County Health Department, Waterloo, IA; [5]Texas A&M University , Department of Health and Kinesiology, Transdisciplinary Center for Health Equity Research, College Station, TX; [6]University of Dhaka, Dhaka, Dhaka, Bangladesh; [7]Aga Khan University, Nairobi, Nairobi Area, Kenya

Introduction: Hypertension is the leading cause of adult mortality in developing nations. However, data on the risk factors of hypertension, especially in Kenya is lacking. This study identified the risk factors associated with hypertension in Kenya.

Methods: Cross-sectional data from the 2014 Kenya Demographic and Health Survey (KDHS) was used to assess the risk factors among 12,578 men (age 15-54 years) and 30,431women (age 15-49 years). Multivariable logistic regression was performed to assess the association between risk factors and self-reported hypertension.

Results: We found a wide variation of risk factors of hypertension among males and females. Only age, diabetes, ethnicity, and region were common risk factors for hypertension in both gender. It was found that older age (OR: 1.80, 95% CI: 1.24, 2.61), having higher education (OR: 1.55, 95% CI: 1.23, 2.14), having diabetes (OR: 26.45, CI: 16.79, 41.67), and drinking alcohol (OR: 1.31, 95% CI: 1.05, 1.63) were significantly associated with the increased risk of hypertension for males. Moreover, living in urban areas (OR: 1.24, 95% CI: 1.06, 1.45) and being obese (OR: 2.44, 95% CI: 2.04, 2.93) were factors significantly associated with the higher risk of hypertension for females.

Conclusions: Regardless of gender, individuals over the age of 35 years were more likely to self-report hypertension compared to the individuals younger than 35 years. However, there were significant variations between gender and the risk factors associated hypertension.

Focus on gender-specific health education programs and interventions are critical in the early diagnosis of this debilitating disease in Kenya.

TREATMENT OF METABOLIC ACIDOSIS IN CHRONIC KIDNEY DISEASE WITH FRUITS AND VEGETABLES IMPROVES CARDIOVASCULAR RISK

Nimrit Goraya, MD[1], Jan Simoni, MD[2], Heather Kitzman-Ulrich, PhD[3], Donald E. Wesson, MD MBA[3]

[1]Baylor Scott & White Health, Temple, TX; [2]Department of Internal Medicine, Lubbock, TX; [3]Baylor Scott & White Health, Dallas, TX

Background: Individuals with chronic kidney disease (CKD) have dramatically increased risk for cardiovascular disease (CVD), a major contributor to their premature mortality. Metabolic acidosis is a common co-morbid condition in CKD for which the currently recommended treatment is oral Na^+-based alkali therapy, commonly $NaHCO_3$. Base-producing fruits and vegetables (F+V) also improve metabolic acidosis in CKD and might have additional benefits. We tested the hypothesis that treatment of metabolic acidosis in CKD with F+V rather than $NaHCO_3$ yields a better cardiovascular risk profile. **Methods:** Individuals (N=108) with CKD (stage 3 eGFR 30-59 ml/min) and metabolic acidosis and plasma total CO_2 ($PTCO_2$) between 22-24 mM were randomized to either: F+V (n=36) to reduce dietary potential renal acid load (PRAL) by 50%; Oral $NaHCO_3$ (n=36) to reduce PRAL by 50%; or Usual Care (n=36), and followed for five years. Outcome variables were collected annually including $PTCO_2$, cystatin C calculated eGFR, body mass index (BMI), systolic blood pressure (SBP), and low-density lipoprotein cholesterol (LDL). **Results:** Baseline values were not different among groups. Five-year values for $PTCO_2$ were higher in both F+V (23.8±0.4 mM) and Oral $NaHCO_3$ (23.9±0.4 mM) than Usual Care (21.9±0.4 mM, $p < 0.01$) without significant differences between Oral $NaHCO_3$ and F+V. Similarly, 5-year values for eGFR were higher in F+V (29.3±6.1 ml/min/1.73 m^2) and Oral $NaHCO_3$ (27.4±6.1 ml/min/1.73 m^2) than Usual Care (20.5±6.1 mM, $p < 0.01$), with no differences between F&V and Oral $NaHCO_3$. By contrast, F+V had lower 5-year values than Oral $NaHCO_3$ for SBP (125±5 vs. 135±5 mm Hg, $p < 0.01$), BMI (26.6±1.7 vs. 28.4±1.9, $p < 0.01$), and LDL (116±9 vs. 136±10 mg/dl, $p < 0.01$). **Conclusions:** Treating CKD individuals with either F+V or $NaHCO_3$ improved metabolic acidosis and preserved kidney function. By contrast, those treated with F+V rather than the currently recommended $NaHCO_3$ had lower values for SBP, BMI, and LDL, indicating an improved CVD risk profile. Integrating F+V into CKD treatment has the potential to improve overall cardiovascular risk and population health.

“I JUST WANT TO DO EVERYTHING RIGHT:” PRIMIPAROUS WOMEN’S ACCOUNTS OF BREASTFEEDING FROM BIRTH TO EIGHT WEEKS VIA AN APP DIARY

Jill Demirci, PhD, RN, IBCLC, Erin Caplan, student, Nora Murray, student, Susan Cohen, PhD

University of Pittsburgh, Pittsburgh, PA

Background: First-time mothers are at risk for breastfeeding problems and early, unintended breastfeeding cessation for reasons yet to be fully explored.

Purpose: To describe the lived, early breastfeeding experience of primiparous women.

Methods: Sixty-one healthy, primiparous women intending to exclusively breastfeed downloaded a commercial infant feeding app during their postpartum hospitalization. Women were instructed to free-text breastfeeding thoughts and experiences daily through eight weeks postpartum using the app’s diary feature; diary data were emailed to investigators weekly. Diaries were independently coded by three authors line-by-line for content, implicit meanings, and narrative structure. Coding decisions and emergent themes were discussed in regular team meetings.

Results: Thirty-five participants completed at least one diary entry and were included in the analysis. Participants were primarily white, married, and college-educated. The overarching theme that encompassed the primiparous breastfeeding experience was *seeking validation and sustainability*. Particularly in the first weeks post-birth, women were overwhelmed, frustrated and anxious regarding infant satiety at-breast and the relentless nature of frequent feeds. Adequate sleep and opportunities for self-care were tipping points for the escalation and de-escalation of problems—as mothers despaired or expressed hope that they could withstand breastfeeding under evolving circumstances. Mothers yearned for, and actively sought work-arounds to achieve predictability in feeding routines. Perceived breastfeeding success was inextricably tied to maternal self-worth and identity, and almost entirely adjudicated (and re-adjudicated) through point-in-time weight checks and pediatrician feedback on adequacy of breast milk volume, rather than mother’s own day-to-day observations and enjoyment of the breastfeeding experience. When success was not immediate, or when setbacks occurred, self-trust plummeted; some sought absolution from perceived personal culpability. In later weeks, as problems resolved and the intensity of breastfeeding abated, women voiced a tentative confidence, future orientation, and resolve to establish a sustainable feeding schedule.

Conclusions: The primiparous breastfeeding experience is fraught with internally-imposed, and externally reinforced, negative pressure to produce rather than connect, to succeed rather than develop, and to control rather than accommodate.

ADAPTIVE SIGNIFICANCE OF PERSONAL PRONOUN USE IN FAMILIES OF ADOLESCENT SUBSTANCE ABUSERS

Florencia Lebensohn-Chialvo, Ph.D.

University of San Diego, San Diego, CA

A growing body of research suggests that patterns of personal pronoun use in couples – particularly *we*-talk (first person plural pronouns) and *you*-talk (second person pronouns) – are potentially meaningful markers of adaptive and maladaptive functioning, respectively. These associations have not only been demonstrated in terms of relationship quality, but couples pronoun use has also shown to correlate with various indicators of physical health. Very little, however, is known about the relational implications of personal pronoun use in larger social units like families, where relevant interaction patterns are often triadic and multigenerational. The present study employed data from a multi-site study of family therapy for adolescent substance drug abuse to (a) describe patterns of pronoun use in families during conversations that had a collaborative and a conflictual valence; and (b) explore associations between pronoun patterns and indicators of adaptive adolescent and family functioning. As hypothesized, automated text analysis of transcripts from 74 families revealed more *we*-talk in the cooperative task, more *you*-talk and *I*-talk in the conflict task, and significant variations in pronoun frequency by family role. Additional coding, guided by structural family systems theory, took into account the source and referent of each pronoun utterance (e.g., parent-parent *we*-talk, cross-generation *you*-talk). As predicted, structural pronoun variables showed stronger associations with adolescent and family functioning than global (raw count) pronoun variables. Contrary to expectation, *you*-talk was a stronger predictor of adaptive functioning than *we*-talk, and associations between pronoun patterns and indicators of functioning were stronger for the conflict task than the cooperation task. The results suggest that relational meanings of pronouns are substantially more complex in triadic intergenerational family interactions than in dyadic romantic relationships. Discussion of these results includes study limitations and possible directions for further research.

PROCESS EVALUATION OF A PROMOTORA-LED, HOME-BASED OBESITY PREVENTION PROGRAM TARGETING LATINO PRESCHOOL CHILDREN

Sharon E. Taverno Ross, PhD[1], Ivonne Smith-Tapia, MSW[1], Ruth P. Saunders, PhD[2], Patricia I. Documet, DrPH[1], Russell R. Pate, PhD[2]

[1]University of Pittsburgh, Pittsburgh, PA; [2]University of South Carolina, Columbia, SC

BACKGROUND. Latino preschool children have higher rates of obesity than children from other racial/ethnic backgrounds. Few effective, culturally-tailored obesity prevention interventions exist that target preschool children. The purpose of this study was to test the feasibility and acceptability of a promotora-mediated, home-based intervention to prevent obesity in Latino preschool children. ANDALE Pittsburgh included 10, 90 minute weekly interactive and tailored sessions that targeted changes in the home social and physical environment to build parental self-efficacy.

METHODS. Guided by a logic model, we assessed fidelity, dose, reach, recruitment, and contextual factors using multiple data sources and quantitative and qualitative methods. Feasibility of recruitment and intervention protocols were assessed using qualitative data from promotoras and parents, and Project Coordinator logs. Intervention completeness and fidelity were assessed through descriptive analyses of multiple data sources.

RESULTS. Six promotoras recruited participants primarily through their own social networks and delivered the intervention to 50 families (child-mother dyads) that were majority Mexican-origin, low-income, dual-parent households. Promotoras delivered 75% of sessions with fidelity (i.e., based on core elements identified pre-intervention, including physical activity breaks, recipe preparation, goal setting, supportive home environment, barrier counseling) and 96% of participants completed the whole 10-week intervention. Participants expressed that session topics were very or extremely useful (95%) and they intended to continue with changes related to physical activity (74.9%) and healthy eating (70.7%) after the intervention. Qualitative analysis revealed that shared cultural characteristics between promotora and participants and the flexible and adaptive intervention approach facilitated implementation. Barriers to implementation included lack of support from family members (e.g., husbands) and multiple families living in one home.

CONCLUSION. Initial evidence suggests that ANDALE Pittsburgh is a highly feasible and acceptable intervention in this sample of Latino families with preschoolers living in an

Emerging Latino Community. Additional research is needed to determine the effectiveness of the intervention on outcomes including child weight status, physical activity, and nutrition.

PROMOTING RESILIENCE IN PARENTS OF YOUTH WITH NEUROFIBROMATOSIS: USING QUALITATIVE DATA TO INFORM INTERVENTION DEVELOPMENT

Catherine Pierre-Louis, BA[1], Carmen Rugamas, N/A[1], Eric Riklin, BS[2], Jessica N. Coleman, BA[3], Ana-Maria Vranceanu, PhD[4]

[1]Massachusetts General Hospital, Boston, MA; [2]Fordham University, Boston, MA; [3]Massachusetts General Hospital, Cambridge, MA; [4]Massachusetts General Hospital/Harvard Medical School, Boston, MA

Introduction: Neurofibromatosis (NF1 and 2) are multisystemic, complex and rare diseases with many still unrecognized features in pediatric patients. Parents of children with NF are at an increased risk of emotional and physical health problems due to the demands associated with carrying for a child with NF, including guilt associated with passing on or potential causes for the NF, dealing with multiple medical, appointments, uncertainty of disease management and progression, cognitive, social and emotional difficulties experienced by the child, and trouble around self prioritization. Anecdotal information and clinical experience has shown that often children sense their parents' level of stress and worry, and shy away from sharing potential concerns, as to not add to their parents' distress; ultimately, this leads to increased stress for children. However, no psychosocial interventions targeting parental stress are available for this population.

Methods: We aimed to determine parents' perceptions of stressors associated with parenting a child with NF in order to inform the development of a resiliency intervention. We conducted three live video semi structured focus groups with parents of youth with NF (N=40), which were subsequently transcribed and coded using grounded theory.

Results: Parents reported heightened stress associated with the child's educational, medical and social needs, as well as concerns about their child's physical and mental health. They also reported stress associated with managing finances, multiple medical appointments, role challenges (i.e. being a parent or partner), and managing uncertainty/unpredictability around their child's NF diagnosis. These stressors reportedly affected employment status (i.e. work scale backs), relationships (i.e. social, familial, with partner, other children), and the self (i.e. negative effects on parents' physical and mental health). Few parents reported engaging in adaptive coping such as mindfulness, exercise, or use of social support.

All participants expressed interest in a mind body program aimed at improving resiliency by teaching coping skills (e.g., mindfulness, adaptive thinking, positive psychology skills) and providing support. Additional topics initiated by parents included facilitating healthy social interactions for the child, resource sharing, managing financial stressors, and parental role challenges. Barriers to participation included travel and time of intervention sessions, and all participants were in favor of the intervention being delivered via a web-based platform (i.e. Skype).

Conclusion: Results show parent’s enthusiasm for a resiliency intervention targeting stress associated with parenting a child with NF, and provide valuable information for the content of the intervention and its delivery modality.

REDUCTION OF PRETERM BIRTH RATE AMONG MEDICAID ELIGIBLE POPULATION THROUGH AN OUTREACH PROGRAM USING COMMUNITY HEALTH WORKERS

Yondell Masten, PhD, WHNP-BC, RNC-OB, Huaxin Song, PhD

Texas Tech University Health Sciences Center, Lubbock, TX

Introduction

The Centers for Medicaid and Medicare (CMS) funded the Strong Start for Mothers and Infants grant in 27 centers across the United States (2013-2017). The focus of the grant was on enhancing prenatal care for at-risk clients to reduce the preterm birth rate and decrease the number of intensive care days required for preterm neonatal care. As one of the funded centers, the Maternity Care Home model using certified Community Health Workers (CHWs) was implemented to provide enhanced prenatal care.

Methods

The Medicaid eligible pregnant clients were referred for care navigation by CHWs from Texas Tech University Health Sciences Center following the initial nurse intake visit. The CHWs followed the clients until 6 weeks after birth. The CHWs provided education and services directed at improving the impact of the social determinants of health on pregnancy and enhancing routine prenatal care with additional support, services, and home visits. The primary outcomes include number of prenatal visits, birth weight, gestational age, and NICU length of stay and secondary outcomes include satisfaction with services, rate of birth control usage after delivery, and breast feeding rate tracked using both electronic medical record and surveys. Chi-Square tests, ANOVA and mixed model were conducted using SAS 9.4.

Results

Among the total of 605 clients who delivered between November 2013 to September 2016, 412 clients received at least one CHW visit in the third trimester and were considered as Active clients. The 193 clients who did not receive a CHW visit during the third trimester due to the shortage of CHWs or lost client contact were considered as Inactive clients. The preterm birth rate for the Active group compared with the Inactive group is 7.77% vs. 17.62% (OR=0.39 [0.23, 0.66], p=0.0004). The average gestational age at delivery among the preterm birth deliveries for Active group compared with Inactive group is 35.10±1.85 vs. 31.89±4.81 ($p < 0.001$). Compared with Inactive group, the Active group also experienced lower NICU admission rate (18.75% vs. 38.24%, p=0.08) and shorter NICU length of stay (26.17±10.80 days vs. 66.58±35.05 days, $p < 0.05$).

Conclusion

This Strong Start Maternity Care Home project provided evidence that enhancing prenatal care through CHW-provided services can significantly reduce the preterm birth risk among

Medicaid eligible clients. Additionally, such outcomes may reduce the cost for NICU length of stay for the preterm new born babies.

SOCIAL RELATIONSHIP DYNAMICS AMONG ADOLESCENTS WITH AND WITHOUT CHRONIC MEDICAL CONDITIONS

Lauren E. Wisk, PhD, Elissa R. Weitzman, ScD, MSc

Boston Children's Hospital and Harvard Medical School, Boston, MA

Purpose: Social relationships have been shown to exert short- and long-term effects on health. As youth with chronic conditions (YCC) may struggle with behavior and adjustment problems or activity limitations that inhibit their social engagement, their social relationships may suffer, contributing to poor health. We sought to quantify disparities in various domains of peer relationships for YCC compared to their healthy peers. **Methods**: Data are from 2721 adolescents (ages 8-19 years) interviewed for the 2002 and/or 2007 Child Development Supplement of the Panel Study of Income Dynamics. We utilized multivariate-adjusted generalized linear mixed models to assess the relationship between having a chronic condition and each of seven scales measuring various domains of social relationships. Models included natural cubic splines (to model non-linear effects of age) and evaluated interactions between splines for age and chronic conditions to determine if age-trends differed for YCC compared to their healthy peers. **Results**: Compared to their healthy peers, YCC (58% of sample) reported experiencing significantly more bullying (1.46 vs 1.34, $p < 0.01$), less closeness to friends (2.59 vs 2.66, $p=0.01$), greater negative peer influence (1.55 vs 1.46, $p < 0.01$), and lower best-friend relationship quality (2.50 vs. 2.59, $p < 0.01$). Adjusted analyses revealed non-linear age-trends in closeness to friends, negative peer influence, and best-friend relationship quality; however, bullying decreased linearly with age. YCC reported higher levels of bullying ($\beta=0.15$, $p < 0.01$) and negative peer influence ($\beta=0.06$, $p=0.03$) across all ages. Disparities in reported closeness to friends appeared in middle adolescence for YCC (e.g., predicted scores: 2.58 vs 2.61 at age 13; 2.71 vs 2.86 at age 16). Disparities in relationship quality diminished in middle adolescence for YCC (e.g., 2.46 vs 2.56 at age 13; 2.52 vs 2.54 at age 16). **Conclusion**: Compared to their healthy peers, YCC report experiencing poorer social relationships and more bullying. As poor social relationships contribute to worse future health, while reports of strong social relationships contribute to better future health, it may be important for providers to assess social well-being as part of overall health, both to better understand disease burden and to improve health outcomes. Yet, additional work is needed to benchmark these measures against clinical metrics to guide clinician evaluation and interpretation of social health.

SOCIO-ECOLOGICAL FACTORS THAT INFLUENCE PERSISTENCE IN BREASTFEEDING AMONG APPALACHIAN WOMEN: A MIXED METHOD STUDY

Ebtihag O. Alenzi, BPharm, PhD Candidate[1], Elvonna Atkins, MSc, BSc[2], Brandon Dolly, PharmD[3], Paul Cornelius, MBA[4], Kimberly M. Kelly, PhD, MS[1]

[1]West Virginia University, Morgantown, WV; [2]Life Treatment Centers, South Bend, IN; [3]West Virginia University, Clay, WV; [4]West Virginia University, Star City, WV

Background: The American Academy of Pediatrics recommends breastfeeding children for at least 1 year, with exclusive breastfeeding for the first 6 months of life. However, the state of West Virginia is among the lowest for persistence in breastfeeding compared to national rates. **Objective:** Guided by Sokol's Social Ecological Model, this study examined the association between persistence in breastfeeding (6-month breastfeeding and extended breastfeeding) and individual, interpersonal, community and public policy level factors among Appalachian mothers. **Methods:** A mixed-method study with convergent parallel design of women who lived and/or worked in WV who had at least one child aged < 36 months was conducted. For quantitative data, unadjusted analyses were conducted using Chi-square and Fisher's exact tests, and adjusted analyses were conducted using multivariable and multinomial logistic regressions. For qualitative data, kappa coefficient coding was conducted by two researchers. **Results:** Out of 131 women, 30.5% had breastfed for < 6 months, 39.7% for 6-12 months, 21.4% for 12-24 months, and 8.4% for ≥ 24 months. In the adjusted analysis, the likelihood of breastfeeding ≥6 months was associated with not having full-time employment (AOR=0.3, 95% CI; 0.1-0.9) and high perceived social support (AOR= 28.1, 95% CI; 2.1-381.2) as compared to full-time work and low perceived social support, respectively. Extended breastfeeding (≥24 months) was negatively associated with higher education (AOR= 0.06, 95% CI; 0.01-0.1), employment in a full-time work (AOR=0.16, 95% CI; 0.03, 1.0), and being a first-time mother (AOR=0.09, 95% CI; 0.01-0.8). With regard to qualitative data, insufficient milk supply, supplement with formula, work, and health issues for child were the most frequent obstacles reported by mothers who breastfed their children < 6 months. Natural nutrition, bonding, economic, and health benefits for children were the most frequent incentives reported by mothers who breastfed their children ≥ 24 months. **Conclusion:** Individual and interpersonal level factors from the Social Ecological Model were key to persistence in breastfeeding among Appalachian mothers. In light of 'lost generations' of breastfeeding mothers, social support is critical during the first 6 months to overcome issues that mothers could experience, such as insufficient milk supply, work, and

health issues, and our study informs future interventions to improve the breastfeeding experience.

MERITORIOUS AWARD WINNER

THE ACROSS-TIME RELATIONS BETWEEN MOTHERS' DEPRESSIVE SYMPTOMS, MOTHERS' PROVISION OF SUPPORT, AND CHILD VERBAL COGNITION

Victoria Wu, B.A.[1], Patricia East, Ph.D.[2], Erin Delker, M.P.H.[3], Sheila Gahagan, M.D., M.P.H[4]

[1]UC San Diego School of Medicine, San Diego, CA; [2]University of California, San Diego, La Jolla, CA; [3]University of California - San Diego / San Diego State University, San Diego, CA; [4]UC San Diego School of Medicine, La Jolla, CA

The trajectory of children's cognitive development is shaped by the interaction of supportive engagement, responsiveness, and provision of learning materials by mothers. Maternal postnatal depression is known to dampen mothers' emotional sensitivity and verbal stimulation to her child and has been linked with lower child cognitive outcomes. However, little is known about this interplay on a longitudinal scale. The current study sought to examine how mothers' depressive symptoms predict their subsequent ability to provide emotional-verbal and learning material support to their child, and how this influences their child's verbal cognitive outcomes from infancy to adolescence.

A sample of 880 Chilean infants and their mothers was studied across a 16-year period as part of an iron deficiency anemia preventive trial and follow-up study. Mothers' depressive symptoms, their emotional-verbal responsivity and learning material support to their child, and child verbal cognition were measured when children were 1 year, 5 years, 10 years, and 16 years. Child gender, family socioeconomic status, family stress, and maternal educational level were controlled at all time points.

Using cross-lagged structural equation modeling, we found that mothers' depressive symptoms were both directly and indirectly related to their child's verbal cognition scores across the 16-year period. Indirect effects indicated that higher levels of maternal depressive symptoms at infancy contributed to lower levels of maternal support at age 5 - both emotional-verbal responsiveness and learning material support, which in turn was related to lower child cognitive scores at age 10. Similarly, higher maternal depressive symptoms at age 5 contributed to lower maternal support at age 10 (both emotional-verbal responsiveness and learning material support), which in turn was related to lower child cognitive scores at age 16.

Findings suggest that the relation between mothers' depressive symptoms and child verbal

cognition is mediated by maternal emotional-verbal and material support throughout a child's lifetime. Ultimately, this may provide clearer entryway into the developmental pathways of child cognition as well as new insight into age-appropriate mother-child intervention approaches for clinical practice.

THE LIVED EXPERIENCES OF MALE PARTNERS OF WOMEN WHO HAVE BEEN PREVIOUSLY DIAGNOSED WITH POSTPARTUM DEPRESSION

Judy Kaye Smith, PhD, MSN, RN

Lamar University, Beaumont, TX

Postpartum depression (PPD) is a real complication in the postpartum period that affects 50 to 80% of all women giving birth but is not a condition that solely affects women (Beck, 2006). This qualitative descriptive phenomenological study based upon Husserl's (1960, 1970) philosophical underpinnings was designed to gain a broader perspective about the phenomenon of postpartum depression (PPD) and its impact on the family structure through the lived experiences of male partners of women previously diagnosed with the disorder. A sample of seven men recruited through a community hospital participated in face-to-face audio taped interviews that were later transcribed verbatim. The transcripts were rigorously, critically, systematically analyzed and compared to identify common thematic patterns within and between the fathers' individual experiences using a two group analysis and Spiegelberg's (1965, 1975) six step process. The men experienced overarching feelings of being vulnerable when their partners' behavior began to change in such a way that they did not recognize the person their partner had become after the birth of their baby. They began to rationalize the cause for the changes, with feelings ranging from annoyance to wanting a divorce. But as things changed within their family, fathers felt the overwhelming need to try to make things better for their families. The second major theme was one of being helpless to know what to do or say; but whatever they did was not right or good enough which they attributed to their lack of knowledge about postpartum depression. Given time, the third overall theme of coping emerged in which they were able to identify methods of dealing with the changes that occurred in their lives when their partner was diagnosed with postpartum depression. Suggestions included the need for more one to one education with parents, Also fathers need to be patient and more attuned to the needs of their partner. The foremost clinical implication from the study is the need for healthcare providers to develop better educational methods to relate information about postpartum depression to childbearing couples.

THE ROLE OF FAMILY IN CURRENT LIFESTYLE CHOICES: A QUALITATIVE SECONDARY DATA ANALYSIS OF INTERRACIAL AND SAME-RACE COUPLES.

Ana Fonseca, M.A. , Emily Butler, Ph.D.

University of Arizona, Tucson, AZ

Loved ones, including family of origin, have a large impact on our long-term eating behavior (Bandura, 1999; Savoca & Miller, 2001). In addition, recent studies have established a recursive link in health patterns (e.g., exercise) between romantic partners; however, how family of origin and romantic partners interact together to impact current individual health related behaviors including eating and exercise has received less attention in the empirical literature. More importantly, how these influences play out between same-versus-interracial couples may differ, given that racial disparities exist among health outcomes (e.g., higher probability of chronic diseases, life expectancy, etc.). Notably, it is important to focus on Hispanic and Non-Hispanic White individuals due to the higher prevalence of obesity found among Hispanics and general unhealthy patterns in ethnic minorities (Morales et al., 2007; Ogden & Elder, 1998). Therefore, the goal of this study is to extent results from previous research by qualitatively exploring how the families of origin for both partners in romantic relationships (same versus interracial) interact together to impact current health related behaviors, with an emphasis on the viewpoints that were held in the families of origin about eating and exercise. Qualitative data analysis and interpretations were based on 14 romantic couples 7 same-race couples (Non-Hispanic White partners) and 7 interracial couples (Non-Hispanic White partner and Hispanic partner). A grounded theory approach was taken to analyze four interview questions to fit the unique needs of the study (Patton, 2002; Strauss & Corbin, 1998). The data was analyzed within two coding cycles using five different coding methods. A total of 4 central themes emerged from the data: family of origin eating patterns; family influence in the adult diet; family of origin physical activity approach; and family influence in physical activity. Individuals described families as being aware and unaware of families making healthy and unhealthy food choices during upbringing. Additionally, individuals described families as making high effort and no effort to be physically active while growing up. The different perceptions of family of origin in food and exercise were narratively related to certain eating habits and physical activity behaviors in romantic couples. Different perspectives from family of origin were found in food and exercise across same-race and interracial couples. Our results advise that prevention and treatment programs should be targeting family systems rather than individuals to captivate permanent healthy lifestyle changes.

RELIGIOSITY AND DIET IN A COLLEGE AND COMMUNITY SETTING

Natalie A. Cyphers, PhD, RN[1], Andrea D. Clements, PhD[2]

[1]DeSales University, Center Valley, PA; [2]East Tennessee State University, Johnson City, TN

Some researchers have indicated more religious individuals have healthier diets; however, research is inconsistent. Diet is known to predict the incidence of a variety of diseases, therefore identifying predictors of diet may inform methods to improve individuals’ overall health. A sample of 903 college students and community members (age 18 to 60) participated in an online survey during spring 2013 or fall 2014. Measures included a demographic questionnaire, the *Perceived Stress Scale* (PSS), the *Religious Surrender and Attendance Satisfaction Scale* (RSASS), an *Intrinsic Religiosity* (IR) question, and *Starting the Conversation* (a brief dietary questionnaire). Our aim was to determine whether religiosity variables predicted diet, while controlling for age, gender, and stress. Hierarchical multiple linear regression indicated 3.5% of diet was predicted by covariates in block one (R^2 = .035, F change (3, 864) = 10.368, p < .001), with the largest proportion predicted by stress (β = .175, p < .001). After entry of IR, religious commitment (RC) and satisfaction with RC in block two, the total variance explained by the model was 4.5%, with one percent of the variance being explained by *RC* and *satisfaction with RC* (R^2 = .045, R^2 change = .011, F change (3, 861) = 3.172, p = .024). Healthier diet was predicted by lower levels of religious commitment (β = .088, p < .05) and by being satisfied with religious commitment (β = -.077, p < .05). In the study region, “breaking bread” is a central activity within religious communities and may partially explain the negative association between RC and healthy diet. Future studies should investigate whether RC may buffer effects of poor diet on health, as the religion/health association is robust across studies.

OLDER ADULTS' AGE AND SEX PREFERENCES FOR VARIOUS PROFESSIONAL PROVIDERS

Ilana J. Engel, B.A., Psychological & Brain Sciences, Washington University in St. Louis[1], Brian D. Carpenter, Ph.D., Clinical Psychology, Case Western Reserve University[2]

[1]Current: University of Chicago, Past: Washington University in St. Louis, Birmingham, AL;
[2]Washington University in St. Louis, St. Louis, MO

Purpose: Previous research has found that people have age and sex preferences when choosing physicians and mental health counselors, but it is not clear whether older adults in particular have similar preferences when choosing these and other service providers. The purpose of this study was to explore older adults' age and sex preferences for various kinds of professionals to understand factors that may influence older adults' help-seeking behaviors, which may have important implications for their health outcomes. **Methods:** Fifty Caucasian, community-dwelling older adults ages 64 and over completed an online survey. The sample was 48% female, and participants ranged in age from 64 to 89 years (*M* = 72.8). The survey included photos of six individuals representing three age categories (young, middle aged, older adults) and two sexes (male, female). For each photograph, participants rated their comfort with and perceived competence of the individual, if their services were sought in five different professional settings (financial, legal, medical, mental health, and religious). Ratings were given on a 6-point scale and photographs were presented in a randomized order. In total, each participant provided 60 ratings (comfort and competence, for each photograph, for each setting). Responses were analyzed using a within-subjects three-way repeated measures ANOVA. **Results:** Older adults preferred older professionals across all five settings. Female participants preferred female professionals across all settings, and a significant interaction between sex and profession revealed that in mental health settings, both male and female participants preferred female therapists. Professionals in the religious setting were rated lower on comfort and competence than professionals in other settings. **Conclusions:** Findings suggest that older adults have age and sex preferences for a broad range of professionals. It may be beneficial for service providers to inquire about preferences and accommodate them when possible. Future work is needed to inform whether these preferences influence actual help-seeking behaviors.

PROSTATE CANCER PATIENTS' UNDERSTANDING OF THE GLEASON SCORING SYSTEM: IMPLICATIONS FOR CLINICAL DECISION MAKING

Erin K. Tagai, PhD, MPH[1], Suzanne M. Miller, PhD[2], Alexander Kutikov, MD[1], Tahseen Al-Saleem, MD[1], Michael A. Diefenbach, Ph.D.[3], Sara Fleszar, N/A[3], David Y.T. Chen, MD[1], Ronak A. Gor, DO[4]

[1]Fox Chase Cancer Center, Philadelphia, PA; [2]Fox Chase Cancer Center/Temple University Health System, Philadelphia, PA; [3]Northwell Health, Manhasset, NY; [4]Fox Chase Cancer Center, Minneapolis, MN

The Gleason Scoring System is critically important for patients in making decisions about their prostate cancer treatment. A patient's Gleason score is designed in part to facilitate risk communication and to help achieve informed treatment decision making. However, the system is complex and difficult to communicate to patients, often undermining well-informed and high-quality decision making. Prostate cancer patients (N=50) that had completed treatment were recruited to complete a survey during follow-up appointments. Measures assessed included demographics, Gleason Scoring System knowledge, perceptions of their Gleason score's impact on their decision making, and anxiety. Biopsy date, cancer stage, Gleason score at diagnosis, PSA score at diagnosis, and treatment type and completion date were obtained from patients' medical records. Patients had low overall knowledge of the Gleason Scoring System (66% scored below 50% on a Gleason knowledge scale). However, a majority of patients (58%) felt their physician's explanation of their Gleason score made sense to them. This was positively associated with health literacy, Gleason Scoring System knowledge, and Gleason score at diagnosis ($p < .05$). Most patients (64%) stated their understanding of their Gleason score significantly impacted their treatment decision. This was positively associated with patients' age, health literacy, Gleason score knowledge, and cancer staging ($p < .05$). PSA anxiety was positively associated with education and time since treatment completion ($p < .05$) and a striking 80% of participants reported a fear of recurrence. While patients have low knowledge of the Gleason Scoring System, most understand their score is an important part of decision making. However, factors such as low health literacy and stage of cancer diagnosis are associated with poorer patient understanding and use of their Gleason score in their decision making. Future research is needed to better understand how physicians can better communicate patients' Gleason score and its impact on decision making.

THE IMPACT OF FINANCIAL INCENTIVES ON ORGAN DONATION INTENTIONS AMONG AFRICAN AMERICANS

Nakeva Redmond, MPH[1], Kimberly J. Arriola, PhD/MPH[2], Dana HZ. Williamson, MPH[3], Shauna Flemming, MPH, MDiv[4], Laura Harker, MPH[5], Jennie P. Perryman, RN, PhD[6], Nancy J. Thompson, Ph.D., M.P.H.[7], Rachel E. Patzer, PhD, MPH[8]

[1]Emory University, Atlanta, GA; [2]RSPH of Emory University, Atlanta, GA; [3]Rollins School of Public Health, Emory University, Atlanta, GA; [4]Emory University, Rollins School of Public Health, Atlanta, GA; [5]Georgia Budget and Policy Institute, Atlanta, GA; [6]Emory Transplant Center/Emory Healthcare/Emory University, Atlanta, GA; [7]Department of Behavioral Sciences and Health education/Rollins School of Public Health/Emory University, Atlanta, GA; [8]Emory University School of Medicine, Atlanta, GA

The Impact of Financial Incentives on Organ Donation Intentions among African Americans

Transplantation is the therapy of choice for many patients experiencing end-stage organ failure, but a lack of available organs inhibits the number of life-saving transplants that occur. Offering financial incentives in exchange for a commitment to organ donation has been explored as a means to increase the donor pool, however, such an act is controversial. Additionally, while the “law of behavior” asserts that incentives heighten behavioral effort[1], prior research shows mixed results regarding the extent to which incentives can influence prosocial behaviors[2], such as organ donation. Understanding how financial incentives may influence donation decisions among African Americans (AA) is of particular importance, as AAs are overrepresented among those in need of organs yet donate at less than comparable rates, and historically have had a stronger distrust in the healthcare system than Whites[3]. Little is known about the extent to which donation decision making is influenced by financial incentives among AAs.

In January 2016, 1,339 AA adults residing in Georgia completed a cross-sectional survey measuring donation-related attitudes and knowledge, and views of financial incentives. Approximately 56% of participants indicated that financial incentives would not influence their decision to donate their organs. Among those who had no intention to donate, approximately half indicated that financial incentives would have no effect on their decision, 27% said that financial incentives would make them less likely, and 24% more likely to donate.

Greater knowledge of organ donation was associated with greater likelihood of changing a decision to donate from ‘no’ to ‘yes’, if given a financial incentive, OR=1.09 (95% CI=1.01, 1.17).

Financial incentives were associated with increasing organ donation intentions among AAs. Efforts exploring the influence of financial incentives on donation decisions should continue to examine the potentially negative effect of financial incentives, particularly among communities with higher levels of distrust of healthcare.

TO TAKE OR NOT TAKE PREP: DIFFERENTIATING PERCEPTIONS OF APPROPRIATENESS AMONG MEN WHO OBJECTIVELY MEET CRITERIA TO BEGIN PREP

Thomas H.F. Whitfield, MA[1], Brett M. Millar, MA[2], H. Jonathon Rendina, PhD, MPH[3], Christian Grov, PhD, MPH[4], Jeffrey T. Parsons, PhD[5]

[1]The CUNY Graduate Center / The Center for HIV Educational Studies and Training, New York, NY; [2]Graduate Center, City University of New York, New York, NY; [3]Hunter College of the City University of New York (CUNY), New York, NY; [4]CUNY Graduate School of Public Health and Health Policy, New York, NY; [5]Hunter College and The Center for HIV Educational Studies and Training, New York, NY

Background: Pre-exposure prophylaxis (PrEP) is the most effective biomedical HIV prevention tool currently available, however implementation has been slow. Existing research has identified that the largest barrier to uptake is not viewing oneself as a suitable candidate for PrEP. The present study sought to investigate what factors contribute to viewing oneself as being a PrEP candidate among GBM who all meet objective CDC qualifications for eligibility.

Methods: Within a larger U.S. national sample of 1,013 HIV-negative GBM, 438 (43.2%) met objective CDC qualifications for PrEP eligibility and had engaged in condomless anal sex in the past 90 days. These men provided demographic characteristics and completed scales measuring depression, anxiety, internalized homophobia, anticipated HIV stigma, and perceived social support.

Results: In bivariate analyses, those who did not consider themselves an appropriate candidate for PrEP were significantlyolder ($t(436) = 9.68$, $p < .01$) and more likely to be in a relationship ($\chi2(1) = 11.0$, $p < .01$). No differences were noted for race/ethnicity or education. In logistic regression analyses with demographic factors, mental health indicators (depression and anxiety) and perceived social support entered as covariates, higher scores on anticipated HIV stigma predicted not seeing oneself as an appropriate candidate for PrEP (OR = 0.96, $p < .01$).

Conclusions: These results indicate that among GBM who are eligible for PrEP uptake, those who have less social support and more HIV stigma are less likely to view themselves as appropriate candidates, thus less likely to initiate a regimen or talk to a health care provider about PrEP. It is important to target this group for intervention as they are objectively at risk for HIV infection despite not viewing themselves as at risk. These findings

indicate that one way to increase uptake for this group may be to focus interventions on building a social support network and destigmatizing HIV.

TRENDS IN GLOBAL COGNITIVE FUNCTIONING AND HEALTH LITERACY IN PATIENTS WITH CHRONIC OBSTRUCTIVE PULMONARY DISEASE

Irina Mindlis, MPH, Li Chen, MPH, Kimberly Muellers, MPH, Juan Wisnivesky, MD, DrPH

Icahn School of Medicine at Mount Sinai, New York, NY

Background

Poor cognition and low health literacy (HL) have been associated with chronic obstructive pulmonary disease (COPD). However, limited information is available about the longitudinal trajectory of cognition and HL in these patients and whether disease progression over time is associated with worsening function.

Methods

We used data from 258 participants from a prospective cohort study of outpatients with COPD. Participants were recruited from two major metropolitan hospitals in New York City, NY and Chicago, IL. Eligible patients were English- or Spanish-speaking, ≥55 years old, and had a physician diagnosis of COPD. Individuals were excluded if they had asthma or other chronic respiratory disease, dementia, or any condition profoundly affecting cognition. Face-to-face interviews were completed at baseline, 12 and 24 months. HL was measured using the Short Test of Functional Health Literacy in Adults (S-TOFHLA), which assesses an individuals' ability to read and understand prose passages selected from commonly found healthcare-related materials. The Mini-Mental State Examination (MMSE) was administered to assess global cognitive functioning. Spirometry was used to determine percent predicted forced expiratory volume at 1 second (FEV_1), a well-established marker of COPD severity. Unadjusted and adjusted fixed effects models were used to analyze the trajectory of MMSE and STOFHLA over the 24-month follow up period.

Results

The study cohort consisted of 258 participants, of whom 61% were women, with a mean age of 67.5 (SD: 7.8) years. Almost half (48%) of the study population was Black, 38% white, and 13% Hispanic. Unadjusted models showed no significant decrease in HL over the 24-month follow-up period (P=0.83). However, cognition significantly decreased over time, with a baseline mean MMSE score of 25.4 (SD:3.4) and a decrease to mean=24.7 (SD:3.9) at 24 months (p1 over time was independently associated with a 2.5% increased odds (95% CI:

1.01-1.03) of impaired cognition.

Conclusions

COPD patients showed significant declines in cognition but not HL over a relatively short follow-up period. Patients with worsening disease severity appear at the highest risk for cognitive decline and may require close follow up and support interventions to maintain adequate functioning and outcomes.

UNDERSTANDING AND PROMOTING ORGANIZATIONAL HEALTH LITERACY IN A PUBLIC HEALTH SETTING

Natalie Kruzliakova, BS[1], Kathleen J. Porter, PhD, RD[1], Molly O'Dell, MD[2], Eleanor S. Cantrell, M.D.[3], Melody Counts, M.D., M.H.M.[4], Jamie Zoellner, PhD, RD[1]

[1]Virginia Tech, Blacksburg, VA; [2]Virginia Department of Health, Christiansburg, VA; [3]Virginia Department of Health, Wise, VA; [4]Virginia Department of Health, Lebanon, VA

Title: Understanding and promoting organizational health literacy in a public health setting

Introduction: Organizational health literacy (HL) is the extent to which health organizations and systems support individuals as they seek, receive, and use information and services. Documented efforts to address organizational HL within a public health setting are lacking. To address this opportunity, a collaborative HL team was formed between researchers and four southwest Virginia Department of Health (VDH) districts serving federally designated medically underserved counties. This study describes an organizational HL needs assessment.

Methods: This research is guided by the Agency for Healthcare Research and Quality (AHRQ) HL Toolkit. VDH staff completed a 56-item survey adapted from the toolkit and based on four domains of organizational HL. VDH customers completed a validated 3-item individual-level HL screening measure (1=lowest HL, 14=highest HL) and seven questions on 4-point scale (1=never, 4=always) pertaining to personal perceptions of VDH services. Analysis included descriptive statistics and Spearman's correlations.

Results: Among 279 VDH staff, about 50% reported "doing well" across each HL domain; however, a subset reported "needs improvement" or "not doing" across written communication (31.4%), self-management and empowerment (23.9%), oral communication (18.7%), and supportive systems (16.5%) domains. Among 177 VDH customers (82% female, 94% white, 40% ≤ high school education) HL scores averaged 12.8 (SD=1.7). Average ratings pertaining to personal perceptions of VDH services ranged from 3.05-3.64, including following instructions (M=3.05, SD=1.01), reference to personal history (M=3.25, SD=.81), comprehension of forms (M=3.43, SD=.73), comprehension of written materials (M=3.51, SD=.70), time spent with staff (M=3.54, SD=.68), encouragement of questions (M=3.55, SD=.73), and explanation of services (M=3.64, SD=.60). Customer HL status was significantly correlated (p< 0.05-0.01) with comprehension of forms (r=.50) and written materials (r=.49), explanation of services (r=.26), following instructions (r=.16), and reference to personal history (*r*=.16).

Implications: Findings reveal notable strengths in current HL practices, as well as opportunities to improve customer experiences. This data has been shared with VDH and the HL Team is developing an Organizational HL Improvement Plan, including implementation of evidence-based resources from the AHRQ HL Toolkit. To capture changes over time, a 3-year evaluation process has been established.

WEBMDON'T: CREATING A SCALE TO MEASURE ONLINE HEALTH INFORMATION SEEKING BEHAVIOR

Allyson Hughes, M.A.[1], Giovanna Perez, B.A.[1], Osvaldo Morera, PhD[2]

[1]University of Texas at El Paso, El Paso, TX; [2]Latino Alcohol and Health Disparities Research (LAHDR) Center, Department of Psychology, The University of Texas at El Paso, El Paso, TX

Individuals examine health information online due to the immediate access to medical information and minimal costs. About 80 percent of internet users search for health information online (Fox, 2011). A consequence of obtaining online health information is inaccurate information. Specifically, reliability and trustworthiness of online health information is a major concern and extremely hard to measure (Morris, 2008). Very few studies have examined how online health information is evaluated by individuals seeking medical advice. For this reason, this study aimed to examine how users assess online health information. Research questions included: What predicts an individual's willingness to go the internet to seek medical information? What criteria are individuals using to assess health information online? What predicts an individual's confidence in the obtained medical information? What barriers are related to an individual seeking health information online? We proposed several inductively and deductively generated themes in response to the qualitative questions. Proposed theoretically grounded themes included: high levels of self-reported digital literacy, high levels of self-reported self-efficacy regarding internet usage and information consumption, high levels of confidence in the obtained medical information, and financial barriers to seeing a medical professional. 152 participants contributed qualitative and quantitative data via Amazon Mechanical Turk. Qualitative prompts assessed health information seeking behavior, specifically, what characteristics make the online information reliable and what antecedents lead participants to pursuing medical information online. Several themes were generated from the qualitative data. One third of the sample reported that information found online is very trustworthy. Obtaining the same medical advice from multiple sites, specifically WebMD, was a method used by participants to check for validity. Severity and longevity of the health condition was directly linked to willingness to seek health information online. Top barriers to seeing a healthcare professional included issues with insurance and financial concerns. Participants reported using information found on google as a decision making tool to decide whether or not they needed to go to the doctor. The results from this study highlight how online information is being used to make important health decisions. The results from this study will also be used to inform the development of a scale to measure online health information seeking behavior.

FAMILY DIABETES HISTORY AND ITS INFLUENCE ON HEALTH OUTCOMES

Silvia Santos, Ph.D.[1], Maria T. Hurtado-Ortiz, PhD[2], Griselda Bernabe, B.A.[3], Karina R. Aguilar, BA[4]

[1]California State University, Dominguez Hills, Carson, CA; [2]California State University, Dominguez Hills, Orange, CA; [3]California State University, Dominguez Hills, South Gate, CA; [4]California State University, Dominguez Hills, Wilmington, CA

The present study is part of a larger NIH funded investigation that examined the influence of family illness-history of diabetes on perceptions of disease threat and health outcomes among Latino college students who are at-risk for diabetes acquisition due to genetic predisposition. Type 2 diabetes is a disease previously seen mostly in older age groups; however, in recent years its prevalence among teens and young adults has increased at an alarming rate. This study aimed to test a theoretical model linking family history of diabetes (i.e., degree of genetic risk, relative's illness severity, and distress caused by a relative's illness) and perceptions of disease threat (i.e., illness seriousness and self-rated risk for disease acquisition), to objective as well as psychological health status indicators (i.e., BMI, diabetes risk score, health importance and self-rated health). The sample consisted of 156 Latino college students who had a first-, second-, or third-generation relative afflicted with Type 2 Diabetes. A path-analysis using linear regression was used to test the proposed theoretical model. The results revealed a direct path between genetic risk of disease to having a higher diabetes risk score ($\beta = .268$). Similarly, psychological distress caused by a relative's illness was also directly related to having a higher diabetes risk score ($\beta = .304$). Furthermore, a relative's illness severity impacted health importance ($\beta = .221$) as mediated by disease threat ($\beta = .353$). This suggests that the severity of a relative's illness influenced perceptions of diabetes as a threatening illness, which impacted the value participants placed on their health. In addition, the degree of psychological distress experienced due to a relative's diabetes was associated with having a higher self-rated risk for disease acquisition ($\beta = .156$), which in turn was related to having a higher BMI ($\beta = .340$) among participants. Lastly, familial genetic risk was positively associated with having a higher perceived risk for acquiring the disease ($\beta = .255$) among participants, which resulted in having a lower self-rated perceived health status ($\beta = - .351$). These results will be discussed in terms of the Health Belief Model and Common Sense Illness Model of disease.

LIFESTYLE INTERVENTIONS FOR PRIMARY PREVENTION OF TYPE 2 DIABETES IN U.S. HISPANIC YOUTH: A SYSTEMATIC REVIEW

Jessica McCurley, M.S.[1], Margaret A. Crawford, B.S.[2], Linda C. Gallo, PhD[3]

[1]SDSU/UC San Diego, San Diego, CA; [2]SDSU/UC San Diego, Encinitas, CA; [3]San Diego State University, Chula Vista, CA

Prevalence of type 2 diabetes in youth has risen rapidly in recent decades along with increases in childhood obesity. Disparities in both risk and prevalence of type 2 diabetes are evident in Hispanic/Latino (hereafter, Hispanic) youth compared to their non-Hispanic counterparts. Targeted diabetes prevention programs have been recommended to reduce risk factors prior to adulthood in this vulnerable, high-risk population. The current systematic review explored effectiveness of lifestyle-based diabetes prevention interventions for Hispanic youth following Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines.PubMed/Medline, PsychInfo, Web of Science, and Cochrane Central Register of Controlled Trials were searched from database inception to August 2016 for studies evaluating lifestyle-based diabetes prevention trials in U.S. Hispanic youth without diabetes. Fourteen publications met criteria for inclusion. Ten of fourteen studies were randomized controlled trials (RCTs); four were uncontrolled. Interventions were heterogeneous in intensity, content, and setting. The majority of interventions were 12-16 weeks in duration and were conceptualized as pilot studies. Mean age of participants ranged from 9.8 to 15.8 years, samples sizes were generally small (15-100 participants), and the majority of participants were overweight [age-and sex-specific body mass index (BMI) ≥ 85th percentile]. Fewer than half of interventions (n = 5) resulted in changes in BMI, and 50% (n = 7) reported changes in fasting glucose or insulin. Of the ten RCTs included, three (33%) reduced BMI and five (50%) reported significant changes in fasting glucose or insulin. Study quality ranged from moderate to strong, but effect sizes were generally small. Only four studies reported cultural tailoring or adaptation of intervention content to improve engagement with the Hispanic community. In conclusion, evidence for the effectiveness of lifestyle-based diabetes prevention interventions targeting U.S. Hispanic youth remains limited. Few interventions demonstrated success in reducing BMI and fasting glucose, effect sizes were small, and follow-up times were brief. More studies are needed that recruit larger samples sizes, extend follow-up times, explore innovative delivery modalities, measure and increase youth engagement, and examine effectiveness across sex and age or pubertal stage groups.

SECURE E-MAIL IN DIABETES CARE. A PILOT STUDY

Elin Børøsund, PhD, RN[1], Cecilie Varsi, MSc, RN[1], Kåre I. Birkeland, PhD, MD[2], Milada Cvancarova, PhD[3], Cornelia M. Ruland, PhD, RN[1]

[1]Center for Shared Decision Making and Collaborative Care Research, Oslo University Hospital, Oslo, Norway, Oslo, Oslo, Norway; [2]Department of Endocrinology, Morbid Obesity and Preventive Medicine, Oslo University Hospital, Oslo, Norway, Oslo, Oslo, Norway; [3]Oslo and Akershus University College, Oslo, Norway, Oslo, Oslo, Norway

Background: Patient-provider e-mail communication has the potential to fill unmet needs of patients with chronic conditions. E-mail use in diabetes care has been associated with improved patient outcomes. This pilot RCT tested the effects of access to a practice-integrated secure e-mail service (EMS), compared to usual care on problem areas such as anxiety, depression, quality of life (QoL) satisfaction with treatment and changes in glycemic control (HbA1C) in patients with Diabetes type I who were followed for 6 months.

Methods: 78 patients at a university hospital were randomized into the EMS group (n=39), whose members could send messages to, and receive answers from nurses, physicians and nutritionists at their hospital or the usual care group (n=39). Linear mixed models for repeated measures were fitted to compare effects on patient outcomes over time, using an intention to treat approach. In addition, interviews were conducted with four patients in the EMS group.

Results: There was a large range in time since diagnosis among the respondents (0-58 years) and the usual care group members were significant older than the EMS group (49 years/39 years; p.041). In the EMS group 23% (n=9) sent e-messages (median 1, range 1-13). There were no significant differences over time between the EMS group and the control group in terms of problem areas in diabetes (PAID), anxiety (Hospital Anxiety and Depression Scale (HADS)), depression (HADS), QoL (WHO-5), satisfaction with treatment (DTSQ) or HbA1c. Interviews revealed that the patients were satisfied with having the opportunity to send messages to their health care providers.

Conclusion: No differences were revealed between the group with access to e-mail compared to the control group on self reported outcomes or changes in HbA1c. Lessons learned are to recruit a more homogenous group in terms of time since diagnosis to be able to detect differences. E-mail access to health care providers might be more beneficial to newly

diagnosed people with diabetes type I and thus address unmet information needs in this patient group.

SELF-CARE TRACKING AND BLOOD GLUCOSE STABILITY AMONG ONE DROP MOBILE APP USERS

Tom Quisel, BS[1], Luca Foschini, PhD[2], David Kerr, MD FRCPE[3]

[1]Evidation Health, Santa Barbara, CA; [2]Evidation Health, San Mateo, CA; [3]William Sansum Diabetes Center, Santa Barbara, CA

Background: Self-tracking of weight, diet and exercise is growing in popularity in the United States. These variables are also important metrics for the self-management of both type 1 (T1D) and type 2 (T2D) diabetes. However, the purported health benefits of consistent tracking behavior using smartphone applications have been hard to quantify. Here, we investigated the impact of self-care tracking on self-reported blood glucose (BG) levels in individuals with T1D and T2D using the One Drop application, a diabetes management app for people living with TD1, TD2 and Pre-Diabetes.

Methods: We analyzed self-care and BG data entered between January 2015 and January 2016 by 3,378 users with T2D and 999 users with T1D having at least 20 BG readings over a 90-day period. Self-care data included self-reported carbohydrate (carbs) intake, medication/insulin doses, and physical activity. We aggregated BG data on a per-user-month basis. For each user-month, we computed the percentage of out-of-range BG readings (%OOR) (range defined as mg/dl below 70 or above 180) and the logarithm of the counts (log-count) of each type of self-care behavior during the month. We used fixed-effects panel regression analysis to model the association between users' self-care and %OOR on a per-month basis while controlling for inter-user variability. We included logged carbs, medication/insulin taking, activity, and BG log-counts as explanatory variables.

Results: Users were 62% male with an average of 21±40 and 16±27 BG readings/month in the T1D and T2D populations respectively. For the T1D cohort, the 37% of BG readings were out of range compared to 20% out-of-range for the T2D cohort. We found an association between increased BG logging and decreased %OOR among users with T2D. Doubling the amount of BG logging was associated with a reduction in %OOR by 0.78 (95% CI [0.28 - 1.29], p = .002). Users with T1D had a similar, but non-significant pattern, decreasing the %OOR by 0.59.

Conclusions: Increased BG logging with the One Drop app was associated with a lower monthly percentage of BG readings outside the 70-180 mg/dl range, after controlling for

inter-user variability in self-care tracking. Future analyses will examine any relationships by user age, insulin status, and duration of diabetes. Further research should assess whether the increased stability in observed BG measurements reflects improved glucose control among One Drop users.

SOMATIC AND COGNITIVE ANXIETY IN TYPE 1 AND TYPE 2 DIABETES PATIENTS USING INSULIN

Irina A. Mason, B.A.[1], Jennifer F. Ward, PhD[2], Barbara A. Stetson, Ph.D.[1]

[1]University of Louisville, Louisville, KY; [2]University of Louisville, Hermitage, TN

Background: Anxiety is established as highly comorbid with many chronic medical conditions, including obesity. Anxiety has been linked to increased number of diabetes mellitus (DM) symptoms and complications, increased pain, and reduced quality of life. However, research on anxiety levels in DM populations is scarce. Recent studies suggest that anxiety symptoms are generally higher in individuals with DM than in the general population, but this relationship is poorly understood**.**

Aims: This study aims to 1) describe somatic (sensations) and cognitive (thoughts) anxiety in DM patients using insulin and (2) explore specific diabetes and health characteristics associated with both types of anxiety.

Method: Forty three DM patients were recruited from a hospital-based diabetes outpatient clinic (44% female, 93% White, *M* age = 42); 72% of the sample had Type 1 and 28% had Type 2 DM. All participants were using insulin, and 44% had a history of significant hypoglycemic episodes; 72% were overweight or obese. Self-report measures assessed DM history, general anxiety (Beck Anxiety Inventory, somatic and cognitive scales), and hypoglycemia-related anxiety (Fear of Hypoglycemia Scale).

Results: Participants' diabetes was moderately controlled (*M* HbA1c = 8.55, *SD* = 2.04). Nearly half of the sample (46%) reported anxiety symptoms. Somatic levels were generally lower (*M* = .41, *SD* = .38) than cognitive (*M* = .45, *SD* = .62). Anxiety was not associated with time since diagnosis, frequency of blood sugar testing, injections, or perception of accuracy in estimating blood sugar. Higher cognitive anxiety was associated with higher levels of worry about hypoglycemia episodes (*r* = .51, *p* < .001) and higher somatic anxiety with higher BMI (*r* = .53, *p* < .001). Somatic anxiety significantly differed by weight classification (ANOVA, *F* = 5.23, *p* = .01) with planned comparisons revealing higher somatic anxiety in obese vs. overweight participants (*t* (36) = -3.00, *p* = .005).

Conclusion: The results support previous findings of high levels of anxiety in DM samples and may point to important differences in anxiety symptom type. While cognitive anxiety may be linked to worry about managing diabetes symptoms, such as hypoglycemia, somatic anxiety may be related to comorbid conditions, such as obesity. Because anxiety has been linked to

poorer diabetes outcomes, further understanding of this comorbidity is needed and may be a key to improved diabetes management.

THE RELATIONSHIP BETWEEN CHANGE IN HBA1C, DEPRESSION, AND DIABETES-DISTRESS FOLLOWING A 6 MONTH, STEPPED CARE INTERVENTION.

Chelsey Solar, M.S./Ed.S[1], Lesley Lutes, PhD[2], Doyle M. Cummings, PharmD[1], Bertha Hambidge, M.D., MPH[1], Alyssa Adams, MPH[1], Marissa Carraway, Ph.D.[1], Kerry Littlewood, Ph.D., MSW[3], Sheila Edwards, RN[1], Peggy Gaitlin, B.S.[1], Shiv Patil, MD, MPH, BC-ADM[1]

[1]East Carolina University, Greenville, NC; [2]University of British Columbia, Kelowna, BC, Canada; [3]AAJ Research and Evaluation, Seminole, FL

Objective: Diabetes and diabetes-related distress are commonly comorbid with Type 2 diabetes mellitus (T2DM) and both depression and diabetes-related distress have been found to be positively correlated with HbA1c. The purpose of this project is to further explore the relationships between HbA1c, depression, and diabetes-related distress following a 6 month integrated, collaborative stepped care intervention for primary care patients with uncontrolled T2DM and co-morbid distress or depression.

Methods: One hundred thirty nine (Mage = 52.6, 77.6% Female, 71% African American) with uncontrolled T2DM (MHba1c = 9.6) were randomly assigned to intervention or control. Intervention group participants were placed into one of three steps based on depression and distress symptoms as assessed by Diabetes Distress Scale (DDS-17) and the Patient Health Questionnaire (PHQ-9). Participants with low distress or depression received assistance with self-management; those with moderate distress or depression received problem-solving therapy; and those with high distress or depression received cognitive behavioral therapy.

Results: At 6 months there was no significant difference in HbA1c change, $t(137) = .737$, $p = .46$, or PhQ9 change, $t(107) = 1.9$, $p = .06$ between intervention and control participants. Participants in the intervention arm ($M = -.75$, $SD = .92$) experienced significantly greater decrease in DDS as compared to controls ($M = -.35$, $SD = .60$), $t(107) = 2.72$, $p = .008$. Reduction in DDS scores significantly predicted decreases in HbA1c within intervention participants $F\,(1, 52) = 9.28$, $p = .004$ with an $R^2 = .15$; however, there was no relationship between change in DDS and change in HbA1c within control participants.

Conclusions: A collaborative, stepped-care intervention approach appears to reduce diabetes-related distress in patients with T2DM and comorbid depression or distress.

WEIGHT GAIN IN YOUTH WITH TYPE 1 DIABETES COMPLETING INTERNET PSYCHO-EDUCATION PROGRAMS

Garrett I. Ash, PhD[1], Sangchoon Jeon, PhD[2], Margaret Grey, DrPH, RN, FAAN[2]

[1]Yale University, New Haven, CT; [2]Yale University, West Haven, CT

Background: Prevalence of overweight among adolescents with type 1 diabetes has grown at alarming rates since the 1980s. Our Internet-based behavioral interventions have successfully maintained glycemic control and improved quality of life and diabetes management, but little is known about the impact of such interventions on weight gain/maintenance.

Methods: We performed a secondary analysis for changes in body weight from the TeenCope study, a multisite clinical trial where 320 youth, age 11-14 years; 37% minority; 55% female; HbA1c 8.5±1.4% were randomized to one of two interventions; TeenCope or Managing Diabetes. Research assistants retrieved height, weight, and HbA1c data from medical records before and 12 months after the intervention for 223 participants, who comprised the cohort for this analysis. We used mixed linear models to examine change in body weight and body mass index percentile (BMI %'ile) over time and whether such changes were influenced by potential moderators [intervention assignment, change in HbA1c, therapy type (pump versus injections), gender, and age of diabetes onset].

Results: Among the patients with normal weight at baseline (n=134, BMI≥5th and < 85th %'ile), average BMI %'ile increased from 59.5±20.7 to 78.3±14.6 ($p < 0.001$) and 41% became overweight. Among the patients with overweight at baseline (n=58, BMI≥85th and < 95th %'ile), average %'ile increased from 90.7±2.3 to 95.4±2.5 ($p < 0.001$) and 62% of them became obese while virtually all others (36%) remained overweight. The patients with obesity at baseline (n=31, ≥95th %'ile) did not change %'ile on average (97.7±1.4 to 98.5±1.6, $p>0.05$) and virtually all (97%) remained obese. None of the potential moderators influenced weight changes.

Conclusion: A substantive number of teens became overweight or obese during the programs. Future studies should investigate behavioral factors moderating these abnormal BMI increases over 12 months and ways our future interventions could address them.

A DIGITAL HEALTH INTERVENTION FOR WEIGHT LOSS IMPROVES DIET QUALITY AMONG MEDICALLY VULNERABLE PATIENTS: RESULTS FROM AN RCT.

Dori M. Steinberg, PhD, RD[1], Jasmine Burroughs, BS[2], Sandy Askew, MPH[1], Gary G. Bennett, PhD[1]

[1]Duke University, Durham, NC; [2]Duke Global Health Institute, Durham, NC

Background: The Dietary Approaches to Stop Hypertension (DASH) dietary pattern is a proven behavioral strategy to manage chronic disease; yet national compliance rates hover around 20%. We examined DASH dietary pattern compliance among high-risk, low-income patients with diabetes, hypertension, and/or hyperlipidemia enrolled in a behavioral weight loss intervention.

Methods: Participants (n=351) were enrolled in the Track study; a randomized controlled trial examining a digital health weight loss intervention that included self-monitoring via mobile technologies and provider counseling in community health centers, as compared to usual care. At baseline and 12 months, we used the Block Food Frequency Questionnaire to assess usual dietary intake. Using valid questionnaires (n=241), we calculated a DASH compliance score based on recommended levels of 10 nutrients; carbohydrates, protein, total fat, saturated fat, cholesterol, fiber, magnesium, calcium, potassium, and sodium. Total scores ranged from 0-10, with higher scores indicative of greater adoption of the DASH dietary pattern.

Results: Participants were on average 50.7 years old and obese (BMI 35.9 kg/m2). Most were female (68%) and Black (54%); 12.5% were Hispanic. Half (51%) had an income ≤ $25,000/y and 21% had all 3 chronic diseases. At baseline, average DASH scores were low (2.04 ±1.16) and 48% had a score ≤ 1.5. DASH compliance improved among intervention participants compared to usual care; although this was marginally significant (mean change: 0.28±1.3 vs. -.01±1.2; p=.08). This difference was driven by group differences in sodium reduction (intervention: -1011mg±1168 vs control: -249mg ±1244; < .0001). Among intervention participants at 12 months, controlling for baseline, women had significantly higher DASH scores compared to men (2.42±1.1 vs. 1.83±1.1; p=.012) and those with all 3 chronic diseases reported poorer DASH scores compared to those with fewer (1.79±0.9 vs. 2.39±1.2; p=.062). Further, improvements in DASH adherence were associated with greater weight loss (r=.27; p=.004).

Conclusion: A digital health intervention marginally improved adoption of the DASH dietary pattern among medically vulnerable patients; particularly among women, those managing fewer chronic conditions, and those who lost weight. Despite these improvements, overall compliance remains poor. Interventions should focus on improving diet quality to reduce chronic disease burden.

DEPRESSION AND DIETARY FACTORS IMPLICATED IN OBESITY DEVELOPMENT: A REVIEW

Elizabeth A. Vrany, MS, Melissa A. Cyders, PhD, Adam T. Hirsh, PhD, Jesse C. Stewart, PhD

Indiana University-Purdue University Indianapolis, Indianapolis, IN

Objective: Although “poor diet” has been proposed as one pathway through which depression promotes the development of obesity, no review has summarized the literature on depression as a potential predictor of dietary factors. Accordingly, our aims were (1) to summarize and evaluate the extant literature on depression and 21 dietary factors implicated in obesity development and (2) propose a conceptual framework and formulate a future research agenda for this area.
Methods: A total of 109 studies were included in this review, which was conducted between March 3, 2016 and July 1, 2016. For 17 of the dietary factors, comprehensive literature searches were conducted using PsycINFO, MEDLINE, and EMBASE databases. For the other four dietary factors, results of recent meta-analyses and/or comprehensive reviews were synthesized.
Results: Findings indicate that there is: (1) strong longitudinal evidence of greater depression predicting greater eating disorder pathology; (2) strong cross-sectional evidence linking greater depression to greater emotional eating, dietary restraint, rates of night eating syndrome, and frequency of skipping breakfast; (3) modest cross-sectional evidence suggesting that greater depression is inversely associated with Mediterranean and healthy diets but is unrelated to Western diet and protein intake; (4) mixed cross-sectional evidence regarding the associations of depression with energy intake, fat intake, carbohydrate intake, fast food intake, fruit and vegetable intake, sweet food/beverage intake, and external eating; and (5) insufficient evidence regarding the relationship between depression and the remaining four dietary factors of adherence to dietary recommendations, meal preparation, snacking, and portion size.
Conclusions: Based on these results, we developed a conceptual framework clarifying the relationship between depression and dietary factors implicated in the development of obesity. We also identify key knowledge gaps and propose a future research agenda for this area. Of greatest importance, there is a critical need for prospective studies utilizing large, representative samples. This review may increase researchers’ and providers’ awareness of the numerous ways in which depression could influence dietary factors and, ultimately, the development and progression of obesity.

ENGAGING EFNEP AUDIENCES: AN ANALYSIS OF SOCIAL MEDIA POST CONTENT AND PARTICIPANT ENGAGEMENT

David N. Cavallo, PhD, MPH[1], Emily Foley, MS[2], Lorelei Jones, M.Ed.[3], Valerie Yen, N/A[4], Vanessa Y. Chen, N/A[5], Alice S. Ammerman, DrPH[6]

[1]Case Western Reserve University, Cleveland, OH; [2]EFNEP, NC State University, Raleigh, NC; [3]NC State University, Raleigh, NC; [4]Case Western Reserve University, Flushing, NY; [5]Case Western Reserve University, Canton, OH; [6]University of North Carolina at Chapel Hill, Chapel Hill, NC

Background: The prevalence of social media use among low-income internet users in the US (56%) suggests that social media may be an appropriate platform for engaging and retaining participants in programs such as the USDA Expanded Food and Nutrition Education Program (EFNEP). Although a growing number of health promotion organizations such as EFNEP are using social media, little formal research has been done to determine best practices in social media message design around health topics. Identifying effective social media messaging strategies could improve program engagement resulting in improved behavioral and health outcomes.

Objective: to describe EFNEP social media campaign message characteristics and identify those that are associated with greater levels of participant engagement.

Methods: We obtained objective server log data on participant interactions from the Facebook Insights analytical platform for 406 moderator messages posted across 24 county and state EFNEP Facebook fan pages over a 26-month period. Codes representing key engagement strategies were developed through qualitative content analysis and from existing categories (e.g., message type). Multiple coders then applied the appropriate set of codes to each message. Using a Welch's adjusted ANOVA due to homogeneity of variance and unbalanced sample sizes between groups, we examined the association between message engagement strategies (e.g., messages including pictures, messages focusing on significant others) and a measure of engagement that summed participant message interactions (Comments + Shares + Likes + Link clicks + Photo views + Video plays + Other clicks).

Results: Categories of engagement strategies included message types [text only (3.9%), text with links (74.4%), text with pictures (75.1%), and text with videos (6.7%)], and message content [use of credible sources of information (21.2%), emphasizing significant others

(48.0%), encouraging discussion of a topic (21.4%), and posing rhetorical questions (35.0%]. The mean number of interactions was 14.84 (SD = 13.35). Engagement strategies positively associated with interactions included having a picture F(1, 136.48) = 5.75, p < .05 and posing a rhetorical question F(1, 271.03) = 5.26, p < .05. Negative associations were observed for emphasizing significant others F(1, 400.42) = 4.54, p < .05; being related to a holiday F(1, 84.38) = 6.39, p < .05; being text only F(1, 15.52) = 15.87, p < .01;and containing motivational language F(1, 39.49) = 4.90, p < .05.

Implications: Social media messages with a greater number of interactive elements can be employed by organizations to increase engagement. In some cases, message characteristics hypothesized to increase engagement produced the opposite effect, highlighting the importance of continued research that can guide practitioners in the design of social media campaigns that maximize engagement.

FAMILY FUNCTIONING MODERATES ASSOCIATIONS BETWEEN MOMENTARY MOODS AND BINGE EATING AMONG URBAN ADOLESCENTS

Anna Lee, MPH, MA, Kim Reynolds, PhD, Alan Stacy, PhD, Zhongzheng Niu, MS, MD, Bin Xie, PhD

Claremont Graduate University, Claremont, CA

Background and purpose

This study builds upon prior research on associations between moods, family functioning (FF), and binge eating behaviors, using ecological momentary assessment (EMA), an intensive longitudinal data collection technique that involves participants' reportage of data from within their natural environments. Momentary associations between moods (e.g. positive and negative emotions) and binge eating behaviors, as well as moderating effects of FF on these associations, were examined among a nonclinical sample of urban adolescents.

Methods

This study included both time-invariant data reported on survey questionnaires, as well as time-variant data reported on handheld PDA devices over a 7-day period. Time-invariant data included demographics and five FF constructs adopted from FACES-IV (e.g. 'balanced cohesion,' 'balanced flexibility' 'communication,' 'satisfaction,' and 'balance,'); time-variant data included moods (13 items from the Daily Affect Scale) and binge eating behavioral responses (2 items from a subscale of the Eating Disorder Diagnostic Scale - binge eating associated with 'embarrassment' (BE1), and binge eating associated with a sense of 'loss of control' (BE2)). A multilevel modeling approach was employed to examine associations between momentary moods and binge eating behaviors moderated by FF constructs, after controlling for age, gender, ethnicity and obesity status.

Results

All negative emotions were significantly and positively associated with at least one form of binge eating (BE1 or BE2; *p*-values < 0.05). The positive association between feeling 'tired' and binge eating was significantly buffered by 'family balanced cohesion' (BE2: $\beta = -0.0016$, $p = 0.04$), 'family satisfaction' (BE2: $\beta = -0.0012$, $p = 0.03$), and 'family balance' (BE1: $\beta = -0.072$, $p = 0.01$; BE2: $\beta = -0.0071$, $p = 0.03$). Such significant main and interaction effects were not observed among positive emotions and binge eating (neither BE1 nor BE2).

Conclusions

Findings indicate that FF buffers positive associations between negative emotions and binge eating behaviors; this finding indicates the importance of inclusion of FF in the development of eating behavior interventions for adolescents.

HOUSEHOLD SOCIAL CONTRIBUTORS TO EVERYDAY DIETARY BEHAVIOR AMONG BLACK AMERICAN ADOLESCENT FEMALES

Megan Winkler, PhD, RNC-NIC, CPNP-PC[1], Sharron Docherty, PhD, PNP-BC, FAAN[2], Gary Bennett, PhD[2], Leigh Ann Simmons, Ph.D., M.F.T.[3], Debra Brandon, PhD, RN, CNS, FAAN[3]

[1]University of Minnesota School of Public Health, Plymouth, MN; [2]Duke University, Durham, NC; [3]Duke University School of Nursing, Durham, NC

Background: Black American adolescent females are disproportionately impacted by obesity and exhibit high rates of obesity-associated dietary behaviors. However, given that food is best understood within a social context, it is essential to examine food-related behaviors situated within a person's household— a place shared and created by its members.

Purpose: The purpose of this research was to deeply explore the household relationships and social processes contributing to Black American adolescent females' everyday food consumption behaviors.

Methods: Data are from a mixed methods, multiple case study conducted with 14 mother-adolescent female cases (7 adolescent females with obesity). Sixteen different data sources, including repeated administrations of questionnaires, anthropometrics, interviews, daily diaries, and field notes, were collected across four home visits for each case and analyzed using within- and across-case techniques. A highly detailed view of dietary behavior, including on average 45 distinct food consumption occurrences (more than 14 days of data), was produced for each adolescent female, along with comprehensive descriptions and evaluations of the social processes within her household.

Results: An explanatory configuration consisting of three sufficient factors (Mother's Consistent Mindfulness of the Healthfulness of Foods, Daughter's Agreement and Accommodation to Household Food, Household Member Available and Willing to Plan, Acquire, and Prepare Food) was developed to elucidate the various household social contributors to a healthy profile of everyday food consumption among adolescent females. The configuration's explanatory power was estimated by illuminating properties for each factor and examining their presence across each case (e.g. one of six properties for Mother's Consistent Mindfulness is whether she frames "healthy eating" as a best practice for life).

Conclusions: This study is an initial step to understanding the multiple household social processes contributing to various forms of healthy and unhealthy everyday food consumption

behavior among adolescents. By examining the nuanced ways the cases varied, context-dependent knowledge essential to understanding the complicated health challenges of obesity-associated dietary behaviors among Black American adolescent females was produced; thus, informing both the development and refinement of household-level obesity interventions.

A CONTENT ANALYSIS OF A BARIATRIC SURGERY SUPPORT PAGE ON FACEBOOK: IMPLICATIONS FOR PROVIDERS

Dylan Jester[1], Sarah Domoff, PhD[2], Shanu Kothari, MD[3], Afton Koball, PhD, ABPP[4]

[1]Gundersen Medical Foundation, La Crosse, WI; [2]Central Michigan University, Mt. Pleasant, MI; [3]Gundersen Health Systtem, La Crosse, WI; [4]Gundersen Health System, La Crosse, WI

Abstract

Background: In-person support groups are an integral part of the post-operative lifestyle for patients after bariatric surgery. Past research shows that patients who attend support groups lose more weight. In today’s technological revolution, online bariatric surgery support groups have formed on social media platforms. Due to the novelty of an online format, a gap exists in the literature on the content of these support groups. The current study hopes to bridge this gap by examining the online posts on a Facebook bariatric surgery support page with over 42,000 members.

Methods: All posts from May 1st, 2016 to June 1st, 2016 were coded (*N* = 3,556 posts). Content analysis was performed by coding the presence of thematic categories in individual posts. Categories included seeking nutritional information, posting about progress after surgery, and commenting about experiences of weight bias. Coders were trained to reliably code the presence of thematic categories (all $\kappa > .70$).

Results: Content analysis indicated that seeking or providing recommendations was most prevalent (66%), followed by writing supportive content to group members (37%) and sharing postoperative progress (21%). When members sought recommendations, questions were frequently related to nutritional (44%) or medical content (56%). When providing recommendations, 23% of these posts suggested a specific product or tool (e.g., specific brand of protein supplement). Patients often described changes in weight (69%) or provided weight statistics before and after surgery (20%) when writing a progress post. Internalizing weight bias or writing about experiencing weight bias was more common when posts centered around changes in appearance (*p’s* < .05).

Conclusion: Results indicate that online bariatric support groups are primarily used for asking and answering questions, receiving support, and sharing experiences. These findings may be useful to inform patients about the risks and benefits of joining these groups, and to develop

higher quality support for bariatric surgery patients. Future research examining the accuracy of online support group content and the credentials of group administrators is warranted.

COLLEGE STUDENTS' USE OF MOBILE APPLICATIONS FOR PHYSICAL ACTIVITY

Matthew C. Whited, PhD, Licensed Psychologist[1], John T. Freeman, B.A.[1], Ansley Taylor Corson, M.A.[1], Jordan Ellis, MA[1], Emily P. Midgette, Psychology, BA (Expected May 2017)[2], Sherry Pagoto, PhD[3], Molly E. Waring, PhD[3], Christine May, PhD[4], Kristin Schneider, Ph.D.[5], Andrew Busch, PhD[6], Brad Appelhans, PhD[7], Eliza Varju, BS (Expected May, 2019)[1], Laura K. Nye, BA in Psychology, May 2017[1]

[1]East Carolina University, Greenville, NC; [2]East Carolina University, Vanceboro, NC; [3]University of Massachusetts Medical School, Worcester, MA; [4]University of Massachusetts Medical School, Fiskdale, MA; [5]Rosalind Franklin University of Medicine & Science, North Chicago, IL; [6]The Miriam Hospital, Rumford, RI; [7]Rush University Medical Center, Chicago, IL

Physical activity (PA) is important for both mental and physical health. Mobile applications (apps) have potential to increase PA, especially among heavy technology users such as college students.

As part of an annual survey of college student health, students were asked: “have you ever used a mobile application (“app”) for physical activity or exercise?” Users, those who reported using an app for PA, were asked about their most and least liked feature for the most used app. Responses to these open-ended questions were categorized by 3 coders (percent agreement ranged 71-82%).

Of total participants (n=1906; 67% female; 30% overweight/obese), less than half (39%) reported using an app for PA. Users were more likely to be women (41% of women vs 35% of men; p=0.008), and more likely to have a BMI of less than 25 (41% of normal BMI vs 35% of ovwt/obese, p=0.02).

Most users (43%) reported primarily using PA apps to track PA, 23% to increase PA, 11% for fun, 11% because an app was recommended, and 8% to lose weight. Many (38%) reported using a PA app for less than one month, 25% 1-2 months, 18% 3-4 months, 19% reported use of 5 months or longer. Length of use did not differ based on reason for use.

Most users (48%) liked tracking/self-monitoring features most followed by receiving tutorial or instruction (24%). Half of students (50%) did not clearly identify least-liked app features in response to open-ended questions, 17% listed activity tracking, 6% tutorial/instruction, and 6% financial or time cost.

Over one third of college students have used an app for PA, although most use them for 2 months or less. Just under half of users were using apps to track a preexisting PA habit while far fewer were using apps to increase PA suggesting that behavioral strategies in apps may not be attracting sedentary individuals. Almost 2/3 of users reported using the app for less than 2 months with only 19% using these apps for 5 or more months. Further research is needed to identify how to enhance PA app features to attract sedentary users for longer periods of time.

DIGITAL FOOD RECORDS: A MIXED-METHODS STUDY TO EVALUATE FEASIBILITY AND ACCEPTABILITY FOR COMMUNITY-BASED INTERVENTIONS

Lauren A. Fowler, BS[1], Gwenyth R. Wallen, PhD, RN[2], Alyssa T. Brooks, PhD[3], Leah R. Yingling, BS[4], Marlene Peters-Lawrence, RN[5], Michael McClurkin, BS[1], Kenneth L. Wiley Jr., PhD[6], Valerie Mitchell, BA[7], Twanda D. Johnson, ABA[8], Allan A. Johnson, PhD[9], Avis P. Graham, PhD, RD, LDN[9], Lennox A. Graham, DM[9], Kendrick Curry, PhD[10], Tiffany Powell-Wiley, MD, MPH[11]

[1]National Heart Lung and Blood Institute, National Institutes of Health,, Bethesda, MD; [2]Clinical Center, National Institutes of Health, Bethesda, MD; [3]National Institutes of Health Clinical Center, Bethesda, MD; [4]National Heart, Lung and Blood Institute, Bethesda, MD; [5]Division of Intramural Research - Hematology Branch, National Heart Lung and Blood Institute, Bethesda, MD; [6]National Human Genome Research Institute, Bethesda, MD; [7]NIH/National Heart, Lung and Blood Institute, Bethesda, MD; [8]NIH Clinical Center, Bethesda, MD; [9]Howard University, Washington, DC; [10]Pennsylvania Ave Baptist Church, Washington, DC; [11]NHLBI, Bethesda, MD

Background

Optimized dietary assessment tools are needed for use in community interventions for vulnerable populations. Digital Food Records (DFR), which use handheld devices to capture dietary intake through text and photography, are a particularly promising mobile assessment method. Less is understood about the acceptability and feasibility of DFR in community-based participatory research (CBPR).

Methods

This CBPR-based pilot study was conducted among church-based populations in resource-limited wards of Washington, D.C. as part of the D.C. Cardiovascular (CV) Health and Needs Assessment (NCT01927783). Participants (n=17) received a mobile device (iPod Touch) to photo-document dietary intake for a 3-day DFR using a mobile application (app), FitNinja (Vibrent Health). After 2 weeks of use, qualitative data were collected in a moderated focus group (n=8). Acceptability of DFR was explored through thematic analysis of verbatim transcripts. Feasibility was evaluated by the percentage of participants complying with instructions (i.e., capturing both before and after meal photos for at least two meals/day for

three days).

Results

Themes identified were related to: 1) feasibility and acceptability of the mobile device and app, including issues in recording dietary information and difficulty with photo-documentation; 2) suggestions for additional support and training experiences; and 3) comparisons to other mobile apps. Overall, participants (all African American, 53% female, 28-80 years old) were accepting of the photo-documentation tool, contributed to the discussion of ways to improve the tool, and expressed interest in receiving expert feedback regarding their diet. Fifteen of the 17 participants (88.2%) photo-documented at least one meal over the study period. Most meals (89.4%) were recorded with at least one photo. Only 3 participants (17.6%) provided before and after photos for at least two meals for three days.

Conclusion

This study demonstrates DFR as an acceptable tool in CBPR. Participation rates and feasibility may be improved with the development of a tailored system of reminders to increase before/after meal pictures. CBPR allows novel assessment methods to be optimized for use in real-world settings by tailoring tools based on feedback from community members. Increasing knowledge of the acceptability and feasibility of digital technology to measure dietary intake in CBPR could improve interventions that promote healthy eating and reduce CV health disparities.

DIGITAL HEALTH TOOLS FOR SLEEP SELF-MANAGEMENT: WORKING MOTHERS USE CASE

Katarzyna Wac, PhD[1], Laura Montanini, MSc[2], Kimie Bodin Ryager, MSc[3], Homero Rivas, MD[4]

[1]Stanford University, Stanford, CA; [2]Marche Polytechnic University, Italy, Stanford, CA;
[3]University of Copenhagen, Denmark, Palo Alto, CA; [4]Stanford University, USA, Palo Alto, CA

Ever sophisticated wearable activity trackers and mobile applications enable to assess individual’s daily life patterns and factors influencing their long-term health state. Working mothers may be especially vulnerable to experience poor sleep hygiene – as they try to balance work with family obligations, suffering from chronic stress, and having poor social support and insufficient personal resources to deal with daily challenges. Poor sleep hygiene may be developing over a longer period, resulting in fatigue and exhaustion and may have destructive long-term influences on the individual’s psychological and physical health, cognition, and behavior, leading to a burnout state.

We present an approach to operationalizing the major risk factors for the prevalence of poor sleep hygiene in working mothers - including physical factors (e.g., physical activity, alcohol, time to bed), psychological factors (e.g., stress, feeling 'lack of control'), social factors (e.g., family settings, social pressure for socializing) and environmental factors (e.g., light, noise, room temperature). We have thoroughly examined these factors to identify which of those can be operationalized via ICT-based tools and quantified by leveraging unobtrusive sensors, including sensors embedded in personal smartphones and wearables. Such an operationalization will enable to provide reliable assessment and prediction of risk exposure, which, in turns, will permit early recognition and preventive interventions.

To support our research claims we have conducted an explorative pilot study with six working mothers wearing BASIS PEAK activity and sleep tracker for a minimum of three months each. We have collected both their subjective views (via interviews) and the underlying smartphone and wearable device usage logs ‘in situ’. The results expose, on the one hand, the low physical activity levels, late time to bed, high stress and social pressure as well as poor environmental conditions of most of the mothers. On the other hand, the results indicate a high importance of routines and predictability in the daily lives of mothers, which may enable better sleep hygiene. Additionally, a wearable device’s features like interaction design, battery lifetime and fashion-ability; influence the quality of the data collected. Given the results and existing research so far, we discuss design implications for monitoring and assessment of multi-dimensional events, subjective symptoms as well as physiological and behavioral variables in

the natural daily settings of the working mothers for assurance of their sleep hygiene and prevention of burnout condition in a long term.

EFFECTS OF AN ONLINE BOOSTER INTERVENTION ON BEHAVIORAL CHANGE IN A LONGITUDINAL BONE HEALTH TRIAL

Eun-Shim Nahm, PhD, RN, FAAN[1], Barbara Resnick, PHd, CRNP, FAAN, FAANP [2], Shijun Zhu, PhD[2], Michele Bellantoni, MD[3], Kathleen Charters, PhD, RN[4]

[1]University of Maryland School of Nursing, Baltimore, MD; [2]University of Maryland, School of Nursing, Baltimore, MD; [3]Johns Hopkins School of Medicine, Baltimore, MD; [4]Uniform Health Services University, Columbia, MD

Osteoporosis is a serious public health problem affecting 52 million Americans. Although several interventions have been shown to be effective in optimizing bone health, they have not been fully incorporated into individuals' daily lives. In an online dissemination study, our research team assessed the impact of two online theory-based bone health programs on selected health outcomes in older adults. The two interventions were the (1) Bone Power program (8-week) and the (2) Bone Power Plus program, including a 10-month online booster intervention followed by the 8-week Bone Power program. The aim of the study was to test the impact of the online booster intervention on self-efficacy/outcome expectations for calcium intake and exercise, and calcium intake and exercise behaviors. (8-week outcomes of the study were published elsewhere.) The study was guided by social cognitive theory. This was a 3-arm RCT with 4 observations (baseline, 8 weeks, 6 months, and 12 months). Individuals were eligible if they were age 50 or older and could use the Internet/e-mail independently. Participants were recruited from two online communities*, SeniorNet* and *My HealtheVet.* The 8-week Bone Power program was comprised of learning modules, moderated discussion boards, Ask-the-Experts, and a virtual library. Participants also had access to video lecture libraries and a health toolkit. The booster intervention used for the Plus program was a 10-month biweekly eHealth Newsletter. The newsletters included contents that highlighted major health topics in the learning modules, recent research findings, calcium-rich recipes, an interactive goal attainment form, and participants' success stories. For the primary analysis, linear mixed models were used to compare the intervention effects between intervention groups on each of the outcomes. A total of 866 participants were randomized into either the control (n=263), Bone Power (n=301), or Bone Power Plus (n=302) group (mean age, 62.8±8.5 years). At 12 months, participants in the Plus group showed substantially greater improvement compared to the control group in calcium self-efficacy (t[1309]=1.99; p=.046), exercise self-efficacy (t[1309]=2.1, p=.036), amount of exercise (t[1309]=2.38, p=.018) and minutes of exercise (t[1309]=2.48, p=.013). Participants in the Bone Power group showed greater improvement in calcium outcome expectation (t[1309]=2.68, p=.008) than those in

the control group. Although no statistical significance was observed, participants in the Plus group tended to have a higher improvement than those in the Bone Power group in self-efficacy for calcium and exercise and amount of exercise. Overall, the findings suggest promising potential for using eHealth behavior interventions for large numbers of older adults. The effects of booster interventions, however, need further investigation using varying approaches.

ENGAGEMENT OVER ONE YEAR IN A BILINGUAL TEXT MESSAGING INTERVENTION PREDICTS WEIGHT LOSS AMONG OVERWEIGHT/OBESE ADULTS: CONTXT

Margaret A. Crawford, BS[1], Gina Merchant, PhD[2], Matthew Allison, MD, MPH, FAHA[2], Job Godino, Ph.D.[3], Kevin Patrick, MD, MS[4]

[1]UC San Diego, Encinitas, CA; [2]University of California San Diego, La Jolla, CA; [3]UC San Diego, La Jolla, CA; [4]UCSD School of Medicine and The Qualcomm Institute, La Jolla, CA

Purpose: Text messaging is a promising weight-loss intervention tool because it allows for continuous support, minimizes cost, and maximizes distribution. However, limited work has investigated how participant engagement with study-delivered text messages impacts weight loss, especially among diverse populations. We present a quantification of engagement and its association with change in weight throughout a 12-month intervention.

Methods: 197 participants were randomized to receive the text messaging intervention (BMI > 27 to < 40, ages 21-62, 128 female, 66 Hispanic). Our analyses include participants who had complete information for the respective timepoints: 171 participants at 6 months and 159 participants at 12 months. Participants received 2-4 messages/day that were tailored on baseline weight management strategies. Messages were iterative and interactive, enabling goal setting and self-monitoring of physical activity and diet. Engagement was defined as: the number of texts participants replied to / the number of texts received that asked for a reply ("interactive messages"). Engagement was anchored to participants' individual study start dates, and was aggregated across two time periods: baseline-6 months and 6-12 months.

Results: Participants received a total of 210+24 and 278+36 interactive messages from baseline-6 months and 6-12 months, respectively. Participants sent 230+98 and 230+140 replies from baseline-6 months and 6-12 months, respectively. Average engagement score from baseline-6 months was 1.1+ .48, and 0.85+ .52 from 6-12 months. Average weight change was -2.5 kg+5.79 from baseline-6 months, and .05 kg+4.73 from 6-12 months. In multiple linear regression models that adjusted for baseline weight, age, sex, and ethnicity, higher engagement was significantly associated with lower weight at 6 and 12 months. For every SD increase in engagement, participants lost 1.63 kg of weight from baseline-6 months, and 1.62 kg of weight from 6-12 months (p's < .001). Separate models assessed the association of weight change with the number of replies sent, instead of the engagement

variable, and adjusted for number of interactive messages recieved, age, sex, and ethnicity. In these models, the number of replies sent by the participant remained signficiantly associated with weight loss at 6 and 12 months (p < .001).

Conclusion: An engagement score that accounts for replying to text messages and the number of interactive messages received predicts weight loss in participants who received a 12-month texting intervention. Our findings indicate that participants who have higher levels of engagement with the texting system are more successful in losing weight. Future mobile health interventions should include measures to monitor participant engagement during the intervention and to include as a dosing variable when assessing intervention effects.

EVALUATION OF PRO MUJER, A FACEBOOK-BASED WORKSITE WELLNESS PROGRAM IN LATIN AMERICA

Erica Levine, MPH[1], Sandy Askew, MPH[2], Gary G. Bennett, PhD[2]

[1]Duke Global Health Institute, Durham, NC; [2]Duke University, Durham, NC

Title: Evaluation of a Facebook-based Worksite Wellness Program in Latin America

Purpose: Chronic conditions account for 68% of mortality in Latin America. This is largely attributed to increasing obesity, and adoption of a Westernized diet along with inactivity. Latin America is also the fastest growing social media market; 94% of Internet users in the region are on social media. Pro Mujer is a women’s development organization that offers financial services and healthcare in 5 countries in Latin America. In 2014, Pro Mujer launched a Facebook page, Pro Mujer Salud, to help its employees adopt healthy eating and physical activity habits. The page now has over 5,000 followers.

Methods: We conducted a mixed-methods evaluation to assess the relationship between the Facebook page, employees’ self-reported adoption of healthy eating and physical activity, and on social norms promoted by the page. The evaluation consisted of 2 focus groups (n=16) and 3 key informant interviews in Nicaragua, and a survey to all employees in Bolivia, Argentina, Peru, Nicaragua, Mexico and the United States.

Results: Survey respondents (n=728; 36% of staff) were mostly female (73%), with a mean age of 33 years and mean BMI of 26.7 ± 4.7 kg/m^2. The majority (80%) of employees with Facebook follow Pro Mujer Salud; most followers (76%) interact with the page by clicking "like" on posts or photos. After adjusting for BMI, country and education, there were marginally statistically significant relationships between the length of time an employee followed Pro Mujer Salud and the odds of reporting more exercise (OR [95% CI]: 1.16, [1.01, 1.34], p= .04), as well as eating healthier (OR [95% CI]: 1.15, [1.001, 1.32], p= .048). The perception that coworkers were exercising more was a strong predictor of diet and exercise change. For each increase in amount of agreement that coworkers exercise more as a function of a Facebook page campaign called Sábado Saludable (Healthy Saturday), the odds of *also* reporting more exercise nearly doubled (OR [95% CI]: 1.92 [1.45, 2.56], p< .0001), and the odds of reporting diet related behavior change increased by 79% (OR [95% CI]: 1.79 [1.36, 2.34], p< .0001). Qualitative data analysis revealed high trust in the health information on the Pro Mujer Salud page. It also revealed themes of increasing anxiety about a changing food

environment (increasing processed foods and a loss of connection to the local food landscape) and low confidence in the ability to achieve recommended levels physical activity.

Discussion: This is the first evaluation of a Facebook-based worksite wellness program in Latin America. This highly scalable intervention holds great promise for being able to influence social norms, promote behavior change, and support a workplace culture of health.

CITATION AWARD WINNER

EVIDENCE-BASED NOVELTY IN THE DELIVERY OF ONLINE CBT: THE IMPACT OF USER-DRIVEN PROGRESSION THROUGH CBT CONCEPTS AND TECHNIQUES

Megan Jones Bell, PsyD[1], Clare Purvis, PsyD[2], Tess Brown, BA[2]

[1]Lantern / Stanford University, San Francisco, CA; [2]Lantern, San Francisco, CA

The efficacy of digital CBT-based interventions for common mental health disorders is clearly demonstrated, with many studies showing that digital interventions are equally effective to face-to-face treatment. Despite this, digital interventions are plagued by low engagement and poor user retention; fully 50% of people using a digital health tool discontinue use within six months. One contributing factor may be that digital health interventions have traditionally followed fixed protocols and, as a result, have been unable to account for individual user characteristics, situations, and needs - a mandate of effective evidence-based practice. We propose that digital interventions can address this limitation by providing users a more personalized experience. For example, by adopting a more flexible design, digital interventions can allow users to select the content most relevant to their current concerns and practice skills at a self-determined pace. This approach mirrors a “flexibility within fidelity” approach to implementing empirically-supported treatments in face-to-face settings.

The present study investigates the effect of specific changes to the protocol and design of a mobile app-delivered, guided CBT program, Lantern, on user engagement, retention, and clinical outcomes. Two methods for delivering digital CBT were compared: a traditional protocol in which CBT concepts and skills are delivered following a fixed sequence and pace (standard CBT), versus an innovative delivery in which users determine the sequence and pace at which they progress through CBT (nonlinear CBT). The same concepts and skills are delivered across both conditions; users in both conditions also receive individual, in-app, text-message based coaching.

Data from two ongoing deployments of Lantern with N=1000 adults (500 per condition) in employer settings will be collected from January, 2016 to January, 2017 in quarterly cohorts. All users have provided informed consent to data being used for research and product development purposes. The first three cohorts of the N=1000 target have already been recruited and are actively enrolled in Lantern. Outcome measures to be reported include engagement (completion of sessions, techniques, coach messaging), retention, primary symptom reduction (anxiety and/or stress). The study highlights the impact of an innovative, evidence-based delivery of digital CBT.

FORMATIVE EVALUATION OF A TEXT MESSAGE-BASED INTERVENTION FOR ABNORMAL PAP SMEAR FOLLOW-UP CARE TARGETING UNDERSERVED WOMEN

Erin K. Tagai, PhD, MPH[1], Suzanne M. Miller, PhD[2], Kuang-Yi Wen, PhD[3], Enrique Hernandez, MD, FACOG, FACS[4]

[1]Fox Chase Cancer Center, Philadelphia, PA; [2]Fox Chase Cancer Center/Temple University Health System, Philadelphia, PA; [3]Fox Chase Cancer Center, Philly, PA; [4]Lewis Katz School of Medicine at Temple University, Philadelphia, PA

Women of low socioeconomic status (SES) have poorer adherence to follow-up care after an abnormal Pap smear. Text messaging is widely used among low SES populations and has been reported as a feasible method to deliver health behavior messages. A formative evaluation was conducted to assess the receptivity of a text message-based intervention guided by the Cognitive-Social Health Processing Model (C-SHIP) for women of low SES to increase adherence to abnormal Pap smear follow-up care. Women (N=28) attending a colposcopy appointment for an abnormal Pap smear were recruited to complete a short demographic survey and qualitative interview. Interview questions sought to identify participants' interest in a text message-based intervention and psychosocial factors. Participants evaluated 25 prototype counseling messages previously used in a telephone-based counseling intervention and targeted to psychosocial barriers to adherence, with content guided by C-SHIP. The messages were evaluated on a scale of 1 to 5 for personal helpfulness, understandability, and culturally appropriateness. Participants were predominately African American (68%) and Latino (21%), and had a household income below $15,000 (71%). Participants expressed strong interest in receiving counseling messages to be delivered via text (68%). Most participants (68%) felt nervous or worried before their follow-up appointment. However, participants reported colposcopies as helpful (96%) and important (89%). Evaluations of prototype messages indicated high favorability with mean scores of 4.7 (*SD*=0.4) for personal helpfulness, 4.8 (*SD*=0.4) for understandability, and 4.6 (*SD*=0.6) for cultural appropriateness. Women of low SES undergoing follow-up care for an abnormal Pap smear reported interest in a text messaging-based intervention to increase adherence to follow-up care. High message favorability indicates prototype messages guided by C-SHIP are appropriate for the target population. Findings will be used to develop a text message-based intervention to increase adherence to abnormal Pap smear follow-up.

INSPIRATION OR THINSPIRATION: THE ASSOCIATION AMONG PROBLEMATIC INTERNET USE, EXERCISE DEPENDENCE, AND EATING DISORDER RISK

Brian Cook, PhD[1], Danika Quesnel, BHk, MSc [2], Kellen Murray, .[1], Jessica Zamudio, .[1]

[1]California State University Monterey Bay, Seaside, CA; [2]University of British Columbia, Winnipeg, MB, Canada

Introduction: Internet use provides the opportunity to access helpful information about health behaviors, but excessive use of the Internet has been associated with engaging in pathological health behaviors. Specifically, engagement and use of online social media platforms may negatively impact health by promoting unhealthy behaviors and providing inappropriate recommendations aimed at manipulating one's body shape and size. Problematic Internet Use (PIU) has been associated with eating disorder (ED) risk factors and pathological patterns of exercise (e.g., Exercise Dependence, EXD). Similarly, previous research has demonstrated an association between EXD with increased risk of developing an ED. However, no study to date has examined the co-occurrence among PIU, EXD, and ED risk simultaneously. The purpose of this study was to examine the co-occurrence of PIU and EXD in ED risk in a population-based sample of women. We hypothesize that PIU and EXD scores will be higher in individuals with ED risk. **Method:** Participants were 898 women [*M* age = 27.61(±10.22); 65.02% Caucasian; *M* Body Mass Index = 26.87(±6.36)] who completed the Exercise Dependence Scale, Eating Disorders Examination-Questionnaire (EDE-Q), and Problematic Internet Use Questionnaire as part of a larger online survey study. First, participants were grouped by ED risk status. PIU and EXD categories were also determined using previously published algorithms. Next, differences in continuous PIU and EXD scores by ED risk were assessed. Finally, Chi-square analyses were used to examine differences in PIU and EXD risk categories were examined by ED risk status. **Results:** Overall, 14.32% reported PIU, 1.96% reported EXD, and 35.07% reported EDE-Q scores ≥ 2.3 indicating ED risk. Independent samples t tests revealed significantly higher EXD [t(637) = -4.79, *p*=.01] and PIU [t(673) = -8.40, p < .01] scores in individuals at-risk for ED. Chi-square analyses revealed significant differneces in PIU [X^2(2)=33.81, p.01] and EXD risk status by ED risk (X^2(2)=8.71, p=.01]. **Conclusion:** Excessive use of the Internet may allow for misinformation regarding body shape satisfaction that encourages pathological health behaviors related to exercise and eating. The main clinical implication of this study is that health professionals should be aware of potential overlapping symptoms and consequences of Internet use, exercise, and ED behaviors. The results also suggest a common factor may explain increased use of the internet, exercise, and ED behaviors. Further research is needed to elucidate such factors.

INTEGRATION OF PEER SUPPORT AND DIGITAL HEALTH: CONSIDERATIONS FOR CHRONIC DISEASE MANAGEMENT INTERVENTIONS

Sarah Kowitt, MPH[1], Rebeccah L. Sokol, B.S. [2], Nivedita Bhushan, MA[3], Patrick Y. Tang, MPH[4], Edwin Fisher, PhD[5]

[1]University of North Carolina at Chapel Hill, Gillings School of Global Public Health, Chapel Hill, NC; [2]Gillings School of Public Health, UNC Chapel Hill, Carrboro, NC; [3]Gillings School of Global Public Health - University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Peers for Progress, Gillings School of Global Public Health, UNC Chapel Hill, Durham, NC; [5]The University of North Carolina at Chapel Hill, Gillings School of Global Public Heealth, Chapel Hill, NC

Peer support and digital health are often used independently to address chronic disease management barriers. Few studies have examined their integration in real-world settings. In this study, we evaluated how integration occurred in the context of a feasibility trial that combined health coaching and an "app" for patients with diabetes in a primary care practice. Semi-structured interviews were conducted with 12 patients, 2 health coaches, and 5 project staff (e.g., care coordinator, program manager) affiliated with the program. Coding of transcripts used deductive and inductive codes and consensus among three coders to ensure accuracy. Integration of the coaching and the app occurred in several domains. In terms of organization of care, the health coaching and diabetes app provided distinctive, but complementary roles for diabetes management; most patients reported using both program components, while a minority reported only using one. A common theme of this integration was that patients saw the diabetes management app as providing instrumental and informational support to participants, whereas they saw the health coaching as providing emotional and appraisal support. Both patients and coaches valued reports of blood glucose measures and other indicators as anchoring their discussions. Further integration with the electronic health records and general clinical care remain important opportunities. Lastly, study staff discussed the potential role of digital health and peer support to increase efficiency and reach of diabetes management interventions, carefully weighed with the need for more resources required by such integration. These findings indicate that peer support and digital health address distinctive, unique roles in diabetes management support and that their integration may benefit future chronic disease care in diabetes and other areas.

MIXED METHOD EXPLORATION OF USER ENGAGEMENT WITH A MOBILE APP-SUPPORTED SMOKING CESSATION ATTEMPT: PRELIMINARY FINDINGS

Christian Cerrada, BS[1], Kathleen Colao, BS, MPH[2], Mojgan Sami, PhD[3], Jimi Huh, PhD[1]

[1]University of Southern California, Los Angeles, CA; [2]University of Southern California Keck School of Medicine, Venice, CA; [3]University of California, Irvine, Irvine, CA

Introduction: Despite rapid development in the area of mobile health (mHealth), there remains a dearth of research on user engagement, the specific ways and extent to which users interact with a system over time. Although studies generally suggest that increased user engagement leads to better behavior change outcomes, little is known about the variety of patterns in which users might interact with mHealth apps to support behavior change. The present study seeks to explore different user engagement patterns with a mobile smoking cessation app, “MyQuit USC (MQU)”, over the course of four weeks using a mixed methods approach.

Methods: Data came from a preliminary subset of 18-25 year old Korean American smokers (N=16) participating in an ongoing smoking cessation study. To explore patterns of engagement with MQU, individual user interaction logs of the app during the study period were used to generate engagement plots detailing number and type of app interactions each day. Semi-structured interviews were conducted on the same participants shortly after completing the study. Interview data were analyzed deductively using pre-identified codes corresponding to different dimensions of user engagement of interest to researchers.

Results: Our data revealed notable heterogeneity in user engagement patterns and suggested potential influential factors on different patterns. Individual engagement plots indicated varying patterns differentiated by average number of daily app interactions over time (min=1.1, max=11.2) and extent of daily variation in interaction volume (SD min=0.8, max=6.1). Interview data shed light on several factors that appear to influence user engagement patterns. App-related factors included novelty of intervention content and whether a given interaction with MQU was user- or app-initiated. User-related factors included users’ perceived role of MQU in their quit attempt, cessation progress and success, and momentary mood.

Conclusions: In combination, our data shed light on diverse patterns of engagement with MQU and factors that may influence an app-supported quit attempt. To improve future

versions of MQU, intervention content should be responsive to dynamic app- and user-related factors, e.g. tailoring intervention contents to patterns of engagement or behavior change success at a previous time point.

PREFERENCES IN WEIGHT LOSS APP FEATURES AMONG AFRICAN AMERICANS

Martinus Evans, B.S., M.S.[1], Christine May, PhD[2], Molly E. Waring, PhD[1], Danielle E. Jake-Schoffman, PhD[3], Amanda Okpoebo, BS[4], Sherry Pagoto, PhD[1]

[1]University of Massachusetts Medical School, Worcester, MA; [2]University of Massachusetts Medical School, Fiskdale, MA; [3]University of Massachusetts Medical School, Worcest, MA; [4]UMass Medical School- Preventive Behavioral Medicine, Leominster, MA

More than 75% of African Americans are overweight or obese. Research has shown that culturally tailored interventions may be more effective in improving dietary habits and increasing physical activity in African Americans, yet treatment models that require frequent in-person visits have poor feasibility, especially among low-income African Americans. 56% of African Americans own a smartphone, suggesting that a culturally-tailored weight loss mobile app may be an effective way to reach this population with weight loss programming. This study examined commercial weight loss apps used by African Americans, features they find most and least useful, and features they would find most relevant. We conducted 4 in-depth semi-structured interviews and 2 focus group discussions (N=10). We content analyzed resulting open-ended question using an inductive method with pair coders. Participants self-identified as African American, smart phone users, on average were 35 years old (SD=6.0), and 80% were college-educated. MyFitnessPal was the most commonly used app (kappa=1.0), reported by 5 participants. Other apps included S Health (n=3), Fitbit (n=3), Weight Guru (n=1), C25k (n=1), Apple Health (n=1), and LoseIt! (n=1). Of the apps they have used the features they found most useful (kappa=.83) were tracking (n=4), auto-syncing to other devices/apps (n=2), feedback about tracked data (n=2), ease of use (n=1), exercise suggestions (n=1), diet suggestions (n=1), community (n=1) and calculate activity into calories burned (n=1). Least useful app features (kappa=1.0) included missing relevant/ethnic foods (n=3) and tracking is time consuming (n=3), issues with delayed syncing of steps and weight (n=1), difficulty setting helpful calorie goal (n=1), notifications of progress w/o context (n=1), and ads on free versions of apps (n=1). The feature requested for a culturally-tailored weight loss app by the most participants (kappa=.91) was nutrition education including healthy alternatives to ethnic food (n=4), stress management (n=2), music w/ exercise prompts (n=2), exercise suggestions (n=2), community chat (n=1), voice to text (n=1), and diversity in visual representation (n=1). Further research should examine which features are wanted by a larger population of African Americans.

PROFILING APP USERS FROM NUTRITION, WEIGHT MANAGEMENT, AND FITNESS-RELATED WEBSITES

Steriani Elavsky, Ph.D.[1], David Šmahel, Ph.D.[1], Hana Machackova, Dr.[2]

[1]Faculty of Social Sciences, Masaryk University, Brno, Jihomoravsky kraj, Czech Republic;
[2]Masaryk University, Brno, Jihomoravsky kraj, Czech Republic

The use of online communities and websites for health information has proliferated along with the use of mobile apps for managing health behaviors such as diet and exercise. The evidence available to date suggests that users of these websites and apps differ in significant ways from non-users but most data come from US and UK-based populations. In this study we recruited users of nutrition, weight management and fitness-oriented websites in the Czech Republic to better understand their motives, expectations, and usage patterns with respect to app use. The online survey was initiated by 1096 users and data were analyzed for respondents aged 13-39 who provided information on app use (n=719; $M(SD)$ age=24.0(5.2); 84%female). Respondents using apps for managing nutrition, weight and fitness (n=420, 58%) were more likely to be female (OR 2.111, 95% CI 1.364–3.268) and reported more expert telephone skills (OR 1.450, 95% CI 1.305–1.611). Among app users, male users reported less frequent use of diet-oriented apps but more frequent use of weight-gaining apps as did younger users (13-18yrs). Underweight app users reported more frequent use of weight loss apps while obese users reported less frequent use of exercise-related apps (all $p < .05$). There was a positive relationship between app use and drive for thinness (EDI-3), self-reported excessive exercise (EPSI), internalizing, and social support, and for neuroticism with weight loss apps and conscientiousness with exercise-related apps, respectively (all $p < .05$). Significant differences were also found based on age, BMI, and gender in the frequency of use and value of specific app functions such as those for monitoring, planning, comparing with others, and communicating with others, along with differential impact of app use on self-reported outcomes. These data unveil the motives and expectations of nutrition, weight management and fitness website users with respect to smartphone apps, helping inform subsequent development of mobile intervention strategies in this non-US based select population.

REDUCING THE PATIENT INTERVAL FOR BREAST CANCER: THE DEVELOPMENT OF A DIGITAL INTERVENTION USING THE PERSON-BASED APPROACH

Emma M. Carr, BA (Hons), HDip (Psych), MSc (HlthPsych) [1], Jane C. Walsh, BA, PhD[2], AnnMarie Groarke, BA, MA, HDipED, PhD, AFPsSI, CPsychol[1]

[1]School of Psychology, National University of Ireland, Galway, Galway, Galway, Ireland; [2]National University of Ireland, Galway, Galwau, Galway, Ireland

Background

Early detection of breast cancer increases survival rates. The key to improving early detection is decreasing the Patient Interval. This refers to (i) the time taken to interpret a bodily change and (ii) the time taken to act upon that change and seek help from a health care professional (HCP). The most successful interventions designed to decrease the Patient Interval to date have been delivered by a HCP in a clinic setting. HCP delivered interventions however are costly and time intensive. A novel way to decrease the Patient Interval is through a digital intervention (DI). Research to date has established that DIs are a feasible and acceptable way to deliver healthcare interventions. Furthermore, interventions incorporating public and patient involvement throughout the design process are more successful. This study represents phase one of the Person-Based Approach (PBA) to intervention development. This approach is meant to complement the traditional evidence- and theory-based approaches to intervention development while including end-user input at multiple stages of design process.

Objectives

The objective of this study is to complete phase one of the PBA by eliciting feedback from potential end-users of the (currently) hypothetical DI that will then be used to shape the design of the DI. The study aimed to facilitate broad discussion about the acceptability of a hypothetical DI with end-users.

Research Design

A qualitative design was used to collect data via focus group interviews which were audio-recorded, transcribed verbatim and thematically analysed. Participants (n=28) were sampled purposively based on age, sex and occupation and were either individuals who would potentially use the DI i)for their own healthcare purposes or ii) in an official capacity to recommend to others e.g. Doctors.

Results

Five theme’s emerged: uncertainty, interest, legitimacy, aesthetics/usability, efficiency. Participants expressed uncertainty that a website could help them manage their health but they were interested in trying it. Participants highlighted time as a primary barrier to using a website for this purpose. It was stressed that the website would have to be aesthetically pleasing and easy to use. Furthermore is was discussed that it should be obvious that it was provided by a reputable source e.g. a university/hospital so that they could trust the information provided.

Conclusion

Participants were eager and motivated to contribute to research at this early stage. It is now accepted as good practice to elicit end-user/patient views at the design phase of interventions. It is hoped that incorporating the views of theses participants will enhance the acceptability and therefore success of the DI.

Future Plans

These results will be combined with a literature review of both qualitative and quantitative research to allow the research team to design the DI.

ENHANCING CARE OF THE AGING AND DYING IN PRISONS (ECAD-P): USABILITY OUTCOMES FOR AN END-OF-LIFE TECHNOLOGY TRAINING IN PRISONS

Valerie H. Myers, PhD[1], Susan J. Loeb, PhD, RN, FGSA, FAAN[2], Brenda L. Baney, MS[2], Sophia M. Strickfaden, BA[1], Janice Penrod, PhD, RN, FGSA, FAAN[2]

[1]Klein Buendel, Inc., Golden, CO; [2]Pennsylvania State University, University Park, PA

About 18% of U.S prison inmates are 50 years or older. The growth of the older inmate population increases burden of care on prisons. Inmates are significantly more likely to have chronic conditions or disability, and despite advances in the free world, best practices for managing geriatric issues and end-of-life care (EOL) have not be adapted for use in corrections settings. Geriatric and EOL care training via technology has had a marked impact on disseminating best practices. However, these technology approaches have been inaccessible within prison walls due to the need to maintain care, custody, and control. *Enhancing Care of the Aging and Dying in Prisons (ECAD-P;* R41AG049570*)* was a Phase I Small Business Technology Transfer (STTR) project that examined the acceptability and feasibility of developing a media-rich, technology-based program for training prison staff on geriatric and EOL care. Previously developed and tested empirical materials for this setting and population were adapted using instructional designapproaches and then programmed into an interactive, web-based prototype. The prototype was evaluated by multidisciplinary prison staff on its user interface, ease-of-use, perceived barriers, and for understanding and optimizing the organizational culture for implementation. *ECAD-P* contained three modules each with multiple interactive features (e.g., drag and drop, hover, click and reveal, video, etc.) and a quiz. Usability and acceptability were tested to identify and rate the severity of potential problems (n=16) with staff from two state correctional institutions (SCIs). Actions, eye movements, utterances, and problems encountered were observed, and the System Usability Scale (SUS), a validated tool for assessing the usability and acceptability of technology-based products, served as the criterion measure.The SUS score was 87.8% (68% is “above average”) suggesting a high level of acceptability and usability for visual design, functionality, and content. Fisher’s exact and Wilcoxon Mann-Whitney tests were conducted to assess whether there were any differences in usability outcomes between the two SCI facilities. Analyses revealed non-significant findings (*p*s > .05) suggesting there were no significant differences among usability testers regardless of their SCI affiliation.Additional usability results, the design and development process for creating *ECAD-P*, and programming updates on the recently funded Phase II project will be presented.

INTEGRATING THREE EVIDENCE-BASED PROGRAMS TO CONSTRUCT A RURAL COMMUNITY-BASED CARDIOVASCULAR DISEASE PREVENTION PROGRAM

Rebecca Seguin, PhD, CSCS[1], Meredith Graham, MS[1], Lynn Paul, Ed.D., RDN[2], Anna Diffenderfer, MS, RDN, LN[3], Emily Morgan, PhD, MPH[1], Galen Eldridge, M.S.[2], Miriam Nelson, Ph.D.[4], Sara Folta, PhD[5]

[1]Cornell University, Ithaca, NY; [2]Montana State University Extension, Bozeman, MT; [3]Montana State University, Department of Health and Human Development, Bozeman, MT; [4]University of New Hampshire, Durham, MA; [5]Tufts University, Boston, MA

BACKGROUND: Strong Hearts, Healthy Communities (SHHC) is a lifestyle modification program that aims to reduce body weight, improve dietary habits, and promote physical activity among overweight/obese women aged 40 and older.

METHODS: Program development included in-depth community assessments and integration of core concepts from three nationally disseminated evidence-based curricula. In 10 medically underserved rural towns in Montana, 17 focus groups were held with 126 sedentary, overweight/obese adults aged 40-91 years; 30 key informant interviews were conducted with community leaders, educators, and healthcare providers; 10 community assessments were conducted by local educators and researchers. The focus group and key informant topic guides focused on barriers and enablers to health (nutrition, physical activity, and tobacco) and access to healthcare services. Findings from the community assessments and qualitative data informed the integration of three evidence-based programs to create the SHHC curriculum.

RESULTS: The resulting SHHC is a 24-week program with twice weekly hour-long classes, plus six out of class community-focused sessions. SHHC components include progressive strength training, aerobic exercise, nutrition education, and civic engagement. The program has 13 evidence-based behavioral aims and is divided into three phases: (1) Get moving and eat well (Weeks 1-8); (2) Assess individual progress and create supportive community (Weeks 9-16); (3) Maintenance strategies and social support for healthy lifestyle (Weeks 17-24).

CONCLUSION: Integrating formative data with multiple evidence-based curricula into a comprehensive, tailored program presents unique opportunities and challenges. Based upon preliminary feedback, future implementation should consider the timing and framing of content as well as dose adjustments.

NURSE COORDINATOR ADOPTION OF AN ADAPTED, EVIDENCE-BASED WEIGHT LOSS PROGRAM: A HYBRID EFFECTIVENESS-IMPLEMENTATION TRIAL

Paul A. Estabrooks, PhD[1], Sarah Johnson, MCHES[2], Fabio Almeida, PhD[1], Anne Jessie, DNP, RN[3], Deirdre Rea, MSN, RN[3], Wanda Bowman, RN[3], Caroline Butt, RN[3], April Vaughan, RN[3], Mark Greenawald, MD[3], Sarah Frazier, RN[2]

[1]University of Nebraska Medical Center, Omaha, NE; [2]Virginia Tech/Carilion Clinic, Roanoke, VA; [3]Carilion Clinic, Roanoke, VA

The purpose of this study was to determine, if, when compared to a continuing medical education (CME), a consultee-centered implementation strategy (IS) with goal setting and feedback would improve the reach, effectiveness, adoption, implementation, and sustainability of an adapted evidence-based weight loss intervention that included 20 patient sessions over 12 months (Healthy Lifestyles). The IS included a 2.5 hour CME workshop and a package of ready-to-deliver Healthy Lifestyles resources but added ongoing consultation at 1-3-6, and 12-months to address patient recruitment and engagement in Healthy Lifestyles. In addition, electronic medical record smart-phrases were used facilitate and document Healthy Lifestyle session completion, fidelity, and costs. All nurse care coordinators in a regional health care system participated (n=45) and 14 nurses in one region received the IS. Reach did not significantly differ over 12 months (n=14±21.9/CME nurse; n=24±31.4/IS nurse), but IS trained nurses were significantly more likely to adopt Healthy Lifestyles (100% vs 61%, p=5% weight loss was higher for patients that received the intervention from IS trained nurses (14% CME; 19% IS, $p < .05$). By 12 months there were no differences in weight loss (-2.1±5.9 CME; -2.4±6.5 IS) or the proportion reaching a 5% weight loss (14% CME; 16% IS). Consultation and action planning may accelerate adoption and organizational maintenance of evidence-based weight loss programs compared to a CME approach while supporting a higher proportion of patients to achieve a clinically meaningful weight loss, though a focus on weight loss maintenance in future trainings appears warranted.

RETURNING AGGREGATE RESEARCH RESULTS TO PARENTS OF YOUTH IN A DISEASE REGISTRY: ADVANCING PATIENT-CENTERED OUTCOMES RESEARCH

Elissa R. Weitzman, ScD, MSc[1], Kara M. Magane, MS[2], Lauren E. Wisk, PhD[1]

[1]Boston Children's Hospital and Harvard Medical School, Boston, MA; [2]Division of Adolescent/Young Adult Medicine, Boston Children's Hospital, Portsmouth, NH

Background. To improve the evidence base about pediatric onset chronic disease, sustainable approaches are needed for engaging cohorts in providing patient-reported outcomes (PROs) about child wellbeing, disease and treatment experiences. Returning research results has been touted as a means for contextualizing healthcare decision-making and motivating research engagement, areas of top national interest. We tested whether returning aggregate research results (ARR) to parents of children with rheumatic disease (RD) would affect interest in research participation and spur action on behalf of a child.

Methods. Parents of children enroled in a national clinical rheumatic disease registry provided validated PROs about child quality of life, disease and treatment experiences, side effects and problems (response rate: 69.2%). Subsequently, parents viewed ARR in the form of a slide-deck of curated, annotated data about cohort patterns of these measures and then reported their reactions and the perceived value of this information. We used principal components analysis (PCA) to analyze reaction patterns elicited by ARR and multivariate logistic regression to model the effect of reaction patterns on interest in future research participation and planned next steps.

Results. Among 196 participating parents, 107 (54.6%) received ARR; 89 did not. Groups did not differ on measures of child socio-demographics, clinical characteristics, or disease and treatment PROs. Parents perceived ARR as “very valuable” for understanding their child’s condition and making care decisions; 76.6%, 57% and 41% reported ARR to be "very valuable" for understanding medication side effects/problems, pain interference, and morning stiffness, respectively. PCA identified two ARR reaction domains from 6 questions: Affirmation/Validation (AV) of own experiences and Information Burden (IB). Overall, 54.2% of parents reported being *more* interested (versus less or unchanged) in participating in future research after seeing ARR. Parents with higher AV scores had twice the odds of reporting more interest in future research compared to those with lower AV (AOR=2.04; 95%CI:1.20-3.50). IB scores were related to planned actions: Compared to parents with lower IB scores, those with higher IB were less likely to discuss ARR with their child (AOR=0.60; 95 CI:0.36-0.98), and more likely to discuss ARR with providers (AOR=1.81; 95%CI:1.04-3.16).

Conclusion. Returning ARR to cohorts may foster a “virtuous cycle” of sustainable research engagement to advance patient reported outcomes research and affect planned actions to share and discuss ARR in support of a child’s chronic disease care and treatment via a model with high translation potential across pediatric chronic disease.

SETTING THE STAGE FOR ENGAGING COMMUNITY IN EVIDENCE-BASED PROGRAMS TO REDUCE TYPE 2 DIABETES

Nicole Vaughn, PhD[1], Crystal Wyatt, N/A[1], Beatriz O. Reyes, DrPH[2], Kimberly Kalupa, PhD[3], Kimberly Arnold, MPH[4], Laura Hunter, MPH[5], Longjian Liu, MD, PhD, MSc, FAHA[1]

[1]Drexel University School of Public Health, Philadelphia, PA; [2]Northwestern University, Evanston, IL; [3]University of New Mexico, Albuquerque, NM; [4]Johns Hopkins University, Baltimore, MD; [5]GlaxoSmithKline, Philadelphia, PA

Diabetes is one of the top 10 leading cause of death in urban settings such as Philadelphia. Unfortunately, African Americans have the highest rate of diagnosed diabetes. Thus, there remains a critical role for understanding how community, academic and industry partnerships can operate to engage with and offer evidence-based programs that align with a community's need to reduce health disparities, particularly for minority and high-need populations. The Getting People in Sync (GPS) study worked with lay facilitators to implement a diabetes prevention program. Implementation strategies of the GPS study across the partners included a multi-step process involving church identification, memorandums of understanding, a detailed communication plan, non-disclosure agreement, as well as facilitator and data training sessions. While this program demonstrated that intervention participants could lose weight (-7.96 lbs., SD=10.62; t(56)=-5.66 p < .000), aspects of the partnership were critical to the successful implementation in the community. Lessons learned from this multi-sectorial partnership included communication, connectivity, seasonality and training needs. Additional considerations for implementation included flexibility in timelines for legal documentation. In conclusion, community, academic and industry partnerships can be models for implementation of quality evidence-based programs that have measurable and clinically meaningful outcomes however, more information discussing successes and challenges across these types of partnerships is needed.

USING CBPR TO UNDERSTAND LOCAL COLLABORATIONS ADDRESSING CVD RISK

Phenesse Dunlap, MPH[1], Leah Frerichs, PhD[2], Brenda Boone, .[3], Shirley McFarlin, BA[4], Giselle Corbie-Smith, MD, MSc[1]

[1]UNC Center for Health Equity Research, Chapel Hill, NC; [2]UNC Department of Health Policy and Management, School of Public Health, Chapel Hill, NC; [3]James McFarlin Community Development, Rocky Mount, NC; [4]James Mcfarlin Community Development, Inc., Rocky Mount, NC

Introduction: Rural African Americans suffer from considerable cardiovascular disease (CVD) disparities that no single agency can address alone. Inter-organizational networks and collaboration can impact a community's capacity to address CVD by influencing activities such as coordination of services, diffusion of information, and adoption of evidence-based interventions. In rural African American communities, grassroots community-based organizations (CBOs) and faith-based organizations (FBOs) potentially play a critical role in these activities; yet, we have limited understanding how they collaborate. The objective of our study is to describe the inter-organizational networks among CBOs and FBOs in a rural, African American community and explore factors that influence their collaboration around CVD-related activities. **Methods:** We used a mixed-methods CBPR approach to develop a survey and in-depth interview guide using existing network and collaboration assessment tools. We used respondent-driven sampling to establish a census of organizations currently collaborating on CVD-related activities and services. We completed surveys with an initial seed sample of n=53 organizations and are currently in the process of conducting additional surveys and interviews to obtain a more comprehensive understanding of collaboration. **Results:** About half (n=25, 49%) of the seed sample of fifty-three CBOs and FBOs are currently collaborating with at least one other organization on CVD-related activities. They most commonly indicated collaboration with one of 11 healthcare service agencies (e.g., hospitals, county health departments). Few (n=4) indicated collaboration with other CBOs/FBOs, and preliminary results indicate current network density for CVD collaboration is low, 0.06. A non-profit healthcare system and a community health center had the highest betweenness centralities (i.e., are key connectors between other organizations in the community). **Conclusions:** This CBPR approach was successful in identifying inter-organizational networks of CBOs and FBOs and will improve understanding of factors that influence collaboration. We will use the findings to identify strategies for creating stronger partnerships and will continue to collect information over time in order to understand how networks influence CVD services in the community such as adoption of evidence-based CVD interventions.

CONCEPTUALIZATIONS OF PRIVACY AMONG EARLY ADOPTERS OF EMERGING HEALTH TECHNOLOGIES

Cynthia Cheung, MPH/MA (c)[1], Matthew J. Bietz, Ph.D.[2], Kevin Patrick, MD, MS[3], Cinnamon S. Bloss, Ph.D.[1]

[1]University of California - San Diego, La Jolla, CA; [2]University of California, Irvine, Irvine, CA; [3]UCSD, La Jolla, CA

Introduction: Advances in health technology such as genome sequencing and wearable sensors now allow for the collection of highly granular personal health data from individuals. It is unclear how people think about privacy in the context of these emerging health technologies. An open question is whether early adopters of these advances conceptualize privacy in different ways than non-early adopters. **Purpose:** This study sought to understand how early adopters of emerging health technologies conceptualize privacy. **Methods:** Transcripts from in-depth, semi-structured interviews with early adopters of genome sequencing and health devices and apps were analyzed with a focus on participant attitudes and perceptions of privacy. Themes were extracted using inductive content analysis. **Results:** Interviewees were proponents of sharing personal data to support scientific advancements, however they still voiced concerns, as well as uncertainty about who has access to their data, and for what purpose. In short, they were not dismissive of privacy risks. Key privacy-related findings are organized into four themes: (1) contributing personal data to science; (2) concerns about discrimination; (3) control over personal information; and (4) personal data security. **Conclusion:** Early adopters of emerging health technologies appear to have more complex and nuanced conceptions of privacy than might be expected based on their adoption of personal health technologies and participation in open science. Early adopters also voiced uncertainty about the privacy implications of their decisions to use new technologies and share their data for research. Though not representative of the general public, studies of early adopters can provide important insights into evolving conceptions of privacy in the context of emerging health technologies and personal health data research.

FITSPO AT EVERY SIZE?: A CONTENT ANALYSIS OF #CURVYFIT VS. #CURVYYOGA INSTAGRAM IMAGES

Jennifer B. Webb, Ph.D.[1], Victoria N. Clark, B. S. Student[1], Elizabeth N. Burris, B. S. Student[2], Davina Y. Putz, B. S.[1], Erin R. Vinoski, MPH, CHES[1]

[1]UNC Charlotte, Charlotte, NC; [2]North Carolina State University, Raleigh, NC

Recent scholarship indicates that “fitspiration” or “fitspo” content posted to popular Internet sites frequently conflates notions of “health” and “fitness” with a thin-toned athletic appearance ideal and conveys problematic themes emphasizing weight loss, body objectification, and aspects of disordered eating. To extend this burgeoning line of research, the present study examined how aspects of fitness were represented in more size-inclusive social media contexts. The current analysis compared relevant themes depicted in images posted to #curvyfit versus #curvyyoga on Instagram. Three hundred images (i.e., 150 per hashtag) were systematically coded for type (i.e., visual, text, visual + text) and for the following key thematic content domains: 1) image attributes (e.g., gender, race/ethnicity, body size, and body shape), 2) health-exercise focus (e.g., health or fitness at any size, functional body pride, problematic relationship with exercise, etc.), and 3) weight-appearance focus (e.g., weight loss, body skin exposure, objectifying attire, etc.). Categorical tests of association and ANOVA models were computed to address the primary study aims. Overall, the findings indicate that #curvyyoga posts exhibit greater inclusion of individuals with higher body weights ($p < .001$) and rounder body shapes ($p < .001$) and tend to represent health and fitness in terms of body competence (e.g., endorsing health/fitness at every size: $p < .001$; performing an action: $p < .001$; functional body pride: $p < .001$). Conversely, like traditional “fitspo” content, #curvyfit images more often convey appearance-focused and objectified attributes of “fitness” (e.g., weight loss: $p < .001$; bare midriff: $p < .001$; bare thighs/legs: $p < .01$; visible cleavage: $p < .001$). Preliminary results help clarify the ways in which the Health at Every Size® health promotion paradigm is disseminated and differentially actualized among peers in social media contexts who identify as “curvy”. Findings also contribute to illuminating how such content could help transform current stereotypes regarding the embodiment of “fitness” along with who can and does practice yoga.

HEALTHCARE PROVIDER ADVICE ON GESTATIONAL WEIGHT GAIN: UNCOVERING A NEED FOR MORE EFFECTIVE WEIGHT COUNSELING

Rebecca L. Emery, MS[1], Rachel P. Kolko, PhD[2], Michele D. Levine, PhD[3]

[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University Of Pittsburgh, Pittsburgh, PA

Women who gain excessive gestational weight are at risk of serious health complications both during and after pregnancy. In an effort to reduce the disease burden associated with excessive gestational weight gain (GWG), the Institute of Medicine reissued guidelines for GWG that are based on prepregnancy body mass index (BMI). However, limited research has assessed whether women are adequately counseled on these revised GWG guidelines by their healthcare providers. Participants for the present study were women who began pregnancy overweight or obese (N = 116) and who were enrolled in a larger study assessing changes in disordered eating symptoms and other psychological variables across the perinatal period. Between 12 and 20 weeks gestation, women provided demographic information and were asked to report whether they knew the recommended amount of gestational weight they should gain during their current pregnancy. At 6 months postpartum, women were asked whether a healthcare provider, such as a doctor, nurse, or midwife, ever advised them on weight gain during pregnancy and how much weight they were told to gain. On average, women were 27.08 ± 5.26 years of age and 60% (n = 69) were black. At the beginning of pregnancy, 48% (n = 56) of women reported knowing how much gestational weight to gain. However, only 52% (n = 29) of these women reported a GWG within the recommended range for their prepregnancy BMI. Women were more likely to have knowledge on appropriate GWG if they were more highly educated, had a greater income, were white, or began pregnancy overweight (ps < 0.02). Interestingly, only 35% (n = 41) of women received specific advice about GWG from a healthcare provider, and only 39% (n = 16) of these women were instructed to gain weight within the recommended range for their prepregnancy BMI. Healthcare providers were more likely to appropriately inform women about GWG if they began pregnancy overweight and tended to advise women who began pregnancy obese to gain more weight than what is recommended ($p = 0.03$). Taken together, these findings indicate that women who belong to a racial minority group, are socioeconomically disadvantaged, or begin pregnancy obese are less likely to be knowledgeable on appropriate GWG and that healthcare provider advice on GWG is largely insufficient and may be inappropriate. Thus, there is room for behavioral interventions to aid both in the delivery of

education about GWG and in the management of weight gain during pregnancy among overweight and obese women.

INFLUENCE OF PARENTAL HEALTH LITERACY ON REACH, RETENTION, AND OUTCOMES IN A FAMILY-BASED CHILDHOOD OBESITY TREATMENT PROGRAM

Jamie Zoellner, PhD, RD[1], Jennie L. Hill, PhD[2], Wen You, Ph.D.[3], Donna Brock, MS[1], Madlyn Frisard, PhD[1], Ramine Alexander, PhD, MPH[4], Fabiana Brito, BSN, MSPH, PhD[5], Bryan Price, BS[6], Ruby Marshall, RN,BSN,CPC[7], Paul A. Estabrooks, PhD[2]

[1]Virginia Tech, Blacksburg, VA; [2]University of Nebraska Medical Center, Omaha, NE; [3]Virginia TEch, Blacksburg, VA; [4]UNC Center for Health Promotion and Disease Prevention, Durham, NC; [5]University of Nebraska Medical Center, La Vista, NE; [6]Danville River District Consulting, Danville, VA; [7]Danville / Martinsville Physician Practices, Danville, VA

Introduction. Few interventions have evaluated the influence of parent health literacy (HL) status on weight-related child outcomes. This study explores how parent HL impacts the reach, attendance, retention, and outcomes from a three-month multi-component family-based childhood obesity treatment program (iChoose).

Methods. This pre-post, quasi-experimental trial occurred in the Dan River Region, a federally designated medically underserved area. iChoose research protocol and intervention strategies were designed using a HL universal precautions approach. Validated measures and standardized data collection techniques were used, along with generalized linear mixed effect parametric models to determine the moderation effect of parent HL on outcomes.

Results. There was no statistically significant difference in HL scores between parents who enrolled their child in the study [14.07 (1.52)] and parents who did not [14.13 (1.37)]. Of 94 enrolled parents, 34% were low HL, 49% income < $25,000, and 39% <high school education. Of 101 enrolled children, 61% were black, and the mean age was 9.8 (1.3) years. Children with low and high HL parents attended and were retained at similar rates. Significant main effect improvements were observed for child BMI z-score [-0.05 (0.02)], ounces of SSB [-9.06 (3.17)], and quality of life [3.00 (2.74)] and for parent BMI [-0.28 (0.04)], minutes of moderate to vigorous physical activity [110.64 (40.74)], servings of fruits and vegetables [0.58 (0.27)], and ounces of SSB [-6.63 (0.37)]. Parent HL status did not significantly influence improvements in these outcomes, with the exception of child video game/computer screen time (coefficient 0.52, SE=0.11, $p < 0.001$; low HL decreased, high HL increased).

Conclusion. By incorporating design features that attended to the HL needs of parents/caregivers, children with low HL parents engaged in and benefited from a family-based childhood obesity treatment program similar to children with high HL parents.

SELF-DETERMINATION THEORY, INTEREST IN AN MHEALTH INTERVENTION FOR IMPROVING EXERCISE, AND EXERCISE MOTIVATION

Arturo Durazo, BA, Linda D. Cameron, Ph. D. , Roberto Corona, BA psychology, Martha P. Blanco, BA

University of California, Merced, Merced, CA

With a mixed-methods approach, we examined the acceptability of HealthyYouTXT-Physical Activity, an mHealth intervention developed by the US National Cancer Institute and self-determination theory's (SDT) motivations as predictors of physical activity intentions. The mHealth program is grounded in SDT, which predicts that intrinsic motivations, over extrinsic motivation and amotivation, promotes intentions. The study was conducted in California's Central Valley, a majority-Hispanic region with high poverty and low education levels.

A community sample of 130 (61% female; M age=32, range=18-76), completed an initial survey and structured interview in English (n=102) or Spanish (n=28). Participants received and reviewed SMS text messages from the HealthyYouTXT-Physical Activity in English or Spanish. Participants identified as Hispanic (62%), White (22%), Asian (9%) and Black (5%); 25% had 12th grade education or less; 37% were unemployed.

Thematic analyses of interviews revealed that most participants viewed the program favorably. Many expressed strong interest in using it to overcome barriers such as amotivation, work/family demands, lack of support, and weather conditions. Age-related differences in receptivity to the program included younger adults being motivated by its utility to assist in weight control and older adults being drawn to its potential to improve health and longevity. Those who were already physically active perceived the program as a valuable maintenance tool. Surprisingly, the program was viewed as a valuable source of extrinsic motivation that would hold users accountable to adherence. Regression analyses revealed that extrinsic motivation was the strongest predictor of physical activity intentions (B=.26, $p <$ .01); intrinsic motivation and amotivation were not significant predictors. Interviews revealed positive evaluations and demand for the HealthyYouTXT program among adults in rural areas. Although the program is grounded in SDT and based on promoting intrinsic motivation, extrinsic motivation emerged as the primary predictor of physical activity intentions. Future research can further explore extrinsic motivation as a target of this and other mHealth programs, particularly for ethnically diverse populations.

THE ROLE OF MENTAL ILLNESS IN THE SELECTION OF SOURCES FOR HEALTH INFORMATION

Jennifer A. Lueck, Ph.D.

Texas A&M University, College Station, TX

Depression and anxiety symptoms make up a large proportion of the global disease burden of mental illness. Although there is evidence that depression and anxiety symptoms might make coping and seeking help particularly difficult, less is known about the specific patterns in which affected individuals engage with sources of health information – patterns that could inform effective health communication interventions. Using 2014 data from the nationally representative Health Information National Trends Survey, the present research tested the effects of depression and anxiety symptoms (e.g., "Over the past 2 weeks, how often have you been bothered by –little interest or pleasure in doing things/feeling down, depressed, or hopeless/feeling nervous, anxious, or on edge/not being able to stop or control worrying?") on engagement with health information ("The most recent time you looked for information about health or medical topics, where did you go first?"). Confirming previous findings in the literature, preliminary results from binary logistic regression analyses indicated that more severe symptoms of depression showed a negative relationship with seeking health information from health professionals (OR=.81, 95%CI=.67-.98), indicating a preference for internet sources, whereas mild symptoms of depression showed a positive relationship with seeking health information from health professionals (OR=1.32, 95%CI=1.12-1.56). Anxiety symptoms, on the other hand, showed a strong positive relationship with seeking health information from health professionals (OR=1.23, 95%CI=1.03-1.47) and a negative relationship with seeking health information from internet sources (OR=.80, 95%CI=.69-.93). An encouraging result emerged from the data – neither depression nor anxiety symptoms showed a negative relationship with seeking health information from interpersonal sources, suggesting potentially effective pathways for reaching highly vulnerable individuals with health information. Implications for the design and dissemination of such interventions will be discussed.

A MOBILE APP TO PROMOTE ART ADHERENCE AND FRAMED IN THE INFORMATION-MOTIVATION-BEHAVIOR SKILLS MODEL: BASELINE DATA

Marcia Holstad, PhD, FNP-BC[1], Melinda Higgins, PhD[2], Igho Ofotokun, MD, MSc[3], Eugene Farber, PhD, ABPP[3], Drenna Waldrop-Valverde, PhD[1]

[1]Emory University, Atlanta, GA; [2]Emory University, Decatur, GA; [3]Emory University School of Medicine, Atlanta, GA

Rural HIV + populations often have difficulties adhering to antiretroviral therapy (ART). The Music for Health Project (MFH) is a randomized controlled trial that tests the efficacy of a smart phone application (app) on ART adherence and symptom self-management in rural Georgia. The intervention app contains a music-based messaging program and manual designed to educate and motivate HIV+ rural dwelling persons to adhere to ART and self-manage symptoms and side effects. The control app contains a general education program in a comparable format. Eligibility criteria are HIV+ and: ART naïve or ART change due to drug resistance or detectable VL or ART prescribed. We analyzed baseline data of all 149 enrolled to examine associations of self-report ART adherence (3 scales) self-efficacy (2 scales), ART motivation, depressive symptoms (CESD-R), and HIV health literacy with the components of the Information-Motivation-Behavior (IMB; Life Windows Scale) model and determine if differences existed by eligibility groups and demographics. Analyses included descriptive statistics, Spearman's rho correlations, Mann Whitney tests and Kruskal-Wallis ANOVA. The average age of the group was 39.1 years old, 66% were male, 77% African American (AA) and 48% self-reported as heterosexual. The majority (80%) lived with others versus alone; and 16% lived with another HIV+ person. The regimen change and treatment naïve groups had higher Information scores ($p=.048$). AA had higher Behavior skills scores ($p=.041$). Higher ART Information, Motivation and Behavior skills scores were significantly correlated with better self-reported adherence ($p < .001$), higher self-efficacy for symptom self-management ($p < .05$) and ART adherence ($p < .001$), and higher intrinsic motivation for adherence ($p < .001$). Higher HIV health literacy was associated with higher Information scores ($p=.015$). Depressive symptoms were associated with lower Motivation and Behavior scores ($p < .001$). These data support use of the IMB model for ART adherence behavior technology interventions for rural dwelling HIV+ persons.

ACCEPTABILITY OF A SMOKING CESSATION AND EMOTION REGULATION INTERVENTION FOR ADULTS LIVING WITH HIV

Jessica N. Coleman, BA[1], Allison K. Labbe, PhD[2], Julianne G. Wilner, M.A.[3], Samantha M. Marquez, MSW[4], Jesse D. Kosiba, BA[5], Michael J. Zvolensky, PhD[6], Jasper Smits, PhD[7], Conall O'Cleirigh, PhD[2]

[1]Massachusetts General Hospital, Cambridge, MA; [2]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [3]Boston University, Boston, MA; [4]Fenway Health, Boston, MA; [5]Syracuse University, Syracuse, NY; [6]Department of Psychology, University of Houston, Houston, TX; [7]Department of Psychology, University of Texas at Austin, Austin, TX

Background: The prevalence of cigarette smoking among persons living with HIV (PLWH) is three times that of the general population. PLWH who smoke experience greater morbidity and mortality than non-smokers and tobacco use is associated with poorer HIV-related health outcomes among this population. Similarly, mood and anxiety disorders are especially common among PLWH. We developed a novel 8-week, integrated, transdiagnostic cognitive-behavioral intervention for PLWH aimed at (1) promoting successful smoking cessation, and (2) improving emotion regulation skills. The aim of this study was to assess the acceptability of the intervention via qualitative interviews and preliminary outcome data.

Methods: HIV+ smokers were recruited from a community health center and an infectious disease clinic at a large medical center in Boston, MA. Exit interviews were conducted with a subsample of participants (N = 10, 90% Male, 50% Black/African America and 40% White, Mcpd = 17.64) who completed through the 6-month follow-up visit. Interviews were recorded, transcribed, and analyzed using an iterative approach.

Results: The majority of participants indicated that quitting smoking, becoming healthier, and finishing what they started were primary motives for starting and completing the intervention. Participants reported that the homework, handouts, and cognitive restructuring skills were helpful in quitting smoking, whereas thought tracking and awareness aspects were reported as helpful for managing distress. Five of the participants described using intervention components to maintain abstinence at their 6-month follow-up, and almost half of the participants reported using skills learned in treatment to manage distress. Participants described some aspects of the treatment as challenging (i.e., using the patch consistently, delaying smoking a cigarette, practicing certain skills), but also indicated that these aspects were helpful. All participants reported that they would recommend the treatment to others.

Five participants had quit completely and four participants reduced the amount of cigarettes smoked per day by the 6-month follow-up.

Discussion: Overall, participants found this newly developed treatment to be acceptable. Preliminary outcome data suggest the intervention was successful in helping participants to quit or reduce smoking at the 6-month follow-up. Further randomized controlled studies are needed to test the efficacy of this novel, transdiagnostic treatment.

ADHERENCE TO PRE-EXPOSURE PROPHYLAXIS FOR HIV AND SEXUAL RISK COMPENSATION AMONG MEN WHO HAVE SEX WITH MEN AND TRANSGENDER WOMEN

Michael J. Li, M.P.H.[1], Joel Milam, Ph.D.[1], Michael Dube, MD[1], Jessica Tobin, M.A.[1], Katya Corado, MD[2], Eric Daar, MD[2], David J. Moore, Ph.D.[3], Sheldon Morris, MD, MPH[4]

[1]Keck School of Medicine, University of Southern California, Los Angeles, CA; [2]Los Angeles Biomedical Research Institute at Harbor-UCLA Medical Center, Torrance, CA; [3]UCSD HIV Neurobehavioral Research Program, San Diego, CA; [4]UCSD Antiviral Research Center, San Diego, CA

Introduction: There is mixed evidence suggesting that use of pre-exposure prophylaxis for HIV prevention predicts increases in sexual risk behaviors, also known as sexual risk compensation. It is unclear whether the degree of change in risk behavior depends on how well a PrEP user adheres to the regimen.

Objective: The purpose of this study is to test whether adherence to PrEP affects changes in sexual risk behavior among a cohort of men who have sex with men initiating PrEP.

Methods: Participants (N = 377, mean age 35.1 yrs; 28.9% Latino, 11.4% Non-Hispanic Black, and 9.3% other non-White) were obtained from multiple clinics in Southern California taking part in a PrEP demonstration study and were followed for 60 weeks following PrEP initiation. Self-reported PrEP adherence and sexual risk behaviors in past 4 weeks were assessed after baseline at 4 , 12, 24, 36, 48, and 60 weeks, with participants who self-reported having ever missed a dose within the prior 4 weeks considered non-adherent. We used negative binomial mixed modeling, adjusting for age, race (White or non-White), drug abuse, clinic site, and study arm to test whether adherence to PrEP predicts changes in prior-4-week sexual risk behavior over 60 weeks.

Results: Over 60 weeks, participants overall reported increased unprotected receptive anal intercourse (URAI) acts ($p < .001$). Participants who never missed a dose (ranging 66.6-80.1% across all waves) had a significantly greater increase in URAI ($p = .037$) and UIAI ($p = .002$) in the prior 4 weeks compared to participants who reported imperfect adherence in the prior 4 weeks. Participants who reported imperfect adherence did not significantly change in any sexual risk behavior.

Discussion: Sexual risk compensation behaviors increased following PrEP initiation in those that reported they did not miss a dose in the past 4 weeks. This suggests that PrEP users

conscientiously adhere to F/TDF when they they have increased sexual risk behaviors to minimize HIV acquisition.

BODY IMAGE AND SEXUAL RISK AMONG SEXUAL MINORITY MEN LIVING WITH HIV

Benjamin M. Rooney, B.A.[1], Shadi Gholizadeh, M.Sc., M.S., M.P.H. [2], Erin L. Merz, PhD, MPH[3], Vanessa L. Malcarne, Ph.D.[1], Steven A. Safren, PhD[4], Aaron Blashill, Ph.D. [1]

[1]San Diego State University, San Diego, CA; [2]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA; [3]California State University, Dominguez Hills, Carson, CA; [4]Department of Psychology, University of Miami, Coral Gables, FL

Background: It is unclear under what conditions body image impacts sexual risk behaviors (SRB). It is possible that body dissatisfaction only predicts increased sexual risk for individuals who also have high appearance investment. However, to date, there are no known studies that have examined the interaction of body dissatisfaction and appearance investment in predicting SRB.

Methods: Participants were 105 sexual minority men living with HIV who reported having sex with a man within the previous 12 months. Participants completed a battery of self-report measures, including the Appearance Orientation (AO) subscale from the Multidimensional Body Self-Relations Questionnaire (MBSRQ) as a marker of appearance investment, the Muscle Dysmorphic Disorder Inventory (MDDI) as a marker of body dissatisfaction, and SRB (i.e., a count of the number of condomless anal intercourse acts with HIV-negative or HIV-unknown status male partners in the past 3 months).

Results: A generalized linear model with a Poisson distribution (to account for the count SRB outcome variable) was employed, with the main effects of appearance investment, body dissatisfaction, and their interaction term entered as independent variables. The main effects of appearance investment and body dissatisfaction were non-significant. A significant appearance investment by body dissatisfaction interaction was revealed ($b = .08$, $SE = .03$, 95% CI: .007, .159, Wald $\chi^2 = 4.5$, $p = .033$). To probe this significant interaction, simple slope analyses were conducted, setting values of appearance investment at ± 2 SD from the mean. Results suggested that body dissatisfaction negatively predicts SRB at low levels of appearance investment ($b = -.07$, $t = -1.89$, $p = .06$), whereas it positively predicted SRB at high levels of appearance investment ($b = .10$, $t = 1.9$, $p = .05$).

Conclusions: Appearance investment significantly moderated the relationship between body dissatisfaction and SRB, underscoring the multidimensional impact of body image in SRB for sexual minority men living with HIV. Further understanding of the mechanisms through which

body image concerns impact SRB has the potential to inform future screening and treatment efforts meant to promote psychological well-being and reduce HIV sexual transmission risk behaviors.

EXAMINING THE ACCEPTABILITY OF MHEALTH TECHNOLOGY IN HIV PREVENTION AMONG HIGH-RISK DRUG USERS IN TREATMENT

Roman Shrestha, MPH[1], Frederick Altice, PhD[2], Michael Copenhaver, PhD[3]

[1]University of Connecticut Health Center, Willimantic, CT; [2]Yale University, New Haven, CT; [3]University of Connecticut, Storrs, CT

Introduction: Despite promising trends of the efficacy of mobile health (mHealth) based strategies to a broad range of health conditions, very little if any studies have been done in terms of the examining the use of mHealth in HIV prevention efforts among people who use drugs (PWUDs) in treatment. Thus, the goal of this study was to gain insight into the real-world acceptance of mHealth approaches among high-risk PWUDs in treatment.

Methods: A convenience sample of 400 HIV-negative drug users, who reported drug- and/or sex-related risk behaviors, were recruited from a methadone clinic in New Haven, CT. Participants completed standardized assessments of drug- and sex-related risk behaviors, neurocognitive impairment NCI), and measures of communication technology access and utilization, and mHealth acceptance. Chi-square and t-tests were conducted to examine the statistical differences on ownership or utilization of communication technologies and mHealth acceptance between individuals with and without NCI.

Results: We found a high prevalence of current ownership and use of mobile technologies, such as cell phone (91.5%) including smartphone (63.5%). Participants used mobile technologies to communicate mostly through phone calls (M = 4.25, SD = 1.24), followed by text messages (M = 4.21, SD = 1.29). Participants expressed interest in using mHealth, particularly text messaging service, for medication reminders (72.3%), to receive information about HIV (65.8%), and to assess drug-related (72.3%) and sex-related behaviors (64.8%). Participants who were neuro-cognitively impaired were less likely to own a cell phone (OR = 0.453, χ^2 = 4.976, p = 0.026), particularly smartphone (OR = 0.476, χ^2 = 11.251, $p < 0.05$) and more likely to use cell phone without internet [$t(398)$ = -2.747, p = 0.006, d = -0.301] . Furthermore, individuals who were cognitively impaired were significantly more likely than those without NCI to show interest in using mHealth to remind them to take medication(s) [$t(398)$ = -2.490, p = 0.013, d = -0.262], to receive information about HIV [$t(398)$ = -4.220, $p <$ 0.001, d = -0.437], to assess drug-related risk behaviors [$t(398)$ = -2.003, p = 0.046, d = -0.242], and sex-related risk behaviors [$t(398)$ = -2.617, p = 0.009, d = -0.312].

Conclusions: The findings from this study provide empirical evidence that mHealth-based programs, specifically cell phone text messaging-based health programs, may be acceptable to this high-risk population. Researchers are encouraged to conduct formative research to explore opportunities to integrate cell phone text messaging into HIV prevention programs designed for implementation, followed by practical development, implementation, and evaluation among PWUDs in treatment.

HIV TREATMENT OPTIMISM AS IT RELATES TO PERCEIVED SEXUAL TRANSMISSION RISK IN MSM

Matthew Sullivan, B.A., Seth Kalichman, PhD

University of Connecticut, Storrs, CT

Greater perceived risk of contracting HIV or other sexually transmitted infections has been linked to increased use of protective health measures such as condoms. In the US, men who have sex with men (MSM) are at particularly high risk for HIV infection, and thus these perceptions may be especially consequential for preventing risky sex behavior within this population. Recent research has found that optimism about HIV treatment advances may reduce the perceived risk associated with acts such as unprotected anal sex, thereby potentially increasing risky sex behavior. Thus, treatment optimism may be an important consideration in understanding and reducing sexual risk-taking. This study sought to examine the relationship between HIV status, treatment optimism, and the perceived reduction of HIV transmission risk associated with antiretroviral (ARV) treatment in sample of 318 sexually active MSM recruited at a 2015 Atlanta Gay Pride event (mean age=35.17 years; 96% Caucasian; 17.3% tested HIV positive). To examine this relationship, a mediation model was tested by bootstrapping the indirect effect. As hypothesized, a direct effect of HIV status on perceived risk reduction was found (b=-0.48, 95% Confidence Interval: -0.88 to -0.05, p=0.03), such that HIV-positive men perceived a greater risk reduction associated with ARV treatment than HIV-negative men. However, this effect was not significantly mediated by treatment optimism. One potential reason for this lack of a mediation effect is that treatment optimism was relatively high across all individuals surveyed (mean score of 12.8 (range of 4-16)). When these relationships were examined within HIV status subgroups, no relationship between treatment optimism and perceived risk reduction was found among HIV-positive individuals. However, among nonpositive individuals, greater treatment optimism was associated with greater perceived risk reduction (p=0.057). This finding suggests that optimistic nonpositive individuals may be more likely to perceive HIV treatment as reducing the risk of unprotected anal intercourse with an HIV-positive partner. Such beliefs may predispose such individuals to a greater likelihood of engaging in risky sex behaviors.

PROGRESO EN SALUD, AN HIV RISK REDUCTION INTERVENTION FOR LATINA SEASONAL FARMWORKERS: PRELIMINARY FINDINGS

Mariano Kanamori, PhD[1], Mario De La Rosa, PhD[2], Stephanie L. Diez, MSW[2], Jessica Weissman, MS[1], Mary Jo Trepka, MD[3], Alicia Sneij, MA[1], Peter Schmidt, PhD[4], Patria Rojas, PhD[5]

[1]Center for Research on U.S. Latinos HIV/AIDS and Drug Abuse, Robert Stempel College of Public Health & Social Work, Florida International University, Miami, FL; [2]1 Center for Research on US Latino HIV/AIDS and Drug Abuse, Florida International University, Miami, FL; [3]Department of Epidemiology, Florida International University, Miami, FL; [4]Department of Political Science, University of Gießen, Gießen, N/A, Germany; [5]Health Promotion and Disease Prevention. Florida International University., Miami, FL

Introduction. Latina seasonal workers in the US are an underserved population with limited access to health care and health education. In 2015, the HIV diagnosis rate in South Florida, a region where many Latina seasonal farmworkers reside and work, was the highest among all metropolitan areas in the US (38.8 per 100,000). The lack of culturally tailored evidence-based HIV prevention programs for Latina seasonal workers led to the development and implementation of Progreso en Salud, which is a cultural adaptation of the CDC's evidenced based intervention VOCES/VOICES. We will present preliminary findings of our adapted intervention.

Methods. We measured sex behaviors at baseline and 6-month follow-up among 114 Latina seasonal workers who participated in the Progreso en Salud intervention. Analyses included McNemar's test, Related Samples Marginal Homogeneity Test, Related Samples Wilcoxon Signed Rank Test, and Mediation Analysis.

Results. A higher percentage of women at 6-month follow-up used condoms during the past 30 days every time (13.5% vs. 9.6%) or sometimes (24.0% vs. 17.3%) when they had vaginal and/or anal sex. There was also a decrease in the percentage of women who never used condoms (57.7% vs. 49.0%) when they had sex. There was a significant increase in HIV testing from baseline (15.0%) to 6-month follow-up (27.9%). There were also significant increases in the percentages of HIV/AIDS-related communications with friends, HIV knowledge, condom use self-efficacy, and correct use of condoms. Condom use self-efficacy had a positive effect on the relationships between: (a) HIV knowledge and condom use; and (b) Communication with friends regarding HIV prevention and condom use.

Conclusions. Our results suggest that existing best practice interventions (e.g. VOICES/VOCES) can be tailored to improve HIV knowledge, HIV testing, and condom use among Latina seasonal workers. For such interventions to be successful, they should address Latino cultural values and be conducted in an environment that allows Latina seasonal workers to feel comfortable discussing these culturally taboo and sensitive topics. Our findings suggest that Progreso en Salud may have helped participants increase their knowledge about HIV, assisted with practices regarding condom use, and increased rates of HIV testing. Also, many participants maybe in the process of forming their condom use self-efficacy as a result of the intervention. Future research is needed to support our findings.

PSYCHOSOCIAL CORRELATES OF INSULIN RESISTANCE IN AN ETHNICALLY AND RACIALLY DIVERSE SAMPLE

Violeta Rodriguez, MSEd, Deborah Jones, PhD, Phillip Szewc, Mahendra Kumar, PhD

University of Miami Miller School of Medicine, Miami, FL

Introduction: Methamphetamine (MA) use has increasingly common in the United States and is prevalent among MSM in South Florida (18%). Among HIV infected MSM who report drug use, 43% reported trading sex for MA, and overall, MSM are at great risk for MA use. Long term MA use has been implicated in insulin resistance, which in turn has been associated with sleep disorders, antiretroviral use, trauma, and obesity. Despite the high prevalence of MA use among MSM, insulin levels and associated risk factors have not been assessed in this population. This study examined the relationship between MA use, HIV status, and insulin resistance among ethnically and racially diverse MSM living in South Florida.
Method: Participants (n = 335) were men 18-55 years of age recruited in South Florida, and comprised three groups: 1) HIV uninfected-non-MA-using (HIV-MA-; n = 136, 2) HIV-infected, MA-using, MSM (HIV+MA+; n = 147) and 3) HIV-uninfected, MA using, MSM (HIV-MA+; n = 52). Participants completed assessments on demographics, depression, trauma history, sleep disturbance, and drug use, provided a fasting blood sample to assess glucose and insulin. Body mass index (BMI) was derived from measurement of height and weight and insulin resistance was calculated using the Homeostasis Model.
Results: Participants were aged 18 - 55 years (mean = 37, SD = 9.91). The majority were Hispanic, 60% of participants had completed at least high school, 60% were overweight or obese, and 50% had a monthly income of less than US$500. Groups differed with regard to age, race, income, BMI, insulin resistance and severity of sleep disturbance. Polydrug use was associated with insulin resistance in bivariate analyses, but in multivariable analysis, insulin resistance levels were highest among obese men in comparison with normal weight men, highest among HIV-MA- men in comparison with other groups, and highest among Hispanics in comparison with non-Hispanic whites.
Discussion: Insulin resistance levels among this sample of ethnically and racially diverse methamphetamine-using HIV-negative men were higher than among HIV-infected men, likely due to decreased hunger associated with stimulant use and those participants either overweight or obese in the non-MA group, many of whom were Hispanic. Future studies should explore the association of insulin resistance with a history of marijuana use in comparison to polydrug use, as decreased levels of insulin resistance may also be specific to marijuana use, and continue to examine the relationship between antiretroviral use and insulin levels. Funded by a grant from NIDA, R01DA031201.

SOCIAL ISOLATION AND AFFECT IN OLDER ADULTS LIVING WITH HIV: NEW INSIGHTS USING MOBILE TECHNOLOGY

Alexandra Rooney, B.A.[1], Christopher N. Kaufmann, PhD, MHS[2], Brent Mausbach, PhD[3], Colin Depp, PhD[3], Anne Heaton, N/A[4], Jeremy Delgadillo, N/A[5], Sheena Dev, B.S.[5], David J. Moore, Ph.D.[6], Raeanne C. Moore, PhD[7]

[1]University of California San Diego, San Diego, CA; [2]UC San Diego, La Jolla, CA; [3]University of California San Diego, La Jolla, CA; [4]UCSD HIV Neurobehavioral Research Program, Del Mar, CA; [5]San Diego State University, San Diego, CA; [6]UCSD HIV Neurobehavioral Research Program, San Diego, CA; [7]University of California, San Diego, San Diego, CA

Older adults with HIV are more likely to live alone than their peers without HIV, which puts them at risk for loneliness and social isolation. Social isolation is a major and prevalent health problem, and is an under-assessed condition in older HIV+ adults. The repeated sampling of daily experiences in a naturalistic setting, known as ecological momentary assessment (EMA), offers a potentially useful method for examining social isolation in relation to other health-related factors. We examined the real-time relationship between social interactions with concurrent and future affect and physical symptoms in a sample of older HIV+ adults. Twenty older adults infected with HIV (*Mean* (*M*) age=59; 85% male; 70% Caucasian; *M* current CD4: 476.21; *M* duration of HIV: 20.4 years) participated in one week of intensive daily monitoring via smartphones. Participants' provided five real-time reports per day of their current social functioning (alone vs. not alone and number of social interactions since last report), as well as their current affective state (sadness, stress, happiness), tiredness, and pain. HIV disease characteristics were obtained in-person prior to the EMA portion of the study. Participants spent an average of 63% of their time alone. HIV disease characteristics were unrelated to being alone or number of social interactions. Mixed-effects models showed being alone was related to lower concurrent happiness (*Wald F*=10.22, $p < 0.01$); however, being alone was unrelated to concurrent sadness, stress, tiredness, or pain. The average number of social interactions over the week was unrelated to affect, tiredness, or pain. Within-day time-lagged analyses were conducted with alone vs. not alone at one time point predicting affect and physical symptoms at the next time point. Lagged analyses found participants felt more pain (coef=0.027, p=0.02), were more tired (coef=0.17, $p < 0.001$) but had less stress (coef= -0.05, $p < 0.001$) over the course of the day. Increases in social activity predicted greater increases in tiredness. Our findings support a framework for understanding happiness in the context of social interactions among older HIV+ adults. While participants became more tired and had

increasing reports of pain over the course of the day, they experienced greater happiness when spending time with others as compared to being alone. Clinical interventions that promote social engagement, despite the presence of pain and fatigue, may positively impact well-being in this growing population.

THE RELATION OF HEROIN USE, A REGULAR SOURCE OF HEALTH CARE, AND AMBULATORY CARE UTILIZATION IN HOMELESS ADULTS

Jared Israel, Ph.D.[1], Kamila White, Ph.D.[2]

[1]Washington University School of Medicine, Seattle, WA; [2]University of Missouri - St. Louis, St. Louis, MO

The physical and mental health care needs of homeless adults are extensive, however, those needs regularly go unmet. Substance use in homeless adults is associated with worse health outcomes and decreased access to health care services. Overall, health care patterns in homeless adults are characterized by elevated rates of emergency department and inpatient services coupled with low levels of ambulatory care. Studies have consistently found that having a regular source of health care is related to improved ambulatory care utilization. Little research has been conducted to examine the relationships between substance use, a regular source of health care, and rates of ambulatory care. This study investigated the association between heroin use in the past year and ambulatory care use during that same period while controlling for whether participants had a regular source of health care.

Data were collected at a community mental health clinic in Midtown St. Louis. The sample consisted of 131 homeless adults, the majority of whom were male (70%) and African-American (70%). Mean age was 39 years 4 months (*SD* = 12.2). Because ambulatory care use in the past year was a dichotomous variable (one or more ambulatory care visits vs. none), a hierarchical logistic regression was used. Use of heroin in the past year and having a regular source of health care were entered as independent variables. At Step 1, regular source of care was a significant predictor (b = 1.43, *Wald Statistic* = 13.87, $p < .01$). At Step 2, regular source of care remained a significant predictor (b = 1.44, *Wald Statistic* = 13.87, $p < .01$), and heroin use was a significant predictor (b = -1.45, *Wald Statistic* = 4.28, $p = .04$).

These results fit with previous findings that show 1) heroin use in homeless adults decreases the likelihood of ambulatory care use and 2) a regular source of health care increases the likelihood of ambulatory care use. These results also demonstrate that while having a regular source of health care may buffer the negative affect of heroin use on ambulatory care access, additional efforts are required to ensure that this vulnerable group receive sorely needed ambulatory care services.

A CUSTOMIZED ADHERENCE ENHANCEMENT INTERVENTION + LONG ACTING INJECTABLES FOR HIGH RISK PATIENTS WITH SERIOUS MENTAL ILLNESS

Jennifer B. Levin, PhD[1], Luis Ramirez, MD[2], Edna Fuentes-Casiano, MSSA[3], Jamie Cage, MS[4], Curtis Tatsuoka, Ph.D.[5], Ashley Bukach, BS[5], Kristin A. Cassidy, MA[5], Martha Sajatovic, MD[6]

[1]Case Western Reserve University School of Medicine/UH Cleveland Medical Center, Cleveland, OH; [2]Department of Psychiatry, Case Western Reserve University School of Medicine/University Hospitals Cleveland Medical Center, Cleveland, OH; [3]Case Western Reserve Univsersity, Cleveland, OH; [4]University Hospitals Case Medical Center, Cleveland, OH; [5]Case Western Reserve University, Cleveland, OH; [6]Case Western Reserve University, Gates Mills, OH

Aims: Long-acting injectable antipsychotic medication (LAI) can be a practical treatment option to optimize adherence for high-risk groups such as homeless individuals with serious mental illness (SMI). The authors of the current study developed a Customized Adherence Enhancement (CAE) intervention and combined it with LAI to improve treatment adherence of recently homeless individuals with schizophrenia (SZ) or schizoaffective disorder (SA). For this analysis, preliminary data from 2 prospective, 6-month open-label, uncontrolled studies of LAI + CAE were pooled. Haloperidol decanoate as used in Study 1 and paliperidone palmitate was used in Study 2. Since the literature suggests that SA is more complex to treat because of the added mood component, this analysis investigated differences in baseline and follow up (6 months) between the two diagnostic groups, SZ and SA.

Methods: Both trials combined CAE + LAI in recently homeless individuals with SZ (N=16) or SA (N=44) for a total combined sample of 60. Clinical outcomes included medication adherence using the Tablets Routine Questionnaire (TRQ), LAI injection frequency and psychiatric symptoms measured by the Positive and Negative Syndrome Scale (PANSS), Brief Psychiatric Rating Scale (BPRS) and global psychopathology (Clinical Global Impressions /CGI).

Results: Mean combined age of the sample was 42.7 years (SD=9.0), majority male (56.7%), minorities (88.3% African-American), single/never married (71.2%) with a mean of 11.4 years of education. Baseline rate of substance abuse within the past year was 25.0% and rate of incarceration within the past 6 months was 21.6 %. Non-adherence at screen was 55% of missed doses in the past week for SZ and 57% in SA. No demographic differences were found between the SZ and SA group at baseline aside from a larger number of Hispanic ethnicity in

the SZ group (20%) than the SA group (2.3%) (x^2=5.56, p=.02) and no difference in severity of clinical symptoms or medication adherence (t=-.200, df=55, p=.84). There was a trend of more homeless days spent outdoors for SAs than SZs at baseline (x^2=20.2, p=.09). There was no difference between the groups on response to treatment with both groups improving adherence to oral medications (t=.2.64, df=4, p=.058 and t=3.02, df=20, p=.007 for SA and SZ, respectively) and no difference in injection frequency between the two groups at 6 months (t=-.47, df=48, p=.64).

Conclusion: Highly symptomatic SMI is common in the homeless population and LAI combined with a targeted adherence enhancement approach may be a useful therapeutic approach in these high-risk individuals, both for those with SZ and those with SA. Despite the added burden of mood symptoms for the latter, they are as likely to benefit from this combined treatment and show an equally strong response.

A MIXED-METHODS EXPLORATION OF THE ROLE OF PARTNERS IN BREAST CANCER SURVIVORS' ADHERENCE TO AROMATASE INHIBITORS

Moriah Brier, MA[1], Dianne Chambless, PhD[2], Susan Zhang, BA[3], Jun Mao, MD, MSCE[4]

[1]University of Pennsylvania, Seattle, WA; [2]University of Pennsylvania, Philadelphia, PA; [3]NIH, Bethesda, MD; [4]Memorial Sloan Kettering Cancer Center, New York, NY

Background:The relationship between marital status and cancer-specific mortality is particularly strong among breast cancer patients. It has been suggested that partner support provided in marriages may improve adherence rates to treatment, thereby increasing survival rates. The purpose of this study was to explore whether partner specific support for aromatase inhibitors (AIs), an adjuvant hormonal therapy for breast cancer survivors, was associated with increased AI adherence. ***Method:*** We used both qualitative and quantitative methods to explore this topic. In the qualitative study, using a grounded theory approach, we interviewed 25 breast cancer survivors and 15 partners about the role of partner support in decision-making around AI initiation and continuation, and management of AI side effects. The sample represented both survivors who were still on treatment and survivors who had prematurely discontinued. In the quantitative study (n = 240), we examined cross-sectional associations between different types of received support (informational, tangible, emotional, and affection), and satisfaction with support. ***Results:***In both studies, we found that breast cancer survivors placed greater value on emotionally nurturing support than on solution-focused support. In the qualitative study, partners of adherent survivors were more frequently aware of the impact of AI treatment on survivors' self-concept and provided more support around sexual dysfunction caused by AIs than partners of non-adherent survivors. Quantitative findings showed that after accounting for depression, received affection had the strongest association with women's satisfaction with AI-specific support from partners (sr = .30, p < .001), followed by emotional/esteem support (sr = .11, p = .052). Neither AI-related tangible support nor informational support was significantly associated with support satisfaction. These relationships were the same among women with both high and low levels of AI side effects. ***Conclusion:*** The findings of these studies suggest that spousal support, especially in the form of emotional support and affection, is relevant to the experience of AIs and persistence with treatment. Survivors with adverse effects, who are vulnerable to premature discontinuation of treatment, may benefit from interventions that not only target personal coping, but also their romantic relationships, to enhance couples' abilities to be emotionally expressive and partners' abilities to provide support that is responsive to survivors' needs.

AVOIDANCE AND DISEASE MODIFYING TREATMENT (RE)INITIATION AMONG MS PATIENTS

Rachel Schoor, MA[1], Jared Bruce, Phd[2], Amanda S. Bruce, Ph.D.[3], Kathy Goggin, Ph.D.[4], Bethany R. Schanfarber, Bachelors of Arts in Psychology[5], Andrea Bradley- Ewing, MPA, MA[6], Joanie M. Thelen, M.A.[7], Morgan Glusman, Ph.D.[7], Sharon Lynch, MD[8], Lauren Strober, Ph.D.[9], Delwyn Catley, Ph.D.[10]

[1]University of Missour-Kansas City, Kansas City, MO; [2]Umkc, Leawood, KS; [3]University of Kansas Medical Center, Kansas City, KS; [4]Children's Mercy Hospital & University of Missouri - Kansas City, Kansas City, MO; [5]University Missouri Kansas City, Los Angeles, CA; [6]Children's Mercy, Kansas City, MO; [7]University of Missouri - Kansas City, Kansas City, MO; [8]University of Kansas MEdical Center, Kansas city, KS; [9]Kessler Foundation, West Orange, NJ; [10]Children's Mercy Hospital & University of Missouri-Kansas City, Kansas City, MO

Disease modifying therapies (DMTs) reduce annualized relapse rates and disease progression among those with relapsing-remitting MS (RRMS), yet the majority of MS patients choose not to take DMT or prematurely discontinue taking them. Anecdotal evidence from a successful randomized trial of Motivational Interviewing – Cognitive Behavior Therapy to promote initiation of DMT suggested avoidant coping was the main reason for not taking DMT.

The aims of this study were to follow up on these observations to (1) determine whether avoidant patients could by reliably identified, (2) compare the clinical and psychological characteristics of these patients to those with other reasons for not taking DMT, and (3) examine whether their outcomes differed from those with other reasons for not taking DMT.

Audio recordings (N=77) from the first of 5 counseling sessions from the trial were examined. Using a grounded theory approach researchers identified cost barriers, mild course, side effects, and avoidance as the main reasons participants were not taking DMT. Avoidant participants tended to downplay the seriousness of MS, and provided irrational justifications for not taking medications characterized by distorted reasoning and exaggerated or paranoid concerns. Criteria were developed and two raters independently classified each participant according to their main reason (K= .88). Coding data was analyzed with baseline and end of treatment surveys of psychological and clinical characteristics as well as follow-up assessments of motivation and confidence to initiate and self- reported initiation.

Coding indicated that 33 participants (42.9 %) were avoidant. Chi-square and one-way

ANOVAs revealed few differences between groups on clinical and self-reported psychological characteristics other than those that validated the categorization (e.g., those in the cost barriers group were more likely to report not being able to afford medication, those in the side effects group were more likely to report side effects being intolerable). One-way ANOVAs and post hoc tests indicated that compared to each of the other groups avoidant individuals self-reported lower motivation to take DMTs at the end of treatment ($p < .001$), but did not differ in confidence ($p=.78$). Chi squares analyses revealed that avoidant participants were less likely to initiate DMTs (24% compared to 52.5% of non-avoidant participants) by week 10 follow-up, $p=.023$, $X^2(3, 69)= 5.14^2$.

Patients that appeared to be avoidant were not distinguishable with self-report clinical and psychological measures and likely present a particular challenge for intervention because they appeared less responsive to a generally effective intervention.

DISPARITIES IN MEDICATION ADHERENCE PERSIST AFTER CONTROLLING FOR SOCIODEMOGRAPHICS AND LITERACY/NUMERACY SKILLS

Abel B. Belachew, MA[1], Andrea E. Lagotte, MA[2], Lyndsay A. Nelson, PhD[2], Mariya P. Kristeva, BS[3], Arathi S. Nandyala, BS, BA[4], Chandra Y. Osborn, PhD, MPH[5]

[1]Marshall University, Huntington, WV; [2]Vanderbilt University Medical Center, Nashville, TN; [3]University of Central Florida College of Medicine, Kissimmee, FL; [4]University of South Florida College of Medicine, Tampa, FL; [5]Informed Data Systems Inc., Nashville, TN

Background:

Taking antihyperglycemic agents and/or insulin improves glycemic control, preventing diabetes complications. Several factors facilitate medication adherence such as sufficient literacy and numeracy skills, and one’s motivation, self-efficacy, financial/practical support and resources. Populations with fewer facilitators and more barriers to adherence (e.g., limited diabetes knowledge, negative beliefs about medication) often have high rates of non-adherence, and, in turn, high rates of suboptimal glycemic control. We used the Adherence to Refills and Medications Scale for Diabetes (ARMS-D) to assess the relationship between race and adherence among adults with type 2 diabetes (T2D).

Methods:

We analyzed cross-sectional data from English-speaking adults with T2D recruited for a medication adherence trial at Vanderbilt University Medical Center in Nashville, TN. We collected self-reported demographics (age, gender, race, education, income), diabetes characteristics (diabetes duration, insulin status), and responses to the Brief Health Literacy Screen (BHLS), Subjective Numeracy Scale (SNS), and ARMS-D. We performed a hierarchical regression model to examine the association between race and medication adherence adjusting for demographics, diabetes characteristics, and health literacy and numeracy skills.

Results:

Participants (N=151) were 55.3±10.9 years old, 60% female, and 24% non-White (69% were Black/African American), with 15.2±1.8 years of education, 25% annual incomes < $40K, and 43% on insulin. In the unadjusted model, being non-White was significantly associated with less adherence ($\beta = -.31$ $p = -.29$ $p < .01$), explaining 9.4% of the variance in adherence.

After adjusting for covariates, being non-White remained significantly associated with being less adherent (β=-.29 $p < .01$).

Conclusions:

Non-Whites were less adherent to diabetes medications than Whites after accounting for sociodemographics, diabetes characteristics, and literacy/numeracy skills often associated with medication adherence. Disparities in adherence may contribute to persistent disparities in glycemic control and other diabetes outcomes.

LINGUISTIC ACCULTURATION AND ADHERENCE TO CARDIAC MEDICATIONS AMONGST HISPANICS IN THE UNITED STATES

Noor Habboosh, B.A.[1], Marin Kautz, B.A.[1], Carmela Alcantara, PhD[2], Ian Kronish, MD, MPH[3]

[1]Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; [2]Columbia University, New York, NY; [3]Columbia University Medical Center, Center for Behavioral Cardiovascular Health, New York, NY

Background: According to the Hispanic Paradox, Hispanics in the US have a lower rate of cardiovascular disease mortality and longer life expectancy among the three largest racial/ethnic groups despite a higher prevalence of CVD risk factors. Differential adherence among racial/ethnic groups to cardiovascular medications might help explain this paradox. We tested the independent association of Hispanic ethnicity and linguistic acculturation with medication adherence.

Methods: Between 2013 and 2015, we enrolled a consecutive cohort of 654 English and Spanish-speaking patients who were evaluated for suspected acute coronary syndrome (ACS) in the emergency department of an academic medical center in New York City. Participants self-reported ethnicity and first language at enrollment. Medication adherence was assessed 1 month after discharge by asking "How much of the time do you take your heart medications?" Participants who reported missing their medications at least some of the time were categorized as nonadherent. Logistic regression was used to determine the association between Hispanic ethnicity and language with and with adjusting for age, sex, race (white vs non-white), education, comorbidity (Charlson score), prior history of established coronary artery disease, discharge diagnosis (ACS vs non-ACS), and depressive symptoms (8-item Patient Health Questionnaire score).

Results: The mean age was 62 ±13 years, 43% were women, 73% were White, 55% were Hispanic, and 35% had less than a high school education. Among Hispanics, 19% identified English as their first language. Overall, a lower proportion of Hispanics than non-Hispanics was nonadherent (11.9% vs 18.3%, p=0.03). Amongst Hispanics, a greater proportion of those who spoke English as a first language versus those who did not speak English as a first language were nonadherent (23.1% vs 9.3%, p=0.002). In unadjusted models, Hispanic patients were less likely to be nonadherent (OR 0.60, 95%CI 0.39, 0.94; p=0.03). In a model adjusting for first language and other covariates, first language as English (AOR 2.30, 95% CI 1.12, 4.76; p=.02), but not Hispanic ethnicity (AOR 1.09, 95%CI 0.55, 2.16; p=0.80) was associated with increased likelihood of nonadherence. In an adjusted model limited to participants who did not speak

English as a first language, increasing ability to speak English well was associated with increased likelihood of nonadherence (p=0.002).

Conclusion: Hispanics with increasing English language acculturation are at increased risk for nonadherence to cardiovascular medications.

MHEALTH TECHNOLOGY INTERVENTIONS FOR ANTIHYPERTENSIVE MEDICATION ADHERENCE: A SCOPING REVIEW

Cheryl Griffith, MSN RN-BC[1], Rebecca J. Bartlett Ellis, PhD, RN, ACNS-BC [2]

[1]Indiana University School of Nursing, Brownsburg, IN; [2]Indiana University School of Nursing, Indianapolis, IN

The purpose of this scoping review was to identify and describe how mHealth technologies have been used in interventions to support antihypertensive medication adherence in adult patients. Google Scholar, Ovid, and EBSCOhost databases were searched to find primary studies of adult patients published in English between January 2010 and June 2016. Extracted data included: descriptions of mHealth interventions; measurement of medication adherence; whether adherence data were shared with patients and/or providers; and patient satisfaction with mHealth intervention.

Ten studies met inclusion criteria and were included in this review. Reviewed studies used different combinations of Smartphone technologies as an intervention: unidirectional text messaging where patients only received messages (n=8); bi-directional text messaging (i.e. patients received and sent messages) (n=3); scheduled reminders and alerts (n=6); real-time reminders (n=2); voice messaging (n=2); email (n=4); app (n=1); and internet of things (IoT) (n=2). A combination of self-reporting (n=6) and/or electronic/manual pill counts (n=1/n=4) were used to measure medication adherence and this data was emailed to providers either on a weekly or bi-monthly basis (n=5). Adherence data was used to send text-message reminders for patients to pick up medication refills (n=1) or notify patients who had not accessed their electronic pillbox within a prescribed timeframe (n=1). Provider satisfaction of shared data was measured in one study. Patient satisfaction with the intervention was measured in five studies.

This review found relatively few published studies that used mHealth interventions for antihypertensive medication adherence. Of those published, the mHealth interventions varied in the technologies used to support adherence. Further studies and meta-analysis linking behavior change techniques with mHealth technology components would be useful as the knowledge base of mHealth interventions grow. Future research is needed to determine which mHealth technologies and technology strategies are the most effective and for whom, along with exploring how mHealth can be leveraged to provide patients with feedback regarding their medication adherence behavior.

THE ASSOCIATION OF MARITAL CONFLICT WITH ADHERENCE TO LONG-TERM OXYGEN THERAPY AMONG CHRONIC LUNG DISEASE PATIENTS

Ellen M. Kinner, MA[1], Karin F. Hoth, PhD[2], Frederick Wamboldt, MD[3], Jeff Swigris, DO, MS [3], Robert Sandhaus, MD, PhD[3], Mark Aloia, PhD[4], Kristen Holm, PhD[3]

The Association of Marital Conflict with Adherence to Long-term Oxygen Therapy among Chronic Lung Disease Patients

Ellen M Kinner[1], Karin F Hoth[2], Fred Wamboldt[3], Jeff Swigris[3], Robert Sandhaus[3], Mark Aloia[3,4], Kristen Holm[3]

[1] Department of Psychological and Brain Sciences, University of Iowa; [2] Department of Psychiatry, University of Iowa; [3]Department of Medicine, National Jewish Health; [4]Philips

Background: Long-term oxygen therapy (O_2) is often a critical component for the treatment of chronic lung diseases such as chronic obstructive pulmonary disease (COPD) and interstitial lung disease (ILD). Rates of adherence to long-term O_2 therapy are below 50%. No studies have yet examined the potential impact of interpersonal relationships on O_2 adherence. The aim of this study is to examine the impact of marital conflict on O_2 adherence in patients with chronic lung disease.

Methods: Patients with COPD or ILD who were married and had a prescription for 24-hour oxygen use completed self-report questionnaires regarding their demographic and medical history, interpersonal relationships, mood, and oxygen adherence. Conflict was assessed using the conflict subscale of the Quality of Relationship Inventory (QRI). Oxygen adherence was coded as adherent or non-adherent based on any admission of non-adherence on six questionnaire items. Logistic regression was used to determine whether conflict was associated with adherence to oxygen after adjusting for age, education, smoking history, type and duration of lung disease, symptoms of depression and anxiety, and length of marriage.

Results: Data were analyzed from 132 patients (mean age = 70.14; 75% COPD, 25% ILD; mean duration of oxygen use = 8.13 years). 76% of the sample was categorized as being adherent.

Conflict had a negative association with O_2 adherence (OR = .36, 95% CI = .18 – .75, p = .006) after adjusting for demographic and medical characteristics as well as length of marriage and symptoms of depression and anxiety.

Conclusions: Patients who reported less conflict in their marital relationship were more likely to be adherent to their O_2 than patients who reported higher levels of conflict. These findings suggest that patients with higher levels of conflict may be at risk for poorer adherence. Given that marital conflict is a potentially malleable factor, it may be an important target for psychosocial interventions that aim to promote adherence to O_2 in patients with chronic lung disease who are married.

ACUPUNCTURE AND MINDFULNESS-BASED STRESS REDUCTION AMONG ADULT SURVIVORS: A RANDOMIZED WAIT-LIST CONTROLLED STUDY

Catherine Dempsey, PhD[1], Margaret A. Chesney, PhD[2], Lixing Lao, PhD, MB[3], Mary Bahr-Robertson, BA[4], Patti Vegella, MS, MA[5], Brian Berman, MD[6], Elizabeth Kimbrough, PhD[7]

[1]Uniformed Services University, Bethesda, MD; [2]UCSF School of Medicine, Menlo Park, CA; [3]University of Hong Kong, School of Chinese Medicine, Pokfulam, Hong Kong, N/A, China (People's Republic); [4]Center of Integrative Medicine, Baltimore, MD; [5]Henry Jackson Foundation, Washington, DC; [6]University of Maryland Baltimore, Baltimore, MD; [7]Center of Integrative Medicine, Department of Family and Community Medicine, University of Maryland School of Medicine, Baltimore, MD

Background. Adult survivors of childhood sexual abuse (CSA) often suffer psychological consequences: Post-Traumatic Stress Disorder (PTSD) and depression. To relieve these symptoms, this study compares efficacies of Mindfulness-Based Stress Reduction, Acupuncture, and Wait-List Control in CSA survivors.

Methods. Randomized were 83 CSA survivors to Mindfulness-Based Stress Reduction, 2.5 hours weekly/ 8 weeks; Acupuncture, 35-40 minutes bi-weekly/ 8 weeks; or Wait-List Control. Outcomes were assessed at baseline, four, eight, and 12 weeks, post-randomization. Primary outcomes were measured using the PTSD Checklist and Beck Depression Inventory. Secondary outcome assessment utilized the Pittsburgh Sleep Quality Index and the Mindful Attention Awareness Scale.

Results. Large effect sizes were indicated with Acupuncture for PTSD symptoms, versus the controls (Cohen’s $d = 1.38$). Moderate effects for depression with Mindfulness-Based Stress Reduction (Cohen’s $d = 0.99$) were reported. Both treatments significantly improved mindfulness, sustainable for 12 weeks ($F = 5.85$; $p = .00101$). Acupuncture significantly improved PTSD symptoms ($F =3.37$; $p = .0052$) and sleep quality ($F = 3.74$; $p = .0076$) for up to 12 weeks. Although not as sustainable, both treatments also improved depressive symptoms ($F = 2.78$; $p = .0165$). This study demonstrates and compares the benefits of Acupuncture and Mindfulness-Based Stress Reduction to conventional treatments.

COMORBIDITY AND EATING BEHAVIOR IN INDIVIDUALS WITH SYMPTOMS OF AVOIDANT/RESTRICTIVE FOOD INTAKE DISORDER (ARFID)

Hana F. Zickgraf, MA[1], Jordan Ellis, MA[2], Martin E. Franklin, Ph.D.[3], Matthew C. Whited, PhD, Licensed Psychologist[2]

[1]University of Pennsylvania, Philadelphia, PA; [2]East Carolina University, Greenville, NC;
[3]University of Pennsylvania Perelman School of Medicine, Psychiatry, Philadelphia, PA

Avoidant/Restrictive Food Intake Disorder (ARFID) is an eating disorder (ED) diagnosis for individuals whose eating behavior leads to failure to meet nutritional/energy needs and/or significant psychosocial impairment. ARFID was added to DSM-5 to capture impairing eating pathology without compensatory behavior or shape/weight concerns. DSM-5 describes three types of eating disturbance that can lead to ARFID symptoms: picky eating (PE), low appetite/interest in eating, and fear of negative consequences from eating (e.g., choking, vomiting).

A 2016 study found that adults whose PE led to the nutrition/energy or psychosocial symptoms of ARFID reported just as much distress and comorbidity as individuals screening positive for risk of anorexia or bulimia (AN/BN).The current study extends these findings to ARFID symptoms due to other ARFID manifestations.

Participants were screened for ARFID due to any of the three eating behaviors via self-report measures. Analyses were replicated in two samples: 1219 college students; 450 adults recruited specifically for the eating difficulties of interest. Participants responded online to the Nine-item ARFID screen (NIAS), which assesses the three eating restrictions, and the ARFID symptom checklist (ARFID-cl), which assesses DSM-5 criteria to establish a possible diagnosis. Four groups were created: 1) No restrictions, 2) restrictions/no ARFID symptoms, 3) subclinical ARFID, and 4) full ARFID criteria. Groups were compared on psychological comorbidities (anxiety, depression, eating quality of life) with bootstrapped ANCOVAs, covarying self-reported symptoms of AN/BN.

In each sample, ARFID symptom group was associated with anxiety and depression. Eating quality of life impairment was assessed in the second sample and significantly differed across the ARFID symptom groups. Severity of symptoms/impairment increased with level of ARFID symptomatology with small-moderate to large effect sizes observed ($\eta p^2 = .04 – .27$). Post-hoc comparisons in the general sample revealed differences in reported symptoms/behaviors between ARFID-symptom levels, with the most consistent differences between groups with no ARFID symptoms (groups 1 and 2) and the groups with some degree of ARFID symptoms (groups 3 and 4). In the selected sample, only groups on either end of the continuum (groups 1 and 4) differed on symptoms of anxiety and depression. In this sample, each group differed significantly from all other groups on quality of life impairment.

These findings highlight the need for more recognition of, and research on, ARFID. ARFID is an ED that is associated with a distinct pattern of eating behavior and a high level of comorbidity and distress.

COMPARISON OF SELF-RATING OF COGNITION AND DEPRESSION IN PATIENTS WITH MAJOR DEPRESSION

Kevin Bera, Bachelor of Science

University of Southern California, Irvine, CA

Background: Traditionally clinicians have utilized neuropsychological tsts to evaluate cognitive impairment in patients with major depression. However, the burden of many of these instruments to both clinicians and patients make these tools difficult to access for the majority of patients. These burdens include the time it takes for these tests to be administered, lack of coverage for these tests by insurance carriers and the difficulty in finding a trained clinician who can administer these test. The recently developed Massachusetts General Hospital Cognitive and Physical Functions Questionnaire (CPFQ) is a 7 item self-questionnaire that has been found to have strong internal consistency. To our knowledge this is the only self-Rating scale for cognitive function in existence. Many self-rating scales for depression have been in existence for many years. The Beck Depression Scale (BDI) is one of the most common in use. We set out to assess patient's responses when both scales were administered and to see if there were any particular correlations between items on these two scales.

Methods: 100 adult patients with Major Depression will be evaluated during their regular scheduled outpatient appointment in a mental health clinic. Diagnosis will be based on their medical record. These patients did not carry any other primary psychiatric disorder on Axis I. Everyone will be administered both the CPFQ and BDI. We will also collect patients age, sex and time since first diagnosed with major depression. To date 36 patients have been evaluated and it is estimated that by November 15, 2016, data from 100 patients will have been collected and ready for full analysis.

Results: We will evaluate responses to all 7 items on the CPFQ and all 21 items on the BDI initially to see if there is any correlation of items with patients age, sex and duration of major depression. Then direct analysis and comparison of the items on the CPFQ and BDI will occur to determine if there are particular relationships that emerge between cognitive items and depressive items. All analysis complete by December 15, 2016 for presentation at the Society of Biological Medicine Meeting in San Diego from March 29 to April 1, 2017.

Conclusion: We will discuss our findings comparing patients with major depression self-response on the CPFQ and self-response on the BDI. We will determine with items on each scale have a high correlation with each other. We will also determine how user friendly the

CPFQ is in a general outpatient mental health clinic. This will help clinicians determine the utility of a self-rating cognition scale in major depression patients. Most importantly clinicians will now be able to assess cognition in a rapid fashion and determine if the treatment being prescribed is resulting in improved psychosocial functioning as it is now felt that cognition improvement is a more important marker than depression with regards to patient outcome.

EVENING SALIVARY CORTISOL, DEPRESSION, AND SYMPTOMS OF CHRONIC FATIGUE SYNDROME/ MYALGIC ENCEPHALOMYELITIS

Sara Milrad, M.S.[1], Daniel L. Hall, Ph.D.[2], Devika Jutagir, M.S.[3], Emily Lattie, Ph.D.[4], Sara Czaja, Ph.D.[5], Dolores Perdomo, Ph.D.[6], Mary Ann Fletcher, Ph.D.[7], Nancy Klimas, MD[8], Michael Antoni, Ph.D.[3]

[1]University of Miami, Miami, FL; [2]Harvard Medical School/MGH/BIDMC, Wellesley, MA; [3]University of Miami, Coral Gables, FL; [4]Northwestern University, Chicago, IL; [5]University of Miami Department of Psychiatry and Behavioral Sciences, Miami, FL; [6]University of Miami, miami, FL; [7]Nova Southeastern University, Fort Lauderdale, FL; [8]Nova Southeastern University, Ft. Lauderdale, FL

Introduction: Chronic fatigue syndrome/ myalgic encephalomyelitis (CFS/ME) is commonly comorbid with depression. Individuals suffering from CFS/ME and depression can also share some similar somatic symptoms and markers of neuroendocrine dysfunction, such as fatigue and elevated evening cortisol. Depression is correlated with elevated evening cortisol in otherwise healthy individuals, but less is known about cortisol associations with depression and CFS/ME symptoms in CFS/ME patients.

Methods: Baseline data were drawn from diagnosed CFS patients (N = 150) participating in studies testing the efficacy of a remotely-delivered cognitive behavioral stress management (CBSM) intervention. CFS/ME symptom and depression questionnaires and salivary cortisol were used for multiple regression analyses using SPSS.

Results: The majority of the sample (69%) had clinically significant depressive symptoms (CES-D ≥ 16). Depressive symptoms (β= 0.212, p= 0.019) and CDC CFS Symptom Severity (β= 0.309, p= 0.036) were positively correlated with evening cortisol, while perceived stress, fatigue, tension/anxiety, and sickness impact were not (all p’s>0.05).

Discussion: Results highlight the importance of considering neuroendocrine processes that are associated specifically with both CFS/ME symptoms and depression. Further mechanism-based, longitudinal research might elucidate the underlying etiology of both CFS/ME and depression symptoms.

EXPLORING DEMORALIZATION AMONG PATIENTS WITH MEDICAL ILLNESS

Jay T. Wiles, M.A. in Clinical Psychology[1], Linda Baum, Ph.D.[2], Judith Johnson, Ph.D.[3]

[1]Regent University, Richmond, VA; [2]Regent University, Virginia Beach, VA; [3]Regent University, Norfolk, VA

The experience of demoralization in patients with medical illness has been extensively documented; however, limited research has highlighted the bidirectional relationship between demoralization and medical illness. The current study examined the relationship between medical illness and experience of demoralization (as measured by the MMPI-2-RF). Specifically, the purpose of this study was to explore the multifaceted relationship between demoralization, psychological symptoms, and physical illness. The study sample consisted of 279 adults who completed a valid MMPI-2 or MMPI-2-RF at a university-based outpatient psychological services center. Of the 279 participants, 154 comprised a “medical patient” sample. Results of this study suggest significant differences in mean Demoralization (RCd) T-scores for medical patients with comorbid depressive or anxiety related psychological disorders when compared to medical patients without comorbid depressive or anxiety related disorders. Medical patients with comorbid psychological disorder(s) (i.e., inclusive of all clinical disorders) were found to have significantly higher mean Demoralization (RCd) T-scores when compared to those without a comorbid psychological disorder. The results of this study help to expand the understanding and conceptualization of the interconnectedness between medical illness and experience of demoralization. Based on the results of this study, implications and future research directions are discussed.

FACEBOOK FOR SUPPORTING LIFESTYLE INTERVENTIONS FOR PEOPLE WITH MENTAL ILLNESS

John Naslund, MPH[1], Kelly Aschbrenner, PhD[2]

[1]Dartmouth College, Lebanon, NH; [2]Dartmouth College, Nashua, NH

Objective: Facebook could support efforts to address elevated obesity rates, high cardiovascular risk, and resulting early mortality that disproportionately impact people with mental illness. In this exploratory study, we examined whether actively engaging in a Facebook group as part of a community-based lifestyle intervention was associated with clinically significant weight loss and fitness outcomes among individuals with mental illness.

Methods: We invited participants with mental illness and obesity enrolled in a 6-month group lifestyle program delivered through a community mental health center to join a private Facebook group to promote group support for achieving shared physical activity and weight loss goals. Two volunteer peers moderated the Facebook group. Participants' interactions in the Facebook group were defined as active engagement including posts, comments, or likes. We measured the proportion of participants who achieved ≥5% weight loss or improved fitness (increase >50 meters on the 6-Minute Walk Test). We also explored content of the Facebook posts.

Results: Participants (n=25) were 52% female and had major depressive disorder (44%), bipolar disorder (36%), or schizophrenia (20%), a mean age of 49.2 years (SD=11.8), and a mean BMI of 37.3 kg/m^2 (SD=8.1). Nineteen (76%) participants joined the Facebook group. These participants contributed 956 interactions consisting of 326 unique posts, 275 comments, and 355 likes. Participants who achieved ≥5% weight loss (37%) were more likely to interact in the Facebook group (mean=23.0 interactions, SD=8.3) compared to participants who did not achieve ≥5% weight loss (mean=3.9 interactions, SD=5.9; t=-2.9; df=17; $p < 0.01$). Clinically significant improved fitness was not associated with interactions in the Facebook group. Facebook posts contained content about healthy eating (30%), program reminders (19%), personal sharing about successes and challenges of health behavior change (18%), humor (13%), exercise (8%), community events (7%), and motivational messages (5%). After adjusting for multiple comparisons, posts involving personal sharing generated significantly greater response in terms of interactions compared to posts containing program reminders, motivational messages, and healthy eating content.

Conclusions: Facebook appears promising for supporting community-based lifestyle

interventions for people with mental illness. Given the wide reach of Facebook, our findings can inform future initiatives to scale up health promotion efforts targeting this at-risk group.

HOW IS HEALTH ANXIETY DEFINED AMONG INDIVIDUALS WITH A CHRONIC ILLNESS: A SYSTEMATIC REVIEW

Sophie Lebel, Ph.D., Nicole Rutkowski, B.A., Brittany Mutsaers, B.Sc., Christina Tomei, M.A. , Danielle Petricone-Westwood, B.A. , Caroline Séguin-Leclair, B.Sc., Georden Jones, B.A.

University of Ottawa, Ottawa, ON, Canada

Purpose. One of the difficulties with the literature on health anxiety (HA) among chronically ill individuals is that several terms are used to refer to this phenomenon, such as fear of cancer recurrence, fear of hypoglycemia, or cardiac anxiety. The heterogeneity of HA definitions reflects a lack of agreement on what constitutes the core features of this construct and makes cross-disease comparison difficult. Therefore, the goal of this study was to delineate the differences and the commonalities between these definitions to better understand HA across chronic illnesses. **Methods.** A systematic review of the literature was undertaken on HA in individuals living with a chronic illness. Relevant studies were identified via PsycINFO, PubMED, CINAHL, Web of Science, and SCOPUS, from January 1996 to October 2014. A total of 244 articles and abstracts were retained. A standardized data spreadsheet was designed and utilized to extract and summarize data. **Results.** Of the 244 articles that were reviewed, only 62 cited a definition of the investigated HA construct (cancer n=32, Parkinson’s disease n=8, diabetes n=4, cardiac diseases n=10, other n=8). Among these 62 articles, 6 used a general definition of HA; the remainder defined it as a realistic, disease- or symptom-specific form of HA ranging from normal to pathological. Most definitions included an emotional (e.g., fear) and/or a cognitive (e.g., worry) aspect (n=49 and n=32, respectively). Perceptual (e.g., misinterpreting physical symptoms) and behavioral (e.g., body checking) aspects were much less frequently included. **Conclusions.** Most of the definitions of HA currently in use are symptom- or disease-specific; it is difficult to transpose them to different chronic illnesses. In comparison with general HA definitions, disease-specific definitions exclude the inaccurate perception of illness. Ample work remains to determine if behaviors such as avoidance of activities, body checking, or other compensatory behaviors and perceptual processes should be part of the definition of HA in these populations.

IMPACTS OF OBESITY AND MOOD DISORDERS ON PSYCHOLOGICAL WELL-BEING, COMORBIDITIES, HEALTH BEHAVIOURS AND USE OF SERVICES.

Ahmed Jerome Romain, PhD[1], Jacques Marleau, PhD[2], Aurelie Baillot, PhD[3]

[1]University of Montreal Hospital Research Centre, Montreal, PQ, Canada; [2]Centre intégré de santé et de services sociaux de l'Outaouais, Gatineau, PQ, Canada; [3]Université du Québec en Outaouais, Gatineau, PQ, Canada

Introduction: Obesity is highly prevalent in North-America people with mood disorders (e.g., bipolar disorder, major depressive disorders) are more likely to be affected. Even though obesity and mood disorders frequently co-occur, few studies examined if the presence of a mood disorder can be an aggravating factor of obesity-related conditions.

Objective: to analyze whether people with obesity and mood disorders (POMD) differ from those without mood disorder (Ob) in terms of psychological well-being, comorbidities, health behaviours and use of health services.

Methods: Cross-sectional study based on the Canadian Community Health Survey (CCHS) conducted in 2007-2008. Sample of people with obesity (n = 1298) was weighted to represent the inhabitants from the province of Quebec (Canada). The CCHS used diagnostic criteria outlined in the DSM-IV-TR to screen respondents.

Results: POMD (n = 99) were more likely to be women than Ob (n = 1199), (65%, 95%CI[56.29-75.05%] vs 45%, 95%CI[42.92-48.56%]). In terms of psychological well-being, POMD were more likely to report poor mental health (40%, 95%CI[31.81-51.32%] vs 3.17%, 95%CI[2.32-4.34%]) with more psychological distress (37.5%, 95%CI[28.96-48.55%] vs 4.25%, 95CI [3.23-5.59%]) and anxiety disorders (39.79%, 95%CI[31.19-50.76%] vs 4.01%, 95%CI[3.04-5.28%]).

Regarding comorbidities, higher percentages of POMD reported arthritis (32.65%, 95%CI[24.57-43.39%] vs 16.58%, 95%CI [14.60-18.83%], low back pain (41%, 95%CI[32.41-51.87%] vs 19.48%, 95%CI[17.36-21.86%]). No significant differences were found in migraine, hypertension and type 2 diabetes.

In terms of use of services, compared to Ob, POMD had more frequent consultations to doctors (86.87%, 95%CI[80.46-93.78%] vs 74.21%, 95%CI[71.77-76.73%]), nurses (27.27%, 95%CI[19.77-37.62%] vs 15.44%, 95%CI [13.52-17.63]) and psychologists (21.21%,

95%CI[14.51-31.0%] vs 3.08%, 95%CI[2.25-4.24]).

Regarding their health behaviours, higher percentages of POMD reported to be inactive (79.59%, 95%CI[71.99-87.98%] vs 66.67%, 95%CI[64.05-69.39%]), or to be limited in their physical activity (37.37%, 95%CI[28.96-48.23%] vs 13.90%, 95%CI[12.07-16.01%]). No differences were found on tobacco and fruits/vegetables consumption.

Discussion: The presence of a mood disorder seems to be an aggravating factor in obesity because it was associated with poor health in several areas. There is a need to more consider obesity as health behaviours among POMD.

IMPROVING COMMUNITY-BASED MENTAL HEALTH TREATMENT FOR LATINO IMMIGRANTS

Mark DeHaven, PhD[1], Daniel Gutierrez, LPC, LMHC / Ph.D., M.A. B.A. [2], Amy H. Peterman, Ph.D.[1], Virginia Gil-Rivas, Ph.D.[1], Keri Elliott, MS, CHES[2], Claudia Interiano, MS, LPC-A[3], Roger F. Suclupe, MSW/LCSW[2]

[1]UNC Charlotte, Charlotte, NC; [2]University of North Carolina at Charlotte, Charlotte, NC; [3]University of North Carolina-Charlotte, Charlotte, NC

Background: There is a significant need for mental health treatment and prevention programs, for the 50 million Latinos living in the United States. Twenty-five percent (25%) of Americans suffer from mental disorders and 60% receive no treatment. Although the prevalence rate of mental disorders among Latinos is equal to or greater than the rate among non-Latino whites, Latinos are less likely to access mental health services, and more likely to have chronic and persistent mental illness or receive poor quality mental health care. *Methods:* We developed a mental health treatment program (Tu no estas solo / You are not alone) between a university and a community-based non-profit which serves as medical home for 3,500 Latino patients in an Immigrant Gateway City. Master's and doctoral level health professions trainees in counseling, social work, and health psychology provide individual mental health treatment to adult patients under the supervision of faculty preceptors. Most students and preceptors are bilingual (English/Spanish), but interpreters are available if needed. Patients are referred by medical clinic providers or self-referred from the community, and participate in a 14-session treatment program. We conducted a feasibility pilot from January 1, 2016 – April 15, 2016, to examine enrollment, appointment keeping, and student satisfaction with the program. *Results:* Forty-one (N=41) patients enrolled in the program during the 15-week pilot phase. About 32% of patients (N=13) were unable to complete the program; among those not completing the program the most frequently cited reasons were transportation (5/13, 38%) or conflicts with their work schedule (4/13, 31%). Adherence with appointment keeping was high; 78% of patients (N=22) completed 80% of their scheduled visits and almost 86% (N=24) completed 70%. Student trainee satisfaction with the program was very high; in a focus group session trainees (N=6) agreed that the experience enhanced their understanding and professional development, increased their multicultural awareness, and added to their mental health management skills. All trainees indicated high satisfaction with the program experience. *Conclusions:* There is a shortage of mental health treatment programs and trained mental health providers, for addressing the high and increasing needs of Latinos with mental health disorders. Our pilot study indicated that student trainees can manage the mental health needs of Latino patients and in a way

that contributes to high levels of patient appointment-keeping. University mental health trainees and faculty collaborating with a trusted community organization, offer an innovative means of providing low-cost mental health care to underserved Latino patients.

MENTAL HEALTH CONSEQUENCES OF STIGMA: RESULTS FROM A QUALITATIVE STUDY EXAMINING THE LIVES OF RURAL GAY, BISEXUAL, AND QUEER MEN

Natalia Truszczynski, MPH[1], Danielle N. Lambert, MPH, CHES[2], Anne Marie Schipani-McLaughlin, MPH[1], Carolyn Lauckner, PhD[1], Nathan Hansen, PhD[1]

[1]University of Georgia, Athens, GA; [2]University of Georgia, Atlanta, GA

Background: Gay, bisexual, queer and other men who have sex with men (GBQ men) are more likely to report symptoms of depression and anxiety than their heterosexual counterparts. Additionally, rural, especially Southern, GBQ men may face additional stigma compared to urban men, which may increase their risk for depressive and anxiety symptoms due to perceived and actual social stigma. However, few studies have studied GBQ men in rural and Southern areas, leaving a gap in the literature.

Methods: This qualitative study explored the health, relationships, and technology use of GBQ men in rural areas of the United States, the majority of which resided in the Southeast. Eligibility criteria included identifying as a man who experiences attraction to other men, residing in a rural area, and being at least 18 years old. In total, 20 semi-structured interviews were conducted from July 2015 to June 2016. Interviews were transcribed verbatim and analyzed in NVivo 11 by a diverse coding team using grounded theory approaches.

Results: Social stigma themes, both observed and perceived, of religious conservatism, familial rejection, and peer disapproval were consistently prevalent throughout the interviews, and were all mentioned as resulting in a lack of social support and need to conceal one's identity. The *Minority Stress Model* describes how concealment and isolation (distal and proximal factors) contribute to negative mental health outcomes, such as anxiety and depression. Our participants' did describe experiences, especially with depression, that are consistent with Meyer's *Minority Stress Model*. Additionally, these themes usually corresponded with the participants disclosing that they felt unsafe, insecure in their relationships, and anxious about being in public. Participants who felt the need to conceal their identities often felt that there were very few spaces that they felt safe enough to be themselves, or be open about their relationships. This would, in turn, cause strain on a personal relationship, isolating the individual more.

Conclusion: Understanding the factors that lead to mental health issues among GBQ men is important as researchers and practitioners create more interventions focusing on emotional

wellness. Understanding how stigma impacts individuals' lives through isolation and concealment can help inform programs that intervene on multiple levels.

PASSIVE AND ACTIVE SOCIAL MEDIA USE AND DEPRESSIVE SYMPTOMS AMONG YOUNG ADULTS

Cesar G. Escobar-Viera, PhD, MD[1], Ariel Shensa, MA[1], Nicholas D. Bowman, PhD[2], Jennifer Knight, MA[2], A. Everette James, JD, MBA[1], Brian A. Primack, MD, PhD[1]

[1]University of Pittsburgh, Pittsburgh, PA; [2]West Virginia University, Morgantown, WV

Introduction. Recent research suggests associations between increased social media (SM) use and increased depressive symptoms. However, little research has examined specific associations between depressive symptoms and active (e.g., more frequent posting and responding) versus passive (e.g., observation only) SM use. The purpose of this study was to investigate independent associations between active and passive SM use and depressive symptoms in a convenience sample of US adults.

Methods. In July and August of 2016, we recruited adults ages 18-30 via mental health related message boards on Reddit, a popular social networking platform. We assessed depression using the 4-item Patient Reported Outcomes Measurement Information System short form with a cut off score of 11 (on a scale that ranged from 4 to 20) to define depression. We assessed active and passive SM use using Likert-type items asking about frequency of behaviors on SM such as actively posting, responding to comments, or primarily reading others' posts. We used logistic regression to assess associations between active and passive SM use and depression while controlling for six potentially related socio-demographic variables (age, sex, race/ethnicity, living situation, relationship status, and education level).

Results. Complete data were received from 613 participants. About one-third (36.5%) of respondents were defined as depressed according to our *a priori* criteria. Factor analysis on SM items revealed a two-factor solution representing active ($\alpha = 0.80$, 4 items) and passive ($\alpha = 0.72$, 3 items) SM use. We used weighted averaging to scale each SM variable from 1 to 5. Distributions were normal with a mean of 3.8 (standard deviation [SD] = 1.1) for active use and skewed left with a median of 4 (interquartile range [IQR] = 3-5) for passive use. In multivariable analyses that controlled for all covariates, adjusted odds ratios for depression were 0.80 (95% confidence interval [CI] = 0.69, 0.93) for each 1-point increase in active use and 1.45 (95% CI = 1.21, 1.74) for each 1-point increase in passive use.

Conclusion. In a convenience sample of individuals with relatively high levels of depressive symptoms, active SM use was associated with reduced odds of depression and passive SM use was associated with increased odds of depression. The magnitude of effect was stronger for

passive use. Future longitudinal and qualitative data may help disentangle directionality of these associations.

THE MENTAL AND SPIRITUAL EFFECTS OF A MINDFULNESS INTERVENTION ADAPTED FOR HISPANIC PRIMARY CARE PATIENTS

Kelly Erickson, MA [1], Alexis Ortiz, PhD[2], Bruce W. Smith, PhD[1]

[1]University of New Mexico, Albuquerque, NM; [2]Stanford University, Albuquerque, NM

Substantial risk factors (e.g., high poverty rates, acculturative stress) exist for Latinos that are manifested in significant health needs and inequities. The purpose of this study was to examine the potential of mindfulness-based interventions for facilitating mental and spiritual well-being in Latinos. Specifically, peace, spirituality, and meaning were examined due to the growing focus of their health promotion and coping with illness effects. The participants were 23 Latino primary care patients who completed an eight-week Mindfulness-Based Stress Reduction (MBSR) course. The course was adapted for Latinos by including (1) motivational interviewing, (2) problem-solving retention barriers, (3) testimonial by a past Latino participant, and (4) increasing perceived applicability. Pre-to-post changes in mindfulness were examined through the *Five Facet Mindfulness Questionnaire* (FFM; Baer, Smith, Hopkins, Krietemeyer, & Toney, 2006), as well as in meaning, peace, and faith through the Functional Assessment of Chronic Illness Therapy-Spiritual Well-being Scale (FACIT-Sp; Peterman, Fitchett, Brady, Hernandez, & Cella, 2002). The results indicated significant increases over time in mindfulness, $t(22)=3.49$, $p < .001$, $d=0.88$, as well as the overall FACIT-Sp, $t(21)=3.02$, p=.007. Additionally, there were significant increases in the peace subscale $t(21)=2.36$, p=.028 and spirituality subscale $t(21)=2.32$, p=.030, however not the meaning subscale $t(21)=1.73$, p=.099.

THE PSYCHOLOGY TOOLBOX: IMPLEMENTING A DISTRESS REDUCTION INTERVENTION FOR HIV+ PRIMARY CARE PATIENTS IN CHINA

Joyce P. Yang, MS[1], Jane M. Simoni, PhD[1], Shannon Dorsey, PhD[1], Hongzhou Lu, MD[2]

[1]University of Washington, Seattle, WA; [2]Shanghai Public Health Clinical Center, Shanghai, Shanghai, China (People's Republic)

In China, where there are few mental health resources, the majority of HIV-related efforts have focused on medical treatment and transmission prevention rather than psychosocial support. Yet people living with HIV/AIDS (PLWHA) report high levels of psychological distress, especially upon first receiving their HIV diagnosis. Recently diagnosed Chinese PLWHA who are men who have sex with men (MSM) are particularly vulnerable to psychological distress as they face both HIV and sexual orientation stigma. We conducted mixed methods research of a qualitative study with (N = 31) individual interviews and 3 focus groups (n = 6 in each group), and a quantitative survey (N = 200) with HIV affected participants in Shanghai and Beijing, China. Our qualitative data revealed major themes of *forms of distress* experienced and *types of psychosocial support* that our participants wished they could have accessed upon diagnosis as well as *suggestions for intervention* structure that would be most feasible and acceptable. Our quantitative surveys provided further evidence of the high degree of psychosocial distress among recently diagnosed PLWHA. Our findings informed the development of the Psychology Toolbox intervention, a brief CBT skills-based intervention comprising an Automatic Thought Record, Behavioral Activation, and Paced Breathing, designed to be integrated into primary care for recently diagnosed PLWHA. We then conduct a pilot Type 1 hybrid effectiveness-implementation trial (Curran et al., 2012) implementing the Psychology Toolbox with recently diagnosed MSM for mental health outcome data as well as feasibility, acceptability, and appropriateness information. Ten recently diagnosed MSM at an HIV primary care center in Shanghai China completed the intervention provided by the first author. Paired-samples t tests demonstrate significant reduction in HIV-related distress, depression, problems with adjustment, as well as improvements in coping and perceived social support. Participants found the intervention highly acceptable and appropriate. Community advisory board members of nurses, physicians, a caseworker, a hospital administrator, and community peer leaders suggested that the intervention is feasible and appropriate. Future research will involve randomized controlled testing of the intervention in larger samples as well as among other recently HIV diagnosed populations.

THE ROLE OF DISTRESS TOLERANCE IN ASTHMA OUTCOMES

Talya Alsaid-Habia, B.A.[1], Alison C. McLeish, Ph.D.[2], Kristen Kraemer, MA[3]

[1]University of Cincinnati, Cincinnati, OH; [2]University of Cincinnati, Louisville, KY; [3]University of Cincinnati, Charleston, SC

The Role of Distress Tolerance in Asthma Outcomes

Asthma is a chronic obstructive lung disease that affects nearly 19 million adults in the United States (CDC, 2015). If not well controlled through medical intervention, asthma can result in significant rates of morbidity and mortality. One important contributor to the negative impact of asthma is the presence of psychopathology, particularly panic psychopathology (Goodwin et al., 2010; McCauley et al., 2007). In order to better understand the association between asthma and panic psychopathology, recent literature has begun examining the role of anxiety-related cognitive risk factors in asthma outcomes. This work has primarily focused on the cognitive risk factor of anxiety sensitivity (AS; fear of arousal-related sensations; McNally, 2002) and found that higher levels of anxiety sensitivity are predictive of poorer asthma outcomes (Avallone et al., 2012; McLeish et al., 2011; McLeish et al. 2016). An important next step in this area of work is to explore associations between asthma and other anxiety-related cognitive risk factors. One such factor to examine in this regard is distress tolerance (DT), defined as an individual's perceived or behavioral capacity to withstand distress related to aversive affective states (Simons & Gaher, 2005; Zvolensky et al., 2011). Indeed, low DT is associated with increased risk for anxiety disorders as well as greater AS (Keough et al., 2010). Therefore, the aim of the current study was to examine the unique predictive ability of distress tolerance in terms of asthma control, asthma-related quality of life and lung function among non-smoking adults with current asthma. (n = 61; 61.9% female, 54.8% African-American, M_{age} = 34.72, SD = 13.58). Results indicated that, after controlling for the effects of age, race, and anxiety sensitivity, greater self-reported DT significantly predicted better lung function (β = .39, t = 2.80, p < .01), asthma control (β = .31, t = 2.77, p < .01), and asthma quality of life (β = .27, t = 2.53, p < .05). These findings suggest that developing interventions targeting DT may be an effective way to improve asthma outcomes.

UTILIZATION OF COUNSELING SERVICES FROM RELIGIOUS LEADERS IN AFRICAN AMERICAN CHURCH POPULATIONS: THE ROLE OF RELIGIOUS COPING

Kelsey N. Christensen, M.A. [1], Alexandria G. Booker, M.A.[2], Jannette Berkley-Patton, PhD[3], Marcie Berman, PhD[1], Carole Bowe Thompson, BS[4], Therese Ruhland-Petty, MA[5], Sheila Lister, B.S.[6]

[1]University of Missouri - Kansas City, Kansas City, MO; [2]University of Missouri-Kansas City, Raytown, MO; [3]University of Missouri-Kansas City, Kansas City, MS; [4]Community Health Ressearch Group/School of Medicine/University of Missouri-Kansas City, Kansas City, MO; [5]University of Missouri- Kansas City, Des Moines, IA; [6]University of Missouri-Kansas City, Kansas City, MO

African Americans (AAs) are disproportionality affected by mental health issues. They are 20 percent more likely to experience serious mental health issues than the general population, and suicide is the third leading cause of death amongst AA males ages 15 through 24. AAs are half as likely to seek out mental health services than their White counterparts. The Black church is an institution of influence in the AA community, and has the potential to address mental health concerns for parishioners and community members served through outreach ministries. AAs have the highest rate of church attendance amongst all racial and ethnic groups in the United States, and they are more likely to seek out support for mental health issues and emotional stress within their church compared to other settings. In order to tailor interventions in AA faith-based communities, provide better access to care, and address mental health disparities, predictors of counseling-seeking behaviors within church communities should be examined. The present study examined potential predictors related to participants' seeking counseling (e.g. romantic relationship issues, family issues, mental health issues, financial/employment issues; range 0-9) from their pastor or a religious leader using baseline survey response from Project FIT (Faith Influencing Transformation), a health promotion intervention piloted in AA faith-based settings. Participants (N= 352) were predominantly female (*n* = 240, 68%) and an average age of 54 years old (*SD* = 13). Results indicated that 53% of participants sought counseling from their pastor or religious leader. Findings indicated that the top three reasons for seeking counseling from their pastor/religious leader were spiritual growth (25%), family issues (24%) and romantic relationship issues (22%). Preliminary analyses indicated significant relationships between seeking counseling and religiosity (r = .18, p = .003), past diagnosis of mental health condition (r = .18, p = .002), and mental health screening in the past 12 months (r = .14, p = .013). Seeking counseling was also significantly related to collaborative religious coping (r = .13, p =

.019) and self-directive religious coping (r = -.15, p = .009). Linear regression analyses revealed that collaborative religious coping (β = .12, p = .096) and self-directive religious coping (β = -.13, p = .038) predicted seeking out counseling. Religiosity, past mental health diagnosis, and recent mental health screening were not significant predictors of seeking counseling. Although religiosity and past diagnosis did not meet significance levels, results suggest a trend that they may impact counseling-seeking behaviors. Findings of this study suggest that tailoring interventions based upon religious coping style may increase the effectiveness and scope of mental health interventions in AA faith-based communities.

ASSESSING MEASUREMENT INVARIANCE OF THE MODIFIED WEIGHT BIAS INTERNALIZATION SCALE

Courtney Maclin-Akinyemi, M.S.[1], Idia B. Thurston, PhD[1], Kristina M. Decker, M.A.[2], Kristoffer S. Berlin, PhD[1]

[1]University of Memphis, Memphis, TN; [2]The University of Memphis, Memphis, TN

Objective: The internalization of weight bias (i.e., having negative perceptions of one’s own weight) has been associated with eating disorders, psychopathology, and poorer quality of life. Definitions of weight bias have usually only included perspectives of individuals with overweight or obesity; however, an emerging literature suggests that biases are experienced across varying weight categories, sex, and race/ethnicity. The Modified Weight Bias Internalization Scale (WBIS-M), an instrument to assess internalized weight bias across all weight categories, has adequate internal reliability and validity. Yet to be examined is whether the construct of weight bias internalization is measured similarly across weight categories, sex, and racial groups. Accordingly, we examined measurement invariance of the WBIS-M in a sample of emerging adults.

Methods: Responses to the WBIS-M were collected from 425 college students (18-25 years old, M_{age}=19.6) from a MidSouth university subject pool (47% White, 52% Black, 72% female). Trained research assistants measured participants’ height and weight. Data obtained were used to calculate body mass index (BMI), 52.2% were categorized as normal weight (BMI= 18.5-24.9) and 47.8% as overweight/obese (BMI > 25). Mplus 7.4 was used to run a confirmatory factor analyses (CFA) to confirm the factor structure of the WBIS-M and multigroup CFA was used to examine if the WBIS-M assessed the same construct of internalized weight bias across weight, sex, and race by comparing fit across increasingly stringent models (configural, metric, and scalar).

Results: The CFA suggested that that WBIS-M has an adequate factor structure yielding acceptable fit with CFI of 0.93. Multigroup CFA suggested invariance across weight categories (normal weight compared to overweight/obese) and sex. However, race was not invariant yielding a decrease change in CFI > .01 at the scalar level.

Discussion: Although the WBIS-M adequately assessed weight bias internalization similarly across weight categories and sex, responses should be interpreted with caution when evaluating across racial groups, particularly with regard to mean differences. Future research

should explore potential cultural adaptions of the WBIS-M to ensure that internalized weight bias is captured consistently across race groups.

AUTOMATED MEASUREMENT OF SCREEN TIME USING A WEARABLE LIGHT SENSOR

Richard Fletcher, PhD[1], Daniel Chamberlain, BE[2], Nicolas M. Oreskovic, MD, MPH[3], Elsie Taveras, MD, MPH[4]

[1]MIT, Cambridge, MA; [2]Massachusetts Institute of Technology, Bethesda, MD; [3]Harvard Medical School, Boston, MA; [4]MassGeneral Hospital, Boston, MA

Exposure to electronic screens (TV, computers) has been linked to a variety of health concerns, including obesity, cardiometabolic disease, sleeping disorders, circadian disruption, and socio-emotional disorders in children. These pathological manifestations are not only due to the sedentary behavior often associated with “screen time”, but are also the result of neuro-endocrinological pathways that are stimulated by blue light exposure. Unfortunately, there is currently no convenient automated method for collecting screen exposure data, and clinical research generally relies on fairly laborious or subjective conventional methods such as self-report, interviews, or direct observation. While the use of mobile devices such as smart phones and tablets can be tracked using software installed on the device, measuring the exposure to large (>36”) television or computer screens has remained elusive. Addressing this need, our group has developed a method for automated measurement of electronic screen exposure, which makes use of a color light sensor, which can be worn as a wrist band, necklace or pendant. By computing the time correlation between red, green, and blue light components, we show that is it is possible to create a machine learning model that can distinguish between electronic screens and other sources of ambient light. We present data collected from two different users and two different home environments using wrist band sensors, and achieved a classification score of AUC=0.90 for television alone, AUC=0.89 for computer alone, and AUC=0.83 for computer and TV combined; this compared favorably with traditional methods of screen time measurement. We also present screen time data from an ongoing clinical study (AHRQ R21 HS24001-02) of 60 children ages 6-12, in which we track specific behaviors associated with cardiometabolic risk over a period of 6 months. Given the widespread availability of wearable sensors, we believe that the integration of color light sensors for automated screen time measurement can serve as a useful tool for behavior medicine research. CONFIRMATORY FACTOR ANALYSIS OF ILLNESS BEHAVIOR IN THE SWEDISH ADOPTION/TWIN STUDY OF AGING (SATSA)

Brittany L. Bannon, M.A.[1], Anna K. Dahl Aslan, Ph.D.[2], Nancy L. Pedersen, Ph.D.[3], Chandra A. Reynolds, PhD[4]

[1]University of California- Riverside, San Diego, CA; [2]School of Health and Welfare, Jönköping University, Jönköping, N/A, Sweden; [3]Karolinska Institutet, Stockholm, N/A, Sweden; [4]University of California, Riverside, Riverside, CA

Background: Illness behaviors—or affective, cognitive, and behavioral responses to symptoms of illness—predict patient outcomes, including symptom exacerbation and functional recovery, and they account for a large proportion of U.S. healthcare costs. Although prior cross-sectional work has examined illness behaviors like symptom reporting in isolation, the measurement of illness behavior using a longitudinal, multi-indicator approach has yet to be explored. **Aim:** We evaluated illness behavior as a latent, developmental construct in the Swedish Adoption/Twin Study of Aging (SATSA). **Method:** Participants were up to 1,886 individuals (from 1,223 twin pairs) ages 29 to 102 years (M_{age} baseline = 62.32 years; *SD* = 13.69; 59% Female). Illness behavior indicators included somatic complaints, non-prescription medication use, pain-related disability and perceived illness complications. The psychomotor retardation subscale of the CES-D was used to index somatic complaints, and medication use was a simple composite of 9 dichotomous items on participants' use of non-prescription medications, such as over-the-counter analgesics, in the previous month. Pain-related disability included a simple composite of three dichotomous items on the presence of neck, back, or shoulder pain that prevented participants from performing daily tasks or activities. Perceived illness disability was a composite of difference scores, calculated from subtracting a physician panel's objective ratings of disability for each of 35 medical conditions (on a 3-point scale; 1= *Little or no disability*; 3= *Severe disability*) from participants' self-ratings of how much each of the same endorsed medical conditions interfered with their daily lives (on the same 3-point scale; 1= *Not at all*; 3= *A lot*). Positive composite scores reflected higher perceived disability relative to what was expected from the objective ratings, whereas a composite score of zero reflected "accuracy" or agreement in perceived illness complications. Confirmatory Factor Analysis (CFA) was used to evaluate invariance in the loadings of these four indicators on a latent illness behavior factor across four questionnaire waves (1987-2004). **Findings:** Confirmatory factor analyses revealed moderate factor loadings of the four indicators (standardized loadings ranged from .49 to .52, all *p*s < .0001). Also, practical fit indices from the nested model comparisons suggested strong factorial invariance in the loadings across

time (CFI = .96; TLI = .95, RMSEA= .03, 90% CI: [.026, .035]). **Conclusion:** Illness behavior as a latent, multi-indicator construct represents a promising focus for longitudinal work on behavior change and maintenance.

CURRENT EXPERIENCES SCALE: AN ASSESSMENT OF RESILIENCY CONSTRUCTS

Emma Chad-Friedman, BA[1], Christina M. Luberto, PhD[2], Daniel L. Hall, PhD[2], Elyse R. Park, PhD, MPH[1]

[1]Massachusetts General Hospital, Boston, MA; [2]Benson-Henry Institute for Mind Body Medicine, Massachusetts General Hospital, Boston, MA

Introduction: We present our perspective on resiliency as the ability to maintain effective and adaptive functioning in response to everyday stressors - the chronic stress of living. We propose that there are 3 core resiliency processes that can be intervened upon: (1) promoting relaxation methods through mind-body techniques; (2) enhancing stress awareness through cognitive behavioral techniques which decrease stress response; and (3) promotion of adaptive strategies through a positive psychology lens. Our multi-modal resiliency intervention is assessed by the Current Experiences Scale (CES), a self-report measure of resiliency recently adapted from the Posttraumatic Growth Inventory, is a promising measure for assessing this conceptualization of resiliency, though no research has examined associations between the CES and resiliency processes.

Methods: We used zero-order correlations to explore the relationships between the CES and validated measures of resiliency constructs: General Self-Efficacy Scale, Measure of Current Status (coping), MOS Social Support, Patient Health Questionnaire-8 (depression), Penn State Worry Questionnaire, and Generalized Anxiety Disorder-7 item (stress awareness components), and Life Orientation Test-Revised (optimism), Cognitive and Affective Mindfulness Scale (mindfulness), Gratitude Questionnaire, Interpersonal Reactivity Index (empathy) (positive psychology components). We also administered the Resilience Scale 14-item (RS-14). Measures were administered before 48 patients participated in the resiliency intervention.

Results: The CES significantly correlated with all resiliency constructs (all ps < .001):self-efficacy (r=0.80), coping (r= 0.72), optimism (r= 0.70), mindfulness (r=0.63), gratitude (r= 0.35), empathy (r= 0.51), social support (r=0.51). The CES also correlated with negative constructs; in particular, depression (r= -0.52), worry (r= -0.40), and anxiety (r= -0.33). Moreover, it significantly correlated with a standard measure of resilience (RS-14; r=0.81).

Conclusions: The CES mapped on to our resiliency model, significantly correlating with measures of resiliency processes in expected directions. The CES may be a useful assessment of our proposed resiliency constructs. This study has implications for broader uses of the CES for assessing healthy functioning and resiliency training.

EVALUATING A VIRTUAL REALITY BUFFET TO MEASURE PARENT FOOD CHOICE BEHAVIOR

Susan Persky, PhD[1], Megan Goldring, Bachelor of Arts[2], William D. Kistler, M.S.[3], Rachel W. Cohen, BA[4], Colleen M. McBride, PhD[5]

[1]National Human Genome Research Institute, Bethesda, MD; [2]National Human Genome Research Institute, Washington, DC; [3]National Institutes of Health/National Human Genome Research Institute, Washington, DC; [4]National Human Genome Research Institute, Fairfax, VA; [5]Emory University, Rollins School of Public Health, Atlanta, GA

Childhood nutrition and obesity are priority research areas and require further investigation to understand the feeding behaviors of parents. However, child feeding is difficult to measure, particularly in laboratory settings. As such, many studies rely on parent reports of feeding and feeding intentions, or of choices among static food images. A virtual reality-based buffet food choice simulation can measure parent feeding decisions in a realistic, yet completely controlled environment. In the virtual buffet, parents choose a meal for their child from an array of foods and beverages that vary in nutrient and calorie density. Data collected include type and amount of each food selected, nutritional metrics, timing, and orderings of selections. Given the novelty of this approach, there is a need to assess tool performance and acceptability among parents. Assessments were conducted over two studies. The first study included 221 mothers of 4-5 year old children. Mothers felt the feeding scenario was realistic (M=5.55, SD=1.41; 1-7 scale), and that they were able to select the intended amount of food (M=6.31, SD=1.08). In addition, the higher a mother's reported feeding restriction with respect to her child at pretest, the fewer calories she selected for her child in the virtual buffet; β=-.156, *p*=.023. The tool was also sensitive to intervention effects related to the presentation of childhood obesity information. The second study included 116 mothers and fathers of children ages 4-7. In this study, parents similarly perceived high realism of the virtual buffet simulation (M=4.29, SD=.88; 1-5 scale). In addition, those who indicated serving their child more fruits and vegetables on a food frequency questionnaire at pretest chose more fruits and vegetables in the buffet β=.421, *p*=.045. Accumulating evidence points to the virtual reality buffet simulation as a useful behavioral measure of child feeding that is associated with accepted external measures and is sensitive to feeding-relevant interventions.

INTERPERSONAL VULNERABILITY SCALE: ASSESSING THE WILLINGNESS TO TAKE RISKS IN RELATIONSHIPS

Elizabeth Stein, M.S., Anne Guzman, B.S., Graham Ford, M.S., Bruce W. Smith, PhD

University of New Mexico, Albuquerque, NM

Vulnerability, though commonly regarded with negative connotations in the social sciences, has more recently been explored for its potential value. Brown’s (2006) qualitative research demonstrated that vulnerability may be associated with both relationship and mental health benefits, but quantitative research on this construct is scant or missing, and a scale has yet to be developed to measure vulnerability in this context. The purpose of this study was to develop and assess a newly developed measure of interpersonal vulnerability defined by the willingness to take risks in relationships. The interpersonal vulnerability scale (IVS) included 24 items with 4 six-item subscales assessing the willingness to (1) admit mistakes, (2) ask for help, (3) confront others, and (4) express love. Additional details related to the development of the scale will be published in a manuscript that is in preparation. The participants were 1,042 undergraduates (M_{age}=21.16; SD=6.12; 70.2% female; 46.5% Hispanic, 44.4% non-Hispanic Caucasian). Interpersonal vulnerability and a full range of mental health, social relationship, and personal strength variables were assessed. Exploratory factor analysis (EFA) of the IVS suggested the presence of 4 factors with each item loading onto the expected subscale, and all loadings were between .616 and .846. Confirmatory factor analysis (CFA) was used to examine construct validity. The sample was randomly split into a validation sample and a replication sample to allow for model respecification to improve model fit. After model respecification, the CFA provided acceptable fit ($c^2(184) = 615.858$; RMSEA = .067 (90% CI: .061, .073); CFI = .979). The final model consisted of one higher order factor (interpersonal vulnerability), and 4 lower order factors, which were the subscales. In the final model, one item was removed from each of the subscales except for the “ask for help” subscale which retained all 6 items. The final model demonstrated excellent internal consistency for the overall IVS at .940 and good to excellent internal consistency for each of the subscales, ranging from .878 to .928. The overall scale and subscales were generally related in the expected directions to the mental health, social relationship, and personal strengths measures. Differences in IVS scores according to gender an ethnicity were also explored. The findings suggest that IVS could be a valid and meaningful way to begin to assess vulnerability and how it interacts with health and well-being.

OPTIONS FOR MEASURING THE QUALITY OF BEHAVIORAL AND PSYCHOSOCIAL CARE IN BARIATRIC SURGERY

Eric Schmidt, PhD[1], Alex Harris, PhD[2], Megan Hood, PhD[3], Joyce Corsica, Ph.D.[3]

[1]HSR&D, VA Palo Alto Health Care System, Menlo Park, CA; [2]VA Palo Alto HCS, Palo Alto, CA; [3]Rush University Medical Center, Chicago, IL

Quality of care measurement in behavioral medicine is not well developed relative to mental health or medical care. In particular, the psychosocial care of bariatric surgery patients is an area of behavioral medicine in which measures of care quality are under-developed. Given (a) increased stakeholder interest in measuring quality for system monitoring, (b) need for quality improvement in bariatric surgery, and, critically, (c) the importance of psychosocial evaluation and behavioral treatment options for this patient population, it is essential to identify and develop quality measures for both surgical and behavioral care of the bariatric patient. To this end, we conducted an environmental scan for measures available to research or monitor the quality of behavioral and psychosocial care in bariatric surgery. After developing a conceptual model, we searched accreditation standards, practice guidelines, quality measure inventories, reports from practice organizations, and peer-reviewed manuscripts. Existing quality measures or potentially-measurable concepts were abstracted if relevant to either surgical or behavioral processes of care in bariatric surgery. Of 226 measures or potentially-measurable concepts identified, 17 were related to behavioral or psychosocial care; 14 were potentially-measurable processes of care (e.g., referral to pre-surgical evaluation and support groups) and 3 were fully-developed outcome measures currently used for accreditation (e.g., excess weight loss after surgery). Although current outcome measures are promising, options appear limited for measuring the quality of behavioral health care processes in bariatric surgery. More work is needed to determine which behavioral or psychosocial care processes are most closely linked to outcomes. Future research should investigate how access, engagement, or process of care measures might be used to measure quality, particularly to inform care planning for complex outcomes that share medical and behavioral etiology, such as long-term weight loss and regain.

OUTCOME OF THE STAKEHOLDER ENGAGEMENT IN QUESTION DEVELOPMENT (SEED) METHOD: A STAKEHOLDER DERIVED LUNG CANCER RESEARCH AGENDA

Carlin Rafie, PhD, RD[1], Fatemeh Zarghami, M.D., M.P.H[2], Dawn Moser, MBA, RHIA, CCS[3], Emily B. Zimmerman, PhD, MS[4], Sarah Cook, MPH[5]

[1]Virginia Polytechnic Institute and State University, Blacksburg, VA; [2]virginia polytechnic institute and state university, Blacksburg, VA; [3]Virginia Tech, Martinsville, VA; [4]Virginia Commonwealth University, Hilton Head, SC; [5]Virginia Commonwealth University, Richmond, VA

Background: There is a need to engage the public in research to increase accountability, relevance, and transparency while generating new insights. Research topics are usually selected by researchers or sponsors, with minimal input from community stakeholders, and few frameworks have been developed for the collaborative generation of research questions. We tested a new method for engaging stakeholders in research question development around lung cancer outcomes which was a community identified health issue in this community.

Methods: The SEED (Stakeholder Engagement in quEstion Development) method is a model that engages stakeholders in the development of causal models to predict health outcomes, and development and prioritization of research questions. Stakeholders are engaged at three levels, collaborative, participatory, and consultative. A disparity in lung cancer outcomes was identified in Martinsville/Henry County, Virginia during a cancer needs assessment conducted in 2013. Eleven Martinsville community residents were recruited to be part of a participatory research team that collaborated on the development of a research agenda around lung cancer outcomes. Team members completed a stakeholder identification matrix to identify relevant stakeholder groups to participate in facilitated concept model building, research question development and prioritization. In addition, diverse stakeholders were consulted via interviews and focus groups to gather relevant information.

Results: The research team identified and recruited 22 participants in 3 stakeholder groups, (1) lung cancer patients and caregivers, (2) clinical care providers, and (3) individuals who influence access to healthcare. These groups identified 10 key stakeholders and 5 focus groups with a total of 20 participants from whom information was gathered to inform their lung cancer outcome concept models. Three separate concept models were developed by the groups and an average of 25 research questions were created per group. Through a facilitated process of prioritization, four research questions were selected per group resulting

in a final research agenda of 12 questions. These questions fell into 4 broad categories: barriers to care, quality of care, support systems/coping mechanisms, and social determinants of health.

Conclusions: The SEED Method effectively engaged key community stakeholders in the development of an actionable research agenda that addressed community relevant questions. Participants with diverse viewpoints brought a range of perspectives on the social and environmental factors affecting health behaviors, decision making and health outcomes. The SEED method has the potential to generate stakeholder centered research agendas on a variety of health-related topics.

VALIDATION OF A SHORTENED VERSION OF THE CHILDREN’S EATING BEHAVIOR QUESTIONNAIRE IN A CLINICAL SAMPLE OF LATINO CHILDREN.

Alma I. Behar, MPH[1], Noe C. Crespo, Ph.D., M.P.H.[2], Melawhy L. Garcia, MPH[3], Guadalupe X. Ayala, PhD, MPH[2], Nadia Campbell, MPH[4], Lisa M. Shadron, B.S.[5], John Elder, PhD, MPH[2]

[1]SDSU/UCSD Public Health Joint Doctoral Program, San Diego, CA; [2]San Diego State University, San Diego, CA; [3]San Diego State University, Anaheim, CA; [4]Institute for Behavioral and Community Health, San Diego, CA; [5]Institute for Behavioral & Community Health (IBACH), San Diego, CA

Background: The Children’s Eating Behavior Questionnaire (CEBQ) is a psychometric tool commonly used to assess dimensions of child eating behaviors that contribute to overweight. This study focuses on the validity of the CEBQ through the associations of its three subscale scores with Body Mass Index (BMI). **Methods:** Participants were parents of 5-10-year-old Latino pediatric patients enrolled in an obesity prevention and control study. Parents rated each CEBQ item on a 5-point Likert-type scale (1= never to 5= always) to indicate the frequency of their child’s eating behavior. Child BMI (kg/m^2) was calculated using measured height and weight. BMI-for-age percentile was computed utilizing the standardized program for the 2000 Center for Disease Control Growth Charts. **Analysis:** CEBQ subscale scores were calculated by taking the mean of the item ratings if at least 80% were completed. Cronbach’s alpha was used to assess the internal consistency of the CEBQ subscales (5 FR, 4 SE, 5 SR). A principal components analysis (PCA) was conducted on 14 items of the CEBQ to confirm the theoretical factor structure and determine if its three subscales would be replicated in our sample. Separate multivariate linear regressions were conducted to examine the associations between scores on CEBQ subscales with child BMI-for-age percentile. **Results:** Parents (N = 295) completed the CEBQ in English (n = 22) or Spanish (n = 273). Children’s mean age was 7.6 years; 38% of children were overweight and 45.1% were obese. PCA showed a relatively similar factor structure to the original CEBQ subscales, with acceptable internal consistency and between-subscale correlations. Analyses demonstrated the validity of the three subscales, as child BMI was positively associated with food responsiveness ($\beta = 0.336$, $P \leq 0.001$), and negatively associated with slowness in eating ($\beta = -0.209$, $P \leq 0.001$) and satiety responsiveness ($\beta = -0.211$, $P \leq 0.001$). **Conclusion:** The 14-item CEBQ scale may be a useful tool to assess obesogenic eating behaviors of Latino children. However, further study is needed to replicate our findings.

CHANGES IN CPAP ADHERENCE OVER TIME ARE MODERATED BY PTSD AND DEPRESSION STATUS IN VETERANS

Samina Ahmed, MS[1], Johnna Medina, MA[2], Douglas Wallace, M.D.[2], William Wohlgemuth, Ph.D.[2]

[1]Bruce W. Carter VA Medical Center, Coral Gables, FL; [2]Bruce W. Carter VA Medical Center, Miami, FL

Sleep apnea has great public and personal health costs including risk for morbidity and early mortality. CPAP treatment is clinically efficacious, yet has high rates of non-adherence. To empirically identify risk-factors responsible for this low adherence, this study examines psychological determinants (i.e., PTSD and Depression) of 24-week CPAP adherence. As a secondary analysis from a large parent study on CPAP adherence, *N*=390veteran participants ages 24–88 years (*M*=53.85, *SD*=12.33) were grouped by two independent predictors indicating presence or absence of PTSD and depression. Adherence was objectively measured via average nightly minutes of CPAP machine worn over course of 24-week treatment. We hypothesized veteran participants with *either* PTSD or depression would display poorer adherence than non-disordered participants. In addition, veterans with comorbid PTSD *and* Depression would adhere poorest to CPAP relative to non-disordered veterans and those with either condition alone. A multilevel model (MLM) tested the 3-way interaction between PTSD and Depression over time on CPAP adherence. Controlling for covariates, age, type of PAP, PAP pressure, apnea/hypopnea severity, comorbid insomnia symptoms, and medical comorbidities, results showed a significant main effect of Time (*b*=-7.37, *t*(304)= -2.06, *p*=.04), such that CPAP adherence differed during the first week among the groups. Additionally, we found a significant PTSD*Time interaction (*b*=-10.12, *t*(321)= -2.56, *p*=.01), but not with Depression*Time (*p*= .19), such that having PTSD quickened the decline of CPAP use. However, quadratic change of Time^2*Depression was significant (*b*= .27, *t*(195)= 2.16, *p*=.032), such that those with depression showed early decline but later improvement over time. As hypothesized, we found significant interactions for Time*Depression*PTSD (*b*=12.36, *t*(315)=2.71, *p*=.01) and Time^2*PTSD*Depression (*b*= -.52, *t*(207)= -2.22, *p*=.028), indicating that quadratic change depended on the presence of mental illness. We found those dually diagnosed with PTSD and Depression evidenced the lowest overall CPAP adherence through the initial phase of observation. These results infer potential clinical utility in considering premorbid mental health history in the context of long-term sleep apnea treatment. Findings also underscore the need for targeted intervention strategies to boost behavioral adherence

in patients with mood and trauma conditions—particularly those with psychological comorbidity.

SUICIDALITY AMONG VETERANS WITH GULF WAR ILLNESS

Lauren M. Greenberg, Ph.D.[1], Wilfred R. Pigeon, Ph.D.[2], Christina G. Gonzalez, B.A.[3], Nicole Anastasides, M.S.[3], Jennifer Presnall-Shvorin, Ph.D.[3], David R. Litke, Ph.D.[4], Fiona Graff, Psy.D.[4], Lisa McAndrew, Ph.D.[5]

[1]War Related Illness and Injury Study Center, VA New Jersey Health Care System, East Orange, NJ; [2]VISN 2 Center of Excellence for Suicide Prevention, VHA, Canandaigua, NY; [3]War Related Illness & Injury Study Center (WRIISC), VA New Jersey Health Care System, East Orange, NJ; [4]War Related Illness and Injury Study Center (WRIISC), VA New Jersey Health Care System, East Orange, NJ; [5]University at Albany and War Related Illness and Injury Study Center, Veterans Affairs New Jersey Healthcare System, East Orange, NJ

Background: Suicide, the 10th leading cause of death in the U.S., is a serious public health issue that has warranted national prevention efforts, including the identification of vulnerable populations. Compared to U.S. civilian adults, Veterans are at a disproportionately high risk for suicide (~21% greater), accounting for ~18% of suicides though they only constitute ~8.5% of the population. The majority of Veteran suicides (~65%) are by those $\geq$50 yrs. Veterans deployed to the Gulf War often experience several medically unexplained physical, neurocognitive, and affective symptoms collectively known as Gulf War Illness (GWI). Many aspects of GWI overlap with factors associated with increased suicidality, including chronic pain, insomnia, functional limitation, impaired executive functioning, depression and PTSD. Demographic factors combined with comorbid chronic health problems may increase vulnerability for this subpopulation. **Objective**: Describe suicidal thoughts and behaviors among Veterans with GWI. **Method**: During screening for an active RCT, Veterans who experience symptoms of GWI were assessed for suicidality using the Columbia Suicide Severity Rating Scale (C-SSRS). Those who met eligibility criteria for the RCT were included in the analyses. **Results**: This sample of Veterans with GWI (N=70) was primarily White (66.2%), male (94.1%), M_{age}=50.6 yrs., and 86.8% receiving disability. In their lifetime, 12.9% of these Veterans reported a past suicide attempt. The majority (~75%) of first suicide attempts occurred within 5 yrs. postdeployment, and the modal number of lifetime attempts was one. Examination of current suicidal ideation (past 6 months) showed 22.9% of Veterans endorsed passive ideation (i.e., wishing they were dead or wishing they could go to sleep and not wake up) and 7.1% reported having actual thoughts of killing themselves. Of those with current suicidal ideation, 4.3% reported thinking about how they would commit suicide. **Conclusions**: This preliminary exploration of suicidality among Veterans with GWI suggests that they may

be at an increased risk for suicide given their vulnerability factors and evidenced by their rates of past suicide attempt and current ideation. **Limitations**: This sample consisted of self-selected participants in a research study for GWI. The rates could be an underestimate given that more serious suicidality was an exclusion criterion. A larger sample size is necessary to provide more accurate population estimates.

A PILOT RANDOMIZED CONTROLLED TRIAL TO DEVELOP A PRESCHOOL OBESITY INTERVENTION FOR WIC FAMILIES: OUTCOMES AND LESSONS LEARNED

Elizabeth Towner, PhD[1], Chantelle N. Hart, PhD[2], Kate M Guthrie, PhD[3], April Idalski Carcone, PhD[1], Kobra Eghtedary, PhD[4], Velonda Thompson, PhD, Doctorate in Nutrition & Health Promotion[5], Elissa Jelalian, PhD[6]

[1]Wayne State University, Detroit, MI; [2]Temple University, Philadelphia, PA; [3]The Miriam Hospital / Brown Medical School, Providence, RI; [4]Michigan Department of Health & Human Services, Lansing, MI; [5]Detroit Health Department, Detroit, MI; [6]Alpert Medical School of Brown University, Providence, RI

Background: Preschoolers from low-income backgrounds are underrepresented in weight control trials despite persistent obesity disparities. This study examined the feasibility, acceptability, and preliminary efficacy of a 4-month, 14-session community and home-based preschool obesity intervention for families enrolled in WIC developed from our formative work.

Methods: Families were recruited from Detroit WIC clinics and randomized to WIC standard of care (W-SOC) or W-SOC+behavioral intervention (BI). BI was led by a community health worker, targeted reduction in obesity status for preschoolers and caregivers, and included the following components: diet and activity education, behavioral strategies for weight regulation, child behavior management training, and life skills (e.g., budgeting, time management). Preschooler and caregiver height and weight were measured at baseline, end of treatment (4-months), and 3-months post-treatment (7-months). Caregivers also completed semi-structured qualitative interviews about their intervention experience at the 4- and 7-month assessments.

Results: Nineteen preschooler(47% girls, 100% African American, M_{age}=3.14±0.73 years, M_{BMIz}=2.47+1.34) and caregiver (90% mothers, M_{BMI}=42.32+12.91) dyads enrolled (49% recruitment). At treatment end, BMIz decreases were greater for preschoolers who completed the intervention (n=2; M=-0.33) than partial intervention completers(n=7; M=-0.09) or W-SOC preschoolers (n=4; M_{WSOC}=-0.15). By 3-months post-treatment, BMIz decreases were greater for preschoolers who received at least some intervention ($M_{Completers}$=-0.46, $M_{Partial}$=-0.32) compared to W-SOC(M=-0.19). Caregiver percent weight loss was greater at the end of treatment for those who received intervention compared to W-

SOC $M_{Completers}$=-3.57, $M_{Partial}$=-1.70, M_{WSOC}=0.36) and 3-months post-treatment ($M_{Completers}$=-5.27, $M_{Partial}$=-0.48, M_{WSOC}=0.16). In qualitative interviews, intervention families (including drop outs) reported high intervention satisfaction and offered suggestions to improve feasibility and acceptability (e.g., all home-based program).

Conclusions: Findings suggest brief, intensive, family-based BI may be a promising approach for reducing obesity disparities in early childhood. Future research to identify strategies that improve intervention enrollment and retention among low-income families of preschoolers into weight control trials is necessary to fully evaluate the efficacy of this intervention.

ACCUMULATIVE AND DYNAMIC EFFECTS OF PARENT-CHILD RELATIONSHIP ON CHILD'S ADIPOSITY DEVELOPMENT

Zhongzheng Niu, MS, MD[1], Emily Kiresich, MS, RD[2], Amber Cordola Hsu, MPH[3], Stuart Kusdono, N/A[4], Bin Xie, PhD[1]

[1]Claremont Graduate University, Claremont, CA; [2]Claremont Graduate University, Lakewood, CA; [3]Claremont Graduate University, Marina del Rey, CA; [4]Diamond Bar High School, Chinio Hills, CA

Introduction: Cross-sectional studies found parent-child relationships affect child's development, but the effects may be accumulated and also vibrant through time. Besides, few studies differentiated between maternal and paternal relationship effects on children's health. Using longitudinal Study of Early Child Care and Youth Development, this study explores the dynamic and cumulative effects of child-parent relationships on child's adiposity development.

Methods: From age 12 to 15 years 844 children with 4 complete annual measurements of average triceps skinfold thickness (ATST), body length and weight were included for analyses. Both parents reported their perceived relationship with the child 6 times from child age of 54 months to 12 years. Accumulative effects of parent-child relationship were calculated as the average scores of all measurements, while dynamic effects are calculated as the slopes of relationship scores regressed on child's age. Multilevel models were employed to explore the effects of accumulative and dynamic relationship effects on the development of child's BMI percentile and ATST, with adjustment of family income-to-need ratio, education level, and gender.

Results: In mother-child relationship, both accumulative and dynamic conflict scores were found to increase child's ATST over time (b=0.10 P=0.04, and b=0.20 P=0.02, respectively), while the dynamic total positive score decreased ATST over time (b=-0.13 P=0.03). In father-child relationship, the accumulative effects of closeness and total positive relationship scores decreased child's BMI percentile over time (b=-0.09 P=0.02, and b=-0.03 P=0.04, respectively), but the dynamic effect of conflict decreased child's BMI (b=-0.19 P=0.04) while the dynamics in closeness and total positive scores increased BMI (b=0.29 P=0.01, and b=0.09 P=0.01, respectively). We did not find any significant effects of mother-child relationship on BMI nor effects of father-child relationship on ATST.

Conclusion: Long-term parent-child relationships influence child's adiposity development through accumulative and dynamic processes and the dyadic effects are different from mother to father.

DIETARY INTAKE AND PHYSICAL ACTIVITY RESULTS FROM MIM TARGETING YOUNG LOW-INCOME OVERWEIGHT AND OBESE WOMEN

Mei-Wei Chang, PhD[1], Susan Nitzke, PhD[2], Roger Brown, PhD[3]

[1]The Ohio State University College of Nursing, Clumbus, OH; [2]University of Wisconsin-Madison, Madison, WI; [3]University of Wisconsin-Madison, Middleton, WI

Background. *Mothers In Motion* was a community-based lifestyle behavioral intervention aimed to help young low-income overweight and obese mothers with young children prevent further weight gain. The objective was to test the intervention effect on dietary intake (total fat, fast food, fruit and vegetable) and physical activity. **Method**. Participants (N = 569) were recruited from 7 Special Supplemental Nutrition Program for Women, Infants and Children (WIC) offices in Michigan. Eligible participants were randomly assigned to an intervention (n = 387) or a comparison (n = 182) group. During the 16-week intervention period, intervention participants watched theory-based culturally sensitive videos (in DVD format) at home. The videos featured peers from the target audience who provided personal testimonies and skill demonstrations for recommended lifestyle behavioral changes. Participants also dialed into peer support group teleconferences led by peer educators or WIC dietitians using motivational interviewing and group facilitation skills. Total fat, fast food, fruit and vegetable intakes and physical activity were measured at baseline (T1), immediately following (T2), and 3 months after the 16-week intervention (T3). Intervention effectiveness was tested via general linear mixed modeling. **Results**. Compared to the comparison group, the intervention group ate significantly less total fat (effect size [D] = 0.24) at T2, but intervention effect diminished at T3. Also, the intervention group ate fast foods less frequently (D = 0.31) at T2 but not T3. We did not find any statistically significant differences in fruit and vegetable intake and physical activity between the intervention and comparison groups at T2 and T3. **Conclusion**. *Mothers In Motion* was effective in helping participants make changes in fat and fast food intakes, but the changes did not endure 3 months after the intervention period.

EATING RESPONSES TO EXTERNAL FOOD CUES AND INTERNAL SATIETY SIGNALS IN WEIGHT DISCORDANT SIBLINGS

Kelsey Ufholz, PhD[1], Sarah-Jeanne Salvy, Ph.D.[2], Denise Feda, PhD, MS[3], Leonard Epstein, PhD[4], James Roemich, Ph.D.[5]

[1]USDA Grand Forks Human Nutrition Research Center, Grand Forks, ND; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University at Buffalo, Wheatfield, NY; [4]University at Buffalo, Buffalo, NY; [5]USDA-Agriculture Research Service, Grand Forks Human Nutrition Research Center, Grand Forks, ND

Background: Compared to normal-weight children, overweight children are more responsive to external food cues and less sensitive to internal satiety signals. Both mechanisms may promote greater energy intake. Adolescents show less compensation for prior energy (kcal) intake than children, suggesting that the ability to regulate kcal intake may decrease with age. Studies of fraternal siblings discordant for weight status control for genetic and within-family factors, allowing examination of non-shared environment that may explain intra-family weight differences.

Objective: Two randomized controlled trials determined whether weight-discordant sibs would differ in responsiveness to external food cues and compensation for prior kcal intake. It was predicted that compared to their non-overweight sibs, overweight sibs would consume more kcal in response to external food cues and would compensate less for prior kcal intake.

Methods: Results are from same-sex biological sibs (N = 38 pairs). For cue reactivity, sibs were exposed to an appetizing food (pizza) and allowed to consume as much as they desired. For compensation, sibs were given a low-calorie or a high-calorie preload, followed by dinner. Multilevel models predicted kcal intake, cue responsivity, and compensation. Predictors included gender, birth order, adiposity group, perceived parental control of child's feeding, and children's dietary restraint.

Results: There was little sibling similarity (ρ = 0.08) for cue responsiveness. For compensation, a slight sibling similarity was found, ρ = 0.20. Sib groups did not differ in kcal intake, in both experiments. Sib differences in zBMI were not predicted by differences in cue responsiveness or compensation, but were associated with differences in eating restraint.

Conclusion: Sibs differ in their responses to internal and external food cue responsiveness. However, these differences did not predict differences in sib adiposity. Thus, other non-shared factors must contribute to adiposity differences.

EVALUATION OF METHODS FOR PREDICTING DAILY ENERGY INTAKE AND HANDLING MISREPORTING IN PREGNANT WOMEN

Daniel E. Rivera, PhD[1], Penghong Guo, Master in Chemical Engineering[1], Danielle Symons Downs, Ph.D.[2], Jennifer S. Savage, PhD[3]

[1]Arizona State University, Tempe, AZ; [2]The Pennsylvania State University, University Park, PA; [3]Penn State University, University Park, PA

Background: Energy balance modeling is critical to understanding the effects of an intervention to manage gestational weight gain (GWG); however, its effectiveness is limited as a result of energy intake (EI) misreporting. Traditional methods for identifying under-reporting are limited, as participants are often excluded from analyses if identified as misreporting. **Methods**: We examined a series of novel model-based approaches originating from systems science techniques (system identification and state estimation) to characterize reporting accuracy of 17 overweight and obese pregnant women (OW/OBPW; age *M:* 28.9, *SD*: 5.1, and BMI *M:* 29.6, *SD:* 4.0) participating in an intervention to manage GWG. Method 1 back-calculates energy intake from a closed-form energy balance model and daily weight and physical activity measurements. Method 2 applies a constrained semi-physical identification approach that estimates the extent of systematic under-reporting in the presence of noisy measurements and possibly missing data. Method 3 is an adaptive algorithm that uses Kalman filtering. **Results**: Misreporting was common among the intervention population, with under-reported EI (determined as a percentage of participant-reported EI from MyFitnessPal (MFP)) ranging from 5.2% to 118% for Method 1. Despite conceptual differences between the techniques, the estimated % EI under-reported by the intervention population was similar among the three methods, consisting on average of *M:* 50.9% *SD*: 35% for method 1, *M*: 39.7%, *SD*: 42% for method 2, and *M:* 48.3% *SD:* 29% for method 3. All three methods led to better predictions of GWG in comparison to reported EI. **Conclusion:** Understanding EI under-reporting is an important consideration in a GWG intervention for OW/OBPW, which must be recognized in order to obtain meaningful weight predictions from energy balance models. The examined methods are amenable for use in real-time clinical settings, which remains a topic for further study.

IMPULSIVITY MODERATES THE RELATIONSHIP BETWEEN AFFECTIVE AND PHYSICAL STATES AND DIETARY LAPSES: AN EMA STUDY.

Stephanie Manasse, MS[1], Leah M. Schumacher, M.S.[1], Stephanie P Goldstein, M.S.[2], Ross D. Crosby, PhD[3], Meghan L. Butryn, PhD[1], Evan M. Forman, PhD[1]

[1]Drexel University, Philadelphia, PA; [2]Drexel University, Philadelphi, NJ; [3]Neuropsychiatric Research Institute, Fargo, ND

Lack of success in weight loss programs can be partially attributed to lack of adherence to dietary recommendations, i.e., dietary lapses. Yet, research attempting to identify momentary predictors of dietary lapses is mixed, potentially because there are baseline characteristics that moderate the relation between momentary factors and subsequent lapse occurrence. In particular, baseline levels of impulsivity (i.e., the tendency to make decisions without proper forethought), a well-established correlate of obesity and weight outcomes, may moderate the relation between momentary changes in affective and physical states and likelihood of dietary lapses.

As such, we examined baseline impulsivity as a moderator of the relation between momentary changes in affective and physical states and the subsequent likelihood of lapse occurrence in overweight and obese adults (n=190) completing a 2-week ecological momentary assessment (EMA) protocol at the beginning of a behavioral weight loss intervention. Specifically, we examined inhibitory control (the ability to inhibit a prepotent response) and negative urgency (the tendency to act rashly in the context of negative affect) as baseline moderators. Generalized estimating equations indicated that the relation between increases in stress and likelihood of lapsing was more pronounced for those with poorer inhibitory control (b=.001, p=.01). Similarly, the relation between increases in loneliness and subsequent lapse likelihood was strongest for those higher in negative urgency (b=.32, p =.03). Interestingly, the relationship between momentary increases in hunger and subsequent lapse likelihood was strongest for those lower in baseline levels of negative urgency (b=-.23, p

Results support the notion that baseline impulsivity moderates the relationship between momentary changes in affective and physical states and subsequent lapse likelihood. Impulsivity may strengthen the relationship between affective states and subsequent lapses, while increases in physical states, such as hunger, may be particularly predictive of lapses for those lower in impulsivity. With replication, results could point towards tailoring the provision of weight loss strategies based on impulsivity level.

INDIVIDUALS' PERSPECTIVES ON FACTORS INFLUENCING THE DECISION TO INITIATE WEIGHT LOSS TREATMENT

Megan McVay, PhD[1], William Yancy, MD[1], Gary G. Bennett, PhD[2], Corrine Voils, PhD[3]

[1]Duke University School of Medicine, Durham, NC; [2]Duke University, Durham, NC; [3]Durham VA Health Services Research & Development, Durham, NC

Background: Although effective behavioral weight loss treatments are available, only a small portion of adults with obesity initiate these treatments. We sought to understand individuals' perspectives on factors contributing to initiation of behavioral weight loss treatment. **Methods:** Our population was adults with obesity who reported an effort to lose weight in the past year. Participants were recruited at primary care clinics and at commercial- and health system-based behavioral weight management programs. We conducted three focus groups with individuals who had initiated treatment in the past year (n=27), and three focus groups (n=24) and eight individual interviews with individuals who had not initiated treatment in the past five years. Questions focused on reasons for initiating or not initiating treatment. Directed content analysis was used to analyze transcribed data. **Results:** Participants were 61% female, 51% Caucasian, and had a mean age of 55 years. Five domains were identified: treatment content, practical aspects of treatment, social aspects of treatment, evaluation of the evidence, and identity factors. Treatment content factors that reportedly influenced treatment initiation included prescribing of certain foods, how individualized treatment would be, and how much of the content would be new to participants. Practical treatment features reported to be important included reasonable cost, schedule compatibility, and delivery modality. For some participants, treatment entry was motivated in part by social aspects of treatments, including accountability and enhancement of motivation through support or competition; alternatively, some viewed social aspects as reasons to avoid treatment due to risk of embarrassment, disappointing others, and loss of autonomy. Participants were influenced by their evaluation of the evidence for treatment effectiveness, which was driven by their prior experiences, observation of others' experiences, health care providers' advising, and trust in the information source. Also relevant to treatment initiation were identity factors, including perception of obesity severity, desire to be self-sufficient, and viewing treatment use as consistent with identity. **Conclusions**: These factors can inform strategies to increase treatment initiation, thereby increasing population weight loss.

INTEGRATING MINDFULNESS INTO A PHONE-BASED BEHAVIORAL WEIGHT LOSS PROGRAM: A RANDOMIZED PILOT STUDY

Kelly Carpenter, PhD[1], Katrina Vickerman, PhD[1], Erica Salmon, BA[2], Harold Javitz, PhD[3], Jennifer Lovejoy, PhD[4]

[1]Alere Wellbeing, Seattle, WA; [2]Alere Wellbeing, SEATTLE, WA; [3]SRI International, Menlo Park, CA; [4]Arivale, Seattle, WA

In an attempt to improve weight loss outcomes in those with high levels of emotional eating, the present project integrated mindfulness and mindful eating training into an existing phone-based behavioral weight loss program delivered by health coaches. Participants were enrollees into the employer-sponsored weight loss program with starting BMI between 25 kg/m^2 and 35 kg/m^2 and who had high levels of emotional eating.

Seventy-five participants were randomized to the new mindfulness weight loss program (n = 50) or the standard behavioral weight loss control (n = 25). They ranged in age from 26 to 68, were predominately white non-Hispanic (65.3%) females (92%) with some college (95%), and had a mean BMI (31.5 kg/m^2) in the obese range. Nearly half (46.6) had clinically significant anxiety (GAD-7 scores of > 10).

Results: Percent weight lost did not significantly differ for intervention (m = 2.7%, SD = 4.9%) vs. control (m = 3.1%, SD 3.7%) at 6 months. Intervention participants had significantly better scores at follow-up on mindful eating (F = 9.3 (1, 66), p < .01), binge eating (F = 8.29 (1, 63), p < .01), weight related experiential avoidance (F = 8.55 (1, 63), p < .01), and one mindfulness subscale (F = 21.63 (1, 63), p < .001). At follow-up, 25.6% of the intervention group had clinically significant anxiety compared to 45.5% of control participants, $\chi^2(1,N=65)=2.63$, p = 0.11. Exploratory analyses showed that improvements on several measures predicted more weight loss in the intervention group: mindful eating, $r_\tau(n = 40) = -0.24$, $p = 0.03$, disinhibition, $r_\tau(n = 40) = -0.26$, $p = 0.02$, and weight related experiential avoidance, $r_\tau(n = 38) = 0.25$, p = 0.03. Intervention participants who meditated the most lost twice as much weight (4.39%) as those who meditated less or not at all (1.96%), p = .13.

Conclusions. This small randomized pilot found that integrating mindfulness into a phone-based behavioral weight loss program was feasible and acceptable, but did not produce more weight loss. However, intervention participants decreased binge eating and anxiety.

Mechanisms of change observed in the intervention group suggest that some who embrace mindful eating and meditation may lose more weight with mindfulness. Future research should investigate how to identify those who might benefit from this type of intervention.

META-ANALYSIS OF THE PREVALENCE OF CLINICAL AND SUBTHRESHOLD BINGE EATING BEFORE AND AFTER BARIATRIC SURGERY

Mindy L. McEntee, M.S., Robert Bailey, MA, MS, Jane Ellen. Smith, Ph.D.

University of New Mexico, Albuquerque, NM

Recurrent binge eating has been associated with lower quality of life, impaired functioning, psychological comorbidities, higher body weight, and related cardiovascular and metabolic health problems. Recent studies also suggest distress is comparable among those with Binge Eating Disorder and subthreshold binge eating behavior, yet prevalence varies widely across studies. The present study sought to synthesize this literature by using meta-analytic techniques to better estimate the prevalence of both BED and subthreshold binge eating among obese adults before and after weight loss surgery and assess the degree of heterogeneity among these studies.Odds ratios were extracted from eligible studies using standardized assessments to determine the prevalence of BED or subthreshold binge eating in a single sample of adults at pre-surgical baseline and post-surgical follow-up. Separate meta-analyses were performed for the prevalence of BED and subthreshold binge eating. Odds ratios (ORs) were extracted from 16 published studies reporting on a total of 1,481 bariatric patients; 9 reported the prevalence of BED, 11 reported the prevalence of subthreshold binge eating. A binary random effects model indicated the prevalence of BED was nearly six times greater at baseline than follow-up (OR: 5.89, 95% CI [3.05, 11.39]), with an I^2 statistic indicating 45% of the variance among studies was attributable to heterogeneity rather than chance. Prevalence of subthreshold binge eating was more than four times greater at baseline compared to follow-up (OR: 4.34, 95% CI [2.33, 8.08], with 81% of the variance attributed to heterogeneity. This study is among the first to quantify changes in the prevalence of binge eating before and after bariatric surgery. While not causally interpretable, it is interesting to note that studies consistently reported a large and significant decrease in binge eating following bariatric surgery, even when criteria were adjusted to accommodate the consumption limitations imposed by the procedure. Future research may wish to examine whether differences in heterogeneity stem from variations in study methodology or real variation in treatment effects, as the latter offers the opportunity to identify factors which may modify the impact of treatment.

OBESE GIRLS HAVE LOWER INTERPERSONAL TRUST SCORES THAN HEALTHY WEIGHT GIRLS

Heather K. Hardin, PhD, RN, Shirley M. Moore, PhD

Case Western Reserve University, Cleveland, OH

Purpose: The purpose of this study was to describe the relationship between interpersonal trust beliefs and body mass index (BMI) in a sample of adolescents.

Rationale: A need exists for innovative interventions targeting weight self-management among adolescents. Our study presents preliminary evidence supporting the addition of trust as a component in weight self-management interventions for use with adolescents.

Methods: Participants were 211 adolescents aged 14-19 years attending public high school in the Midwestern United States. Trust beliefs were measured using the total trust score from the ten Likert items of the Interpersonal Trust in Physician Scale. BMI was determined using self-reported height and weight following measurement during a school screening. The relationship between interpersonal trust and BMI was evaluated using correlation. Differences between underweight, healthy weight, overweight, and obese BMI groups were evaluated using ANOVA.

Results: Overall, trust had a small, negative correlation with BMI ($r = -.17$, $p = .02$), and a medium, negative correlation among girls ($r = -.30$, $p = .002$). There were no statistically significant linear relationships between trust and BMI for boys. One-way ANOVA demonstrated significant differences in trust scores according to BMI group among girls [$F(3, 99) = 4.3$, $p = .007$] with a large effect size ($\text{eta}^2 = .12$). Posthoc Tukey comparisons indicated the mean trust scores were significantly different between the healthy BMI and obese BMI groups of girls.

Conclusions: Results of this study support inclusion of trust-building as a component in weight self-management interventions for use with adolescents.

PERCEPTIONS OF WEIGHT STIGMATIZING COMMENTS AND COMMENTERS: THE INFLUENCE OF SOCIAL DISTANCE AND COMMENTER CHARACTERISTICS.

Chelsey Solar, M.S./Ed.S[1], James J. Rossi, MA[1], Reid Hlavka, B.A.[2], Jennifer C. Selensky, Bachelor of Science[1], Emily Hefner, Student[3], Robert Carels, Ph.D., MBA[1]

[1]East Carolina University, Greenville, NC; [2]East Carolina University, Winterville, NC; [3]East Carolina Universtiy, greenville, NC

Objective: The purpose of the study was to examine factors that affect perceptions of weight stigmatizing comments including characteristics of the commenter and their relationship to the individual receiving a weight stigmatizing comment.

Methods: Participants were 844 (*M* age = 18.6, 66.6% Female, 76% European American) students recruited from a large southeastern university. Participants viewed a vignette describing an overweight woman receiving a weight stigmatizing comment from a target individual. The target individual's weight (thin/overweight), social relationship (friend/romantic partner/salesperson) and gender (male/female) were manipulated and participants provided personality trait ratings (hard working, will power, self-sacrificing, good self-control, good self-esteem, intelligent, successful, kind) and ratings of acceptability of the comment made by the target individual.

Results: There was a significant interaction between social relationship and gender $F(2,762)=6.41$, $p=.002$ with $\eta^2=.02$, such that when the target was a male romantic partner or salesperson, they were rated significantly more negatively than male friend targets, while female friend and salesperson targets were rated more negatively than female romantic partner targets. In addition a significant main effect was found for weight $F(1,762) = 35.65$, $p < .001$ with $\eta^2=.05$ indicating that overweight targets were rated more negatively on personality traits than thin targets in all conditions. Additionally, there was main effect of social relationship on social acceptability $F(2, 821) = 36.14$, p2=.08. Post hoc analysis using a Bonferronni correction indicated that participants viewed the stigmatizing comment from the salesperson target as more unacceptable than a comment from a romantic partner or friend, while there were no differences in acceptability of the stigmatizing comment from the friend or romantic partner targets.

Conclusions: The acceptability of weight stigmatizing comments and the perception of commenters is dependent on their social distance from the individual receiving the comments and the gender and weight status of the commenter.

PREVALENCE OF OBESITY IN AUTISTIC YOUTH FROM 2003 TO 2011: TRENDS IN ENVIRONMENTAL AND BEHAVIORAL RISK FACTORS

Madelyn Ruggieri, B.A.[1], Elizabeth A. Jones, B.S[2], Suhani Patel, N/A[3], E. Amy Janke, PhD[4], Jessica Sautter, PhD[4]

[1]Center for Weight and Eating Disorders, University of Pennsylvania, Kennett Square, PA; [2]University of Pennsylvania, Reading, PA; [3]University of the Sciences in Philadelphia, Warminster, PA; [4]University of the Sciences, Philadelphia, PA

Prevalence of Obesity in Autistic Youth from 2003 to 2011: Trends in Environmental and Behavioral Risk Factors

Background: Obesity occurs at higher rates in youth with autism spectrum disorders (ASD); however, little is known about trends in the co-occurrence of ASD and obesity across recent years.

Objectives: Using nationally representative samples from 2003, 2007, and 2011, examine changes over time in ASD diagnosis as a risk factor for obesity, trends in environmental and behavioral factors contributing to obesity independent of ASD, and the impact of functional limitations and diagnostic severity on the likelihood for obesity in youth with ASD.

Methods: Data from youth age 10-17 collected from the 2003, 2007, and 2011 National Survey of Children's Health were used. Binary logistic regression models were conducted for each year examining the impact of ASD diagnosis, environmental and behavioral factors, functional limitations, and diagnostic severity on obesity rates in individuals with and without a self-reported ASD diagnosis.

Results: Prevalence of ASD increased at each time point; prevalence of obesity in ASD youth increased from 2003 (22.64%) to 2007 (30.17%) then decreased in 2011 (23.42%). Youth with ASD demonstrated approximately 1.5 times the risk for obesity compared to those not diagnosed in 2003 and 2011, and nearly twice the risk for obesity in 2011 (2003 OR=1.48; 95%CI=0.99-2.21; 2007 OR=1.94; 95%CI=1.56-2.41; 2011 OR=1.43; 95%CI=1.22-1.68). Environmental and behavioral risk factors consistently associated with increased rates of obesity in youth with ASD included age, race, gender, socioeconomic status, screen time, and physical activity (p's < .001). Prevalence rates of mild and moderate diagnoses of ASD rose from 2007 to 2011, however those who reported a more severe diagnosis were more likely to

be obese compared to those who reported a mild diagnosis in both years (2007 OR=2.27; 95%CI=1.11-4.62; 2011 OR=1.53 95%CI=1.08-2.17). Functional limitations associated with ASD were related to significantly increased risk for obesity in youth with ASD (p’s < .05).

Conclusions: ASD is a significant, consistent risk factor for obesity. Environmental and behavioral factors that increase likelihood of ASD and obesity in youth (i.e., age, gender, race) appear to contribute to the increased risk of co-occurrence. Additionally, severity of ASD diagnosis and functional differences associated with the diagnosis contribute to increased risk of obesity in youth with ASD.

PSYCHOMETRIC EVALUATION OF THE BARRIERS TO HEALTHY EATING SCALE IN FOUR WEIGHT LOSS STUDIES

Ran Sun, MSN, Jeffrey Rohay, PhD, MSIS, Yang Yu, MSN, Susan Sereika, PhD, Jacob Kariuki, PhD, Lora Burke, PhD, MPH

University of Pittsburgh, Pittsburgh, PA

Background: The Barriers to Healthy Eating (BHE) scale was developed to measure factors that may thwart adherence to a weight management eating plan such as food shopping, affordability, or emotions related to food intake restriction. **Objective:** The purpose of this study was to evaluate the internal consistency, construct validity and convergent validity of the BHE in four independent weight loss intervention studies conducted over a 12-year period. We hypothesized a moderate negative correlation between the BHE total score and the Weight Efficacy Lifestyle Questionnaire (WEL) total score. **Methods:** Internal consistency was assessed using Cronbach's α and convergent validity was tested by correlating baseline BHE and WEL total scores. Principal component analysis (PCA) with Promax rotation was performed to examine the factor structure of the BHE. Analyses were conducted separately for the four sequential studies: PREFER (2002-2004, N=176), SMART (2006-2008, N=197), SELF (2009-2011, N=129), and EMPOWER (2012-2014, N=129). **Results:** The four samples had similar gender (female 82.9% - 89.9%) and race (white 70.5% - 81.4%) distributions. Compared to the two earlier studies, participants in SELF and EMPOWER studies were significantly older (51.9 ± 10.2 vs. 45.4 ± 9.1). Across the four studies, Cronbach's α for the BHE ranged from 0.85 to 0.88. Total scores for the BHE and the WEL were moderately negatively providing support for the convergent validity of the BHE (r = -0.51 to -0.59, pself-control and motivation, food preparation, *absence satisfaction*, and *social support*. *Food preparation* accounted for a larger proportion of variance (28.6%) in the EMPOWER study. **Conclusion:** The BHE showed very good psychometric properties across the four studies, supporting its use in measuring factors that may influence an individual's ability to overcome barriers to adopting a healthy eating pattern that supports improved weight loss and maintenance. Additional work is needed to examine the psychometric properties in more diverse samples having a greater proportion of males and those with less education.

TARGETING BODY IMAGE AMONG ADULT WOMEN ATTEMPTING WEIGHT LOSS: IMPACT ON EATING, EXERCISE, QUALITY OF LIFE, AND WEIGHT

KayLoni Olson, MA[1], Charles F. Emery, PhD[2], Tyler Thaxton, B.S. in Psychology and Neuroscience[3]

[1]Brown University, Providence, RI; [2]Ohio State University, Columbus, OH; [3]The Ohio State University, Columbus, OH

Body dissatisfaction (BD) is prevalent among overweight and obese adults. Because negative body image is a risk factor for maladaptive eating and exercise behaviors, it may be a barrier to weight loss. This study targeted BD among overweight and obese women by evaluating effects of a randomized intervention on eating and exercise behavior, quality of life (QOL), and weight loss.

Overweight and obese women (n=44; 71%white; 7.9±7.6years; BMI: 30.5± 2.9) were recruited and screened for BD and a desire to lose weight. Participants were randomized to one of two, 4-week, treatment conditions: a usual care (UC) group (n=21) engaged in daily tracking of diet and activity level; or an intervention (INT) group (n=23) engaged in daily tracking with four weekly, one-hour Body Project group meetings. The Body Project is a widely studied intervention designed to target BD among adolescent females. At baseline and program completion, height/weight were measured and participants completed self-report questionnaires of body image, eating and exercise, and QOL. Analysis of variance (ANOVA) was utilized for analyses.

Results indicated time main effects for BMI (F(1, 33)=8.00, p=.01), BD (F(1, 33)=14.93, p < .001), and QOL: mental (F(1, 33)=7.05, p=0.01), physical (F (1, 32)=5.19, p=0.03) and weight-related (F(1, 33)=17.33, p < .001). In both groups, BMI and BD decreased and quality of life improved. Neither group reported change in thin ideal internalization, body appreciation, eating- and exercise-related variables, or negative affect. Post-hoc repeated measures ANOVAs among individuals who endorsed elevated BD (n=26) at baseline revealed significant time by group interactions for body appreciation, thin ideal internalization, and BMI. Improvements in all outcomes were observed only in the INT group.

The results suggest that BD can be targeted successfully among adult women attempting weight loss, but not all individuals may benefit from body image treatment. Among women with elevated BD, the Body Project intervention generated beneficial results and could be useful in treating select participants in behavioral weight management.

THE EFFECT OF NEIGHBORHOOD WALKABILITY ON BMI, A RETROSPECTIVE LONGITUDINAL STUDY OF 1.7 MILLION MILITARY VETERANS

Elizabeth Tarlov, PhD[1], Shannon Zenk, PhD[2], Stephen Matthews, PhD[3], Coady Wing, PhD[4], Sandy Slater, PhD[2], Aster Xiang, M.S.[2], Hao Tong, MS[1], Lisa Powell, PhD[2]

[1]Edward Hines, Jr. VA Hospital, Hines, IL; [2]University of Illinois at Chicago, Chicago, IL; [3]The Pennsylvania State University, University Park, PA; [4]Indiana University-Bloomington, Bloomington, IN

Background

Attributes of the built environment thought to support or present barriers to physical activity are correlated with residents' body weight but causal relationships have proven difficult to demonstrate. The Weight and Veterans' Environments Study I is a retrospective longitudinal study of over 2.5 million military veterans living in U.S. metropolitan areas and receiving Department of Veterans Affairs health care. The objective of this analysis was to determine the extent to which neighborhood walkability helped people to maintain healthier BMI over time, up to 6 years.

Methods

The analytic sample was 1,522,848 men and 183,619 women aged 20-65 at baseline. For each study year, we constructed a walkability index based on population, housing, street intersection, and walking destination density and percentage of 4-way intersections within 1 mile of veterans' homes. The VA Corporate Data Warehouse provided veteran BMI, demographics, and health conditions. Gender-stratified panel data regression models including time and person fixed effects and controlling for area SES, parks, and commercial fitness facilities estimated the effect of walkability on BMI. This approach exploited change in walkability arising from neighborhood change and residential moves.

Results

BMI (SD) at baseline was 30.2 (6.0) for men and 29.5 (6.4) for women. Among men and women (6,668,095 and 773,506 person-year observations), greater walkability led to significant though small BMI reductions (for a 1 SD increase in walkability: men b -0.035, $p < 0.000$; women -0.044, $p=0.001$). These effects were 75% smaller than cross-sectional model results (not shown). In longitudinal sensitivity analyses using a 1/4-mile walkability measure, effects were even smaller and statistically insignificant.

Conclusions

Results provide some support for the hypothesis that greater neighborhood walkability has salutary effects on BMI among adults. The longitudinal study design rules out reverse causality

as an explanation. However, the results are sensitive to the scale at which walkability is measured and the much smaller coefficients obtained from models more robust to selection bias suggest that walkability effects on BMI are modest. Additional work is needed to determine whether policy interventions aimed at increasing walking may be more productive in certain subpopulations (e.g., older age, lower income, central city) or when directed at specific walkability components (e.g., walking destination density).

THE MEDIATING EFFECT OF PSYCHOLOGICAL AND ENVIRONMENTAL FACTORS BETWEEN SOCIOECONOMIC STATUS AND UNHEALTHY DIET BEHAVIORS

Sunyoung Jung, PhD, RN[1], Robin Whittemore, PhD, APRN, FAAN[1], Soohyun Nam, PhD, APRN, ANP-BC[2]

[1]Yale University, School of Nursing, Orange, CT; [2]Yale University, School of Nursing, West Haven, CT

Unhealthy diet is one of major modifiable risk factors of obesity in African Americans (AAs). While many independent risk factors of unhealthy diet behaviors have been identified, little is known about the potential associations between them or the complex mechanism explaining diet behaviors. The aim of the study was to examine the direct and indirect effects of socioeconomic status (SES) on the latent variable of unhealthy diet behaviors through psychological and environmental factors in overweight or obese AAs.

A total of 225 AAs overweight or obese (mean BMI = 33.3 ± 6.1 kg/m2; mean age = 54.4 ± 13.6 years; 76.4 % women; median income=about $40,000) participated in a cross-sectional study. The model included four latent variables: SES (education, employment, income), psychological factors (diet self-efficacy, barriers to healthy diet, health perception), environmental factors (aesthetic quality, walking environment, food environment, safety, violence, social cohesion), and unhealthy diet behaviors (% energy from fat intake, soda/sweetened beverage consumption, fast food consumption). Data were obtained by using validated measures. Data were analyzed using structural equation modeling with bootstrapping procedures.

In a regression equation without the mediators, the relationship between SES and unhealthy diet behaviors was significant (β=-.20, p=.04). In the multiple mediation model with the two mediators, psychological and environmental factors, SES did not have a significant direct effect (β=.06, p=.61) on unhealthy diet behaviors, which indicated an indirect effect of SES on unhealthy diet behaviors (β=-.27, p=.01). SES had a direct effect on psychological (β=.53, $p < .01$) and environmental (β=-.40, p=.02) factors. Psychological (β=-.31, p=.02) and environmental (β=.26, p=.01) factors also had a direct effect on unhealthy diet behaviors. Thus, the relationship between SES and unhealthy diet behaviors was fully mediated by the two mediators. The fit indices were acceptable for the conceptual model (χ^2/df=1.62, GFI=.92, RMSEA=.05, TLI=.92, CFI=.93), which explained 17.2% of the variance in unhealthy diet behaviors.

Psychological and environmental factors play a significant role in the relationship between SES and unhealthy diet behaviors for overweight or obese AAs. Enhancing diet self-efficacy, reducing barriers to a healthy diet, and improving the physical and social environment of AA adults may be important strategies to promote healthy diet behaviors.

THE MISPERCEPTION OF BODY WEIGHT CATEGORIES IN COLLEGE STUDENTS

Ryan Roberts, Undergraduate Student[1], Christopher Anderson, PhD[2], Ron Hammond, PhD[3]

[1]Utah Valley University, Alpine, UT; [2]Utah Valley University, orem, UT; [3]Utah Valley University, Orem, UT

Background: Current literature suggests that approximately 20%-33% of Americans inaccurately predict their own BMI category. This can be a problem for many since this perception can contribute to one’s perceived need to integrate healthy behaviors into their lifestyle.

Purpose: The purpose of this study was to determine the frequency of individuals with an inaccurate view of their Body Mass Index (BMI) category. More understanding of individual perceptions regarding body weight can assist in increasing awareness and promoting behavior change.

Method: 966 were participants recruited from college classes and social media outlets completed an online survey regarding their gender, height, weight, and perception of their body weight category. The traditional calculation of BMI, as well as the established categories of underweight, normal weight, overweight, and obese were calculated after data collection and compared to participants’ perceptions.

Results: 39.4% of our sample reported a self-perceived weight category different than their traditional BMI category. Additionally, 39.8% of overweight participants felt they were normal weight. Amongst obese participants, 74.3% reported feeling overweight, 8.7% believed they were normal weight, and just 17% reported belonging in the obese category.

Discussion and Conclusions: Clinicians would benefit from this study by more fully understanding the scale of patient misperception regarding their obesity status. Increased awareness can encourage patients to make necessary adjustments to manage their weight. Future research should employ clinical samples regarding patient perception of weight category. Health care providers should take into account that people often misperceive their weight categories as they discuss individual's health status and need for behavior change.

UNDERSTANDING THE IMPACT OF RURAL WEIGHT LOSS INTERVENTIONS: A SYSTEMATIC REVIEW

Gwenndolyn C. Porter, MS[1], Fabiana Brito, BSN, MSPH, PhD[2], Daniel Petreca, Visiting researcher[1], Gina Schwieger, N/A[3], Paul A. Estabrooks, PhD[1]

[1]University of Nebraska Medical Center, Omaha, NE; [2]University of Nebraska Medical Center, La Vista, NE; [3]University of Nebraska Medical Center College of Public Health, Omaha, NE

Introduction: Adults in rural areas are at a higher risk of developing obesity than their urban counterparts. As a result, a number of interventions have attempted to deliver evidence-based weight management strategies in rural regions where health education, public health, and clinical resources are scarce. However, the impact of these interventions, defined as reach by effectiveness, has not been examined.

Methods: A systematic review was conducted using PubMed, Scopus, Embase, and CINAHL databases to identify interventions that took place in a rural community, targeted adults, and reported weight loss as the main outcome. All non-intervention studies and articles not published in English were excluded. Data on reach (e.g., number of participants, participation rate, representativeness) and effectiveness (e.g., weight change, percent body weight change) were abstracted from each article. A secondary goal was to determine the availability of data on cost of implementation and cost per clinically meaningful weight loss.

Results: 62 articles were identified that reported on rural weight loss interventions, including 51 unique interventions and 4 protocol papers with no published primary outcomes associated with those interventions. Median study duration was 12 weeks (n=43 studies). The median number of participants was 108 (n=51 studies) with a median participation rate, defined as the proportion of participants relative to the number of eligible individuals, of 69.3% (n=20 studies). When participation rate was considered as the proportion of participants relative to those exposed to recruitment, the median rate fell to 35.1% (n=24 studies). No studies reported on the representativeness of the sample when compared to the target population. Median weight loss per participant was 3.15kg (n=41 studies), while the median proportion of participants that reached effective weight loss (≥5% of body weight) was 50% (n=13 studies). Only 2 of the 62 articles reported on cost-effectiveness; depending on the intervention group, costs ranged from \$22-\$33 per kg body weight lost in one study, or \$714-\$1029 per participant that lost 10% body weight in the other study.

Conclusion: Rural weight loss interventions appear to be effective at supporting significant weight loss, but the reach and cost of interventions delivered to a rural population is still difficult to determine.

CORRELATIONAL STUDY OF OCCUPATIONAL DISTRESS AND HEALTH AMONG PROFESSIONAL CLERGY

Benjamin Webb, PhD, CSCS, Kirstie Chase, BS

Southern Illinois University Edwardsville, Edwardsville, IL

Psychosocial stress is associated with an increased risk for obesity and chronic disease. High rates of obesity and chronic disease has been documented among professional clergy. Occupational distress may be a contributing factor to poor health outcomes among professional clergy. Thus, the purpose of this study was to examine correlations among occupational distress, physical and mental health, and health behaviors among a sample of clergy. A convenience sample of full-time clergy in Illinois (*N* = 221) completed a self-report questionnaire regarding their demographics, job characteristics, personal health, physical activity, and sedentary behavior. Clergy also completed the Clergy Occupational Distress Index (CODI). Data were analyzed using descriptive statistics and Pearson's product moment correlations. Clergy were mostly middle-age (*M*=51.9 years, *SD*=12.1), male (74%), white (95%), and held a Master's degree or higher (93.1%). The average years in ministry was 18.7 (*SD*=13.2) and the average hours worked per week was 46.1 (*SD*=16.1). Many clergy reported being treated for high blood pressure (33.5%), high cholesterol (29%), diabetes (10.4%), heart disease (6.8%), depression (14.9%), and anxiety (12.7%). Many of the clergy were also obese (52.0%), yet the majority perceived they were in good physical health (58.4%). Clergy reported spending an average of 6.58 hours/day sitting (*SD*=3.47) and a median of 87.5 min/week (*IQR*=0 – 255) in moderate-to-vigorous physical activity. The average score on the CODI was 11.5 (*SD*=3.41). Perceived occupational distress was positively correlated with hours worked per week ($r(221) = .277$, $p < .001$), diabetes ($r(221) = .148$, $p = .028$), depression ($r(221) = .262$, $p < .001$), anxiety ($r(221) = .234$, $p < .001$), and hours/day spent sitting ($r(221) = .157$, $p = .020$). Perceived occupational distress was negatively correlated with years in ministry ($r(221) = -.184$, $p = .006$) and age ($r(221) = -.318$, $p < .001$). The present study provides support for the negative influence of occupational distress on the health of full-time clergy, especially those who may be less experienced. Further research is needed to examine the temporal associations among occupational distress, health, and health behaviors among full-time clergy.

MERITORIOUS AWARD WINNER

DOSE RESPONSE RELATIONSHIP BETWEEN MATERNAL WORK STRESS AND EARLY CHILDHOOD AGGRESSION IN THE FRAGILE FAMILIES COHORT

Kathryn P. Smith, MPH[1], Cassandra A. Okechukwu, ScD, MSN[2], Janine Bacic, MA[3]

[1]Harvard T.H. Chan School of Public Health, Charlestown, MA; [2]Harvard T. H. Chan School of Public Health, Boston, MA; [3]Harvard University School of Public Health, East Greenwich, RI

Introduction

Much of the research on working mothers has concentrated on whether or not maternal employment influences children's behavioral and health outcomes. However, studies of impacts of employment on workers' health demonstrate that deleterious effects arise not from employment per se, but from hazardous workplace exposures, such as psychosocial stress. We contend that maternal work stress is an underexplored exposure associated with behavioral outcomes in children, especially in early childhood. Informed by the ecological systems model (Bronfenbrenner, 1986), the goal of this project is to investigate whether the levels of maternal work-stress during child's first year is associated with early childhood aggression.

Methods

Our sample includes 1471 mothers from the Fragile Families & Child Wellbeing study, a cohort of nearly 5,000 children born in large U.S. cities between 1998 and 2000. Mothers eligible for the analytic sample reported working during their child's first year of life and also completed the Child Behavioral Checklist (CBCL) when child was 3 years old. Work stress was measured using an adapted version of the Emlen Scale of Work Flexibility, categorized as low (36.44% of sample), medium (44.73%), high (18.83%) work stress based on data distribution. Child aggression scores were generated by adding 19 aggression-related items from the CBCL. We estimated multivariable associations using linear regression, controlling for mother's age, race/ethnicity, education, marital status, income, and # of other biological children. Further complex analyses controlling for other parental and child variables are planned. Additionally, analyses to test potential mechanisms explaining this association will be conducted.

Results

The study sample is comprised of non-Hispanic Black (53.16%), non-Hispanic White (23.93%), Hispanic (19.31%), and Other (3.60%). Over 76% of mothers were unmarried at baseline and over 57% had a high school education or less. Nearly 43% of the sample reported a pre-tax total household income less than $19,999 in the previous year. Unadjusted models revealed that each 1 point increase in maternal work stress score is associated with a 0.44 increase in child aggression score ($p < 0.001$). The relationship held in multivariable models. Compared to mothers with low work stress, those with medium work stress reported, on average, a 1.06 higher aggression score in child ($p=0.006$), while those with high work stress reported, on average, a 2.33 higher aggression score in child ($p < 0.001$).

Conclusion & Policy Implications

Analyses to date reveal a positive association between maternal work stress and early childhood aggression. This research supports the need to consider parenting interventions and childcare policies in tandem with workplace interventions focused on stress reduction.

ORGANIZATIONAL AND CO-WORKER SUPPORT, DIABETES RISK AND JOB STRESS AMONG EMPLOYEES

Marilyn Wolff, MPH[1], Jennifer L. Gay, PhD[2], Mark G. Wilson, HSD[3], David DeJoy, PhD[4], Robert Vandenberg, PhD[2]

[1]University of Georgia/College of Public Health, Atlanta, GA; [2]University of Georgia, Athens, GA; [3]University of Georgia/College of Public Health, Athens, GA; [4]College of Public Health, University of Georgia, Athens, GA

Purpose: Examine the moderating role of perceived organizational and coworker support on the relationship between job stress and type 2 diabetes risk among employees.
Design: A cross-sectional survey was administered to employees at the workplace.
Setting: One national retail organization.
Subjects: Baseline data were obtained from 1,595 employees in 21 retail stores.
Measures: Self-reported organizational and coworker support to encourage and fulfill job responsibilities, and job stress. Diabetes risk was calculated using age, gender, race/ethnicity, blood pressure, physical activity, weight status, and self-reported diagnosed type 2 diabetes.
Analysis: Multilevel multiple regression was conducted to test the interaction effect of support on the association between job stress and diabetes risk.
Results: Mean age was 37.95 years (±12.03) and BMI was 26.72 (±4.95). Three percent of participants reported diagnosed diabetes. Organizational support was positively associated with co-worker support. Both were negatively associated with job stress. Organizational support, but not coworker support, moderated the relationship of job stress with diabetes risk. Participants with greater perceived organizational support had lower diabetes risk scores compared to those with lower perceived organizational support.
Conclusion: Organizational support may be a key factor for workplaces to reduce stress and diabetes risk. Further testing of organizations' supportive role on employee health may be helpful in developing future workplace programs.

SELF-COMPASSION PREDICTS BETTER SUPERVISOR EVALUATIONS IN UNIVERSITY FACULTY AND STAFF

Fawn Walter, M.S.[1], Ryan Lackner, M.A.[1], Joel W. Hughes, PhD[2]

[1]Kent State University, Stow, OH; [2]Kent State University, Kent, OH

Self-Compassion Predicts Better Supervisor Evaluations in University Faculty and Staff

Fawn A. Walter[1], M.S., Ryan Lackner[1], M.A., & Joel W. Hughes[1], Ph.D.

[1]Department of Psychological Sciences, Kent State University, Kent, OH

Introduction

Self-compassion, an attitude of self-kindness, mindfulness, and a sense of common humanity, has been consistently related to numerous health behaviors[1], stress and procrastination[2], psychopathology and resilience[3], and well-being[4]. Self-compassion has also been linked to increased compassion toward others and greater professional quality of life[5]. Thus, self-compassion appears to be an important factor in personal health and well-being across multiple domains. This study examined the relationship between self-compassion and supervisor evaluations in the workplace.

Methods

The sample (N = 54) was aged 46.52 ± 10.76, 79.6% female, and 83.3% Caucasian. Participants completed the Self-Compassion Scale (SCS), which measures three components, including self-kindness, common humanity, and mindfulness. Supervisor evaluations (scaled from 1 to 4) of employees at a large Midwestern university from four consecutive years (2011-2014) were used as dependent variables. Hierarchical linear regressions were performed to determine whether self-compassion explained variability in supervisor evaluations after controlling for age, sex, and education.

Results

Demographic variables did not explain variability in supervisor evaluations of employee work performance for any year. Adding the SCS composite improved model fit, such that overall self-compassion accounted for significant variability for each year that supervisor evaluations were recorded.

Discussion

In this sample of employees at a large Midwestern university, self-compassion predicted work performance, such that those who exhibited more self-compassion were more positively evaluated by their supervisors. Self-compassion likely promotes greater resilience, by encouraging individuals to see personal flaws and weaknesses accurately and approach them with kindness rather than judgment and harsh criticism[6]. Additionally, a self-compassionate approach includes being more mindful of one's environment and internal experiences and a sense of shared experiences with others, which most certainly influences workplace behaviors and achievement. These findings should be used to promote a focus on increasing self-compassion and foster healthier work environments.

FACTORS ASSOCIATED WITH LOW PAIN DISABILITY AMONG PATIENTS WITH HIGH PAIN INTENSITY

B Morasco, PhD[1], S Dobscha, MD[2], Ning Smith, PhD[3], Richard Deyo, MD, MPH[2], Carla A. Green, PHD, MPH[4], Bobbi Jo H. Yarborough, PsyD[3]

[1]VA Portland Health Care System, Portland, OR; [2]Oregon Health & Science University, Portland, OR; [3]Kaiser Permanente Center for Health Research, Portland, OR; [4]Kaiser Permanente Northwest, Portland, OR

Purpose:
A subset of patients with chronic pain report very high pain intensity, but low pain-related disability; little is known about this group. The purpose of this study is to examine the extent to which demographic and clinical variables are associated with low pain-related disability among patients with high self-reported pain intensity.

Methods:
Patients with chronic pain who were prescribed long-term opioid therapy (LTOT) (n=517) were recruited from two large integrated health care systems. We identified a subset of patients who endorsed severe pain intensity and compared demographic and clinical factors among three groups of patients based on their scores of pain-related disability (low, moderate, or high pain disability). All patients were administered a battery of commonly used and well-validated measures assessing pain, mental health, and quality of life.

Results:
One hundred eight-nine of 517 patients (36.6%) endorsed severe pain intensity on the Chronic Pain Grade. Of these patients, 16.4% endorsed low pain disability, 39.2% moderate pain disability, and 44.4% endorsed high pain disability. There were no differences among the three groups on any demographic variable, current opioid dose, or alcohol and substance abuse variables (all *p*-values>0.05). Those in the low pain disability group endorsed less impairment on measures of depression, anxiety, physical and mental quality of life, pain catastrophizing, and self-efficacy for managing pain. In a multinomial logistic regression, after adjusting for demographic and clinical factors, variables that were significantly associated with pain disability were depression severity (OR=1.14, 95% CI=1.03 – 1.26) and self-efficacy for managing pain (OR=0.93, 95% CI=0.89 – 0.97).

Conclusion:

Among patients prescribed LTOT with severe pain intensity, 16% endorsed low pain disability. The variables most strongly associated with pain disability in the subset of patients with severe pain intensity, were depressive symptoms and self-efficacy for managing pain. These results provide targets for optimizing chronic pain interventions among patients with severe pain intensity.

PAIN SELF-EFFICACY AS A MEDIATOR BETWEEN DEPRESSIVE SYMPTOMS AND PAIN OUTCOMES FOR PERSONS WITH CHRONIC PAIN AND DISABILITY

KATHERINE A. Raichle, PhD[1], Anne Arewasikporn, PhD[2], Dawn Ehde, PhD[3], Mark Jensen, PhD[3]

[1]Seattle University, Seattle, WA; [2]University of Washington School of Medicine and VA Puget Sound Health Care System, Seattle, WA; [3]University of Washington, Seattle, WA

Depression, a common predictor and outcome of pain interventions, consistently varies directly with pain intensity and pain-related disability, yet the mechanisms underlying these relationships is poorly understood. Pain self-efficacy, also a consistent predictor of pain-related outcomes, may mediate the relationship between depression and pain treatment outcomes. Here we sought to examine depressive symptoms as a predictor of pain intensity and interference, and pain self-efficacy as a mediator of these relationships at both trait- and state-levels. Data were from a randomized controlled trial evaluating the efficacy of telephone-based interventions (cognitive-behavioral therapy and pain education) for persons with chronic pain and disability. Participants (N=188) were individuals with chronic pain and multiple sclerosis (n=81), spinal cord injury (n=70), amputation (n=33), or more than one disability (n=4). We utilized multilevel structural equation modeling (MSEM) to test the study hypotheses across three time points (before, during, and after treatment), controlling for participant race, treatment group, and disability. MSEM allows for questions of “who” (between-person/individual differences) and “when” (within-person/changes in state over time), while accounting for within-person clustering.The between-person analysis found that people who tended to be more depressed reported greater pain interference (b = .22, pb = .08, p = .014) on average. Pain self-efficacy mediated the relationship between depressive symptoms and pain interference (ab = .05, p = .007), but not depressive symptoms and pain intensity (ab = .004, p = .864). The within-person analysis showed that when individuals felt depressed they reported feeling greater pain intensity (b = .09, p and pain interference (b = .18, $p\text{ab}_{\text{INTENSITY}}$= .033, $p\text{ab}_{\text{INTERFERENCE}}$ = .04, p < .001) for the within-person analysis. Findings suggest that trait pain self-efficacy may have stronger effects on outcomes related to pain interference versus intensity, while state pain self-efficacy partially explains both relationships. Research examining the mechanistic role of pain self-efficacy in in this context is warranted. This work was supported by a grant from the Department of Health and Human Services, National Institutes of Health (Grant #: 5R01HD057916; PI: Ehde, PhD).

PROVIDERS’ INTEREST IN USING A MOBILE APP WITH PATIENTS WITH CHRONIC PAIN

Sara N. Edmond, PhD[1], Diana Higgins, PhD[2], Mary Driscoll, PhD[1], Kathryn LaChappelle, MPH[3], Crystelle Egan, PhD[4], Alicia Heapy, PhD[5]

[1]VA Connecticut Healthcare System, West Haven, CT; [2]VA Boston Healthcare System, Boston, MA; [3]VA Connecticut Healthare System, West Haven, CT; [4]VA Northern California Health Care System, Martinez, CA; [5]VA Conecticut/Yale University, West Haven, CT

Mobile apps for health are increasingly popular, but little data exists on healthcare providers’ interest in using apps with patients. VA Pain Coach is a mobile app that allows patients to learn about pain, complete pain self-assessments, set goals, and practice skills; app data can also be shared with providers. As part of a pre-implementation study, members of primary care patient aligned care teams (PACTs) including physicians, psychologists, PA/APRNs, RNs, and health technicians, completed self-reported surveys (N=61) and semi-structured interviews (N=20) to gauge interest in using a brief stepped intervention to promote use of VA Pain Coach. Current frequency of recommending apps or websites about chronic pain was low; the majority of providers had never recommended websites (53.5%) or apps (52.6%) about pain to patients. Despite current practices, providers responded that they were likely (28.1%) or very likely (49.1%) to recommend the VA Pain Coach to patients. They expressed willingness to demonstrate the app to patients during an appointment (55.6% likely/very likely) and to use the app collaboratively with patients for assessment (60.0% likely/very likely) and goal setting (64.2% likely/very likely).The three most commonly endorsed facilitators for recommending the app to patients included availability of technical support for using the app, clear instructions about how to best recommend the app to patients with chronic pain, and the perception that pain management is necessary. Thus far, themes from qualitative data include beliefs that apps would be especially well-received among younger and already motivated patients and that the pain coping skills training portion of the app would be particularly important in promoting improvement in the pain and functioning; providers expressed concern about limited time to use the app and its data during appointments. In summary, PACT staff report a willingness to use the VA Pain Coach app. Primary barriers include time to use app during visits; app use could be facilitated by technical support availability and clear instructions regarding when to recommend the app.

PSYCHOLOGICAL PREDICTORS OF FUNCTIONING AND DEPRESSION IN ACTIVE DUTY NAVY AND MARINES WITH CHRONIC PAIN

Emmanuel P. Espejo, PhD, Kathleen McChesney, PsyD, Sheila Medina-Torne, MPH, Steven Hanling, MD

Naval Medical Center San Diego, San Diego, CA

Various psychological factors have been implicated in the functioning and well-being of patients with chronic pain, including pain self-efficacy, kinesiophobia, pain catastrophizing, and pain acceptance. Isolating those psychological factors most pertinent to patient impairment can lead to the refinement of chronic pain treatments toward improved functional outcomes. The current study includes 61 active duty service members (43 Navy, 18 Marines) with chronic pain conditions enrolled in an intensive outpatient functional pain restoration program (FRPP) at Naval Medical Center San Diego. The FRPP was developed to promote the return of service members whose careers are threatened by chronic pain conditions to full, world-wide, deployable duty status. Prior to participation in the program, patients completed measures assessing pain interference, physical and social functioning, and depression, as well as measures of various purported psychological mediators. Pain self-efficacy, kinesiophobia, pain catastrophizing, and pain acceptance were examined simultaneously in the prediction of the various measures of functioning and depression in a series of regression analysis while controlling for patient’s average pain level. Both pain self-efficacy ($p < .005$) and kinesiophobia ($p < .05$) were significant predictors of pain interference, along with pain level ($p < .001$). Both pain self-efficacy ($p < .05$) and pain acceptance ($p < .05$) significantly predicted physical functioning. Pain acceptance was the sole predictor of social functioning ($p < .05$) whereas pain self-efficacy was the sole predictor of depression (p < .005). Pain catastrophizing was not a significant predictor of any functional measure or of depression after accounting for the other psychological factors. Results indicate that the psychological factors most pertinent to functioning in active duty service members with chronic pain vary by functional domain. Interventions for active duty service members with chronic pain aimed at increasing both pain self-efficacy and pain acceptance are indicated for improving functioning across various domains.

EXAMINING ACTIVITY AND DIET AS MEDIATORS OF THE RELATIONSHIP BETWEEN TV TIME AND BMI IN YOUTH

Carolina Bejarano, B.S.[1], Jordan A. Carlson, PhD, MA[2], Terry L. Conway, PhD[3], Brian E. Saelens, PhD[4], Karen Glanz, PhD, MPH[5], Sarah Couch, PhD, RD[6], Kelli L. Cain, MA[7], James F. Sallis, PhD[3]

[1]University of Kansas Clinical Child Psychology Program, Lawrence, KS; [2]Center for Children's Healthy Lifestyles & Nutrition, Kansas City, MO; [3]University of California, San Diego, San Diego, CA; [4]University of Washington, Seattle, WA; [5]University of Pennsylvania, Philadelphia, PA; [6]University of Cincinnati, Cincinnati, OH; [7]University California San Diego, San Diego, CA

Objective: To investigate sedentary time, physical activity, diet quality, and energy intake as potential mediators of the relationship between TV time and BMI in youth.

Methods: 928 youth ages 12-16 (*M* age=14.1, 65.8% white, non-hispanic) reported time spent watching television during non-school time and completed a 3-day dietary recall. Adolescents wore an accelerometer for 7 days to measure moderate-to vigorous physical activity (MVPA) and total sedentary time, which were summarized only for non-school time. Youth height and weight were reported by the parent. MPlus was used to test direct and indirect effects (through the diet and activity variables) of TV time on BMIz in boys (n=460) and girls (n=468).

Results: The total direct effect for TV time and BMIz was significant in boys ($B = .002$, $p < .05$) and in girls ($B = .001$, $p < .05$). Significant direct effects in the sample of boys included negative associations between MVPA and BMIz ($B = -.009$, $p < .01$), TV time and diet quality ($B = -.022$, $p < .01$), and unexpectedly with energy intake and BMIz ($B = -.00$, $p < .05$). In girls, significant direct effects included negative associations between MVPA and BMIz ($B = -.008$, $p < .05$), TV time and diet quality ($B = -.028$, $p < .01$), and energy intake and BMIz ($B = -.00$, $p < .01$). There were no signficiant indirect effects between TV time and BMIz of sedentary minutes, MVPA minutes, diet quality, or caloric intake.

Conclusions: There was a consistent association between TV time and BMI in this study and numerous prior studies. However, none of the four activity/diet variables examined in the present study explained this association. Future research should continue to examine variables that may mediate the relationship between time watching television and weight status.

ADVENTURE PHYSICAL ACTIVITIES AND PERSONALITY: A SYSTEMATIC REVIEW

patrick boudreau-alguire, B.Ed.[1], Ryan E. Rhodes, PhD[2]

[1]The University of Victoria, Victoria, BC, Canada; [2]University of Victoria, Victoria, BC, Canada

Adventure Physical Activities and Personality: A Systematic Review

Context: The popularity of adventure physical activities such as rock-climbing, white-water kayaking, and skydiving has grown increasingly in the last two decades (Brymer, 2010). Participation in adventure physical activities can lead to positive outcomes such as courage, humility, and a positive psychological connection with the natural world (Brymer & Oades, 2009). Several consistent and enduring traits, which define personality, may predispose participants to engaging in behaviors such as taking part in adventure physical activities. The purpose of this article is to review, for the first time, the research on personality profiles of adventure physical activity participants. The term adventure physical activities describes physical activities that are challenging, are out of the ordinary, and are usually associated with higher levels of risk. Evidence Acquisition: The studies reviewed include the physical activities labeled as ‘alternative sports’, ‘extreme sports’, ‘action sports’, and ‘lifestyle sports’ in previous academic research. Papers were considered eligible if they were published in English or French language peer-reviewed journals and examined correlates of adventure physical activities and trait personality. Literature searches were conducted in accordance to PRISMA guidelines in September 2016 among five search engines yielding 876 potentially relevant records; of these, 35 papers (34 independent samples) passed eligibility criteria. Evidence Synthesis: The dominant trait applied to understand adventure activities has been sensation seeking, using Zuckerman’s sensation seeking scale (80% of studies). However, studies have also explored excitement seeking via Arnett’s inventory of sensation seeking. Most studies showed a significant correlation in the small to medium effect size and compared adventure physical activity participants to low-risk sport participants. It is possible that a certain threshold for sensation seeking is necessary to initially participate in certain adventure physical activities. Conclusions: Over 42 years, research on the personality traits of adventure physical activity participants has been limited to the study of sensation seeking traits, but other personality traits are not well understood. It is recommended that future studies also examine the bi-directional correlation between adventure physical activities and personality. Recent studies examining social, environmental, or individual factors such as flow states may better explain motivations to participate in adventure physical activities.

AFFECTIVE IMPROVEMENTS FOLLOWING ACUTE EXERCISE ARE NOT DEPENDENT ON HABITUAL PHYSICAL ACTIVITY LEVELS IN MDD

Jacob Meyer, PhD[1], Laura Ellingson, PhD[2], Dane Cook, PhD[1]

[1]University of Wisconsin-Madison, Madison, WI; [2]Iowa State University, Ames, IA

Exercise is an effective treatment for major depressive disorder (MDD), yet few patients are physically active. Habitual physical activity can moderate the mood response to a single bout of activity in healthy people, resulting in limited acute psychological benefit for those with low levels of regular activity. However, it is unknown whether habitual activity affects mood responses to exercise in MDD. Exercise-induced elevations of brain-derived neurotrophic factor (BDNF), a protein implicated in the pathophysiology of depression and its treatment, may be similarly influenced by low habitual physical activity. This investigation aimed to determine the relationships between regular physical activity participation and both mood and BDNF responses to acute exercise in depressed women.

METHODS:

Females with MDD (n = 24) participated in three exercise bouts at light, moderate and hard intensities, each separated by at least 1 week. Prior to, 10min and 30min after exercise the Profile of Mood States (POMS) was completed. Blood was drawn before and within 10 minutes post-exercise. Serum BDNF content was assessed via enzyme-linked immunosorbent assay. Participants wore an accelerometer (Actigraph GT3X+) for one week to assess habitual physical activity, and were divided into two groups based on whether or not they accumulated at least 60 minutes of moderate or vigorous physical activity (MVPA) each day. Independent samples t-tests compared mood and BDNF responses to exercise between groups.

RESULTS:

Participants who accumulated 60 minutes of MVPA each day (n = 15) had similar improvements in POMS Depression after the exercise bouts at 10m and 30m compared to those who did not accumulate an hour of MVPA/day for each of the three intensities (all $p > .05$). Statistically similar increases in BDNF were found in response to exercise between the groups for each of the three intensities (all $p > .05$).

DISCUSSION:

Patients with MDD can realize the acute mood-enhancing effects of exercise regardless of pre-existing activity level. Low levels of regular activity did not significantly alter the BDNF increase following acute exercise. Although exercise may appear daunting for patients, reductions depressed mood occur even in patients who do not regularly exercise across a range of intensities. Practitioners should encourage all patients to engage in exercise as a method of acute psychological relief as improvements are likely to occur regardless of pre-existing activity level.

AGE MODERATES THE EFFECT OF SELF-PACED WALKING ON EXERCISE ADHERENCE AMONG OVERWEIGHT ADULTS

Harold Lee, MS, MAPP[1], Shira Dunsiger, PhD[2], Lauren Connell, Ph.D.[3], Holly Boyle, MA [1], Jessica Emerson, MS[4], David Williams, Ph.D.[5]

[1]Brown University, Providence, RI; [2]The Miriam Hospital and Brown University, Portsmouth, RI; [3]The Miriam Hospital and Alpert School of Medicine at Brown University, Providence, RI; [4]Brown University, East Providence, RI; [5]Brown University School of Public Health, Providence, RI

National guidelines recommend exercise of at least moderate intensity. However, recent evidence suggests that exercising at one's own pace (self-paced exercise) may lead to better adherence to exercise programs relative to prescribed moderate intensity exercise. The present study tested the hypothesis that the positive effects of recommending self-paced exercise, relative to prescribing moderate intensity exercise, on adherence to exercise programs are more pronounced among adults who are older rather than younger. Fifty-nine low-active overweight adults (18–65yr) were encouraged to walk 30–60 min/day, and randomized to either a self-paced (n=30) or prescribed moderate intensity (64–76% maximum heart rate; n=29) condition. Affective response to exercise and perceived exertion were measured using ecological momentary assessment. Using mixed-effects-models, we confirmed our hypothesis that the effect of the randomization was moderated by age (main effect of condition: b=6.14, SE=2.54, p=0.02; condition * age effect: b=-11.55, SE=3.77, p=0.002). Among participants > 50 years, those in the self-paced condition exercised 6 more minutes/day than participants in the prescribed moderate intensity condition (p=0.02); however, among participants ≤ 50 years, those in the self-paced condition exercised 5.4 *fewer* minutes/day than those in the prescribed moderate intensity condition (p=0.05). We further investigated affective response to exercise and perceived exertion as potential mediators of the age moderator effect. Perceived exertion, but not affective valence, mediated the moderating effect of age (indirect effect for those over 50: ab=7.15, p < .01). As age increases, adults may more likely to adhere to self-paced exercise versus prescribed moderate-intensity exercise, because of higher perceived exertion with increasing age.

CAN WE PREDICT SEDENTARY BEHAVIOUR? USING THE TPB TO PROSPECTIVELY PREDICT OCCUPATIONAL SITTING AND STANDING BREAKS.

Madelaine Gierc, MPH[1], Larry R. Brawley, PhD[2]

[1]University of Saskatchewan, Duncan, BC, Canada; [2]University of Saskatchewan, Saskatoon, SA, Canada

In 2008, Healy and colleagues observed that office workers who frequently interrupted their sitting had better cardiometabolic risk profiles relative to those who engaged in prolonged sitting. Standing breaks have since been proposed as one solution to the problem of excessive sedentary behaviour; however, little research has examined the psychological predictors of standing breaks. Are people motivated to take such breaks? What factors influence standing break engagement? Do the psychological predictors of sitting differ from those of standing breaks? The purpose of our research was to prospectively predict workplace sitting and standing via the Theory of Planned Behaviour (TPB). Participants (N = 325 office workers) completed questionnaires, with measures of attitudes (AT), subjective norms (SN), perceived behavioural control (PBC), behavioural intentions, and self-reported behaviour at several prospective time points. AT, SN, and PBC emerged as significant predictors of intention, collectively accounting for 3.6% to 18.1% of variance in sitting intentions; and 2.7% to 32.7% of variance in standing break intentions, *p*s < 0.05. Intention and PBC significantly predicted between 62.0% and 79.7% of sitting variance; and between 28.4% and 68.6% of standing break variance, *ps* < 0.05. Collectively, results speak to the importance of intentions in predicting occupational sitting and standing breaks: can changing intentions produce significant changes in sedentary behaviour? Results also raise questions about how we measure the cognitive predictors of sedentary behaviour: as AT, SN, and PBC accounted for a small proportion of variance in intention, what other psychological factors might be important? Suggestions for future sedentary behaviour research will be discussed.

CHANGES IN MOTIVATION FOR PHYSICAL ACTIVITY FOLLOWING AN AEROBIC TRAINING AND PHYSICAL ACTIVITY INTERVENTION: ICAN RESULTS.

Chelsey Solar, M.S./Ed.S[1], Ashley Rhodes, MA[1], Lesley Lutes, PhD[2], Damon L. Swift, Ph.D.[1], Tyara R. Nevels, M.S., CCEP [1], Patricia Brohpy, MS[3]

[1]East Carolina University, Greenville, NC; [2]University of British Columbia, Kelowna, BC, Canada; [3]East Carolina Diabetes and Obesity Institute, Greenville, NC

Background: Increased aerobic activity and decreased sedentary time have been shown to reduce risk of cardiovascular disease and therefore interventions to aid in the increase and maintenance of regular activity are an important public health initiative. Physical activity motivation and behavioral regulation have been shown to be important factors in physical activity engagement; however, little is known how these psychological factors change in response to exercise training and increasing physical activity.

Methods: Participants were randomized to one of three treatments: 1) supervised aerobic training (AERO), 2) supervised aerobic training plus an individual behavioral coaching intervention focused on increasing non-exercise physical activity 3,000 steps from baseline (AERO-PA), or 3) non-exercise control (CON) for a period of 6-months. Changes in motivation and behavioral regulation for physical activity between baseline and post-test were compared between arms.

Results: Forty-five individuals were enrolled and thirty-nine individuals (AER0 = 13, AERO-PA = 12, CONTROL = 14) (mean age = 53.5, 71% White, 21% male) completed the randomized clinical trial. Completer-only analyses were conducted to examine group differences. There was a significant difference between groups in identified regulation for physical activity change $F(2, 34) = 4.87$, $p = .014$. Tukey post hoc tests indicated greater increase in identified regulation in the AERO-PA arm relative to the CON arm at $p =.014$ and a trend towards greater increase in the AERO-PA arm relative to the AERO arm at $p = .071$. Additionally, a non-statistically significant trend was found for differences between groups in interest-based motivation for physical activity $F(2, 36) = 3.08$, $p = .058$. Tukey post hoc tests indicated a trend towards a greater increase in interest-based motivation in the AERO-PA arm relative to the AERO arm at $p = .052$.

Conclusions: The combination of exercise training and increasing non-physical activity through behavioral coaching may increase participant motivation for physical activity through the increase of identified regulation and the increase of interest in engaging in physical activity.

DEMOGRAPHIC AND CLINICAL CORRELATES OF ACCELEROMETER-ASSESSED PHYSICAL ACTIVITY AND SEDENTARY TIME IN LUNG CANCER SURVIVORS

Jeff K. Vallance, PhD[1], Terry Boyle, PhD[2], Gwyn Bebb, MD[3], Steve Johnson, PhD[1], Adrijana D'Silva, BSc[4]

[1]Athabasca University, Athabasca, AB, Canada; [2]Curtin University, Perth, Western Australia, Australia; [3]Tom Baker Cancer Centre, Calgary, AB, Canada; [4]Athabasca University, Calgary, AB, Canada

Background: The primary purpose of this study was to determine demographic and clinical correlates of accelerometer-assessed moderate- to vigorous-intensity physical activity (MVPA) and sedentary time among a sample of lung cancer survivors. **Methods**: Lung cancer survivors in Southern Alberta (N=527) were invited to complete a mailed survey that assessed self-report demographic variables. Clinical variables were extracted from participant medical records. Consenting participants wore an Actigraph® GT3X+ accelerometer on their hip for seven days. Average daily MVPA and sedentary time were derived from the accelerometer data, and processed using 60-second epochs. Linear and logistic regression was used to determine correlates of physical activity (including meeting MVPA guidelines of at least 150 minutes per week) and total sedentary time. All models were adjusted for accelerometer wear time. **Results:** A total of 127 lung cancer survivors participated (Mean age = 71 years; Mean time since diagnosis = 75 months) for a 24% response rate. MVPA (minutes) was significantly associated with being over 60 years of age (B=-7.1, CI: -14.2 to -.14, p=.015) and having smoked at least 100 cigarettes (B=-9.2, CI: -18.1 to -.3, p=.043). Total sedentary time (minutes) was associated with having smoked at least 100 cigarettes (B=60.0, CI: 21.9 to 97.3, p=.002), and being overweight/obese (B=39.2, CI: 10.9 to 67.5, p=.007), and not having received surgery (B=-36.1, CI: -70.2 to -1.9, p=.039). Meeting physical activity guidelines was positively associated with having at least a post secondary education [Odds ratio (OR)=3.9, CI: 1.1 to 13.7, p=.037], negatively associated with smoking at least 100 cigarettes (OR=.29, CI: .10 to .94, p=.040) and being over 60 years of age (OR=.27, CI: .09 to .78, p=.016). **Conclusion:** In this sample of lung cancer survivors, different demographic and clinical correlates emerged across accelerometer assessed behaviours including MVPA and sedentary time. These results have implications for developing programs and interventions directed toward faciltating physical activity and reducing sedentary behaviour in lung cancer survivors.

DETANGLING EFFICACY AND EXPECTANCY: A PROSPECTIVE, CROSS-LAGGED PANEL STUDY OF CANCER SURVIVORS’ PHYSICAL ACTIVITY

Elizabeth Fallon, Ph.D.[1], Robert L. Stephens, PhD, MPH[1], Bennett R. McDonald, MPH[1], Corinne Leach, MS PhD MPH[2]

[1]American Cancer Society, Atlanta, GA; [2]American Cancer Society's Behavior Research Center, Atlanta, GA

While interventions based on the social cognitive theory have proven successful for increasing cancer survivors’ moderate-to-vigorous physical activity (MVPA), scientists continue to debate the temporality of the relationship between the two most studied constructs: self-efficacy and outcome expectancy. Data from the American Cancer Society’s Survivor Transition Study was used to prospectively examine relationships among self-efficacy, outcome expectancy, and MVPA across two time points within a sample (N = 1099) of prostate, breast and colorectal cancer survivors within 12 months of completing their treatment. A fully saturated cross-lagged panel model, with covariates (age, cancer stage, cancer type by gender, time since treatment, education, cancer symptom burden, comorbidity burden, and body mass index), and using FIML was conducted using Mplus (version 7.4). Results indicated that baseline self-efficacy has a significant positive effect on follow-up outcome expectancy (standardized: 0.08; unstandardized: 0.05, s.e. = 0.02, p = 0.03). The relative size of this effect, however, is smaller than the association between baseline outcome expectancy and follow-up self-efficacy (standardized: 0.10; unstandardized: 0.16, s.e. = 0.53, p = 0.002). Thus, Bandura’s assertion that perceived capability to perform a behavior causally influences perceived behavioral outcomes, but not vice versa, is not supported. Furthermore, baseline outcome expectancy did not have a significant direct relationship with follow-up MVPA (standardized: 0.04; unstandardized: 1.16, s.e. = 0.96, p = 0.23), while baseline self-efficacy did maintain a significant direct relationship with follow-up MVPA (standardized: 0.11; unstandardized: 1.95, s.e. = 0.61 , p = 0.001). Overall, results from this study suggest the most likely model is one in which self-efficacy mediates the relationship between outcome expectancy and MVPA. This study adds to the literature by using a prospective design, advanced statistical techniques, and a large sample of cancer survivors. Results suggest the need for the modification of existing theory, and can inform the development and implementation of optimally effective social-cognitive interventions to improve MVPA among cancer survivors during post-treatment re-entry.

EFFECTS OF WORKSITE-BASED WEIGHT LOSS INTERVENTIONS ON PHYSICAL ACTIVITY AND SELF-EFFICACY: A RANDOMIZED CONTROLLED TRIAL

John Noble, PhD[1], Kathryn Wilson, PhD[2], Fabio Almeida, PhD[2], Jennie L. Hill, PhD[2], Paul A. Estabrooks, PhD[2]

[1]University of Nebraska - Omaha, Omaha, NE; [2]University of Nebraska Medical Center, Omaha, NE

Worksite physical activity interventions have demonstrated efficacy in producing changes in employee activity time. However, there are relatively few studies that examine the changes in physical activity and potential mediators as the result of scalable worksite weight loss interventions. Further, relatively little data exists on the maintenance of physical activity in the months following the intervention period. The purpose of this study was to determine the magnitude of change in moderate to vigorous physical activity (MVPA) and self-efficacy for physical activity (PASE) as a result of exposure to minimal contact, electronically supported weight loss programs. Twenty-eight worksites were randomly assigned to one of two intervention groups both lasting 12 months: an internet-based intervention with monetary incentives delivered via daily e-mails (n=14 worksites; 1001 employees) or a less intensive intervention delivered quarterly via both newsletters and on-site educational sessions (n=14 worksites; 789 employees). Both programs recommended graduated exercise from beginner (working up to 150 minutes of moderate intensity PA/week), to intermediate (introduced resistance training), and to advanced (vigorous activity 3-5 days per week and resistance training). PASE and MVPA were assessed with validated tools at baseline, 6 months, 12 months (program completion), 18 months and 24 months. Group x Time ANCOVAs for MVPA and PASE, controlling for worksite, both revealed a significant main effect for time (F(df)=2.46-3.07(4);*p*<.05), with no group effect (*p*>.05). MVPA increased from baseline to 6-months (23.14±95.0), with no significant changes at 12, 18, or 24 months. Across time points men reported more MVPA than women (*p* < .01). PASE significantly decreased from baseline to 6 months (-15.34±75.1), but gradually increased from 6 to 24 months (6.8±82.4;*p*=.02). Gender moderated this relationship, such that PASE did not significantly change in men, whereas women demonstrated the same pattern as the main effect. Finally, correlations (r) between change in MVPA and PASE ranged from 0.10 to .22, *p* < 0.01. Positive correlations between change variables indicate that those who increased MVPA the most experienced the least amount of decline in PASE. In conclusion, a detailed graduated protocol for physical activity

embedded within scalable worksite weight loss interventions may produce sustained changes in physical activity for up to a year after intervention completion.

GOTTA CATCH 'EM ALL: POKEMON GO MOTIVATES ITS PARTICIPANTS TO INCREASE PHYSICAL ACTIVITY AND DECREASE SEDENTARY BEHAVIORS

Claudio R. Nigg, PhD, FSBM, Desiree Joi Mateo, N/A, Jiyoung An, PhD, MPH

University of Hawaii, Honolulu, HI

Pokémon Go is an interactive internet-based mobile game that incorporates physical activity (PA, primarily walking) as a major game component using real-time and location-based augmented reality technology with cooperative and competitive elements. No research to date has evaluated the influence of Pokémon Go on PA or sedentary behavior. Therefore, this study investigated if playing Pokémon Go increased PA and decreased sedentary behaviors. Participants (n=486; 57.8% female; most prevalent ethnicities: 59.9% White and 28.5% Asian; mean age = 28.6 (SD=8.5) years; mean BMI = 26.4 (SD=6.8)) played Pokémon Go an average of 23.3 (SD=10.0) days and completed an online survey assessing their PA and sedentary behavior retrospectively pre-starting to play Pokémon Go and post-currently. Significant increases were seen for strenuous PA (pre: 80.74 (SD=92.63) minutes/week, post: 94.96 (SD=101.36), t(483)=5.72, $p < .001$), moderate PA (pre: 112.06 (SD=109.55) minutes/week, post: 150.54 (SD=124.83), t(484)=8.34, $p < .001$), and mild PA (pre: 163.11 (SD=136.14) minutes/week, post: 210.72 (SD=137.66), t(483)=9.77, $p < .001$). Significant decreases were seen for TV watching (pre: 2.69 (SD=1.97) hours/day, post: 2.14 (SD=1.73), t(478)=9.65, $p < .001$) and Internet surfing (pre: 3.22 (SD=2.37) hours/day, post: 3.02 (SD=2.33), t(479)=3.58, $p < .001$), whereas video game playing (about 1 hour/day) did not change (t(481)=1.95, ns). No interactions with sex, age or ethnicity were found. BMI was positively related to strenuous, moderate and mild PA change ($ps < .01$) and there was a dose-response effect of number of days playing Pokémon Go and moderate and mild PA change ($ps < .05$). Pokémon Go seems to have a positive effect on increasing PA and decreasing sedentary behavior of individuals who play the game. This supports the potential of internet games being able individually tailor the game, both motivationally and geographically, to promote health behaviors reaching large populations. Long-term, rigorously designed studies should look at mechanisms, long-term effects, and generalizability to investigate the potential impact of Pokémon Go and other promising internet-based mobile games on health outcomes.

GUT MICROBIAL COMPOSITION ASSOCIATED WITH CARDIORESPIRATORY FITNESS, PSYCHOSOCIAL FACTOR CHANGES IN BREAST CANCER SURVIVORS

Jesseca A. Paulsen, B.S.[1], Travis Ptacek, Ph.D.[2], Stephen J. Carter, Ph.D.[2], Nianjun Liu, Ph.D.[3], Ranjit Kumar, Ph.D.[4], Lakeshia Hyndman, M.D.[2], Elliot Lefkowitz, Ph.D.[2], Casey Morrow, Ph.D.[2], Laura Q. Rogers, MD, MPH[2]

[1]The University of Alabama at Birmingham, Birmingham, AL; [2]University of Alabama at Birmingham, Birmingham, AL; [3]University of Alabama at Birmingham, Bloomington, IN; [4]UAB, birmingham, AL

Background: Breast cancer survivors (BCS) are often plagued by significant psychosocial sequelae post treatment including fatigue and anxiety. The mechanisms whereby physical activity improve these symptoms have not been fully elucidated. *Objective*: To determine correlations between gut microbiota composition and changes in cardiorespiratory fitness and psychosocial outcomes among post-primary treatment BCS. *Methods*: Composition of the gut microbiota of BCS (n=12) was assessed at baseline (M0) and at the end of a 3 month physical activity trial (M3) using Illumina MiSeq DNA Sequencing of the 16S rRNA gene. Gut microbiota composition was analyzed using QIIME bioinformatics software and represented through diversity metrics and taxa analyses. Cardiorespiratory fitness, fatigue, anxiety, depression, and sleep dysfunction were assessed at M0 and M3 via submaximal treadmill test, Fatigue Symptom Inventory, Hospital Anxiety and Depression Scale, and Pittsburgh Sleep Quality Index, respectively. *Results*: Increased fatigue interference in BCS was associated with increased mean within-sample Shannon diversity (organism richness and evenness) (p=0.009). Weighted UniFrac analysis (shifts in taxa relative abundance) revealed significant differences in between-sample (beta) diversity for changes in fatigue interference (p=0.01) and anxiety (p=0.022), with a trend observed for fatigue intensity and sleep dysfunction ($p < 0.1$). Unweighted UniFrac analysis (shifts in taxa types) found significant beta diversity differences for cardiorespiratory fitness (p=0.026). Prior to false discovery correction (FDR), changes in fitness, fatigue, anxiety, and sleep dysfunction were associated with the frequency of certain gut bacteria genera (e.g., Faecalibacterium, Prevotella, Bacteroides)($p < 0.05$). *Conclusions*: These pilot results indicate that correlations may exist between alterations in gut microbiota composition and longitudinal changes in cardiorespiratory fitness, fatigue, and anxiety in BCS. Further research examining the role of the microbiota-gut-brain axis in exercise-induced effects on psychosocial outcomes in breast cancer survivors is warranted.

HEALTHY AGING IN MIDLIFE: MODELING PSYCHOLOGICAL CORRELATES OF PHYSICAL ACTIVITY

Brenna N. Renn, PhD[1], Leilani Feliciano, PhD[2]

[1]University of Washington School of Medicine, Seattle, WA; [2]University of Colorado at Colorado Springs, Colorado Springs, CO

Background: Physical activity (PA) is an important determinant of health and well-being across the lifespan. Middle-aged adults are increasingly sedentary compared to younger cohorts, but are poorly represented in the exercise science literature. This segment of the population represents a key target for health promotion, as engaging in PA in midlife may help establish an active lifestyle that continues into older adulthood and prevents the medical and functional complications associated with physical inactivity and aging.

Method: The present study used structural equation modeling (SEM) to assess the relationship of three social cognitive latent variables (self-efficacy, self-regulation, and outcome expectations) and PA. Cross-sectional data were collected from 225 community-dwelling adults aged 45-64 (M_{age} = 56.86±5.45 years, 66.1% female, 11.1% ethnic minority) with varying activity levels. Manifest variables were modeled using multiple self-reported measures of self-efficacy, self-regulation, and outcome expectations. PA was assessed using the International Physical Activity Questionnaire-short form (IPAQ-SF) and supplemented with two simple, validated questions assessing exercise over the past week and month.

Results: The sample tended to be active; 44.4% reported moderate-to-vigorous activity of at least 150 min/week. The three latent variables of self-efficacy, self-regulation, and outcome expectations were highly correlated with one another ($r > 75$, $p < .001$). Univariate analyses of the manifest variables suggested that self-efficacy, self-regulatory strategies, and attitudes and outcome expectations were all significantly associated with physical activity levels reported by participants. The hypothesized model provided an adequate fit to the data and explained a large amount (63%) of the variance in PA. The best fitting model was one in which outcome expectations exerted an indirect, rather than direct, effect on PA through self-efficacy and self-regulation. This final model explained 58% of the variance in PA and had adequate fit indices, CFI = .94, TLI = .90, RMSEA = .09, 90% CI = .08-.11.

Conclusions: These findings extend the centrality of these three social cognitive constructs to PA in middle age. A more thorough dismantling of PA determinants in each decade of mid- and later life could inform more effective intervention targets for specific age groups. Future

studies should extend these findings using longitudinal, objective PA data to develop interventions for PA in the context of age-related changes in cognitive, social, environmental, and physical health domains.

HIPPOCAMPAL VOLUME AND PHYSICAL ACTIVITY ACROSS THE LIFESPAN

Elisa Torres, PhD[1], Andrew P. Merluzzi, BS[2], Sanjay Asthana, MD[3], Andrew L. Alexander, PhD[4], Sterling C. Johnson, PhD[3], Barbara B. Bendlin, PhD[3]

[1]School of Nursing, University of Wisconsin-Madison, Madison, WI; [2]Neuroscience and Public Policy Program, University of Wisconsin-Madison, Madison, WI; [3]Wisconsin Alzheimer's Disease Research Center, School of Medicine and Public Health, University of Wisconsin-Madison, Madison, WI; [4]Medical Physics, School of Medicine and Public Health, University of Wisconsin-Madison, Madison, WI

Background and Purpose: Alzheimer's-related brain changes begin during a preclinical stage, 20 or more years before symptoms occur. Physical activity in cognitively asymptomatic adults is associated with attenuated Alzheimer's disease pathology and increased volume in brain structures that are important for memory, such as the hippocampus. Yet it is not known if there is an ideal period during the lifetime to participate in physical activity to preserve brain function and structure into middle- and older- age. The purpose of this study was to examine the association between hippocampal volume and measures of physical activity at periods of school-age, adolescence, young-, middle- and mature adulthood.

Methods: Cognitively asymptomatic adults (N=39, age 48.9-72.0 years, mean = 61.9, SD = 6.0, 72.6% female) from the Wisconsin Registry for Alzheimer's Prevention and the Wisconsin Alzheimer's Disease Research Center completed the Lifetime Total Physical Activity Questionnaire during face-to-face interviews which estimated the average metabolic equivalent (MET) hours per week per year of occupation, transportation, household and leisure-time physical activity for a total physical activity score. Participants also underwent T1-weighted structural magnetic resonance imaging on a GE 3.0 Tesla MR750 scanner (Waukesha, WI) with an 8-channel head coil to obtain hippocampal volumes. Partial correlations controlling for age, sex and APOE4 genotype were performed between hippocampal volumes and physical activity across various developmental stages based on Erikson's Theory of Psychosocial Development: school age (age 6-11), adolescence (age 12-18) and young (age 19-39), middle (age 40-64) and mature adulthood (age 65+).

Results: Right hippocampal volume was associated with physical activity during young ($r = .683$, $p = .007$) and middle adult ($r = .608$, $p = .021$), with a trend during school age ($r = .528$, $p = .052$) and adolescence ($r = .498$, $p = .07$). There was no association between right

hippocampal volume and physical activity in mature adulthood. Left hippocampal volume was not predicted by physical activity at any lifetime stage.

Conclusion: These results are consistent with the hypothesis that physical activity across the lifespan may slow the progression of Alzheimer's disease by preserving brain regions important for memory function in the preclinical stage.

MEDIATION EFFECT OF CHILD DEPRESSION ON PATHWAY FROM PARENT-CHILD RELATIONSHIP TO CHILD PHYSICAL ACTIVITY

Emily Kiresich, MS, RD[1], Zhongzheng Niu, MS, MD[2], Amber Cordola Hsu, MPH[3], Bin Xie, PhD[2]

[1]Claremont Graduate University, Lakewood, CA; [2]Claremont Graduate University, Claremont, CA; [3]Claremont Graduate University, Marina del Rey, CA

Introduction: Childhood activity habits may be important for later obesity development. Limited prior research explore the influence of parent-child relationship in formation of habits of physical activity and potential mediation role of child depression. Prior research has not compared mother-child and father-child relationships to differentiate effect. We seek to examine the associations of parent-child relationships with physical activity participation and if this association may be mediated by child depression.

Method: We used the existing data from the Eunice Kennedy Shriver National Institute of Child Health and Human Development Study of Early Child Care and Youth Development (SECCYD). Sample included 514 children with weekend physical activity of at least moderate intensity and 602 children with weekday and all day physical activity levels of at least moderate intensity as measured by a physical activity monitor at age 15. Parents reported perceived relationships with children 6 times from age 54 months to grade 6, with accumulative effects of parent-child relationships calculated as the average scores of all measurements. The association of parent-child relationship with physical activity was analyzed using multivariate regression models, controlling for income, maternal age, gender, and BMI z-score. Mediation analysis with bias-corrected bootstrapping resampling approach was employed to obtain 95% confidence intervals for indirect effects of childhood depression, measured using the Children's Depression Inventory administered at age 15.

Results: Significant associations of maternal-child relationship with moderate and/or moderate-vigorous activity in children at age 15 (range β -1.50 to β -.330, $p < .05$). Prospective analysis linking parent-child relationships by grade 6 of the study child to child's physical activity levels at age 15 revealed a statistically significant positive or negative relationship depending on relationship type. Maternal or Paternal conflict had a negative total effect (-.113 to -.049, 95% CI: -.245, -.004) while positive relationship had a positive effect (.066 to .086, 95% CI: .019, .1636). These results were consistent for Maternal and Paternal relationships along the spectrum of physical activity levels and days.

Conclusion: Longitudinal parent-child relationships may influence child's physical activity during adolescents through an accumulative process and is mediated by child depression. This relationship suggests that physical activity participation may be regulated by parent-child relationships, which underscores the important role of family dynamics in obesity prevention.

RELATIONSHIPS OF MUSCULOSKELETAL SYMPTOMS, EMPLOYMENT STATUS, OBESITY AND LEISURE TIME PHYSICAL ACTIVITY AMONG NURSES

Soohyun Nam, PhD, APRN, ANP-BC[1], Soo-Jeong Lee, PhD[2]

[1]Yale University, School of Nursing, West Haven, CT; [2]University of California San Francisco, San Francisco, CA

There is established evidence for the benefits of physical activity for health, but high rates of physical inactivity were reported among nurses. Musculoskeletal symptom (MS) comorbidities may be risk factors of physical inactivity but data are limited for nurses who are vulnerable to MS comorbidities. The purpose of this study was to describe the relationships of MS, employment status, body mass index (BMI) and leisure time physical activity among nurses.

This study used cross-sectional data of 454 nurses randomly selected from the California Board of Registered Nursing list. Data on demographic and employment characteristics, MS (past 12 month- low back, neck, shoulder and wrist/hand pain—interval, severity, duration), BMI, and physical activity (aerobic and muscle strengthening) were collected using postal and online surveys. For MS, an aggregate pain index was created.

Of the participants (mean age 49.58 years, 91.2 % female, 65.2 % white, 79.5% currently working nurses), 46.5 % were overweight or obese (mean BMI 25.6 kg/m^2); 44% engaged in regular aerobic physical activity (≥150min/week); and 56% performed regular muscle strengthening activity (≥2 days /week). Low back pain was the most frequently reported (61.7%), followed by neck pain (48.5%), shoulder pain (41.9%), and wrist/hand pain (41.6%). In the bivariate analysis, none of MS variables were associated with physical activity. In the multiple logistic regression adjusting for age and pain index score, nurses who did not currently work were more likely to engage in more aerobic physical activity (≥150min/week) (OR= 2.12, 95% CI: 1.11-4.07) than currently working nurses. Nurses with lower BMI performed more aerobic physical activity (≥150min/week) (OR= 0.92, 95% CI: 0.88-0.97) and muscle strengthening physical activity (≥2 days /week) (OR= 0.92, 95% CI: 0.88-0.96).

Future physical activity promotion interventions should address employment-related barriers among currently working nurses, particularly, those who have high BMI.

REMOTE MONITORING AND COMMUNICATION TO SUPPORT PHYSICAL ACTIVITY AMONG CANCER SURVIVORS: FINDINGS FROM A MIXED METHODS STUDY

Nancy Gell, PhD, MPH[1], Kristen W. Grover, PhD[2], Kim Dittus, MD, PhD[3]

[1]University of Vermont, Burlington, VT; [2]The University of Vermont, Burlington, VT;
[3]University of Vermont College of Medicine, Burlington, VT

Background Physical activity (PA) minimizes the side effects of cancer; yet, participation rates by cancer survivors are low. While technological innovations are often touted as efficient means for communication and remote monitoring, concern for privacy and access to personal data are cited as areas of concern. The purpose of this pilot study was to evaluate the efficacy and acceptability of an intervention using remote monitoring and communication to support PA maintenance in cancer survivors.

Methods Participants were 24 cancer survivors (83% female, mean age 57.5) recruited after completing exercise-based oncology rehabilitation. The four-week intervention consisted of three interactions with a health coach (1 in-person, 2 follow-up meetings by phone), text messages, and self-monitoring with a Fitbit. Text message content was based on participant PA goals and preferences and Fitbit recorded activity. Pre and post-intervention PA was assessed via accelerometer. Changes in outcomes were assessed through paired t-test analysis and repeated measures ANOVA. Post-intervention phone interviews were conducted using a semi-structured question guide. All interviews were audio-recorded, transcribed, and iteratively coded using thematic analysis.

Results Participants maintained weekly minutes spent in moderate-to-vigorous intensity PA from pre-intervention (317.5 ± 222.8) to post intervention (304.7 ± 211.5; $p= 0.57$). Fitbit weekly mean step counts did not change over 4 weeks ($F=1.31$, $p=0.28$). Participants reported acceptance and satisfaction with remote monitoring and communication. Emergent themes related to technology-based support for PA maintenance included 1) appreciation for accountability to a remote partner; 2) support to overcome barriers; 3) influence on maintaining habits; 4) convenience of technology; and 5) reclaiming ownership of health following a cancer diagnosis.

Conclusions Participants attributed PA maintenance to accountability enabled by technology. Communication based on remote monitoring was perceived as encouraging and not intrusive. Participants also valued the support via technology in the transition to a home program after

completing a facility-based program. This study highlights the importance of accountability and support for PA adherence, and the positive role that technology can provide for cancer survivors to regain control of health management.

SPIRITUAL WELL-BEING, MEANING, AND HEALTH AND FITNESS CONFIDENCE PREDICT PHYSICAL ACTIVITY

Christina Rush, MA, Stephanie A. Hooker, M.S., M.P.H., Kaile M. Ross, MA, Kevin Masters, PhD

University of Colorado Denver, Denver, CO

Background: Prior work suggests spiritual well-being and meaning are important correlates of physical health. However, no studies have examined these relationships in the context of confidence (self-efficacy) to prevent chronic illness or improve physical fitness. The goal of the current research was to evaluate associations between spiritual well-being, meaning, confidence in improving physical fitness, and confidence in preventing chronic disease to predict physical activity.

Methods: Participants (*N* = 427; Mean age = 49; 67% female; 78% white, non-Hispanic) were recruited from an online survey research panel and completed self-report measures of spiritual well-being, meaning in life, confidence in improving physical fitness, confidence in preventing chronic disease, and physical activity (International Physical Activity Questionnaire). Controlling for age and gender, regression analyses were used to predict physical activity.

Results: Among participants that ranked improving physical fitness and preventing chronic disease among their top five well-being goals (*N* = 94), spiritual well-being and meaning were positively associated with confidence in improving physical fitness (r = .30, p < .001 and r = .33, p < .001, respectively) and confidence in preventing chronic disease (r = .26, p < .01 and r = .20, p = .03, respectively). In regressions, spiritual well-being (ß = .21, p < .05), meaning (ß = .20, p = .05), age (ß = -.20, p < .05), confidence in improving physical fitness (ß = .33, p < .001), and confidence in preventing chronic disease (ß = .20, p = .05) all significantly predicted physical activity.

Conclusions: Spiritual well-being and meaning are positively associated with confidence in improving physical fitness and confidence in preventing chronic disease. Further, all 4 variables were significantly associated with physical activity. Future research should evaluate the potential efficacy of spiritual well-being and meaning to change physical activity utilizing longitudinal and RCT methodologies. Future work should also examine potential mediation effects on changes in physical activity via confidence in improving physical fitness and confidence in preventing chronic disease.

SYSTEMATIC REVIEW OF YOUNG ATHLETES' PSYCHOSOCIAL EXPERIENCES ACROSS SPORT TYPES, SETTINGS, AND ACTIVITY PATTERNS

M. Blair Evans, PhD[1], Veronica Allan, MSc[2], Karl Erickson, PhD[3], Luc J. Martin, PhD[2], Ross Budziszewski, B.S. Kinesiology[4], Jean Côté, PhD[2]

[1]Pennsylvania State University, University Park, PA; [2]Queen's University, Kingston, ON, Canada; [3]Michigan State University, East Lansing, MI; [4]The Pennsylvania State University, State College, PA

Although youth sport is a powerful organized activity for promoting positive psychosocial outcomes and health behaviors, participation in and of itself does not guarantee positive outcomes (Coakley, 2011). Indeed, theories of youth development support the assumption that athletes' psychosocial experiences differ as a result of variations in the design of their sport activities. To examine this prediction, we conducted a systematic review of youth sport literature to explore variations in psychosocial constructs (e.g., self-esteem, quality of life, depression) when assessed in youth who participate in differing sport types, settings, and activities. The Preferred Reporting Items for Systematic reviews and Meta-Analyses guidelines (PRISMA: Moher et al., 2009) were applied throughout the search protocol, which involved a scan of academic databases (e.g., SPORTDiscus; MEDLINE; PsycINFO) and a manual search—ultimately resulting in 6938 records to review at the level of title. Search criteria were applied during screening at the level of title, abstract, and finally full-text review. A coding sheet was used to extract information from included articles and code for risk of bias. Thirty-five studies were located that assessed an array of psychosocial constructs, with the most prevalent investigations predicting outcomes such as youth development, self-esteem, and depression according to: (a) sport types (e.g., team or individual; contact or non-contact), (b) sport settings (e.g., school- or community-based; competitive or recreational), or (c) across differing individual patterns of involvement (e.g., weekly hours of involvement; self-reported practice). Across studies, the majority of findings were inconsistent, dependent on moderating factors (e.g., age or gender), or had only been examined in a limited number of studies. As such, one conclusion of this review was that it is vital for researchers to conduct more detailed assessments of sport types, settings, and activity patterns–and use analyses that are suited to understand how these factors influence youth outcomes. Despite these limitations, the body of evidence indicates that sport involvement can facilitate psychosocial outcomes when youth engage in certain forms of sport activities (e.g., greater individual engagement in sport; teams with greater degrees of interdependence). These results could guide efforts to shape sport policies and practices to support healthy development and youth sport adherence.

THE IMPACT OF PHYSICAL ACTIVITY EXPERIENCE ON PHYSICAL ACTIVITY LEVELS: DO GENDER AND SOCIOECONOMIC STATUS MATTER?

Hui Xie, Ph.D[1], Linda Caldwell, PhD[2], Edward Smith, DrPH[3], Lisa Wegner, PhD, MSc., BSc.[4]

[1]California State University Northridge, Northridge, CA; [2]Penn State, University Park, PA; [3]Penn State University, Centre Hall, PA; [4]University of the Western Cape, Bellville, Western Cape, South Africa

The Impact of Physical Activity Experience on Physical Activity Levels: Do Gender and Socioeconomic Status Matter?

Introduction: Positive physical activity (PA) experience is associated with higher PA levels among youth. However, few studies explored the impact of negative PA experience on youth's PA levels. Further, little is known whether the impact of PA experience varies between males and females of different socioeconomic statuses (SES). Therefore, this study aims to examine the relationships of positive and negative PA experiences (POS and NEG) to leisure time PA levels (LTPA) using a sample of Black South African youth of different SES.

Methods: The sample consists of 2038 Black (48% females) 8th graders from 56 schools in South Africa. LTPA was measured by a question that asked participants to indicate their frequency of doing sports or physical activity after school and over weekends. POS and NEG were measured for participants who do LTPA. POS was measured by 3 items on a 4-point scale (e.g., *When you are playing sports or physical activity, how often do you feel good about yourself?*), while NEG was measured by 6 items (e.g., *When you are playing sports or physical activity*, *are you feeling stressed or anxious?*). SES was determined by the housing condition. Participants living in brick house, flat or apartment were grouped into high SES (58%), while those living in other types of housing (e.g., shack, tent) were grouped into low SES (42%). Multiple-group structural equation models were used to examine the effect of POS and NGE on LTPA for males and females of high and low SES (i.e., 4 groups).

Results: The measurement model had a good fit as indicated by RMSEA (.046) and was invariant across the 4 groups. Results showed significant differences in path coefficients between low SES males and the other 3 groups. POS did not have a significant effect on LTPA for low SES males but had a significant positive impact for the other 3 groups. NEG had a significant negative effect on LTPA for low SES males but did not had a significant impact for the other 3 groups.

Conclusions: The impact of PA experience on PA levels may vary between genders of different socioeconomic statuses. We will discuss possible reasons and implications for these findings.

A US POPULATION-BASED STUDY OF SES AND HEALTH-RELATED QUALITY OF LIFE IN CERVICAL CANCER SURVIVORS

Jessica N. Rivera-Rivera, MPH, Erin Aubrey, BS, Gabriella E. Puleo, M.S., Jessica L. Burris, PhD

University of Kentucky, Lexington, KY

In the United States, it is well accepted that low socioeconomic status (SES) increases risk for cervical cancer (CC) incidence and mortality, but there is little information about the influence of SES on CC survivors' health-related quality of life (HRQOL). This study helps address this gap in the literature via analysis of data from the Behavioral Risk Factor Surveillance System, a population-based phone survey of adults in the United States. In 2014, six states included the cancer survivorship module, ultimately yielding a sample of 344 women who reported a CC history. In the sample (age *M*, *SD*=54, 16 years), 48% were in a relationship, 87% were White Non-Hispanic, 43% were employed, and 85% had health care coverage. Linear and logistic regressions were performed to identify the association between SES (as measured by education and income) and several indicators of HRQOL (i.e., overall health status, unhealthy days due to mental and physical functioning, and activity limitations due to poor health). To assess the unique influence of SES, it was entered into each regression model after these covariates: 1) total number of chronic diseases (e.g., heart disease, asthma, diabetes) and 2) past month tobacco use, alcohol use, and sedentary behavior. After controlling for chronic disease and health risk behaviors, lower income levels were significant predictors of worse overall health status (β=.23, $p < .01$), more unhealthy days due to mental functioning (β=.30, $p < .01$), more unhealthy days due to physical functioning (β=.14, $p < .05$), and greater activity limitations (β=.17, $p < .05$). The same pattern of significant findings arose in the logistic regression models where the aforementioned HRQOL outcomes were dichotomized using accepted cut-scores (ORs=1.39-2.06, all *p*s < .05). In contrast, lower education levels were only found to be a significant predictor in one (unhealthy days due to mental functioning; β=-.13, $p < .05$) of the 8 aforesaid regression models (βs=-.06-.02 & ORs=.62-1.30, all *p*s>.05). In sum, lower income – but not education – was associated with worse HRQOL in CC survivors, and its predictive utility was demonstrated above and beyond other well-established HRQOL correlates. Cancer is known to cause economic hardship, and for some CC survivors, the financial strain associated with lower income levels may reduce HRQOL. Future studies should explore the mechanisms by which low income impacts CC survivors' HRQOL, and ways to remediate its negative influence.

EFFECT OF ACCULTURATION ON OBESITY AND PREGNANCY IN HMONG-AMERICAN WOMEN FROM 1985 TO 2015: A CASE-CONTROL STUDY

Brenda Rooney, PhD[1], Jedidiah Barton, N/A[2]

[1]Gundersen Health System, La Crosse, WI; [2]Gundersen Health System, Brownsville, WI

Effect of Acculturation on Obesity and Pregnancy in Hmong-American Women from 1985 to 2015: a Case-Control Study

Introduction: Obesity has risen significantly over the past several decades and is known to affect pregnancy outcomes. Asian Americans from Laos and Thailand (i.e., Hmong), have been immigrating to the United States since the mid-1970s. We explored the change in weight (BMI) at delivery and weight gained in pregnancy for Hmong compared to White women, and corresponding pregnancy complications and outcomes.

Methods: From 1985 to 2015, 4.3% of all deliveries at our facility were by Hmong women. A case-control study was conducted randomly selecting 10 Hmong deliveries each year and matching by year, age, gravida and parity to White deliveries. A medical record review gathered pre-pregnancy characteristics and delivery outcomes. Acculturation was loosely measured by subject's birth location and language spoken.

Results: 557 (282 Hmong, 275 White) subjects were reviewed. Each year, Hmong women's BMI was lower than White women's. BMI at delivery increased significantly for both Hmong and White women, however, the slope of this increase was steeper for Hmong women than for White women (p=0.001). Pregnancy weight gain was also higher among White women than Hmong women every year, and significantly increased over the 30-year span, however, it increased more for Hmong women (p=0.001). There was an increase in pregnancy and delivery complications overall, but a decrease in infant complications. White women were more likely to have pre-existing complications. Hmong women were more likely to have maternal complications including postpartum anemia and hemorrhage. Hmong women who were born in the US were more like their matched White women in BMI at delivery and weight gain. Hmong women not born in the US had lower BMI and pregnancy weight gain. Hmong women who were fluent in English were similar to White women in their weight gain and BMI at delivery. Hmong who were not fluent in English had lower BMI and smaller

pregnancy weight-gain.

Conclusions: Acculturation is impacting obesity and outcomes in Hmong-American women at pregnancy. There was a significant increase in obesity in Hmong-American women and increasing complications rates. This is particularly important to consider as we explore the health of other ethnic and racial groups and immigration continues to be examined world-wide.

FACTORS ASSOCIATED WITH SELF-REPORTED EATING PROBLEMS AND DESIRE FOR TREATMENT AMONG LATINAS WHO BINGE EAT

Brooke Palmer, M.A.[1], Virginia Gil-Rivas, Ph.D.[2], Alyssa Vela, M.A.[1], Alyssa Minnick, M.S.[3], Fary M. Cachelin, PhD[1]

[1]University of North Carolina Charlotte, Charlotte, NC; [2]UNC Charlotte, Charlotte, NC; [3]University of North Carolina at Charlotte, Charlotte, NC

Binge eating (BE) is a common disordered eating behavior among women, and is associated with negative health implications such as obesity, diabetes, and cardiovascular disease. Group differences are seen in BE; Latinas report equal if not greater rates of BE compared to women of other racial/ethnic backgrounds. Latinas who engage in disordered eating may report more frequent BE, higher levels of depression, and greater concerns about body shape and weight. Complicating the picture is the fact that Latinas are less likely to seek specialized treatment. When they do discuss weight and eating issues, Latinas are also less likely to be diagnosed and receive proper treatment from providers.

The current study examined factors associated with Latinas' perceptions of having an eating problem and their desire to receive treatment. Specifically, researchers assessed if BMI, insurance coverage, and ED symptomatology (frequency of BE and overvaluation of shape and weight) were associated with Latinas' perceptions of having an eating problem and desire for treatment. These factors are integral for increasing Latinas' access to treatment.

Latinas (N =167) were recruited from Charlotte, NC and Los Angeles, CA to participate in an interview related to BE and comorbid symptoms. The Eating Disorder Examination, 12th edition (Fairburn & Cooper, 1993) was used to assess eating disorder diagnoses and symptoms. Participant average age was 27.25 (*SD* = 8.4) and 67.7% were either overweight or obese. Average BE frequency was 6.2 (*SD* = 7.31) objective binge episodes in the past 28 days. Over half (54.3%) met DSM-5 criteria for an eating disorder, either binge eating disorder or bulimia nervosa. Over half of the participants (69.2%) said they felt they had a problem with eating, and 56% wanted help for an eating problem. Only 9% of the participants had received treatment for an eating problem. Correlation analyses revealed that BMI, BE frequency, and overvaluation of shape and weight were positively associated with participants' perception of having an eating problem and wanting help. Using logistic regression, BMI and BE were not associated with self-reported eating problems but overvaluation was. However, BMI and overvaluation were associated with wanting treatment. Surprisingly, frequency of BE was not associated with either outcome. An interesting finding was that many women who had a desire for treatment had insurance but still did engage in treatment.

Overall, the results suggest that there is a great deal of heterogeneity among Latinas who report binge eating and the way in which they view disordered eating. These results provide insight to health care providers and may encourage them to ask about binge eating symptoms and treatment needs for Latinas exhibiting various levels of symptomatology.

FACTORS IMPACTING AFRICAN AMERICAN RENAL PATIENTS' COMPLETION OF THE MEDICAL EVALUATION PROCESS FOR KIDNEY TRANSPLANTATION

Camilla W. Nonterah, MA[1], Heather M. Traino, PhD[2], Shawn O. Utsey, PhD[3], Gaurav Gupta, MD[3], Faye Z. Belgrave, PhD[3], Micah L. McCreary, PhD[4]

[1]Virginia Commonwealth University/ Medical University of South Carolina, Charleston, SC; [2]Temple University, Philadelphia, PA; [3]Virginia Commonwealth University, Richmond, VA; [4]McCreary and Madison Associates, Inc, Mechanicsville, VA

African Americans are more susceptible to end-stage renal disease (ESRD) as a result of genetic characteristics and socioeconomic factors. Treatment options for patients with ESRD include dialysis therapy (i.e., hemodialysis, peritoneal dialysis) and transplantation, with the latter typically producing better outcomes. African Americans are less likely to seek kidney transplantation or complete the medical evaluation process to be placed on the waitlist for transplantation. The medical evaluation or pre-transplant work up, which requires patients to consult with doctors and undergo a series of tests and examinations, is a tedious process that may impede a patient’s ability to be placed on the waitlist. The current study sought to determine the factors that predict completion of the medical evaluation for African American ESRD patients using a mixed methods design. Participants consisted of transplant professionals (*N*=23) recruited from nine transplant centers in the Mid-Atlantic, Mid-Western and Southeastern parts of the United States, and kidney patients (*N*=30 patients) recruited from one transplant center in the Mid-Atlantic region. Semi-structured interviews and nominal focus groups were conducted to gather qualitative data enlisting barriers and motivators to patients’ completion of the medical evaluation process; quantitative survey data were also collected. The results revealed several barriers and motivators which were then classified as impacting patients at the individual-level and systemic level, and others classified as health-related and informational/educational. Participants ranked insurances issues, limited income, lack of a personal means of transportation, lack of patient motivation, the number of procedures required to complete the evaluation, scheduling difficulties and time constraints as top barriers to completing the medical evaluation process. Top motivators consisted of informational support, social support, religious beliefs, patients’ desire to get off dialysis, support from the transplant staff, center-based education, patient’s knowledge of the benefits of transplantation and patient navigators. These findings provide valuable information on the factors that impact African American renal patients’ completion of the medical evaluation process.

FOOD ADVERTISING DURING CHILDREN’S TV PROGRAMMING IN NEPAL

Andrew D. Ogle, PhD[1], Ashlie Johnson, B.S, B.A[2], John Morgan, B.S.[3], Dan J. Graham, PhD[2]

[1]CH Smith & Associates, LLC, Springdale, OH; [2]Colorado State University, Fort Collins, CO;
[3]Clemson University, Clemson, SC

Television advertising of foods to children has been criticized in recent decades by health advocates because a) a high volume of the foods are unhealthful (Kelly et al., 2010), and b) children are less able to scrutinize advertising messages than adults (Kraak & Story, 2015). The World Health Organization has released a multi-pronged agenda directed at regulation agencies and food industry marketing with the aim of reducing children’s overall exposure to media messages that can lead to less healthful diet choices.

The purpose of this study is to describe the TV food marketing landscape that children experience in the southeast Asian country of Nepal. Sixty one hours of television were recorded over a 20-day span from three channels during hours that children’s programming was played. We conducted a content analysis on 12 hours of commercials, categorizing commercials based on existing coding schemes for food nutrition (Schermbeck & Powell, 2015) and marketing appeal type (Batada et al., 2008). Foods were categorized by the authors via inductive coding based on regional salience.

Principal findings of this study were that nearly 20% of airtime during children’s programming was dedicated to commercials, and 55% of that was dedicated to foods. Over 80% of the food commercials had excessive amounts of saturated fat, trans fat, sugar or sodium. High sugar levels were perhaps the most apparent trend, as over half of the commercials featured products that contained excess sugar. The most prevalent food types shown were ice cream and popsicles (20.7%), energy/nutritional supplements (20.2%), and candy (14.6%). Additionally, the three most commonly occurring marketing appeals were those featuring animated effects (82.6%), movie, cartoon, animated, or costumed characters (36.8%), and TV or movie tie-ins (16.5%).

Results from this study suggest that the media landscape in Nepal isn’t meeting WHO recommendations for advertising foods to children. As food markets and marketing practices become more and more global, nutrition transitions in developing nations may result. The food media trends targeting Nepal’s youth may already be foretelling a rise in less healthful diets among the new generation.

INDIVIDUALISM-COLLECTIVISM OF BLACK ETHNIC GROUPS AND PERCEIVED STRESS

Betty Braxter, PhD[1], Elisabeth Beaudouin, BS[2], Willa Doswell, PhD, FAAN[3]

[1]University of Pittsburgh, School of Nursing, Pittsburgh, PA; [2]Villanova University, Philadelphia, PA; [3]University of Pittsburgh, Harrison, PA

Social scientists have redefined the construct of culture to include such dimensions as individualism and collectivism. An individualistic culture (IC) promotes and supports individual needs over group needs. IC fosters autonomy compared to cultures promoting collectivism in which group needs are more relevant, and supportive of cooperation. A small body of work suggests IC is linked to varied psychological issues. Respectively, at the individual level IC is measured in terms of idiocentrism and allocentrism. With three different racial ethnic groups, the purpose of the study was to: 1) assess idiocentrism and allocentrism within each group, and 2) examine the relationship by group of idiocentrism, allocentrism and perceived stress. Using a descriptive design, participants completed a 20-item Allocentrism Inventory using a rating scale format (0-Not in the Least Agree to 10-Entirely Agree) and the 10-item Perceived Stress Scale with descriptive statistics employed for data analysis. Sample was comprised of 53 African (AF; n=10), African American (AA; n=27), and Afro Caribbean (AC; n=17) young adults. By group, the mean idiocentrism score was highest for AC young adult (56.9+ 17.7) followed by AA (54.5+ 8.0) and AF(53.9+8.1). The mean allocentrism score was highest among AF young adults (67.6+10.2) compared to both AA (60.1+11.2) and AC counterparts (60.1+15.2). An Allocentrism over idiocentrism mean relative balance score among AF young adults was 4 times higher than the score for AC. High scores on idiocentrism and high stress scores were found among 27% of AC young adults versus 25% AA and 22% AF counterparts. The findings suggest that Afro Caribbean young adults' scores reflect a more individualistic culture than African or African American counterparts. A need to implement stress management strategies specifically among Afro Caribbean young adults exists. Research is needed to better understand the relationship between individualism and collectivism dimensions of culture and stress among African, African American, and Afro Caribbean young adults.

LINGUISTIC ACCULTURATION AND SKIN CANCER PROGRAM PREFERENCES AMONG U.S. HISPANICS

Adrienne Viola, MPH[1], Elliot Coups, PhD[2]

[1]Rutgers Robert Wood Johnson Medical School, Lawrenceville, NJ; [2]Rutgers, The State University of New Jersey, New Brunswick, NJ

Introduction: Although the incidence of melanoma is lower among Hispanic individuals in the United States than non-Hispanic Whites, they are more likely to be diagnosed at an earlier age and with more advanced disease. Little research has focused on Hispanic individuals' preferences for information and programs related to skin cancer prevention. In this study, we examined the association between linguistic acculturation and preferences for information delivery and skin cancer prevention programs.

Methods: 788 Hispanic adults (49.6% female; *M* age 41.0 years; 70.9% Mexican) were recruited from KnowledgePanel Latino, a nationally representative web panel of U.S. Hispanic adults. Participants were eligible if they had no history of skin cancer and resided in Arizona, California, Florida, New Mexico, or Texas. Participants completed an online survey in Spanish or English that included measures of linguistic acculturation and preferences regarding skin cancer prevention programs.

Results: In terms of linguistic acculturation, just over a third (35.7%) of the participants were denoted as Spanish-acculturated, 19.6% were English-acculturated, and 44.7% were bicultural. Overall, reading information on the Internet (70.8%) and receiving newsletters (62.4%) were the most preferred methods of information delivery, while speaking on the phone with a health educator (33.9%) and meeting in person with a health educator (42.1%) were the least popular. Spanish-acculturated participants were more willing to meet with a health educator (57.6%) than those who were English-acculturated (23.9%; $p < 0.001$), with a similar trend for speaking by phone with a health educator (52.7% and 16.4% respectively, $p < 0.001$). Individuals who were Spanish-acculturated were also significantly more interested in programs related to skin cancer prevention, including programs to promote sun protection behaviors ($p < 0.001$), learning more abot sun protection and skin self-examination ($p < 0.001$), using sunscreenif it was available at public locations ($p < 0.001$), and having a free skin cancer examination at a public location ($p < 0.001$).

Conclusions: Preferences for skin cancer program delivery among Hispanic individuals differ according to linguistic acculturation. The results of this study provide insight on targeting skin cancer prevention programs for Hispanic individuals.

PATERNAL SOCIALIZATION AND HEALTH HELP-SEEKING AMONG BLACK MEN

Leslie Adams, MPH, Wizdom Powell, PhD, MPH

University of North Carolina at Chapel Hill, Chapel Hill, NC

Black males are less likely to obtain routine health screenings and seek help for health problems than White men. Many barriers to health help-seeking among Black males are unrelated to lack of insurance or access to care. Yet, such factors are less understood. Health socialization, or the process by which individuals acquire health-specific attitudes, knowledge, and behaviors, is one potential early-life factor contributing to Black men's health help-seeking barriers. Most studies examining the role of heath socialization in health outcomes focus on maternal influences. Scarce attention is paid to the role fathers play in minimizing or exacerbating health help-seeking barriers. The current study addresses this gap by examining the relationship between early-life paternal health socialization and barriers to health help-seeking among Black men. Using data from the African American Men's Health and Social Life study, a community sample of 458 adult Black men (mean age = 32 years, SD: 10.9) were recruited primarily from barbershops from four regions of the United States. Participants completed previously validated measures assessing barriers to help-seeking, masculinity norms, and John Henryism. Paternal health socialization was measured with a 3-item scale designed to assess the frequency men received direct instruction from their fathers encouraging health help-seeking. Bivariate correlations and multivariate linear regression analyses were used to assess relationships between the study variables. After controlling for age, masculinity norms, insurance status, marital status, education, and John Henryism, paternal health socialization was significantly and positively associated with barriers to health help seeking (ß=0.10, $p< .05$). The regression model accounted for 24% of the variance in barriers to health help-seeking, F (8, 357)=15.20, $p < 0.001$, adjusted $r^2=0.24$. Behavioral interventions designed to improve health help-seeking among Black men should focus on enhancing paternal health socialization. Implications for research and policy will be discussed.

PERCEIVED RISK AND PROTECTIVE FACTORS FOR HPV ACROSS TIME AND ACROSS SEXUAL ORIENTATIONS

Stephanie D. Finneran, MA[1], Devon Price, MS[2], Seth Kalichman, PhD[2], Lisa Eaton, PhD[2]

[1]University of Connecticut, Vernon, CT; [2]University of Connecticut, Storrs, CT

The leading cause of cervical cancer is human papillomavirus (HPV), a sexually transmitted infection that can be spread between female sexual partners. Though data among women who have sex with women (WSW) are limited, there is evidence that WSW have a higher prevalence of cervical cancer than heterosexual women (Boehmer, 2011). In 2006, Eaton et al. (2008) surveyed 275 WSW at the Atlanta Gay Pride parade, of which 31% had received abnormal pap smear results and 6% had been diagnosed with HPV. Additionoally, receiving an abnormal pap result significantly predicted perceived HPV risk. Now, almost a decade since the HPV vaccine Gardasil® has been introduced, little is known in regards to HPV risk perceptions and protective factors among WSW, which is crucial for reducing HPV and cervical cancer rates.

We surveyed 161 women at 2015 Atlanta Gay Pride about risk perceptions, pap smear history, and HPV vaccine uptake. Interestingly, there was no significant difference in perceived risk between 2006 and 2015, t(442)=-.14, p=.96. Consistent with Eaton (2008), an abnormal pap result predicted perceived personal risk, t(158)=2.37, p=.02. For the current study, we also compared lesbian (n=78), bisexual (n=46), and heterosexual women (n=37) on risk perceptions and protective factors. Controlling for age, logistic regression showed no significant differences between sexual orientations for receiving pap smears, either lifetime or within the past 3 years (all ps>.6). However, there were differences in vaccine uptake across sexual orientations: less than 40% of lesbians received the HPV vaccine, compared to 67% of bisexual women and 57% of heterosexual women. Among participants sexually active in the past year, an ANOVA controlling for age showed lesbians perceive a significantly lower risk of getting HPV than bisexual and heterosexual women, F(2,128)=3.85, p=.02. Lastly, vaccine uptake was a significant predictor of perceived risk: those who had received the vaccine had significantly higher perceived personal risk than those who had not received the vaccine, F(1,126)=4.0, p=.05.

Pap smears and HPV vaccination are the primary focus for reducing rates of cervical cancer, and there is evidence that perceived HPV risk predicts these behaviors. Our results demonstrate the importance of considering differences across sexual orientations.

RELIGIOUS HEALTH FATALISM AND ELEVATED CHOLESTEROL AMONG CHURCH-GOING AFRICAN AMERICAN ADULTS

Sarah D. Childress, B.S., Edna Paredes, B.S., Sarah Fasanando, Student, Marcel A. de Dios, PhD

University of Texas MD Anderson Cancer Center, Houston, TX

Objective: In the U.S., 47% of African-American Adults (AAs) are affected by cardiovascular disease (CVD). Elevated cholesterol, which is the greatest risk factor of CVD, is highly prevalent among AAs, which has been linked to lifestyle and behavioral risk factors such as smoking, sedentary lifestyle, excessive alcohol use, and poor diet. Religiosity, or religious involvement, has been shown to have a beneficial effect on the health risk behaviors associated with CVD, but findings have been mixed depending on methods employed. Furthermore, religious health fatalism (RHF), defined as “the belief that health outcomes are inevitable and/or determined by God”, has received little research attention. Yet, domains of RHF (Divine Provision, Destined Plan, and Helpless Inevitability) are thought to be critical constructs underlying the relation between religiosity and health. The current study examines the association between RHF and elevated cholesterol among church-going AAs. **Methods:** Participants (*n*=135) were recruited from a large, predominately African American church. A multiple logistic regression model was used to test whether the three subscales of the Religious Health Fatalism Questionnaire (RHFQ) were significant predictors of self-reported lifetime history of elevated cholesterol. Sex, age, level of education, employment status and Lukwago Religiosity Scale (LRS) scores were entered as covariates in Block 1. The three RHFQ subscales were entered in Block 2. **Results:** After adjusting for covariates, likelihood of elevated cholesterol increased significantly ($p < .001$). **Conclusions:** We speculate that individuals with a greater degree of Helpless Inevitability may view their health behaviors as less impactful and are less likely to follow health recommendations for promoting healthy cholesterol levels. Future research is needed to understand the complex interplay of factors associated with religiosity and fatalism that contribute to an increased risk of elevated cholesterol among AAs.

TESTING THE FEASIBILITY AND ACCEPTABILITY OF A CULTURALLY ADAPTED PHYSICAL ACTIVITY INTERVENTION WITH ADULT SOMALI WOMEN

Kate Murray, PhD, MPH[1], Sarah Linke, PhD, MPH[2], Amina Sheik Mohamed, MPH[2], Jacqueline Kerr, PhD, MSc[3], Deborah Bowen, PhD[4], Bess H. Marcus, Ph.D.[5]

[1]Queensland University of Technology, Kelvin Grove, Queensland, Australia; [2]UC San Diego, La Jolla, CA; [3]Department of Family Medicine and Public Health, UC San Diego, La Jolla, CA, USA, La Jolla, CA; [4]University of Washington, Seattle, WA; [5]University of California, San Diego, La Jolla, CA

Changing lifestyles and disease profiles have been evident for Somali women living in countries such as the US, but there is little research on culturally appropriate and effective methods to promote healthy lifestyles within this population. This pilot study tested the feasibility and acceptability of a culturally adapted physical activity intervention for use with sedentary adult Somali women living in the US. Participants were randomly assigned to a 12-week physical activity (PA) intervention (n = 13) or a wait-list control group (n = 14). Self-report and objective PA measures were obtained at baseline, post-program, and at 3-months post-intervention. All intervention and assessment materials were available in both English and Somali and delivered by bilingual/bicultural research team members with the intervention groups facilitated in Somali.

The sample was on average 41-years-old and all women were born overseas, having lived in the US for an average of 14 years. The sample reported on average greater affiliation with Somali culture than US culture and limited access to environmental resources to engage in PA (M = 0.78 resources per person). Overall, the sample was highly sedentary at baseline, with no differences between the groups. Participants reported approximately 20 minutes per week of moderate-to-vigorous physical activity at baseline according to the 7-day Physical Activity Recall. Post-intervention there was a significant increase to approximately 100 minutes per week ($p < .01$). Significant increases were found in self-efficacy for PA, behavioral processes of change, and environmental access to PA resources (e.g. exercise or sports equipment, exercise videos or other resources) for the PA group (all $p < .05$). The control group showed significant increases for environmental access and behavioral processes of change ($p < .05$), and approached significance on the 7-day PAR ($p = .05$) at the end of the 3-month wait. Data on program delivery and measurement challenges and successes inform further adaptation and considerations for future trials.

A larger trial of the adapted intervention is needed to test the efficacy of the intervention. The results have implications for future outreach and intervention with other refugee, low-income, and Muslim populations. Further research is critical to ensure equitable access to evidence-based interventions for underserved communities.

THE IMPACT OF SOCIAL CONTEXT ON RISK-RELATED ATTITUDES AND BEHAVIORS AMONG AFRICAN AMERICANS

Danielle E. Reece, MPH Candidate[1], Danielle N. Lambert, MPH, CHES[2], Erin R. Johnson, MPH, CHES[3]

[1]Emory University, Atlanta, GA; [2]University of Georgia, Atlanta, GA; [3]American Institutes for Research, Washington, DC

The impact of social context on risk-related attitudes and behaviors among African Americans

Background: Members of the African American community are disproportionately affected by adverse health outcomes, including HIV and STIs. Research suggests that effective health communication from a trusted source can help to mitigate risk behaviors and subsequent negative health consequences. This study investigates the extent to which social influences differ for African Americans compared to those of other racial backgrounds, and examines the potential impact social context has on individuals' preferred source of risk communication.

Methods: Data were collected from an online survey that was disseminated through academic institutions, community organizations, and social media platforms. The sample consisted of 1,011 respondents, of which 158 (15.6%) identified as Black or African American. Chi Square tests of independence were performed in SPSS 23 to investigate the relationship between social influences and racial background.

Results: Analyses show that African Americans were more likely to claim that their religious community (X^2=44.77, df=1, p < .001), and personal religious beliefs (X^2=22.80, df=1, p < .001), and less likely to claim that teachers (X^2=11.41, df=1, p=.001) and social media (X^2=6.51, df=1, p=.01), influence their viewpoints. Additionally, African American respondents were more likely to report that their religious community (X^2=35.80, df=1, p < .001) and personal religious beliefs (X^2=16.36, df=1, p < .001) influenced their behavior, while social media was found to have less of an influence (X^2=15.71, df=1, p < .001). African Americans were also more likely to prefer to learn about sex education from a church or other religious institution than were individuals of other racial backgrounds (X^2=36.38, df=1, p < .001) and to have their children

learn about sex from a church/religious institution (X^2=31.68, df=1, $p < .001$).

Conclusion: The findings of this study suggest that, compared to individuals of other racial backgrounds, African Americans place significant influence on religion, and subsequently prefer to get information from religious sources. This information can be used to inform future risk reduction interventions and programming to educate African American communities.

ADOLESCENT SUBSTANCE USE AND SENSATION-SEEKING ON SEXUAL BEHAVIORS AMONG YOUNG ADULTS FROM CONTINUATION HIGH SCHOOLS

Lilia Espinoza, MPH, PhD[1], Jean Richardson, DrPH[2], Chih-Ping Chou, PhD[3], Kristin Ferguson, PhD[4], Lourdes Baezconde-Garbanati, PhD, MPH, MA[3], Alan Stacy, PhD[5]

[1]California State University, Fullerton, Fullerton, CA; [2]University of Southern California, Los Angeles, CA; [3]University of Southern California, Department of Preventive Medicine, Institute for Health Promotion and Disease Prevention Research, Los Angeles, CA; [4]Arizona State University, Phoenix, AZ; [5]Claremont Graduate University, Claremont, CA

Background: Adolescents and young adults of color are disproportionately affected by HIV with sexual behaviors as the primary mode of transmission. Extant research on the relationships between substance use, sensation seeking and sexual risk-taking among adolescents in continuation high schools (CHS) is limited. CHS youth are at risk of dropping out of school and are exposed to a social environment where HIV-related risk behaviors are high. Substance use is higher among CHS youth than other high school (HS) youth. Sensation seeking may produce some disinhibition that impacts decision-making and impacts sexual risk-taking. CHS youth report an earlier age at sexual onset; a larger proportion report multiple sexual partners; and these behaviors vary by gender and race/ethnicity. Trend data show decreasing sexual risk-taking among HS youth, but trend data are not available for CHS youth. The long-term consequences of substance use and sensation-seeking on sexual behaviors are unknown. It was hypothesized that substance use, sensation-seeking and number of sexual partners would vary by gender and race/ethnicity and these relationships would be partially mediated by age at sexual onset.

Methods: Baseline and four-year follow-up data from 111 young adults (56.8% Latino; 51% female; mean age 20.6 years) originally recruited from 14 CHS in southern California to participate in an intervention aimed at altering substance use perceptions were analyzed. Inclusion criteria for the present study were a minimum age of 18 years and self-identification as Latino, White or Black. Baseline substance use and sensation seeking were treated as predictors. Sexual behavior information was collected at follow-up with age at sexual onset treated as the mediator and numbers of sexual partners as outcomes. Structural equation modeling was used to assess the effects of substance use and sensation-seeking on sexual behaviors.

Results: Latinos had lower sensation seeking and substance use and a later age at sexual onset than non-Latinos. Females were less likely to have multiple lifetime and recent sexual partners and use marijuana. The effects of adolescent substance use on the number of sexual partners was fully mediated by their age at sexual onset.

Discussion: Factors of and actual sexual risk behaviors among CHS youth vary by race/ethnicity and gender. CHS youth who reported greater substance use during adolescence were more likely to initiate sex at an earlier age. Early initiation of both activities was predictive of the number of lifetime and recent sexual partners by young adulthood. Sensation-seeking was not predictive of the number of sexual partners and may indirectly impact the number of sexual partners through other factors not previously assessed. Targeting specific variables by race/ethnicity and gender may improve prevention efforts.

ALCOHOL USE, SEXUAL RISK BEHAVIORS, AND HIV AMONG NIGERIANS: A SYSTEMATIC REVIEW AND META-ANALYSIS, 1997-2014

Uzoamaka J. Okoro, BA[1], Lori A. J. Scott-Sheldon, PhD[2], Kate B. Carey, PhD[3], Blair T. Johnson, PhD[4], Michael P. Carey, PhD[2]

[1]The Warren Alpert Medical School of Brown University, Providence, RI; [2]The Miriam Hospital and Brown University, Providence, RI; [3]Brown University, Providence, RI; [4]University of Connecticut, Storrs, CT

Background: Nigeria has the second largest population of people living with HIV as well as one of the highest rates of alcohol consumption in Africa. Prior research shows that alcohol consumption influences sexual decision-making but the relation between alcohol and sexual risk behaviors in Nigeria has not been documented. Therefore, this study examined the (a) prevalence of and (b) association between alcohol use, sexual risk behavior, and HIV among Nigerians.

Methods: We searched electronic databases and reviewed reference sections of relevant papers to locate studies that (a) sampled populations in Nigeria (b) assessed both alcohol and sexual risk behavior. Of the 696 unique records identified, 35 manuscripts reporting on 42 separate studies met inclusion criteria. Effect sizes were calculated to determine both the prevalence of, and association between, alcohol use and sexual risk behaviors. Moderators were examined to determine if sample characteristics predicted behavioral or biological outcomes.

Results: Participants (N = 83,967; M age = 26; 49% women) reported high rates of heavy drinking (59%) and low rates of consistent condom use (22%). Many participants reported using alcohol before sex (40%). A positive HIV diagnosis was reported in 10% of the samples. We also found a significant association between alcohol use and sex such that participants who engaged in sex were more likely to drink alcohol, $d+ = 1.32$ (95% CI = 1.09, 1.54), $Q(2) = 0.20$, $p = .90$, $I^2 = 0$ (0, 84). Participants belonging to high-risk groups (e.g., commercial sex workers, patients from STI clinics, prisoners) were more likely to consume alcohol and less likely to use a condom compared to participants from low-risk groups.

Conclusion: Our findings indicate that Nigerians engage in high rates of heavy drinking and low rates of condom use. The results from this meta-analysis can be used to inform critically needed alcohol-related HIV interventions.

COMFORT WITH SEXUALITY IN ORTHODOX JEWISH WOMEN

Sara Rozner[1], Terry DiLorenzo, PhD[2]

[1]Yeshiva University Stern College for Women, New York, NY; [2]Yeshiva University, New York, NY

Comfort with sexuality is an understudied component of sexual health. Encompassing attitudes and emotions about sex as well as communication competency, comfort with sexuality has been positively associated with sexual health outcomes, including delayed onset of sexual activity, contraceptive use, and relationship satisfaction. Comprehensive sex education, both from parents and in school, has been associated with higher levels of comfort, while religiosity has been associated with lower levels of comfort with sexuality.

The present study examined the association between comfort with sexuality, sex education, religiosity and sexual health in Orthodox Jewish young women. Because of conservative sexual values and a scarcity of comprehensive sex education in this community, Orthodox Jewish women are an important population for study. We predicted that women who had received comprehensive sex education and those who reported higher levels of religiosity would report higher comfort with sexuality.

A total of 76 students (mean age = 20.78) from a female religiously-affiliated college completed online surveys assessing school and parental sex education, religiosity (subjective religiosity, religious practice, and faith), and comfort with sexuality. 65.8% reported some sex education in high school, but only 44% of those received comprehensive sex education. 51.3% reported sex education from parents. Women who received comprehensive school sex education reported more comfort with sexuality than those who had abstinence-only education ($t(46) = -2.18$, $p < .05$). Likewise, women who had parental sex education reported more comfort with sexuality than those who did not ($t(74) = 2.61$, $p < .05$). Each of the three religiosity measures was negatively correlated with sexual comfort ($r = -.44$, $p < .001$; $r = -.56$, $p < .001$; $r = -.33$, $p = .003$, respectively).

Both hypotheses were supported. Despite the Orthodox Jewish community's unique culture surrounding sexuality, women in this sample reported results similar to women in the general population. In light of this population's high levels of religiosity and low rates of sex education, the results of this study point to the need for comprehensive sex education as a potential intervention to promote sexual comfort. Future research should explore culturally appropriate

educational interventions, and compare Orthodox Jewish women with other religious and secular populations.

DO CHANGES IN INFORMATION, MOTIVATION, AND BEHAVIORAL SKILLS PREDICT CHANGES IN CONDOMLESS SEX?: AN INTEGRATIVE DATA ANALYSIS

Jennifer L. Walsh, PhD[1], Lance S. Weinhardt, PhD[2], Michael P. Carey, PhD[3]

[1]Center for AIDS Intervention Research, Department of Psychiatry and Behavioral Medicine, Medical College of Wisconsin, Milwaukee, WI; [2]Joseph J. Zilber School of Public Health, University of Wisconsin-Milwaukee, Milwaukee, WI; [3]The Miriam Hospital and Brown University, Providence, RI

Background. One basis for sexual risk reduction interventions is the Information-Motivation-Behavioral Skills (IMB) model, which posits that knowledge of STI/HIV, motivation to reduce risk, and behavioral skills contribute to reductions in risk behavior. However, few studies have investigated how *changes* in IMB constructs relate to *changes* in sexual risk behavior. Weused advanced statistical methods to determine which IMB constructs predict changes in condomless sex across 3 samples.

Methods. Patients participating in HIV prevention trials from urban clinics in the northeastern and midwestern U.S. (N = 3,150, 57% male, 70% Black) completed measures at 3mo intervals over 12mo. Composite measures of information (HIV knowledge), motivation (condom attitudes and subjective norms), and behavioral skills (condom use self-efficacy and skills) were created using integrative data analysis. Parallel process latent growth models (PPLGMs) tested whether IMB changes were correlated with changes in condomless sex, and cross-lagged models tested bidirectional relationships between IMB constructs and condomless sex

Results. PPLGMs showed that improvements in attitudes were associated with increases in skills, B = 0.38, p < .05. Improvements in norms were associated with increases in self-efficacy, Bs > 0.93, ps < .001. Improvements in norms and skills were associated with decreases in condomless sex, Bs < -0.28, ps < .001 and Bs < -0.42, ps < .001. However, increases in knowledge were associated with *decreases* in skills, Bs < 0.24, ps < .05, resulting in a *positive* indirect effect of changes in knowledge on changes in condomless sex, b = 0.25, p < .05. Cross-lagged models showed that more positive attitudes and norms and higher self-efficacy and skills were all associated with later decreases in condomless sex, Bs < 0.33, ps < .05. In contrast, higher knowledge was associated with *increases* in condomless sex, Bs > 0.03, ps < .001. More engagement in condomless sex predicted decreases in attitudes, norms, and skills, Bs < -0.03, ps < .01.

Conclusions. Results suggest knowledge may not be the best focus for interventions aiming to decrease condomless sex in at-risk populations. However, in line with the IMB model, motivation and behavioral skills seem useful targets for interventions. Bidirectionality in relationships suggests that those with the highest risk may be most resistant to changes in motivation and skills; interventionists should continue to refine programs to reach these individuals.

EXPLORING PREGNANCY-RELATED INTENTIONS AND BEHAVIORS AMONG PREGNANT YOUNG WOMEN IN KWAZULU-NATAL, SOUTH AFRICA

Jessica N. Coleman, BA[1], Karmel W. Choi, MA, PhD Candidate[2], Jennifer A. Smit, PhD[3], Cecilia Milford, MA[3], Nzwakie Mosery, BA[3], Letitia Greener, MA[3], Lynn T. Matthews, M.D., M.P.H.[4], Abigail Harrison, PhD[5], David R. Bangsberg, M.D.[6], Steven A. Safren, PhD[7], Christina Psaros, PhD[2]

[1]Massachusetts General Hospital, Cambridge, MA; [2]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [3]Maternal, Adolescent, and Child Health Research Unit, Department of Obstetrics and Gynecology, Faculty of Health Sciences, University of the Witwatersrand, Durban, KwaZulu-Natal, South Africa; [4]Massachusetts General Hospital, Boston, MA; [5]Department of Behavioral & Social Sciences and the Population Studies & Training Center, Brown University, Providence, RI; [6]Harvard Medical School/Massachusetts General Hospital, Boston, MA; [7]Department of Psychology, University of Miami, Coral Gables, FL

Background: Unintended pregnancy in adolescence and young adulthood can negatively affect health care engagement and outcomes for mother and infant, interrupt life trajectories, and increase future risk for unintended pregnancies. In South Africa, unplanned pregnancies among young women reach as high as 79%, indicating that youth are engaging in unprotected sex at the risk of becoming pregnant and acquiring or transmitting HIV and other STIs. The goal of this analysis is to provide a comprehensive picture of pregnancy intentions and contraceptive use among young South African women.

Methods: Qualitative data from interviews with 35 women receiving antenatal care from a district hospital in KwaZulu-Natal, South Africa were analyzed. The recorded interviews were translated, transcribed, and qualitative content analyses were conducted using NVivo 10 software.

Results: Participants were Black South African women with a mean age of 19.3 years (SD = 1.1). 37% were HIV-infected, and 83% were currently in a relationship with their pregnancy partner. All reported that their current pregnancy was unintended. Participants described various reasons as to why they had not intended to become pregnant across several domains: personal (e.g., wanting to prioritize their education, wanting to enjoy their youth, not feeling ready to have a child), social (e.g., fear of disappointing family, stigma from their community),

health (e.g., fear of childbirth, fear of CD4 decline during pregnancy, fear of transmitting HIV to their baby), and economic (e.g., not being able to financially support a child). Despite these motivations to avoid pregnancy, women cited multiple factors that led to conception, including discordance between their intention and partner intention to use contraceptives, failed condom negotiation, inconsistent and unsuccessful contraceptive use, and logistical barriers to accessing contraceptives. Almost half of the participants were not using any contraceptive method at conception, but several women did not think they would get pregnant.

Discussion: Despite reasons for desiring to prevent pregnancy, women reported multiple risk factors for unintended pregnancy, including challenges with personal adherence to a contraceptive regimen and negotiating condom use with a partner. Findings point to the need for the development of multi-level interventions to minimize unintended pregnancy and sexual risk behavior, and support safe, wanted pregnancies among youth.

FACTORS INFLUENCING PREGNANCY INTENTIONS AMONG ADOLESCENT GIRLS IN SAN DIEGO COUNTY: A QUALITATIVE EXPLORATION

Emily M. Romero, B.A. [1], Marissa Salazar, M.A.[2], Marianna Torreblanca, B.A. [2], Anita Raj, PhD[2], Elizabeth Reed, SCD[3]

[1]University of California San Diego, San Diego, CA; [2]University of California San Diego, La Jolla, CA; [3]San Diego State University, San Diego, CA

Background: Adolescent motherhood increases neonatal health risks, including prematurity and low birth weight. Hispanics are disproportionately represented among adolescent mothers, and 57% of US Hispanic adolescent births occur at the US-Mexico border.

Objective: This study qualitatively examines factors that influence adolescent girls' perceptions of the costs and benefits of adolescent pregnancy in the context of the US-Mexico border.

Methods: Adolescent girls between the ages 15-19 were recruited from a health clinic in San Diego county near the US-Mexico border to participate in a survey study examining risk factors for pregnancy and STI risk. A subset of participants (n-21) were invited to complete qualitative interviews; interviews were coded and analyzed for themes related to pregnancy intentions.

Results: Almost half of participants were Latino (43%); 24% and 19% were White and Asian, respectively. Long-term contraception (e.g., the implant, shot, or patch) was reported most frequently (85%). Emergent themes highlighted girls' reasons to delay pregnancy, including: 1) greater time to achieve educational goals and financial stability and 2) recognition of the time commitment and financial and social costs associated with adolescent parenthood. Girls responsible for younger siblings were particularly cognizant of the challenges of childrearing. No girls reported benefits of adolescent pregnancy.

Conclusion: The current study highlights adolescent girls' reasons for intending to delay pregnancy. Given the high rates of adolescent pregnancy near the US-Mexico border, more work is needed to understand factors that may interfere with girls' intentions to delay pregnancy and that increase risk for adolescent pregnancy.

INTEROCEPTIVE AWARENESS MODERATES THE RELATIONSHIP BETWEEN PERCEIVED AND PHYSIOLOGICAL GENITAL AROUSAL

Ariel Handy, BA, Cindy Meston, PhD

University of Texas at Austin, Austin, TX

Rationale: In general, laboratory studies have shown low correlations between mental (i.e., self-report) and physiological (i.e., vaginal pulse amplitude) measures of sexual arousal in women. One explanation for this presumed low concordance is that women may not be attending to their genital responses, and/or may be unable to accurately perceive their genital responses.

Aims: The current study had three aims:

1. To examine whether women are able to accurately perceive their level of genital arousal when specifically told to attend to genital sensations.

2. To examine whether a self-report measure of interoception can identify the women who are able to accurately perceive their genital responses.

3. To examine whether interoception can explain, in part, the low correlation between mental and physiological sexual arousal in women.

Methods: Sexually healthy women (N = 26) were presented with a neutral and erotic film sequence while their genital responses were measured using vaginal photoplethysmography. Perceptions of genital arousal were captured continuously throughout the films. Women then completed questionnaires on genital and bodily awareness (Multidimensional Assessment of Interoceptive Awareness). Hierarchical linear modeling was used to analyze the agreement between women's perceived and physiological genital arousal. Interoceptive awareness subscales were assessed as moderators of this effect.

Results: Women exhibited a significant degree of agreement between perceived and physiological genital arousal ($p < .001$). Interoception was found to significantly moderate this effect ($p = .015$), such that a greater degree of interoceptive awareness facilitated a stronger relationship between perceived and physiological genital arousal. Interoceptive awareness was also found to increase the relationship between mental and physiological sexual arousal ($p < .05$).

Conclusions: An overall tendency to focus on bodily sensations can partially explain women's awareness of their genital arousal, as well as the relationship between their subjective and genital arousal.

Implications: This study suggests that an overall tendency to focus on bodily sensations helps facilitate women's awareness of their genital arousal. This has important clinical implications such that assessing interoception can give clinicians insight regarding treatment matching. Women who are unable to perceive their genital sensations may benefit from treatments designed to increase awareness of bodily sensations such as mindfulness training or biofeedback.

SINGLE SESSION OF AUTOGENIC TRAINING INCREASES ACUTE SEXUAL AROUSAL IN WOMEN WITH SEXUAL AROUSAL PROBLEMS

Amelia Stanton, BA, Lindsey Nichols, N/A, Cindy Meston, PhD

The University of Texas at Austin, Austin, TX

Rationale/Background: Below average heart rate variability (HRV) has been associated with sexual arousal dysfunction and overall sexual dysfunction in women (Stanton, Lorenz, Pulverman, & Meston, 2015). Autogenic training, a psychophysiological relaxation technique, has been shown to increase HRV (Miu, Heilman, & Miclea, 2009). In a recent study, sexually healthy women experienced acute increases in both physiological and subjective sexual arousal, as well as increases in resting HRV, after one brief session of autogenic training (Stanton & Meston, in press). The present study builds on these recent findings by testing the effects of a single session of autogenic training on sexual arousal in women with diminished or absent physiological (i.e., genital) sexual arousal and/or diminished or absent subjective (i.e., mental) sexual arousal.

Research Question(s): Will increasing HRV via autogenic training lead to significant increases in physiological and subjective sexual arousal in women with sexual arousal dysfunction?

Method: Vaginal pulse amplitude (VPA), an index of genital sexual arousal, and subjective sexual arousal were assessed in 24 premenopausal women, aged 20-47, before and after listening to an autogenic training recording. Heart rate variability was assessed with electrocardiography. Subjective sexual arousal was measured both discretely via the subjective sexual arousal subscale of Heiman and Rowland’s (1983) Film Scale and continuously with an Arousometer (Rellini, McCall, Randall, & Meston, 2005), a device that allows women to report their mental sexual arousal during an erotic stimulus. Data were analyzed with hierarchical linear modeling and paired samples t-tests.

Results: Participants exhibited a significant increase in resting HRV following the intervention ($t(23) = 2.50$, $p = .02$), as was expected. Post-autogenic training, significant increases in both

VPA (β = 0.23, t(4944) = 2.84, *p* = .005), continuous subjective arousal (β = 0.07, *t*(4944) = 9.84, *p* < .001), and perceived genital arousal (t(23) = 2.917, p = .008) were observed. When subjective sexual arousal was measured discretely, there was a trend toward a significant increase post-manipulation (t(23) = 1.872, p = .07).

Conclusions: This cost-effective intervention led to significant increases in acute physiological, subjective sexual arousal, and perceived genital arousal. If these gains are maintained, the results of this study suggest that autogenic training, and other interventions that aim to increase HRV, may be a useful addition to treatment protocols for sexual arousal problems in women.

THE ASSOCIATION BETWEEN SALIVARY CORTISOL AND FREQUENCY OF SEXUAL INTERCOURSE IN A 56-DAY DAILY DIARY STUDY OF MARRIED COUPLES

Chelsea Romney, BS, Theodore Robles, PhD, Rena Repetti, PhD

UCLA, Los Angeles, CA

There is extensive research suggesting that positive interactions with romantic partners might reduce hypothalamic-pituitary-adrenal (HPA axis) response. Specifically, physical intimacy and positive tactile contact have been associated with lower salivary cortisol. The aim of this study was to determine if frequency of sexual intercourse in married couples would significantly predict lower daily salivary cortisol levels. To test this, we used data from the UCLA families and health study, in which 43 couples completed at-home diaries reporting daily sexual intercourse for 56 days. In this study, salivary cortisol samples were collected four times per day for eight out of the 56 days of data collection. We analyzed cortisol using the area under the curve with respect to ground (AUCg) trapezoid formula. Regression analyses revealed that wives who reported a higher frequency of sexual intercourse during the study period had lower average AUC values of cortisol for the 8 days of measurement ($r = .341$, $B = -9.737$, $SE = 4.299$, $p = .029$). Analyses also revealed that there was no relationship between AUC measures of cortisol and sexual intercourse for the husbands in the sample. Our results are in line with previous studies on the protective effects of physical intimacy on cortisol stress responses and add to the literature on gender-specific health benefits from positive close relationships.

EFFECT OF THERAPY ADHERENCE ON QUALITY OF LIFE IN PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

Tania Zamora, BA, Carl Stepnowsky, PhD, Sean Deering, BS, Kathleen Sarmiento, MD

VA San Diego Healthcare System, San Diego, CA

Introduction:

Obstructive sleep apnea (OSA) results in impaired daytime alertness that impacts daily functioning. The gold standard treatment for OSA is positive airway pressure (PAP) therapy, but it is unknown whether extended use of PAP will provide greater symptom alleviation. The goal of this study was to evaluate the effect of adherence to PAP treatment on quality of life in OSA patients.

Methods:

One hundred twenty-nine predominately male (91%) OSA patients from an existing clinical trial on a positive airway pressure (PAP) therapy adherence were examined. Patients had a mean age of 52.7±14.5 (p=0.8), mean body mass index of 31.1±4.9 (p=0.6), and mean apnea-hypopnea index (AHI) = 26.4±13.3 (p=0.9). All were given identical PAP instruction and follow-up visits were held two and four months from start of treatment. Data from baseline AHI was obtained from diagnostic sleep testing. Follow-up AHI was an average of the residual AHI provided by the PAP device over the treatment period. The Calgary Sleep Apnea Quality of Life Index (SAQLI) was used for sleep apnea symptoms and was self-reported.

Results:

HRQOL as measured by the SAQLI was significantly correlated with PAP adherence at both the two-month timepoint (r=0.300; p=0.15) and the four-month timepoint (r = 0.212; p =.045).

Discussion:

This study suggests that higher levels of PAP adherence are associated with greater improvements in quality of life. The data supports the hypothesis that extended use of PAP provides greater symptom alleviation. Future research needs to examine the nature of this relationship to better inform the length of PAP use that best impacts key clinical outcomes.

SLEEP CHARACTERIZATION OF SELF-REPORTED INSOMNIA IN THE UNITED STATES

Robert Morlock, PhD[1], Christopher L. Drake, PhD[2]

[1]YourCareChoice, White Lake, MI; [2]Sleep Disorders and Research Center, Henry Ford Hospital, Detroit, MI

Background: Insomnia is a frequent medical complaint resulting in over five million office visits per year in the United States (US). Less than half of patients with insomnia spontaneously report their sleep problem to their clinician.

Objectives: To evaluate sleep characteristics (difficulty initiating sleep [DIS], difficulty maintaining sleep [DMS], non-restorative sleep [NRS] and time slept on weekdays) in patients with self-reported insomnia.

Methods: Using data from the 2016 National Health Research Survey (NHRS), sleep characteristics, quality of life, emergency department visits and productivity loss were assessed in patients with insomnia. The NHRS surveyed a nationally representative sample of the US adult population in December 2016. Standardized sleep questionnaires were used to characterize sleep complaints. Descriptive and multivariable models with US population-based weighting was used to obtain adjusted odds ratios (ORs) and 95% confidence intervals (CIs) across patient groups.

Results: Insomnia was reported in 26.8% of the US adult population. The most frequent sleep complaints reported for those with insomnia were NRS alone (30.6%), DIS, DMS and NRS (27.8%) and DMS and NRS (10.9%). Comparing patients with DIS alone or DMS alone (4.6%) and NRS alone (30.6%) weekday hours slept were 7.5, and 6.6, respectively. Days with reduced productivity in the past week were higher for those with NRS alone compared to those reporting DIS alone or DMS alone (3.43 vs. 0.42; $p < 0.001$). Emergency department visits over the last 6 months were higher for those with DIS alone or DMS alone compared to those with NRS alone (0.91 vs. 0.38; $p < 0.001$). Scores on the Restorative Sleep Questionnaire (v2) were lower (worse) for those with NRS alone compared to those with DIS alone or DMS alone (50.23 vs. 53.41; $p < 0.001$).

CONCLUSION: Insomnia is common complaint expressed in several ways. How patients characterize insomnia symptoms is related to health related quality of life, productivity and resource utilization.

SUBJECTIVE-OBJECTIVE SLEEP DISCREPANCY IN OLDER ADULTS WITH INSOMNIA: A RANDOMIZED CONTROLLED TRIAL OF BEHAVIORAL THERAPY

Wai Sze Chan, Ph.D.[1], Jacon Williams, MA[2], Natalie D. Dautovich, Ph.D.[3], Joseph P.H. McNamara, Ph.D.[4], Ashley Stripling, Ph.D.[5], Joseph M. Dzierzewski, Ph.D.[6], Richard Berry, Ph.D.[4], Karin McCoy, Ph.D.[7], Christina McCrae, PhD[8]

[1]University of Missouri, Columbia, MO; [2]TIRR Memorial Hermann, Houston, TX; [3]Virginia Commonwealth University, Richmond, VA; [4]University of Florida, Gainesville, FL; [5]Nova Southeastern University, Fort Lauderdale, FL; [6]Virginia Commonwealth University, Richmond, FL; [7]South Texas Veterans Health Care System, San Antonio, TX; [8]University of Missouri-Columbia, Columbia, MO

Objectives: The discrepancy between subjective and objective reports of sleep is a clinically meaningful feature of insomnia and might be predictive of the onset and maintenance of insomnia. Sleep discrepancy and the night-to-night variability of sleep discrepancy are especially elevated in older adults who have insomnia. This study examined (a) whether BBT-I was efficacious in reducing sleep discrepancy and the night-to-night variability of sleep discrepancy, and (b) whether baseline sleep discrepancy moderated treatment efficacy on primary sleep outcomes.

Methods: 62 older adults who had chronic insomnia (68% female; age: mean=69.45, SD=7.71) were randomly assigned to BBT-I (sleep hygiene, stimulus control, sleep restriction, and relaxation components), or waitlist control (WLC). Participants completed daily sleep diaries and wore an actigraph from baseline to post-treatment, and for two weeks at 3-month follow-up. Primary sleep outcomes were sleep onset latency (SOL), wake after sleep onset (WASO), and total sleep time (TST). Sleep discrepancy (D) was based on weekly averages of daily diary *minus* actigraphy values for SOL-D, WASO-D, and TST-D. Sleep discrepancy variability (DV) was defined as the weekly within-individual standard deviations of daily sleep discrepancy values (SOL-DV, WASO-DV, TST-DV). Mixed modeling was used to examine (a) the effects of BBT-I on the intra-individual changes of sleep discrepancy and night-to-night sleep discrepancy variability and (b) the moderation effect of baseline sleep discrepancy on the effects of BBT-I on primary sleep outcomes.

Results: TST-D and WASO-DV decreased significantly across treatment in BBT-I compared to WLC (pseudo R^2s=.14 and .11, *p*s < .05), controlling for time-varying changes of the diary- and

actigraphy-assessed TST and WASO. Higher baseline SOL-D was associated with stronger effects of BBT-I on the reduction of diary-assessed SOL (pseudo R^2=.77, $p < .001$).

Discussions: BBT-I is efficacious in reducing TST-D and WASO-DV in older adults. Older adults who had higher baseline SOL-D may receive greater benefit from BBT-I with respect to their improvement in primary sleep outcomes. Future research examining sleep discrepancy as an important clinical outcome in its own right and as a treatment efficiency moderator appears warranted.

ASSOCIATIONS BETWEEN ROMANTIC RELATIONSHIP COMMITMENT AND ALCOHOL USE AMONG YOUNG ADULTS

Tiffany Berzins, Ph.D. [1], Logan Stigall, B.S.[1], Manfred van Dulmen, PhD[2]

[1]Kent State University, Stow, OH; [2]Kent State University, Kent, OH

It is well established that rewarding marriage and marriage-like relationships promote healthy lifestyles and buffer against negative physical health outcomes. However, methodological decisions to both evaluate romantic relationship stability according to structural commitments (marriage, cohabitation, etc.) and sample predominantly middle and older adults restrict the generalizability of the existing research to young adult couples, who often have few structural commitments. Accordingly, little is known about how *stable* romantic involvement influences physical health during young adulthood. Extending research with young adult couples remains critical given that many lifestyle habits and interdependent bonds form during this period. The current study addresses limitations in the literature by investigating if psychological commitment to the romantic relationship serves as a viable and parsimonious indicator of romantic relationship functioning for health research with young adults. Psychological commitment is a multi-dimensional construct that captures individual differences in numerous indicators of relationship quality (e.g., satisfaction; Rusbult, 1980; Sprecher, 1988), and we expected high commitment to generate healthier behavior.

We focused on drinking behavior as an outcome for this project because young adults are often at heightened risk for alcohol abuse (Johnson et al., 2015). Ninety-five heterosexual couples (*M* age = 19.85), who were dating less than one year, responded to surveys measuring alcohol use in the past week, alcohol-related problems in the previous month (White & Labouvie, 1989), and 3 commitment items (e.g., “I expect to be with my partner in 5 years”). Using a dyadic path analytic framework, we examined the associations between couple-level commitment and each partner’s scores on the alcohol variables. Controlling for relationship length, results showed that high commitment was associated with lower levels of alcohol use and problems, for men (β: -.37 for use; -.36 for problems) and women (β: -.32 for use; -.35 for problems). Drinking concordance within the partnership was also high. Results reflect that psychological commitment to the romantic relationship deters drinking, and may be an important construct for consideration in future studies with young adult couples. Results also show that drinking patterns form at a dyadic level, providing further evidence that individual level young adult alcohol interventions would benefit from including both partners.

ASSOCIATIONS OF STRESS AND TRAIT SELF-CONTROL WITH HEALTH RISK BEHAVIORS

Melissa Auerbach, PhD in Social and Health Psychology[1], Cheyanne Busso, B.A.[2], Marci Lobel, Ph.D.[3]

[1]Fox Chase Cancer Center/Temple University Health System, Williamstown, NJ; [2]Stony Brook University, deer park, NY; [3]Stony Brook University, Stony Brook, NY

Self-control failure is a potent predictor of behaviors such as drinking, smoking, and overeating, which can increase risk for cancer and other diseases (de Ridder et al., 2012). Personal resources such as stress may affect the extent to which self-control influences such risk behaviors. According to the limited strength model, trait self-control may not protect well against risk behaviors during periods of high stress, as stress can exhaust an individual's personal resources essential for maintaining healthy goals (Hagger, 2009). Moreover, those who are highly stressed and poorly controlled may be particularly vulnerable to engaging in risk behaviors. In the current study, analyses tested the interaction of trait self-control with contextual stress (i.e. environmental demands over the past month) on risk behaviors occurring over the past 2 weeks, including smoking, drinking, overeating, and fatty food consumption (1 item each). 611 undergraduates completed well-validated measures of trait self-control and stress. Self-control was associated inversely with all four risk behaviors (all p's < .05). Stress was positively associated with all risk behaviors (all p's < .05) except for alcohol use. The interaction of self-control and stress was a significant predictor of overeating (p = .03). Post hoc analyses indicated that, for those reporting little stress, there was no association between self-control and overeating (r = .08, ns); for those with high stress, self-control was inversely associated with overeating (r = -.33, p < .05). Interactions of stress and self-control did not predict fatty food consumption, smoking, or drinking, despite moderate correlations among several of these risk behaviors. Findings suggest that individuals with lower self-control or higher stress are more likely to smoke, overeat, and consume fatty foods; and that under high stress, people with poor self-control are especially likely to overeat. Thus, during periods of high stress, people with fewer dispositional resources are less able to resist overeating, whereas during periods of low stress, these resources are less influential. Findings suggest that future interventions aimed towards stress-reduction may be helpful at improving eating behaviors among highly stressed, poorly self-controlled individuals.

CHARACTER STRENGTHS RELATED TO PREDICTING RESILIENCE IN HURRICANE KATRINA VOLUNTEERS: A STRUCTURAL EQUATION MODEL

Amy L. Ai, PhD[1], Catherine M. Lemieux, PhD[2], Ashley Leon, Research Assistant[1]

[1]Florida State University, Tallahassee, FL; [2]Louisiana State University, Baton Rouge, LA

Using structural equation modeling (SEM), this study examined how *altruism* and *perceived spiritual support*, indicating two major character strengths,spirituality and Kindness*,* might enhance resilience (indicated by low depressive symptoms) of Black and White volunteers three months after Hurricane Katrina-Rita(H-KR). Based on the literature, we hypothesized that *altruism* and *perceived spiritual support* would contribute to H-KR resilience, mediated through positive attitudes, *Optimism* and *Hope,* as indicators of a third character strength. *Methods*: we recruited of 554 volunteers The majority of the combined sample was female(88%) (African American =54%). The mean age was 28.9 years(*SD*=9.6). Standardized instruments included CES-D, the *Hope Scale*, the LOT, the *Altruism Scale*, and the *Spiritual Support Scale*(SSS). *Results:* The results indicated that the SEM final model fit the data adequately. The chi-square value was within the acceptable range[c^2(23, *N*=527)=42.242]. The CFI(.987) and TLI(.972) exceeded the benchmark criteria of .95. RMSEA(.040, 90% CI .020 to 0.059) and SRMR(.027) were within the range of good fit. Squared multiple correlations suggested that this model accounted for 25% of the variance in resilience. All effects of two main pathways, spiritual support and altruism, on depression were indirect, mediated through positive attitudes. While faith contributed to both pathways, prayer was directly linked only with spiritual support. White race-identity was positively linked with altruism directly, whereas non-White-identity race was associated with both pathways indirectly, mediated through faith factors, with an additional effect on altruism through prayer and spiritual support. The finding implies the importance of character strength in behavioral and mental health.

COLORECTAL CANCER SCREENING DISPARITIES: SOCIAL DETERMINANTS IMPACTING RURAL RESIDING HISPANICS

Angelina Wittich, MA, PhD, MPH[1], Belinda Flores, BS,RN[2], Elisabeth DeLaRosa, MS[3], L. Aubree Shay, PhD, MSSW[4], Melissa Valerio, PhD, MPH[5]

[1]University of Texas School of Public Health, San Antonio Regional Campus, San Antonio, TX; [2]University of Texas Health Science Center at San Antonio, Corpus Christi, TX; [3]UT Health Science Center San Antonio, San Antonio, TX; [4]UT School of Public Health, San Antonio Regional Campus, San Antonio, TX; [5]UTHealth School of Public Health, San Antonio Regional Campus, San Antonio, TX

Background: Although CRC screening rates have improved, disparities persist among minority populations with screening rates lagging most in Hispanics (1). Moreover, Hispanics residing in rural areas are among those least likely to have been screened (2). We conducted a pilot study to explore social determinants of low screening rates among Hispanic residents of the Texas South Coastal Region.

Methods: A mixed-methods approach was utilized. A total of 58 participants agreed to participate in one of six focus groups conducted across three counties. Demographic information, self-reported medical history, screening history, risk perceptions, screening efficacy perceptions, and cancer attitudes were obtained by surveys. Also assessed were barriers and challenges in communication and completion of CRC screening within the rural community context.

Results: A majority of the participants were Hispanic (96.6%) and female (79.3%). A minority (38%) of participants self-reported having undergone CRC screening. Survey results revealed that participants with a high school education or less education were significantly more likely to believe that they were at high risk for developing CRC polyps ($p = 0.05$) and, yet, had a preference for remaining uninformed about a cancer diagnosis ($p = 0.02$). Emergent themes from qualitative analysis included concerns about maintaining personal privacy at small rural facilities and limited emotional and instrumental social support.

Conclusion: Decisions to obtain CRC screening are influenced by multiple factors beyond commonly identified barriers. Among Hispanics residing in rural areas, social determinants such as low levels of education, privacy at small town facilities, and lack of social support play a role in CRC screening decisions. Further examination of the influence of social determinants in CRC screening decisions and its impact on disparities in the Hispanic population is warranted.

COMPARISON OF SOCIOECONOMIC STATUS INDEXES IN PREDICTING HEALTH OUTCOMES IN ADOLESCENTS FROM LOW-INCOME FAMILIES IN TAIWAN

Ya-Lun Liang, BA[1], Meng-Che Tsai, MD, MSC[2], Chung-Ying Lin, PhD[3], Carol Strong, PhD[4]

[1]National Chen Kung Univerisity, Tainan, Tainan, Taiwan (Republic of China); [2]Department of Pediatrics, National Cheng Kung University Hospital, College of Medicine, National Cheng Kung University, Tainan, Tainan, Taiwan (Republic of China); [3]The Hong Kong Polytechnic University, Kowloon, N/A, Hong Kong; [4]National Cheng Kung University, Tainan, Tainan, Taiwan (Republic of China)

Introduction

Social welfare policy for low-income families is often determined by the household monthly income, however, this index may not fully indentify children in need. An index determined by the available resources for children in poverty may better represent their poverty status and further predict their health status. The aim of this study is to compare asset-based socioeconomic status (SES) index derived from the principle component analysis (PCA) and the monetary-based SES index to investigate the effect of poverty on health among adolescents from low-income families. First, we described the distribution of material and societal resources in a sample of adolescents from low-income families in Taiwan. Second, we constructed both asset-based and monetary-based SES index. Third, we examined and compared associations between two SES indice and self- reported health conditions.

Method

We utilized data from Taiwan Database of Children and Youth in Poverty, a national representative longitudinal survey among children and adolescents from low- income families in Taiwan. A sample of 2,529 adolescents aged 12-18 in junior high school and above was analized. Monetary-based SES index was determined by household monthly income, while assess-based index was based on the weights derived from PCA using a set of self-reported household conditions and resources available. Multivariable logistic regression was conducted to examine the association between these two indices and mental health and physical health conditions among adolescents.

Result

The association between SES and health conditions exists when using the asset-based index, but not monetary-based index. The asset-based index showed social gradient in mental health, injuries and allergy, but not in visual and dental problems. For example, adolescents in the poorest quintile of asset-based index have 7.5 times of odds of reporting poorer mental health than their counterparts in the least poor quintile, followed by odds of 4.1, 3.6 and 1.7 along with the poverty quintile.

Conclusion

Our study demonstrated that asset-based SES index serves as a better index for social gradient in health among adolescents from low-income households than monetary-based index. Healthcare professionals and policy makers should consider including an assessment of household asset and resources as a supplementary index to identify population in need to receive appropriate care.

EXAMINING PSYCHOLOGICAL FLEXIBILITY AS A MEDIATOR OF THE ASSOCIATION BETWEEN CHILDHOOD TRAUMA AND ADULT SOMATIZATION

Anne I. Roche, BS, Emily B. Kroska, MA, Michael W. O'Hara, PhD

University of Iowa, Iowa City, IA

Childhood trauma exposure has been shown to be associated with a variety of adverse mental and physical health outcomes. More specifically, trauma exposure is related to later somatic preoccupation and somatic syndromes and to chronic pain. While these associations have been demonstrated, less work has explored the mechanisms through which these relations may exist. Importantly, it is not uncommon for individuals who have experienced trauma to engage in avoidant coping strategies, which, while potentially effective in the short-term, tend to lead to worse outcomes in the long-term. Conversely, acceptance and mindfulness have been associated with greater resilience after trauma exposure. The present study utilized self-report measures of childhood trauma and current experiential avoidance, mindfulness, and somatic symptoms from a community sample of adults (n = 287) and conducted mediation analyses (with bootstrapping) to examine the mediating roles of psychological inflexibility and mindfulness in the association between childhood trauma exposure and somatic symptoms in adulthood. Results showed that both psychological inflexibility (indirect effect: coefficient: .184, CI: [.1185, .2637]), and the nonjudgment component of mindfulness (indirect effect: coefficient: .0907, CI: [.0484,.1533]), significantly mediated the association between childhood trauma and somatic symptoms. Given the significant percentage of individuals who experience trauma, as well as the substantial proportion of individuals who present to primary care with medically unexplained symptoms, the identification of process-based mechanisms is important for the development and implementation of preventive interventions. More specifically, using mindfulness or acceptance-based therapies, such as Acceptance and Commitment Therapy (ACT), may improve outcomes for individuals who have experienced childhood trauma.

EXPLORATION OF PHYSICAL ACTIVITY BEHAVIORS AMONG MEXICAN SENIORS IN THE US AND MEXICO: IMPLICATIONS FOR RESEARCH AND PRACTICE

Ines Campero, BA[1], Jylana Sheats, BA, MPH, PhD[2], German Blanco, BS, MPH[1], Michele Escobar, BS[3], Betsy Barrera Poma, BS[4], Aldo Chazaro, BS[3], Abby C. King, PhD[3]

[1]Stanford Prevention Research Center, Stanford School of Medicine, Palo Alto, CA; [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [3]Stanford School of Medicine, Palo Alto, CA; [4]Stanford Clinics, Palo Alto, CA

The benefits of physical activity (PA) are well documented and have been associated with improved health and wellbeing. In the US, Latinos are the fastest growing racial/ethnic group, and research indicates that US Latinos report less PA and higher rates of obesity and related chronic conditions relative to non-Hispanic Whites. Nearly two-thirds (64%) of Latinos in the US are of Mexican descent, yet little is known about the PA behaviors among older adults living in Mexico. The purpose of this pilot study was to: 1) explore and compare PA behaviors among Mexican older adults in the US relative to Mexico; 2) utilize a social ecological framework to examine factors that facilitate or hinder PA behaviors; and 3) develop recommendations for practice.

Older Latino adults aged 60+ years were recruited from two senior centers in San Jose, CA and two senior centers in Mexico City. Study staff administered a bilingual survey to eligible and consented participants. The survey assessed demographics, health status, participation in PA, attitudes and barriers and facilitators to PA, and perceptions about the neighborhood built environment. Descriptive statistics were analyzed with SPSS 22.0.

Participants (N=41, US, n=21; Mexico, n=20) were primarily female (75%) (Age, *M*=75, SD=8.3). Among US participants, 86% (n=18) “agreed or strongly agreed” that PA was a priority in their life, compared to 35% in Mexico (n=7). Forty-three percent of US participants engaged in >150 minutes of moderate or vigorous physical activity (MVPA) per week, relative to 25% of Mexico participants. Individual-level PA barriers were similar among both groups and included poor health (US, 38%; Mexico, 45%), perceived safety (US, 38%; Mexico, 50%), and a preference to engage in non-PA activities (US, 38%; Mexico, 30%). At the interpersonal level, participants from both countries generally felt that having encouragement and support from their doctor (US, 76%; Mexico, 50%) or family (US, 47%; Mexico, 30%) was important for their participation in PA. While not currently available to either population, at the environmental level, participants indicated that they would use neighborhood walking paths

(US, 71%; Mexico, 85%) or participate in neighborhood/mall walking programs (US, 76%; Mexico, 60%) if available. Relative to participants from Mexico, US participants reported that they would be more likely to increase PA if they received insurance incentives, had access to phone-based PA support, or were able to obtain low-cost gym memberships.

Initial results indicate that PA barriers and facilitators appear to be reasonably similar at the micro, meso, and macro levels for older Mexican adults residing in urban cities in the US and Mexico. A next step is to expand the sampling frame and further explore possible interventions that could reach both groups, given the regular travel habits of this population across the US-Mexican border.

HIGHER EDUCATION: TESTING THE EFFICACY OF HEIGHT ADJUSTABLE SIT-STAND DESKS IN COLLEGE CLASSROOMS

Matthew Jerome, B.A., Allene Gremaud, B.S., Roberto Benzo, M.S., Katie Hosteng, M.S., Lucas Carr, PhD

University of Iowa, Iowa City, IA

Background: Sedentary behavior has been found to have independent and negative associations with several cardiometabolic risk factors while interrupting prolonged sedentary time may ameliorate these associations. College classrooms are a traditionally sedentary microenvironment and understudied setting for sedentary interventions. Introducing sit-stand desks into college classrooms may be an effective and sustainable approach to reduce classroom sedentary behaviors of college students.

Objective: To test the efficacy of replacing seated desks with sit-stand desks in a college classroom on student’s classroom sitting/standing behaviors. We hypothesize introducing sit-stand desks will significantly reduce classroom sitting time while increasing classroom standing time.

Methods: We recruited 240 undergraduate college students taking class in one of two small classrooms (25 seats per class) to participate. Using a cross-over design, each student’s classroom sitting and standing time will be measured by self-report and objectively (direct observation via video camera surveillance) after having access to only seated desks or only sit-stand desks for six continuous weeks. A process evaluation survey will be administered at the end of the study to explore student’s and instructor’s perceptions of the intervention and its impact on student engagement.

Results: Preliminary results of the baseline testing session indicate 145 students (60.4% response rate) self-reported spending 97.5% of class time sitting when having access to only seated desks. An ongoing analysis of a sub-sample of the direct observation video surveillance data (3 classes; 60 total students) suggests students actually spent 99.5% of class time sitting. These measures will be repeated after students have had access to the sit-stand desks for six weeks.

Conclusions: This is the first intervention trial to test the efficacy of introducing sit-stand desks on student's classroom sitting/standing time in a college classroom. If effective, this intervention could be a sustainable approach for reducing sedentary behaviors of college

students. We anticipate the findings of the study will be useful for informing future college classroom designs.

INSURANCE COVERAGE & COMPLIANCE WITH BREAST & CERVICAL CANCER SCREENING GUIDELINES AMONG IMMIGRANT WOMEN IN TEXAS & CALIFORNIA

Isabelle Kusters, PhD, MPH

Michael E DeBakey VA Medical Center & Baylor College of Medicine, Houston, TX

Although documented immigrants are a large and growing population in the United States, gaps still exist in their access to health insurance and preventive care. Many factors contribute to these disparities, including immigration status, English proficiency, region of birth, socioeconomic status, and usual source of care. This study compared insurance coverage and access to breast and cervical cancer screening services between Harris County (HC), Texas (greater Houston) and Orange County (OC), California. While both counties are metropolitan and have large proportions of immigrant residents, there are important differences between the two areas, rendering a comparison interesting. These differences enable us to understand if location of residence affects access to health services for immigrants and to understand which factors may be mutable, based on geography.

Data collected on adult immigrant women in the 2010 Health of Houston Survey and the 2007 & 2009 California Health Interview Surveys were used. Logistic regression was used to determine the role of predictors for health insurance (n=514,361), and breast (n=277,278) and cervical (n=395,185) cancer screening compliance for the combined samples, and identified which factors differed between the two counties. For those with no health insurance or who had not recently been screened, cost and insurance issues were the most-identified reasons.

Female foreign-born OC residents were more likely than those in HC to have public insurance compared to private or no insurance. Longer residence in the U.S. or any type of permanent status predicted a higher likelihood of having insurance. Immigrant women in OC with any type of insurance were more likely than comparable women in HC to receive cancer screening services. Overall, immigrant women in OC were more likely than those in HC to be more recently screened for breast cancer; stronger county effects were identified for breast than for cervical cancer screening. For those with no health insurance or who had not recently been screened, cost and insurance issues were the most-identified reasons.

This study is the first to examine how geographic location of residence may affect access to health insurance and cancer screening rates for immigrant women in parts of Texas and California. Important differences exist between the two counties; these results can assist local public health organizations in identifying specific immigrant populations to which they can tailor outreach programs. Results provide support for increased funding and focus on community health centers, and have the potential to impact local and state-wide post-Affordable Care Act policy changes.

LONGITUDINAL ASSOCIATIONS BETWEEN SMOKING STATUS AND SOCIAL SUPPORT, SOCIAL NETWORK, AND SOCIAL COHESION

Melanie Sabado, PhD, MPH, Sherine El-Toukhy, PhD, MA, Kelvin Choi, PhD, MPH

National Institute of Minority Health and Health Disparities, National Institutes of Health, Bethesda, MD

Background: Previous studies have examined the effect of smoking cessation related social support on smoking cessation. However, how smoking status influence subsequent social relationship is largely unknown. We explored the prospective associations between smoking status and social support, social networks, and social cohesion in a cohort of adults.

Methods: Data came from the Coronary Artery Risk Development in Young Adults (CARDIA) study, which follows a cohort Black and White participants from four US cities aged 18-30 years in 1985-86. We included individuals who participated at Y10 and Y15 in current analyses (aged 28-45 years, N= 3378). We created 8 categories to reflect stable (non-user, experimenter, former smoker, current smoker) and changed (new experimenter, initiator, relapser, quitter) smoking status from Y10 to Y15. We used PROC MIXED to assess prospective associations between smoking status and on familial social support, social networks (e.g., number of friends and relatives), and perceived neighborhood social cohesion outcomes at Y15. We adjusted for fixed measures (i.e., age, gender, collection site, parent education) and Y10 factors (i.e., education, employment, marital status, and household income).

Results: One-fifth (16%) of cohort changed their smoking status in five years. Current smokers, new experimenters, and relapsers reported receiving less social support than non-users (*ps* < 0.05). In addition, former smokers reported more social support than current smokers ($p < 0.05$). Stable experimenters reported having fewer closer friends and relatives and non-users, but reported having more close friends and relatives than current smokers. Compared to non-users, current smokers reported fewer close friends and relatives (ps < 0.05).

Conclusion: Smoking is associated with less perceived social support, social networks, and social cohesion, all of which are essential for psychological well-being. Tobacco control efforts should highlight effects of smoking on social outcomes to deter smoking behavior.

LOW-INCOME COMMUNITIES' WORKSITE POLICIES INCREASE EMPLOYEE ACCESS TO PHYSICAL ACTIVITY MORE THAN HIGH-INCOME COMMUNITIES

Elizabeth Ablah, PhD, MPH[1], Kurt Konda, MA[1], Aubrey Wiechman, BA[2], Kate Hoppe, MPH, MA[3], Jeff Usher, BA[4]

[1]KUSM-Wichita, Wichita, KS; [2]Wichita Business Coalition on Health Care, Wichita, KS; [3]Kansas Department of Health and Environment, Topeka, KS; [4]Kansas Health Foundation, Wichita, KS

Background: WorkWell KS sought to encourage worksites across Kansas to implement comprehensive worksite wellness initiatives, with an emphasis on health topics, such as physical activity, and on policy strategies. Higher poverty rates are linked to poor health outcomes, less physical activity, and more sedentary behavior. Worksites can serve as an important conduit for employees in poor communities for access to healthier options.

Methods: These are data from 47 WorkWell KS workshops across Kansas, with approximately six to seven worksites present for each workshop, from 2012 through 2015. Each worksite completed a baseline assessment that featured items derived from other established worksite assessments and the academic literature, including whether or not worksites had policies that encourage physical activity at the worksite. One year after participating in the WorkWell KS workshop, participating worksites were asked to complete a similar follow-up assessment. To assess the impact of poverty on access to physical activity, worksites were divided into 'below average' and 'above average' based on the poverty rate in each county relative the average Kansas poverty rate of 13.5% in 2014.

Results: At baseline, in counties with 'below average' poverty levels and in counties with 'above average' poverty levels, 10% of worksites in both types of counties had written policies that supported physical activity at the worksite. At one-year follow-up, among worksites in more affluent counties, there was no difference in the percentage of worksites with physical activity policies than at baseline. Conversely, among worksites in poorer counties, there was a significant increase in the percentage of worksites implementing physical activity policies from 10% at baseline to 23% at follow-up, t(60)-2.398, p = 0.020.

Conclusions: WorkWell KS supports worksites in developing and implementing comprehensive initiatives, including policies, to support healthy behaviors, such as physical activity. The WorkWell KS intervention can be an effective model for improving access to physical activity, especially among employees in low-income communities.

MARITAL STATUS MODERATES THE ASSOCIATION OF VIGILANCE AND AMBULATORY BLOOD PRESSURE

Kyle J. Bourassa, M.A.[1], John M. Ruiz, Ph.D.[1], David Sbarra, PhD.[1], Chul Ahn, PhD[2], Matthew Allison, M.D., MPH[3], Timothy Smith, PhD[4], Joshua Smyth, Ph.D[5], Daniel J. Taylor, Ph.D.[6], Bert N. Uchino, PhD[7]

[1]University of Arizona, Tucson, AZ; [2]UT Southwestern Medical Center, Dallas, TX; [3]University of California at San Diego, San Diego, CA; [4]University of Utah, Park City, UT; [5]The Pennsylvania State University, University Park, PA; [6]University of North Texas, Denton, TX; [7]University of Utah, Salt Lake City, UT

Marriage is associated with a range of health benefits, including lower cardiovascular mortality and morbidity, relative to being never married or divorced. One pathway through which these effects may occur is through differences in daily stress behaviors and physiological reactivity. This study aims to explore whether marital status moderates the association of vigilance of the social environment and daily blood pressure (BP).

Participants were a community sample of 300 healthy adults (150 men, 150 women) ages 21 to 70 years enrolled in the North Texas Heart Study (PI: Ruiz). The sample was stratified by age within gender and race/ethnicity, and the mean age at enrollment was 42.44 years (SD=12.76). All participants completed a physical, surveys, and two days and 1 night of EMA coupled with ABP. The EMA/ABPs were programmed to sample at random times within 45-min intervals to avoid anticipation effects. These analyses compared married (60.3%) to all unmarried participants, and examined social vigilance using three different approaches: a cross-sectional survey, end of day (EOD) questionnaires, and ecological momentary assessment (EMA). Person/day averages were calculated from the EMA and ABP.

No main effects of marital status or social vigilance were observed on mean ABP. However, marital status and social vigilance were interacted to predict measures of BP, all *B*s>6.53, *p*s.05. The association of vigilance and average daytime systolic BP was moderated by marital status, *B* = 11.52, p = .002; whereas married participants showed a positive association between vigilance with ABP, B = 5.93, p = .005, unmarried participants evidenced a negative association, *B* = -5.59, p = .016 (all Bs reported are for models using vigilance assessed by EMA). Matched effects were observed for DBP. In addition, the more proximal and frequent the assessment of vigilance, the stronger the statistical effect, average daily EMA R^2 = 0.030, EOD $R^2 = 0.019$, Survey $R^2 = 0.007$.

These results suggest that highly vigilant married participants showed the highest BP, whereas highly-vigilant, unmarried participants had the lowest daytime BP, which may represent differences in how married and unmarried people are able to select their social environments and face daytime stressors as a result. The study also demonstrates the benefits of more proximal measurement methodologies.

PATTERNS OF CONSULTATION LAISON REFERRALS IN AN URBAN ACADEMIC MEDICAL SETTING: FUTURE DIRECTIONS IN BEHAVIORAL MEDICINE

Philip Fizur, MA[1], Kelly Lynn. Gilrain, PhD[2], Cori E. McMahon, PsyD[3]

[1]MD Anderson Cancer Center at Cooper, Cooper University Hospital, Camden, NJ; [2]Cooper University Hospital, Camden, NJ; [3]Cooper University Hospital/ MD Anderson Cancer Center at Cooper, Camden, NJ

As outlined in Mostofsky (2014), the field of Behavioral Medicine has evolved greatly since its inception. From a focus on issues more closely related to psychosomatic medicine and techniques such as biofeedback into a discipline pursuing the development of a science and set of interventions concerned with maintaining and restoring health through behavioral interventions targeting prevention, diagnosis, treatment, and rehabilitation (Birk, 1973; Schwartz & Weiss 1978). Using such interventions as cognitive therapy, mindfulness-based practices, and applied operant conditioning to improve the individual's health (Agras, 1982; Wilson, 2015), Behavioral Medicine has come to help medical patients manage chronic conditions having behavioral correlates including hypertension, smoking, pain, obesity, diabetes, eating disorders, and sleep disorders (Blanchard, 1992). Today, Behavioral Medicine has become a systems-oriented, public health, and preventative intervention-focused discipline. The present research examines how Behavioral Medicine is being utilized today to better understand how the field will continue to evolve going forward. Given the growing demand for such services, the focus of the present study was on an inpatient Consultation-Liaison Behavioral Medicine service. Descriptive statistics were applied to a database of all referrals to the service describing referral source, patient primary diagnosis, mental health diagnosis, numbers of sessions, and reason for referral as well as demographic variables related to the patient. Consultations come primarily from Trauma (27%) and Hospitalists (33%), diagnosis vary in range but are commonly related to pain and injury secondary to motor vehicle or other accidents (19%) as well as those directly related to cancer (16%). Unsurprisingly, the most common DSM 5 diagnosis in this population was some form of Adjustment Disorder (23%), a fact that may help shape ongoing research and training efforts. The resulting information highlights how Behavioral Medicine has and will continue to evolve by understanding how allied healthcare professionals are utilizing our services to better manage acute conditions (pain and injury) and chronic illness (cancer). The unique contributions of Behavioral Medicine in inpatient care is also discussed as well as the implications for refining our interventions to improve quality of care delivered to the patients we are called by our colleagues in medicine to serve.

PERCEIVED DISCRIMINATION IN RECEIPT OF HEALTH CARE IN SOUTH LOS ANGELES

Juana Gatson, Ph.D.[1], Aziza Lucas-Wright, M.Ed.[1], Mohsen Bazargan, Ph.D.[1], Loretta Jones, Th.D.[2], Rhonda Santifer, M.Min.[1], Roberto Vargas, MD, MPH[3], Annette E. Maxwell, DrPH[3]

[1]Charles Drew University, Los Angeles, CA; [2]Healthy African American Famililes, Los Angeles, CA; [3]University of California Los Angeles, Los Angeles, CA

Background: Racial, gender, sexual orientation, and other forms of discrimination in health care delivery are barriers to cancer prevention, early detection, and high quality health care. This study examined perceived discrimination among adults who attended 2 community-based cancer awareness events in South Los Angeles, one of the most under-resourced neighborhoods in the United States.

Methods: A total of 143 adults completed a survey that assessed socio-demographic characteristics, unfair treatment while seeking health care, and receipt of and communication with a physician about colorectal cancer screening.

Results: The predominately African American (65%) and Latino sample (26%) reported high level of health insurance (99%), the majority had a regular physician (81%) and 34% had a college degree. Slightly more African American than Latino respondents reported unfair treatment when seeking healthcare at least once for self or somebody close to them (52% vs 46%, NS). In addition, women were significantly more likely than men to report unfair treatment (57% versus 35%, $p < .02$). Among African Americans and Latinos, reasons for unfair treatment for themselves included race (80%), ancestry/national origin (47%), gender (42%), skin color (40%), age (38%) and body size (22%). Among respondents 40 years and over, there was a significant relationship between discussion of colorectal cancer screening with a provider (65%) and receipt of a screening test (62%; $p < .001$), but both variables were unrelated to perceived discrimination.

Discussion: Although about half of our sample reported experiencing unfair treatment directly or vicariously at least once in their lifetime, this was unrelated to lifetime receipt of colorectal cancer screening in our predominantly insured convenience sample. Discrimination in healthcare is widely reported by African Americans and Latinos and should be explored more extensively using community-partnered strategies.

REAL WOMEN AND REAL BEAUTY

Jessica J. Taylor, MA[1], Jennifer B. Webb, Ph.D.[2], Amy Canevello, PhD[3]

[1]University of North Carolina at Charlotte, Charlotte, NC; [2]UNC Charlotte, Charlotte, NC;
[3]University of North Carolina, Charlotte, Charlotte, NC

Real Women and Real Beauty: Assessing the Internal Comparison Processes and Target Images in Body-Image Self-Discrepancies

Jessica J. Taylor M.A., Jennifer B. Webb Ph.D, & Amy Canevello Ph.D.

UNC Charlotte Health Psychology Ph.D. Program

Research suggests that unfavorable comparisons with an internalized beauty ideal lead to negative emotional outcomes such as body shame and appearance anxiety. An important, as of yet unexamined assumption, in the body-image literature is the notion that women internalize one, possibly two ideals of beauty, that are utilized as standards when engaging in body-image comparison. To assess this assumption, the current study investigated 1) if levels of state body shame (SBS) and state appearance anxiety (SAA) differed between comparisons with a personal vs. a sociocultural ideal of beauty utilizing a novel experimental study design, and 2) the appearance of the images that women imagined when engaging in comparisons with their internalized ideals of beauty.

A weight-diverse sample of 139 college women attending a large southeastern U.S. public university participated in an imaginal-exposure experimental procedure and completed self-report instruments of the variables of interests. Regression analyses showed significant differences between the body-image neutral control condition and the two experimental conditions (**SBA:** B_{pers}=.36, $p < .05$; B_{socio}=.40, $p < .05$; **SAA:** B_{pers}=.35, $p < .05$, B_{socio}=.31, $p < .05$) while controlling for trait self-discrepancy and body mass index. However, no significant differences were detected between the two experimental conditions (**SBA:** 95% CI [-0.48, 1.24]; **SAA:** 95% CI [-0.35, 0.91]). Finally, analyses further indicated that the number and type of images used as an appearance comparison reference were similar between the two experimental conditions.

Findings from the current study suggest imagining and writing about comparing oneself to an internalized ideal of beauty elicits state appearance anxiety and state body shame regardless of whether these comparisons are made with a personal ideal or a sociocultural beauty ideal. Results also indicate that at least part of the reason for this lack of difference is that women think of both sociocultural and personal ideals of beauty when engaging in body-image comparisons with internalized ideals. Implications for advancing current theory, expanding methodological considerations, and fostering behavioral health outcomes are discussed.

MERITORIOUS AWARD WINNER

RESILIENCY, PSYCHOLOGICAL SYMPTOMS, AND ALCOHOL USE AMONG CYBERBULLIED YOUNG ADULTS

Brett M. Goshe, M.S., Lauren Strainge, M.A., Matthew Sullivan, B.A., Dean Cruess, PhD

University of Connecticut, Storrs, CT

The detrimental impact of cyberbullying on individuals' mental and physical health has been well documented. The ways in which victims react to and cope with the effects of cyberbullying are of interest to both researchers and clinicians, as this information may guide the development of effective treatment interventions. In particular, the ability to harness internal resiliency may serve as an important factor in coping with cyberbullying experiences. The purpose of this study was to examine resiliency among college students who reported a history of being cyberbullied. We recruited 180 undergraduate college students (mean age = 19.32; 52% female; 30% non-white) to complete an online survey assessing the mental and physical health impacts of cyberbullying, as well as their self-reported resiliency. Pearson's correlation coefficients were calculated to determine the relationships between resiliency, subjective impact/severity of cyberbullying, and mental health outcomes. We also conducted a series of hierarchical linear regression analyses predicting each of our mental health outcomes of interest. Resiliency scores were inversely correlated with severity of cyberbullying experience ratings ($r = -0.408$, $p < 0.001$), as well as depression scores ($r = -0.428$, $p < 0.001$), anxiety scores ($r = -0.403$, $p < 0.001$), and alcohol usage scores ($r = -0.168$, $p = 0.029$). Higher ratings of cyberbullying severity significantly predicted higher depression scores ($\beta = 0.158$, $p = 0.042$), anxiety ($\beta = 0.271$, $p = 0.001$), and alcohol usage ($\beta = 0.268$, $p = 0.002$), even after controlling for resiliency scores. These results indicate that the perceived severity of cyberbullying experiences is predictive of increased symptoms of depression and anxiety, and more problematic alcohol use, regardless of whether or not college students are psychologically resilient. These findings emphasize that the detrimental impact of cyberbullying is pervasive among college students who experience such online harassment. Although more resilient individuals may be partially shielded from the negative consequences of cyberbullying, the pervasiveness of cyberbullying's negative impact appears to necessitate additional resources beyond individuals' intrinsic fortitude.

THE ASSOCIATION BETWEEN HOUSEHOLD CHAOS AND SUBSTANCE USE AMONG CHILEAN YOUTH: THE MODERATING ROLE OF SCHOOL SATISFACTION

Erin Delker, M.P.H.[1], Patricia East, Ph.D.[2], Estela Blanco, MPH, MA[3], Gabriela Caballero, BS[4], Pamela Encina, BS[4], Betsy Lozoff, MD[5], Sheila Gahagan, M.D., M.P.H[6], Jorge Delva, MSW, PhD[7]

[1]University of California - San Diego / San Diego State University, San Diego, CA; [2]University of California, San Diego, La Jolla, CA; [3]UC San Diego, Tracy, CA; [4]Institute of Nutrition and Food Technology, University of Chile, Santiago, Region Metropolitana, Chile; [5]Center for Human Growth and Development,, Ann Arbor, MI; [6]UC San Diego School of Medicine, La Jolla, CA; [7]University of Michigan, Ann Arbor, MI

Adolescence is an important period in development during which health behaviors are established. Previous studies suggest that risk- and protective factors for adolescent substance use are multi-contextual. In this study, we examine: (1) the relations between household chaos and adolescents' binge drinking, cigarette and marijuana use and (2) whether effects vary by school satisfaction.

Data are from 766 adolescents who participated in the Santiago Longitudinal Study and have been followed since infancy. At age 16 (SD=0.2), adolescents' mothers completed the Chaos, Hubbub, and Order Scale, designed to measure confusion, noise and lack of routine in the home. Adolescents self-reported school satisfaction and past month binge drinking, marijuana use and cigarette smoking. We utilized multivariable logistic regression to analyze associations between chaos tertiles (mild, moderate, severe) and each outcome. Then, we tested for interactions between chaos and school satisfaction. Analyses adjust for gender, maternal education, family socioeconomic status and age at assessment.

In this sample, 7% of respondents reported past month binge drinking, 23% reported cigarette use and 9% reported marijuana use. Participants living in moderately and severely chaotic households had over twice [OR=2.5(1.2-5.1)] and thrice [OR=3.2(1.5-6.7)] the odds of binge drinking compared to those in mildly or non-chaotic households. Similarly, increasing levels of chaos resulted in greater odds of cigarette [moderate: OR=2.7(1.1, 2.6); severe: OR=2.7(1.7, 4.2)] and marijuana [moderate: OR=2.3(1.2, 4.5); severe: OR=2.5(1.3, 5.0)] use. We found a significant interaction between chaos and school satisfaction for two outcomes: effects on cigarette and marijuana use were attenuated among individuals reporting higher levels of

school satisfaction.

Findings indicate that household chaos is associated with increased odds of substance use. The effects on marijuana and cigarette use varied by level of school satisfaction, indicating a synergistic relationship between school and home contextual factors. School-based interventions promoting satisfaction and belongingness may be effective in reducing adolescent substance use, especially for individuals living in chaotic home environments.

ASSOCIATIONS BETWEEN ANXIETY, DEPRESSION, & GENDER ON CORTISOL REACTIVITY AMONG COLLEGE STUDENTS

Hugo Sanchez, B.A.[1], Antonio McElroy, B.A.[2], Jessica Rayo[3], Guido Urizar, Jr., PhD[4]

[1]California State University, Long Beach, Gardena, CA; [2]California State University, Long Beach, Huntington Beach, CA; [3]California State University, Long Beach, Long Beach, CA; [4]California State University Long Beach, Long Beach, CA

Studies have shown that internalized mental disorders (e.g., anxiety and depression) and gender impact cortisol reactivity to social stress (Villada et al., 2014; Harkness, et al., 2011; Kudielka et al., 2009). Further, lower cortisol reactivity has been shown to lead to adverse health outcomes, such as reduced immune system responses and mood regulation (Lovallo, 2011). The purpose of the current study was to examine whether there were significant differences in cortisol patterns by level of anxiety (i.e., low vs. high; State-Trait Anxiety Inventory-Trait Scale), depression (i.e., low vs. high; Beck Depression Inventory), and gender group (men vs. women) among college students participating in in a laboratory stressor (i.e., Trier Social Stress Test; TSST). The participants' salivary cortisol was collected before the TSST, right after the TSST, and 15, 30, and 45 minutes after the TSST. Results from repeated-measures analyses of variance showed that, contrary to our hypothesis, there were no significant differences between low and high anxiety groups in their cortisol patterns. However, results did show that participants with high levels of depression had significantly lower cortisol levels throughout the TSST than those with low levels of depression, $F(1, 104) = 6.45$, $p < .05$, and that women had significantly lower cortisol levels than men, $F(1, 105) = 7.42$, $p < .05$. These results support the need for additional studies investigating mechanisms that help explain lower cortisol responses among those with high depression and women, as well as their impact on long-term health.

DEVELOPING A STRESS COPING APP FOR HIGH RISK HOSPITALIZED PREGNANT WOMEN: LESSONS LEARNED

Nancy Jallo, PhD, FNP, WHNP, CNS, Leroy R. Thacker II, PhD, Dace S. Svikis, PhD, Predrag Stojanovic, N/A

Virginia Commonwealth University, Richmond, VA

Background: In hospitalized high-risk pregnant women, stress is a significant problem affecting psychophysiological health. In the few studies examining interventions to address this problem, the traditional delivery systems have been outdated devices such as CD, mp3 and tape players which limit the complexity and hinder integration of an intervention into daily use. Such limitations may be addressed by mobile devices, unique means of administering health interventions. However, there is a paucity of research focused on developing and preliminary evaluating a mobile stress coping app intervention in this high-risk population.

Purpose/Method: The purpose of this presentation is to describe the design, development and iterative evaluation of a mobile device stress coping app to reduce stress in hospitalized high-risk pregnant women. Within an interdisciplinary team, the design and development process included literature review, theory based foundation, building app components, programming issues, as well as data collection and download methods. Iterative evaluation was obtained from a prospective mixed methods study using a one-group pre/posttest design. Participants recruited from a tertiary care hospital were instructed to complete study measures, review all components of the app, listen to an audio file incorporating relaxation, breathing, visualization exercise and positive affirmations once a day for 8 days and complete daily stress self-assessments using a programmed visual analogue of stress scale (VASS). Daily interviews were conducted by the research team.

Results: All app components had active users. Participants (n=15) reported positive components of the app as well as opportunities for improvement. 100 % reported they had benefited from using the app. There was a significant decrease between pre and post intervention VASS scores ($p = 0.0001$). The majority of participants requested to continue using the app after the study.

Conclusions: The mobile stress coping app was found to be beneficial in reducing stress and provided a respite from the psychophysiological stress response in this population. The feedback provided will assist in refining the current app for use in a clinical intervention trial.

EFFECTS OF DANCE MOVEMENT THERAPY ON SUBJECTIVE STRESS AND CORTISOL SLOPE AMONG BREAST CANCER PATIENTS UNDERGOING RADIOTHERAPY

Rainbow T. H. Ho, PhD, Ted C. T. Fong, MPhil

Centre on Behavioral Health, Hong Kong, N/A, Hong Kong

Background: Breast cancer patients are at risk for psychosocial distress, which may lead to neuroendocrine dysfunction. Dance Movement Therapy (DMT) is a movement-based psychosocial intervention that incorporates exercise, artistic, and recreational components. This study aimed to examine the effectiveness of DMT on perceived stress and diurnal cortisol slope.

Methods: This clinical trial randomized 121 Chinese breast cancer patients undergoing radiotherapy treatment into the DMT (n = 63) or control group (n = 58). The intervention comprised six 1.5-hour group sessions held twice a week over the course of radiotherapy. The participants completed self-report measures on perceived stress, health and sleep characteristics at baseline. Salivary cortisol samples were collected at five time points and perceived stress at the end of the intervention. Moderated mediation analysis was used to evaluate the DMT effect on the diurnal cortisol slope.

Results: Overall, DMT showed a marginal beneficial effect on diurnal cortisol slope (B = –0.66, 95% CI = –1.36 to 0.06, β = –0.17). Baseline perceived stress significantly and negatively moderated the effect of DMT on diurnal cortisol slope (B = –0.21, 95% CI = –0.36 to –0.05, β = –0.35). At one SD above the pss1 mean, the cortisol slope of the DMT group (M = -6.93) was significantly steeper than the control group (M = -5.35) with 95% CI for the difference of -1.58 = -2.59 to -0.61. The indirect effect of DMT on cortisol slope via Time 2 perceived stress was not statistically significant.

Discussions: The DMT program had a modest overall effect on diurnal cortisol slope in breast cancer patients but appeared to be effective in modulating the neuroendocrine response of those who were distressed. The present findings suggest that perceived stress may play a moderator but not mediator role in the DMT effect on diurnal cortisol slope.

EXPERIENCES OF ETHNIC MICROAGGRESSIONS AND CORTISOL REACTIVITY TO THE TRIER SOCIAL STRESS TEST IN COLLEGE STUDENTS

Angelina Majeno, BA, MPH[1], Guido Urizar, Jr., PhD[2]

[1]California State University Long Beach, Los Angeles, CA; [2]California State University Long Beach, Long Beach, CA

Ethnic discrimination has been linked to stress. Although research regarding overt discrimination is plentiful, less is known about the impact of ethnic microaggressions. Microaggressions are subtle verbal or behavioral exchanges that communicate negative messages about a person's ethnicity. These experiences are particularly stressful and detrimental due to their ambiguous nature and the feelings of uncertainty that they arouse in those who experience them. The purpose of the current study was to examine how the frequency with which young adults experience ethnic microaggressions and their reactions to them relate to a biological marker of stress (i.e. salivary cortisol). Cortisol reactivity, cortisol recovery, and Area Under the Curve (AUC) were assessed. Participants were 109 ethnically diverse undergraduate students (74% females, M age= 18.7 years, SD= 1.3; 44% Hispanic, 23.9% Asian, 19.3% White, 12.9% other) who were exposed to the Trier Social Stress Test (TSST), a widely used paradigm to study stress reactivity. Participants provided 5 saliva samples before and after the TSST. They also answered 12 items about the frequency of ethnic microaggressions and their reaction to such experiences (e.g. getting upset; Ethnic Microaggressions Scale). Results of a repeated measures ANOVA showed that salivary cortisol increased significantly after exposure to the TSST, there was a main effect of time F(2.38, 242.75) =16.79, $p < .001$. Hierarchical linear regressions, which controlled for gender and generation status, showed that overall frequency of microaggressions and reactivity to microaggressions were not significantly associated to cortisol reactivity. A negative reactivity to microaggressions (i.e. getting upset) was associated with faster recovery after TSST exposure ($\beta = -.343$, SE = .033, $p < .001$) and marginally associated to a smaller AUC ($\beta = -.179$, SE = 2.102, $p = .056$, that is lower cortisol output. Finally, when comparing those with high frequency of microaggressions versus those with low frequency, a marginally significant difference was found with those in the low frequency group having a normal reactivity pattern after the TSST and those with high frequency having a blunted response F(2.36, 238.54)=2.42, p=.08. This pattern was also observed for reactivity to microaggressions F(2.30, 238.18)=3.09, $p < .05$. Blunted cortisol responses may have negative health implications, as they have been associated to substance use and obesity.

IMPAIRED BARORECEPTOR REFLEX FUNCTION IN CHRONICALLY STRESSED ELDERLY CAREGIVERS

Kevin Wu, BA[1], Brent Mausbach, PhD[2], Taylor Bos, MA[3], Igor Grant, MD[2]

[1]University of California, San Diego, North Haven, CT; [2]University of California San Diego, La Jolla, CA; [3]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA

Abstract

OBJECTIVE

We examined the relationship between chronic caregiving stress and baroreceptor reflex function.

BACKGROUND

Caregiving stress is associated with an increased risk in cardiovascular disease (CVD). The inability to adequately control blood pressure homeostasis through the baroreceptor reflex is a possible mechanism underlying this increased CVD risk. Evidence suggests that caregiving stress may be linked to atherosclerotic processes, and atherosclerosis has been shown to blunt the baroreflex by reducing arterial compliance. A blunted baroreflex sensitivity (BRS) increases the risk of arrhythmias and sudden cardiac death. We investigated the relationship between chronic caregiving stress and BRS.

METHODS

Elderly individuals (>55 years old; N = 149) participated in this study. Of these, 50 were married to a non-demented spouse, 57 were short-term caregivers (provided care < 4 years), and 41 were long-term caregivers (provided care ≥ 4 years). Multiple linear regression was used to determine if short- and long-term caregivers demonstrated significantly worse BRS relative to non-caregivers, after controlling for relevant health and demographic characteristics.

RESULTS

Long-term caregivers had a significantly worse BRS (mean ±SE = 8.02 ± 0.77) than the non-caregiving controls (mean ±SE = 10.47 ± 0.69; p = 0.047). BRS for short-term caregivers (mean ±SE = 9.89 ± 0.66) was not significantly different from the non-caregiving controls (p = .389).

CONCLUSIONS

These results suggest that chronic caregiving stress may be associated with a blunted BRS, especially in those caring for a longer period of time. We theorize that the accumulated wear-and-tear from caregiving stress could promote physiological processes that worsen BRS function. This finding could provide an explanation for the observed increased in CVD risk in elderly caregivers.

INFLAMMATION AND POSITIVE AFFECT: EXAMINING THE STRESS-BUFFERING HYPOTHESIS WITH DATA FROM ADD HEALTH

Cara L. Blevins, MA, Sara J. Sagui, MA, Jeanette M. Bennett, PhD

The University of North Carolina at Charlotte, Charlotte, NC

The present study examined the influence of positive affect (PA) on levels of inflammation within the context of Pressman and Cohen's (2005) stress-buffering model, which suggests that PA confers protective health benefits through its ability to mitigate the pathogenic influence of stress. We hypothesized that greater PA would buffer against the influence of perceived psychological stress (PPS) on systemic inflammation, operationalized as C-reactive protein (CRP, mg/L). Specifically, we predicted that PA would moderate the relationship between PPS and CRP. Cross-sectional data were drawn from Wave IV (2008-2009) of the National Longitudinal Study of Adolescent to Adult Health (Add Health). Participants (n = 3,093) ranged in age from 25-34 years old (M = 29.0 ± 1.79). Using a moderated hierarchical regression analysis, PPS and PA significantly interacted to predict levels of CRP ($p < .05$). Examination of the simple slopes revealed a disordinal interaction between PPS and PA, such that higher PA was protective against elevated CRP, but only when individuals also reported greater levels of PPS. Thus, the data partially support the stress-buffering model of PA and extend existing evidence regarding the complexity by which PPS and PA influence health. Findings also provide caution of future assumptions that the relationships among PA, PPS, and physical health markers, such as CRP, are always positive (*e.g.,* PA) or negative (*e.g.,* PPS) in nature.

PERFECTLY STRESSED: AN INTERACTION OF EVALUATIVE CONCERNS PERFECTIONISM AND PERSONAL STRIVINGS PERFECTIONISM ON STRESS

Kimberly A. Papay, B.S., Charlie L. Reeve, Ph.D.

University of North Carolina at Charlotte, Charlotte, NC

Despite an ongoing debate regarding the positive versus negative aspects of perfectionism, research has indicated that perfectionism is a stable personality characteristic linked to stress and stress-related outcomes. This relationship is especially concerning from a health outcomes perspective, as stress has long been known to impact physiological and mental health, health behaviors, and overall wellbeing. While multiple studies have proposed a two-factor model that distinguishes between maladaptive and adaptive features of perfectionism (often referred to as evaluative concerns perfectionism (ECP) and personal strivings perfectionism (PSP)), the interaction of these two factors in the context of stress has not been adequately explored. Additionally, the majority of research on this two-domain model of perfectionism has utilized group-based comparisons as opposed to moderations that account for the continuous nature of the variables involved. Therefore, the purpose of the present study was to examine the interaction of ECP and PSP on perceived stress via moderation analysis.

A sample of 144 participants from a large southeastern university completed self-reported measures of perfectionism and perceived stress in an online survey. ECP was positively associated with perceived stress (r= .61, p < .001), while PSP and perceived stress were not correlated. Regression analyses indicated that the linear effects of ECP and PSP accounted for a large proportion of the variance (43%) in perceived stress (R^2 = .43, F(2, 141) = 52.54, p < .001). The interaction of ECP and PSP (β = -.08, p < .05) accounted for an additional 3% of the variance in perceived stress above and beyond the linear terms (ΔR^2 = .03, F(3, 140) = 38.56, p < .001). This suggests that the effect of ECP on perceived stress varies as a function of PSP. Interestingly, graphical representations of these findings indicate that ECP and PSP interact such that when ECP is high, differences in PSP do not affect perceived stress levels, but when ECP is low, differences in PSP have a strong buffering effect against stress.

Although the link between perfectionism and stress has been previously demonstrated, these findings suggest that PSP may result in a drastic buffering effect against the impact of ECP on perceived stress at lower levels ECP. Implications for theoretical advancements, methodological implications, and stress interventions in the context of personality characteristics are discussed.

PSYCHOLOGICAL RESOURCES PROTECT AGAINST HEIGHTENED INFLAMMATION RELATED TO SOCIAL STRAIN AND ADIPOSITY IN LATE ADOLESCENCE

Jessica Chiang, PhD[1], Ahra C. Ko, BA[2], Julienne Bower, PhD[3], Shelley Taylor, PhD[4], Andrew Fuligni, PhD[3]

[1]Northwestern University, Evanston, IL; [2]University of Southern California, Los Angeles, CA; [3]UCLA Departments of Psychology and Psychiatry/Biobehavioral Sciences; Cousins Center for Psychoneuroimmunology, Los Angeles, CA; [4]Department of Psychology, UCLA, Los Angeles, CA

Social strain (i.e., difficulties from social relationships) increases risk for poor health outcomes (e.g., depression, heart disease), which may be partly driven by heightened inflammatory reactivity to stress. Notably, adolescence is marked by significant changes in social relationships and is when adult health trajectories begin to set. Yet, no study has examined how social strain impacts inflammatory reactivity to stress during adolescence. Thus, vulnerability and protective factors have not been identified. The current study examined whether risk (i.e., adiposity) and protective factors (i.e., psychological resources such as mastery, self-esteem, and optimism) moderated the relation between social strain and inflammatory reactivity to stress in late adolescents.

Participants (n = 91; M_{age} = 18.37 years, SD = .51; 57.14% female; 37.36% European and 62.64% Latino) completed measures of optimism, mastery, self-esteem (scores combined to create a composite score indexing psychological resources), and social strain, and had their height and weight measured for BMI. Next, participants completed the Trier Social Stress Task (TSST), a widely used lab stressor that increases inflammation. Blood samples were collected at baseline and 30, 60, and 90 minutes post-TSST, and assayed for proinflammatory cytokine interleukin (IL)-6. IL-6 reactivity was indexed by change scores between baseline and peak IL-6 (i.e., 90 minutes post-TSST).

Hierarchical regression analyses controlling for sociodemographic characteristics revealed that more social strain was marginally related to greater IL-6 responses. This link was moderated by BMI (*b(SE)* = .09(.04), *p* = .01), such that more social strain was related to greater IL-6 responses only among adolescents with high BMI *(b(SE)* = .09 (.04), *p* = .01), but not among those with low BMI (*b(SE)* = .01 (.04), *p* = .72). Psychological resources buffered the inflammatory effects of high social strain and adiposity (*b(SE)*=-.31(.10), *p*=.01). Among adolescents high in BMI, social strain was related to heightened IL6 reactivity for those low in psychological resources (*b(SE)* = .56 (.15), *p* < .001), but not for those high in psychological

resources (*b(SE)* = .05 (.10), *p* = .61). Among adolescents with low BMI, social strain was unrelated to IL-6 reactivity regardless of levels of psychosocial resources (*p*'s > .12). Results suggest that adolescents with greater adiposity are at higher risk for heightened inflammatory activity related to social strain. However, they may be protected if they also have high levels of psychological resources. Efforts to understand and improve adolescents' physical health and wellbeing related to stress should consider the roles of adiposity and psychological resources.

TRAIT HOSTILITY AND CORTISOL SENSITIVITY FOLLOWING A STRESSOR: THE MODERATING ROLE OF STRESS-INDUCED HEART RATE VARIABILITY

Andrea Lugo, N/A, Kyle Murdock, PhD, Christopher Fagundes, PhD

Rice University, Houston, TX

Hostile individuals have greater physiological dysregulation than less hostile individuals. Neuroendocrine dysregulation may underlie these negative health outcomes. In the present investigation, we examined whether self-regulatory strength, as indicated by high stress-induced high-frequency heart rate variability (HF-HRV), moderated the effect of hostility on cortisol secretion. Participants (N = 213) completed a self-report measure of hostility. HF-HRV was assessed at two different time points (at rest and during a social stress task). Cortisol secretion was evaluated by saliva sample collection immediately before (one sample) and over a 50-minute period after (six samples) a stress task. Hostile participants showed less cortisol sensitivity (i.e. change of cortisol over a period of time) when they exhibited high stress-induced HF-HRV. Cortisol sensitivity increases the risk for metabolic and inflammatory diseases. Accordingly, interventions that potentially increase stress-induced HF-HRV could decrease the effect of hostility on health.

WHAT TO EAT, AND WHEN? AN EXPERIMENTAL TEST OF THE PSYCHOPHYSIOLOGICAL EFFECTS OF COMFORT EATING

Laura Finch, M.A.[1], Jenna R. Cummings, M.A.[2], Janet Tomiyama, Ph.D. [2]

[1]University of California, Los Angeles, Johnson City, NY; [2]University of California, Los Angeles, Los Angeles, CA

Objective: Studies in rodents have shown that consumption of high-calorie/fat/sugar comfort foods dampens stress responses, but must comfort foods be characteristically unhealthy foods to provide comfort? This is the first known human study to test the effects of both unhealthy (processed, high-calorie/fat/sugar) and healthy (fruits and vegetables) foods on psychophysiological stress responses, also manipulating the timing of eating. **Method:** Healthy young women (*N* = 150) completed the Trier Social Stress Test (TSST) in the lab, and were randomized to one of five conditions (*n* = 30/group): (1) consumed an *unhealthy* food *before* the TSST; (2) consumed a *healthy* food *before* the TSST; (3) consumed an *unhealthy* food *after* the TSST; (4) consumed a *healthy* food *after* the TSST; or (5) consumed *no food* at all (control). Those in food conditions received a food that they had rated highly as mood-improver. Participants completed repeated measures of mood and stress appraisal. Heart rate (HR) and heart rate variability (HRV) were measured continuously. Rumination was assessed after the TSST. Independent raters blind to experimental condition and study hypotheses rated participants' TSST performance. **Results:** Those who ate unhealthy food before the TSST showed lower perceived self-efficacy (p = .021) and lower secondary appraisal scores (p = .045) than those who ate no food, indicating lower perceived ability to cope with the stressor. Those who ate healthy food pre-TSST showed marginally lower HR during the speech task compared to those who ate no food (*p* = .088). Upon eating post-TSST (whether healthy or unhealthy food), participants showed higher HR compared to those who ate pre-TSST and controls (all *P*s < .002). In addition, those who ate unhealthy food post-TSST showed lower HRV than those who ate either healthy (*p* = .005) or unhealthy (*p* = .007) food pre-TSST. This group also exhibited higher positive affect than controls at 10-minutes post-TSST (p = .013); however, they also expressed higher guilt than all other groups (*P*s < .011) at this time. No other effects were observed for mood, rumination, evaluated performance, or participants' appraisals of how well the TSST went. **Conclusion:** Given the non-human animal literature, we expected unhealthy comfort eating to dampen stress across psychophysiological outcomes. Instead, it showed a transient positive mood boost during stress recovery, no observed benefits for cardiac stress processes, and negative consequences for stress appraisal and cardiac recovery. Alternatively, eating fruits or vegetables during anticipatory stress may buffer normal cardiac reactivity as well as promote enhanced cardiac recovery compared to

unhealthy comfort eating. In sum, healthy comfort eating before an acute stressor may provide an avenue for reducing physiological stress while avoiding potential pitfalls of unhealthy comfort eating.

ALTERED FRACTIONAL ANISOTROPY IN CEREBELLUM OF INDIVIDUALS WITH FETAL ALCOHOL SPECTRUM DISORDERS

Fareshte Erani, B.A.[1], Andrew Pita, B.S.[2], Joseph C. Wu, M.D. [3]

[1]University of California, Irvine, Anaheim, CA; [2]University of California, Irvine, Huntington Beach, CA; [3]University of California Irvine, Irvine, CA

INTRODUCTION

Presently, fetal alcohol exposure is a leading cause of preventable birth defects and developmental disabilities within the United States. The umbrella term fetal alcohol spectrum disorders (FASD) refers to all children affected by prenatal alcohol exposure, including those with fetal alcohol syndrome, as well as those with mild impairment. Prenatal exposure to alcohol is associated with reductions in both overall brain volume and reductions in specific regions including the cerebellum, caudate nuclei, parietal lobe, and corpus callosum. In studies examining functional connectivity, there are significant reductions among the medial prefrontal cortex, posterior cingulate cortex and inferior parietal lobules in individuals with FASD. Other fMRI network efficiency studies have reported disrupted interhemispheric functional connectivity and reduced network capacity for parallel information processing. In this study we take three clinical referrals with FASD and compare them to controls using diffusion tensor imaging and tract-based spatial statistics in order to identify regions with altered fractional anisotropy (FA) values in the cerebellum of our subjects with FASD.

METHODS

The study comprises of three male FASD patients (mean age=49.33, sd±3.79) and two groups of normal controls: 16 age and gender matched controls (mean age= 40.75, sd± 8.44) and 42 controls with age and gender as covariates (28 males, mean age= 34.64, sd± 11.02). Diffusion tensor images for each subject were obtained and processed using the FSL library. Group comparison was performed in MATLAB using the SPM 8 software package. The FASD group images were compared to both control groups using a whole brain voxel-wise two sample T-test.

RESULTS

In the comparison between the FASD subjects and the 42 controls we found significantly increased FA in the middle cerebellar peduncle and the left inferior cerebellar peduncle, and significantly decreased FA in the right and left medial lemniscus and left cerebellar peduncle ($p < .01$, Voxel Threshold 30). In the comparison between the FASD subjects and the 16 controls we found significantly increased FA within the superior cerebellar peduncle and the middle cerebellar peduncle and significantly decreased FA in the superior cerebellar peduncle and the middle cerebellar peduncle ($p < .01$, Voxel Threshold 30).

CONCLUSION
It has been suggested that the corpus callosum and cerebellum are structures that are especially affected by fetal alcohol exposure. Given that alterations in FA within the corpus callosum are a common finding in many disorders, we focused on identifying changes in FA within the cerebellum. Our results show bilateral increases and decreases in FA in the cerebellum. A lack of robust bilateral cerebellar FA abnormalities among other disorders could indicate a hallmark for FASD.

CHILDCARE AS A BARRIER TO MEDICATION ASSISTED TREATMENT: A NEEDS ASSESSMENT AND FEASIBILITY STUDY

Naomi Newman, BS, Emily Zhang, BA , Robert Sterling, Ph.D.

Thomas Jefferson University, Philadelphia, PA

The presence of young children on-site is often viewed as disruptive to the delivery of substance abuse treatment. The present descriptive study aims to determine 1) the degree to which childcare is perceived as a barrier to care in a medication assisted treatment (MAT) population, and 2) whether the absence of available childcare is perceived as a child safety issue. Participants were 25 parenting individuals who completed an investigator-designed 15-item questionnaire that examined the challenges of reconciling parenting and outpatient substance abuse treatment. Clinical staff (n=9) also completed a brief survey about their beliefs regarding the need for childcare and the degree to which its absence interferes with treatment. Patients reported an average of 1.86±1.15 children; the average age of the youngest child was 4.27± 3.11. Almost 70% of respondents reported having missed services during this treatment episode because of the demands of childcare. Three-quarters of respondents reported having needed to bring one or more of their children to the MAT site in the past. A high level of agreement with statements regarding childcare as a barrier to treatment (10=maximum agreement) was observed for patients (M=7.75±.56) and clinical staff, respectively (M=8.90±1.52). Not surprisingly, 100% of clinical staff viewed the presence of children in the environment of care as being problematic and interfering with the delivery of treatment. In an attempt to quantify the disruption, over a one-week period staff were asked to document and describe episodes of children on site. During this time, 22 different children presented at the clinic with their parent/guardian. Behaviors described included going up to the medication counter, going into group therapy for the duration of the session, and loitering in front of the facility. Almost two thirds (n=14) of the children were reported by staff as being disruptive. Results suggest that both patients and clinical staff perceive lack of childcare to be a barrier to treatment and a threat to potential child safety, and that a student-run effort to address this barrier may be a feasible response. While exploring the feasibility of a student-run effort, 36 medical students indicated interest in volunteering their time, both during the school year (85%, n=20) and over summer break (60%, n=20).

CHILDHOOD ABUSE, PTSD, AND LIFETIME SUBSTANCE ABUSE IN LATINO AMERICANS: WHOLE-NATION, US-BORN, AND FOREIGN-BORN MODELS

Amy L. Ai, PhD[1], Jungup Lee, MSW[1], Catherine M. Lemieux, PhD[2]

[1]Florida State University, Tallahassee, FL; [2]Louisiana State University, Baton Rouge, LA

Introduction: Childhood abuse (CA), posttraumatic stress disorder (PTSD) and lifetime substance abuse (LT-SA) are major behavioral health concerns, particularly among underrepresented populations; yet there is limited knowledge regarding their associations for Latino Americans. This study investigated the relationship of childhood physical abuse (CPA) and childhood sexual abuse (CSA) to PTSD and LA-SA among Latino Americans (*N*=2,554) using the National Latino and Asian American Study, including analyses of nativity differences (US-born and foreign-born Latinos). ***Methods:*** We used all Latino American (*N*=2,554) with a mean age at 38.02 years (*SD*=15.03; rage, 18-97). The weighted Latino sample was roughly proportional in terms of gender (48.5% female) and nativity (43% US-born Latinos). Three path models for the whole-nation, US-born, and foreign-born Latino groups were conducted to examine the direct and indirect effects of CPA and CSA on LT-SA, mediated by PTSD. ***Results:*** Results showed higher prevalence rates of CPA (35.3% vs. 24.4%), CSA (17.4% vs. 9.3), PTSD (6.5% vs. 4.6%), and LT-SA (17.1% vs. 5.3%) for US-born Latinos than for foreign-born Latinos. The findings of the three final models (whole-nation, US-born, and foreign-born models) fit the data adequately, with CFI (987-.980), TLI (.936-.984), RMSEA (.015-.063), and SRMR (.006-.015). Path models indicated a direct link between CPA (but not CSA) and LT-SA and an indirect link between CA and LT-SA through PTSD. ***Conclusion:*** The current study is important because it expands the knowledge base regarding the behavioral health impact of inadequate or harmful child-rearing practices in Latino families. Findings underscore the need for intervention research that evaluates culturally-relevant behavioral health assessment and intervention approaches specific to US-born and immigrant Latinos.

FACTORS ASSOCIATED WITH MARIJUANA USE AND PROBLEMS AMONG COLLEGE STUDENTS IN COLORADO

Kristina T. Phillips, PhD, Michael M. Phillips, PhD, Kerry D. Duck, M.A.

University of Northern Colorado, Greeley, CO

Background: Marijuana is commonly used and misused among young adults in the U.S. Of young adults in college full-time, approximately one-third report annual use of marijuana and 21% report use in the last month, with higher rates among male versus female students. Additionally, it has been estimated that up to one-fourth of university students using marijuana within the past year meet criteria for cannabis use disorder. Frequent use and misuse have been associated with a range of psychological (e.g., depression) and personality (e.g., impulsivity) factors in young adults, but there is limited research focused on the college environment. The aim of the current study was to examine whether marijuana use and problem marijuana use were associated with a range of demographic, personality, and psychological variables among college students in Colorado, a state with legalized use. **Methods:** Participants included 300 undergraduate students (60% female, 69% Caucasian) recruited from a psychology research pool. Participants submitted a urine screen and completed measures on marijuana use, problem marijuana use, anxiety, depression, impulsivity, and openness to experience in a lab setting. **Results:** Last year (65%) and recent marijuana use (29%) were high, as assessed through self-report and a urine screen. Two multiple logistic regression models were used to examine factors related to marijuana use. Impulsivity and openness to experience were associated with marijuana use within the last year (χ^2 (3) = 19.93, $p = .001$; $R^2 = .18$), while male gender and openness to experience were associated with recent use (χ^2 (3) = 31.21, $p = .000$; $R^2 = .14$). A hierarchical linear regression showed that gender (b =.22, $p < .01$), impulsivity (b =.15, $p < .05$) and depression (b =.22, $p < .05$), but not general anxiety or social anxiety, were significantly associated with problem marijuana use ($R^2 = .15$). **Conclusions:** Overall, the data suggests that certain personality factors, gender, and mood disruption are associated with marijuana use or misuse in college students. These findings have implications for future prevention and intervention studies with university students both at risk of and who may have problems with marijuana.

INTRAPERSONAL FACTORS, AFFECT, AND DRINKING MOTIVES AS PREDICTORS OF ALCOHOL USE IN COLLEGE STUDENTS

Chris A. Eisenbarth, PhD, MS

Weber State University, Ogden, UT

The high rates of alcohol consumption among college students in the United States is associated with numerous negative consequences—including academic problems, unprotected sex, violence, motor vehicle accidents and other unintended injuries. As such, research is needed to examine the factors that influence alcohol use in this population so that effective prevention and intervention programs can be developed. The purpose of the present study was to examine the effects of intrapersonal variables (i.e., self-esteem, personal control, perceived social support), negative affect (i.e., symptoms of depression, anxiety, and stress), and drinking motives (i.e., coping, conformity, social, enhancement) in the prediction of hazardous and harmful alcohol use in a sample of 279 college students (114 males, 165 females). A self-report, cross-sectional format was used and participants completed previously-validated instruments designed to measure the aforementioned variables. The participants were predominately single (87%), freshman and sophomores (76%), between the ages of 18 and 23 (93%), white (79%), and enrolled as full-time students (94%). To test for group differences, a multivariate analysis of variance was conducted but no significant main effects nor interactions emerged ($p > .01$). Regression analyses revealed that sex ($\beta = -.16$, $p < .01$), symptoms of anxiety ($\beta = .16$, $p < .05$), drinking alcohol to cope with negative affect ($\beta = .31$, $p < .01$), and drinking alcohol to socialize with others ($\beta = .27$, $p < .01$) were significant predictors of alcohol use ($F[12,232] = 25.00$, $p < 0.01$). These findings indicate that campus intervention efforts that help students to manage symptoms of anxiety may result in decreases in drinking to cope motivation and alcohol consumption among college students. The sample was homogenous in terms of age and ethnicity (no minority group exceed 6% of participants) so the results may not generalize to other college student populations. Additional prospective research with varied student populations is needed to ascertain how drinking to cope motivation might exacerbate anxious affect and increase problematic alcohol use in college students.

MULTIDISCIPLINARY PERSPECTIVES OF PROVIDING MEDICATION ASSISTED THERAPY IN A PRIMARY CARE CLINIC

Rebecca Aycock, PhD[1], Sebastian Tong, MD MPH[2], E. Marshall Brooks, PhD[2]

[1]Virginia Commonwealth University, Mechanicsville, VA; [2]Virginia Commonwealth University, Richmond, VA

Rates of opioid overdose from prescription drugs and heroin have risen steadily over the past two decades, resulting in over half a million deaths between 2000-2014. Medication Assisted Therapy (MAT) is a form of opioid addiction treatment combining daily opioid agonist medication with behavioral health interventions. Literature suggests providing MAT in primary care can help combat this opioid crisis. However, timely incorporation of MAT in primary care can either be facilitated or hindered by practice members' preconceptions of addiction and the role of primary care in addiction treatment. This qualitative study explored clinical and support staff members' perspectives on expanding MAT services in their primary care clinic. Semi-structured interviews were conducted with 13 practice members, including MDs, nurses, medical assistants, front desk staff, and behavioral health providers. Interviews were transcribed and analyzed using an inductive, emergent coding process to identify themes related to participants' subjective experiences, perspectives, and preconceptions about providing addiction services. Our analysis revealed four themes: 1) a recognized need for MAT to treat patients with addiction; 2) uncertainty about whether primary care is the most appropriate setting to provide MAT; 3) a close association between the topic of substance use disorder and chronic pain management and related stigmas; and 4) a sensitivity to the overlap between socio-economic disparities and rates of addiction. Although most practice members expressed reservations, the majority (11 out of 13) supported the idea of providing MAT at their practice. Providing MAT in primary care can increase access to treatment and curb rates of opioid addiction and overdose. Our study identifies possible barriers to MAT service uptake among primary care clinics, and points to possible interventions to increase acceptance and effectiveness of MAT in primary care settings, including education to inform practice members on the value and feasibility of incorporating MAT into their practices.

PATIENT SATISFACTION AS A PREDICTOR OF QUALITY OF LIFE FOR INDIVIDUALS ON METHADONE MAINTENANCE

Emily Loscalzo, Psy.D., Angelo Rannazzisi, Psy.D., Robert Sterling, Ph.D., Stephen P. Weinstein, Ph.D.

Thomas Jefferson University, Philadelphia, PA

Studies examining the relationship of patient satisfaction and treatment outcome in individuals with substance use disorders have yielded equivocal results ranging from no observed relationship between patient satisfaction and treatment outcome (McLellan et al., 1998) to high levels of satisfaction being predictive of engagement and positive outcome (Carlson et al., 2001). More recently, studies have examined the relationship of patient satisfaction with methadone treatment and retention/outcome (Kelly et al., 2010; de los Cobos, 2016). The purposes of the present study were to establish the psychometrics (factor structure, reliability, predictive validity) of a newly constructed patient satisfaction measure developed for individuals in methadone maintenance treatment (MMT) called the Jefferson Patient Satisfaction Survey (JPSS), and to examine the relationship between patient satisfaction and quality of life (QOL). Quality of life (QOL) has been identified by Laudet et al. (2009) as an often ignored, yet essential outcome of substance abuse treatment. Over a two-day period, the JPSS and the Scale to Assess Satisfaction with Medications for Addiction Treatment- SASMAT (de los Cobos, 2016) were administered to a convenience sample of 165 individuals enrolled in an outpatient MMT program. Complete data were provided by 145 respondents. Examination of demographics suggested that the respondents were representative of the treatment population in general as participants were 59% male, averaged 40.57 years of age, with a mean time in treatment of 4.39 years. Principal components analysis of the JPSS and the SASMAT revealed two-factor and four-factor solutions, respectively. Extracted factors related to satisfaction with medication and with clinical staff- JPSS, and general acceptance of MMT, perceived health effects, effect of MMT on cravings, and interference with work/school activities-SASMAT. A significant regression model linking patient satisfaction, age and QOL was noted, F(2,106)=18.25, p2 = .242. Specifically being older (b=.12, $p < .01$) and more accepting of MMT (b=.48, $p < .01$) were predictive of QOL. Given the finding that satisfaction with treatment is predictive of quality of life, future research should examine factors that are predictive of treatment satisfaction.

USING ECOLOGICAL MOMENTARY ASSESSMENT TO ASSESS SLEEP QUALITY AND CRAVINGS IN THOSE RECOVERING FROM ADDICTION

Lindsey Freeman, B.S.[1], Nisha C. Gottfredson, PhD[2]

[1]University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]UNC Gillings School of Global Public Health, Chapel Hill, NC

Introduction: Poor sleep quality in people recovering from addiction has been positively correlated with duration of drug use, risk for relapse, and substance use in cross-sectional studies (Tang et al., 2015; Seere et al., 2015). However, it is unknown whether sleep disturbance prospectively predicts more frequent or more intense acute cravings for drugs in those in recovery, whether cravings result in disturbed sleep, or whether both occur simultaneously. The present study investigates the relationship between sleep quality/duration and daily reports of cravings for drugs.

Methods: 113 participants being treated for substance use disorders were included in the study. Participants responded to four brief phone surveys each day for a week, on which they indicated how much they were craving drugs or alcohol at the moment (0 = *not at all* - 4 = *it is all I can think about*). On the first survey of the day, participants were asked to report on their sleep quality from the previous night (0 = *terrible* - 4 = *great*) and the amount of hours slept the previous night.

Results: Multilevel models were used to assess the prospective effects of sleep quality and sleep time on subsequent cravings, and the prospective effects of level of craving on subsequent sleep quality and duration. Increased sleep quality ratings and increased duration of sleep significantly predicted lower craving levels (b = -.07, SE= .02, p b = -.04, SE = .01 p b = -.11, SE = .03, p < .001; b = -.14, SE = .04, p < .01, respectively).

Discussion: Sleep quality ratings and sleep duration significantly predicted reduced subsequent cravings for the average person in our sample, and increased levels of momentary cravings also predicted decreased subsequent sleep quality and numbers of hours slept. These results suggest a potential mechanism through which poor sleep quality may produce increased dysregulation, potentially triggering relapse. Subsequent analyses will consider a cross-lagged model, parse within-person and between-person effects, and will explore the role of caffeine intake and other environmental variables in these associations. These results will provide insight in to the extent to which sleep quality might be used as a marker of risk for relapse or as a target for behavioral interventions.

VOLUNTARY WHEEL RUNNING PROTECTS CORTICAL BLOOD-BRAIN-BARRIER TO PREVENT ALCOHOL RELAPSE

Sucharita S. Somkuwar, Ph.D., B.Pharm[1], McKenzie J. Fannon - Pavlich, BA[2], Tran Nguyen, B.S.[3], Chitra Mandyam, PhD[4]

[1]VA San Diego Healthcare System, San Diego, CA; [2]VA San Dieho Heathcare System, Oceanside, CA; [3]University of California, San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, CA; [4]Veterans Administration San Diego Healthcare System, San Diego, CA

Alcoholism is relapsing disorder with limited treatment options; identifying mechanisms underlying unregulated intake and relapse is essential. Disrupted oligodendroglial homeostasis in the medial prefrontal cortex (mPFC) was suggested to contribute to escalated ethanol intake in the chronic intermittent ethanol vapor (CIE) model of alcoholism; escalated ethanol seeking persisted following prolonged abstinence [1]. Voluntary wheel running (WR) during prolonged abstinence inhibited ethanol seeking and rescued mPFC oligodendroglial homeostasis [2]. Since oligodendroglial turnover and maturation depends cerebrovascular health [3-5], the current study tested the hypothesis that ***ethanol exposure and withdrawal persistently damages vasculature in mPFC, and access to running wheel during protracted abstinence will rescue cerebrovascular integrity.*** Adult male Wistar rats exhibiting escalated ethanol intake (with 7-weeks CIE exposure; CIE rats) and low ethanol intake (no CIE exposure; ED rats) were subject to four weeks of abstinence either in ordinary cages (CIE-Sed and ED-Sed), or in cages with ad libitum access to running wheel (CIE-WR and ED-WR; [2]). CIE-WR and ED-WR exhibited reduced reinstatement compared to CIE-Sed and ED-Sed [2]. mPFC tissue from the above groups as well as age-matched controls (Sed and WR) were probed for PECAM-1, a protein expressed on endothelial cells, and for SMI-71, a protein that indicates healthy blood-brain-barrier (BBB). PECAM-1 expression, via immunoblotting, was increased in both CIE-Sed and ED-Sed compared to Sed, and was decreased CIE-WR and ED-WR compared to CIE-Sed and ED-Sed, respectively. SMI-71 expression via immunohistochemistry (area immunopositive for SMI-71, expressed as %), was increased in CIE-WR and ED-WR compared to CIE-Sed and ED-Sed, respectively; SMI-71 was greater in CIE-WR than both ED-WR and WR. Thus, these results indicate that cerebrovascular health was compromised by ethanol experience and withdrawal. Wheel running reversed these maladaptive changes, particularly in rats with escalated ethanol intake. In conclusion, voluntary wheel running may protect against ethanol relapse, in part, via inhibition of ethanol-induced cerebrovascular damage.

ASSOCIATION OF RECEPTIVITY TO TOBACCO PRODUCT ADVERTISING AND RISK FOR TOBACCO USE IN 12-17 YEAR OLDS: WAVE 1 OF THE PATH STUDY

Madison Noble, MPH[1], John Pierce, PhD[2], David Strong, PhD[2], Eric Leas, MPH[2], Martha White, MS[2]

[1]Moores Cancer Center, UC San Diego, San Diego, CA; [2]Moores Cancer Center, UC San Diego, La Jolla, CA

Receptivity to cigarette advertisements (ads) among those as young as 12 years old has been identified as a causal influence leading to later cigarette smoking. We assess how the association between receptivity and risk of later use varies across age (12-17 years) for four separate tobacco products (cigarettes, e-cigarettes, cigars, smokeless tobacco) using Wave 1 (Sept. 2013-Dec. 2014) of the Population Assessment of Tobacco and Health (PATH) Study, a nationally-representative population study. Household interviews were completed with 13,651 youth aged 12-17 years. All were shown a stratified random sample of 20 recent tobacco ads. An adolescent was receptive to a product's ads if they recalled seeing any of its ads, liked any of its ads, or reported having a favorite tobacco ad. Those who had tried a product or were susceptible to use the product in the future were classified as "at risk". Multivariable logistic regression models tested whether the association between receptivity to each product's ads and risk for later use of the product varied with individual ages and whether there was an interaction effect across ages.

For each product, both age and receptivity were significantly associated with risk for later use. There was not a significant interaction between age and receptivity on risk for future product use for any of the products tested, suggesting a linear model was a good descriptor of the data. We plotted the 3 way association (receptivity x risk x individual ages for each product and identified a very strong, essentially parallel age effect for the receptivity by risk association, especially for cigarettes (slope= 2.7; R^2=0.96), e-cigarettes (slope = 2.6; R^2=0.89) and cigars (slope = 2.9; R^2=0.85). However, for each product, the receptivity x risk term for those aged 17 years was significantly off the 12-16 year linear line. Thus, although risk for future product use increased compared to 16 year olds, there was no evidence that receptivity increased at the same time.

These results suggest the hypothesis that tobacco ads may be most effective in increasing risk for future use with younger adolescents, those under the legal age for purchase. Longitudinal research to test this hypothesis will be available from the PATH study within the next year.

A SYSTEMS-APPROACH TO PROMOTE SMOKING CESSATION IN FOOD PANTRY RECIPIENTS

Mackenzie Perkett, B.S. in Health Behavior Science[1], Varsha Kripalu, Bachelor of Arts in Biology[2], Christina Wysota, B.S in Health Behavior Science[3], Charlotte McGarry, MAed[4], Mia A. Papas, PhD[5], Shannon Robson, PhD[1], Freda Patterson, PhD[1]

[1]University of Delaware, Newark, DE; [2]University of Delaware, Wilmington, DE; [3]New York University, East Islip, NY; [4]Food Bank of Delaware, Newark, DE; [5]Christiana Care Health Systems, Newark, DE

A systems-approach to promote smoking cessation in food pantry recipients

Despite declines in national smoking rates, reports suggest that between 30-55% of food pantry recipients are current smokers. This subpopulation of smokers experience multiple health risks thus, systems-based efforts to increase smoking cessation behaviors and access to cessation resources are needed to promote abstinence. The current pilot-study used a pre and post design to test the impact of a brief, portable smoking cessation education intervention delivered to recipients of food assistance at five food pantries in the state of Delaware between January and May 2016. The 10-12 minute educational intervention was developed in collaboration with the Food Bank of Delaware and designed to increase smoking cessation knowledge, intention to quit, and utilization of the state Quitline. The food security status of the study sample was also examined. Of the total study sample (N=148), 69% were female, 78% were on disability or retired, 53% were African American, and the mean age was 62.8 years (SD=15.2). Half the sample (50%) were current smokers, and of those, 24% (N=18) were highly dependent as defined by having their first cigarette of the day within five minutes of waking. Seventy seven percent of the sample reported moderate or severe food insecurity. Current tobacco use was significantly more prevalent among food insecure (89.8%) than food secure (10.2%) participants (X^2= 10.72; p=.001). As compared to baseline, smoking cessation knowledge score (M_{BL}= 4.9, M_{FU}= 6.0; t=3.8, pBL= 4.2, M_{FU}= 5.1; t= 1.71, p=.1), increased significantly at the 6-week follow-up. At follow-up, 7% of the sample reported calling the Quitline. High smoking prevalence and nicotine dependence levels characterize this food insecure population as a high-priority group for smoking cessation efforts. More intensive programming may be needed to systematically increase quitting intentions and connect this high-risk subgroup to cessation resources.

COMPARING SMOKING BEHAVIORS BETWEEN HISPANIC/LATINO NATIONALITY GROUPS IN THE UNITED STATES

Jamie Q. Felicitas-Perkins, MPH[1], Kari-Lyn K. Sakuma, PhD, MPH[2], Lyzette Blanco, PhD MPH[3], Pebbles Fagan, PhD, MPH[4], Eliseo J. Perez-Stable, MD[5], Bin Xie, PhD[1], Richard Armenta, PhD, MPH [6], Dennis R. Trinidad, PhD, MPH[7]

[1]Claremont Graduate University, Claremont, CA; [2]Oregon State University, CPHHS, Corvallis, OR; [3]Claremont Graduate University, Lakewood, CA; [4]Fay W. Boozman College of Public Health, University of Arkansas for Medical Sciences, Little Rock, AR; [5]National Institute on Minority Health and Health Disparities, National Institutes of Health, ., MD; [6]University of California, San Diego, San Diego, CA; [7]University of California, San Diego, La Jolla, CA

Background/Aim. Hispanics/Latinos (H/L) are the largest and one of the most diverse ethnic groups in the United States (US), yet there is a dearth of research that examines smoking behaviors for specific H/L nationality groups. Disaggregate data on H/L may identify groups at highest risk for smoking and provide more precise data to guide intervention development. Using data from the 2001-2011 Current Population Survey Tobacco Use Supplements, this study estimated the prevalence of cigarette smoking and the association of H/L nationality with the outcomes current, light/intermittent, and heavy smoking among Mexican Americans, Puerto Ricans, Cubans, and Central/South Americans.

Methods. Data were weighted to estimate the prevalence of current, light/intermittent, and heavy smoking. Weighted logistic regression models were used to examine the association of H/L nationality with smoking outcomes while controlling for the covariates age, education, income, employment status, home smoking policy, acculturation, gender, and the interaction between gender and nationality.

Results. Among ever smokers, Puerto Ricans had the largest proportion of current smokers (58.9%). Although Mexican American current smokers had the largest proportion of light/intermittent smokers (LITS; 59.2%), Puerto Rican and Cuban current smokers had the largest proportions of moderate (37.7%) and heavy smokers (31.5%), respectively. Compared to Mexican Americans, Cubans and Puerto Ricans had significantly higher odds of being current smokers (Cubans: OR=1.80, CI=1.63, 1.98; Puerto Ricans: OR=1.27, CI=1.19, 1.35) and heavy smokers (Cubans: OR=3.67, CI=3.06, 4.40; Puerto Ricans: OR=2.16, CI=1.96, 2.38). Cubans (OR=0.31, CI=0.26, 0.36) and Puerto Ricans (OR=0.55, CI=0.52, 0.60) were also shown

to have significantly lower odds of being LITS compared to Mexican Americans. Central/South Americans were shown to have significantly lower odds of being heavy smokers compared to Mexican Americans (OR=0.80, CI=0.68, 0.95).

Conclusions. These results call for tailored intervention efforts that take into account the heterogeneity in smoking behaviors observed among H/L nationality groups. Reduction and cessation efforts should particularly focus on Puerto Ricans and Cubans, who are moderate and heavy smokers.

EFFECTS OF POTENTIAL PRICE CHANGES OF E-CIGS AND CIGARETTES ON SMOKING AND VAPING BEHAVIOR AMONG DUAL-USE SMOKERS

Terence K. Teo, Ph.D.[1], Haruka Minami, Ph.D.[2], Hannah R. Brinkman, B.A.[3]

[1]Seton Hall University, South Orange, NJ; [2]Fordham Univeristy, White Plains, NY; [3]Fordham University, New City, NY

In August 2016, the FDA’s expanded Tobacco Control Act went into effect, extending its regulatory authority to electronic cigarettes (e-cigs) with the goal of improving and protecting public health. One potential implication of this rule is an increase in the cost of e-cigs. This study sought to assess the effects of potential price changes on cigarettes and e-cigs on the behavior of individuals who use both combustible and electronic cigarettes (dual-use smokers). We recruited 118 dual-use smokers in the United States through Amazon Mechanical Turk. Of the 118 smokers, 54% were male, 83% white, 14% Hispanic, 47% had a college degree or higher, and 53% reported history of at least one psychiatric disorder. On average, participants had a mean age of 34.7 (SD=10.6) years, smoked 7.3 cigarettes per day (SD=6.6), vaped e-cigs 5.7 times per day (SD=13.1), and had a mean Penn State Cigarette/Electronic Cigarette Dependence Index of 8.7 (SD=4.6) and 6.2 (SD =4.2) respectively. E-cig types included disposable (19%), pre-filled cartridge (31%), refillable (45%), and two or more types (6%). We examined how smokers' expected behavior change (no change, reduce use, quit use) vary given price increases in e-cigs (while holding cigarette prices constant), vice-versa, and both. At e-cig price increases of 1.5x, 2x, and 3x alone, 7%, 11%, and 20% of participants would quit both cigarettes and e-cigs while 11%, 18%, and 20% would increase cigarette use. A similar rate of participants reported they would quit both cigarettes and e-cigs with cigarette price increases alone. If both e-cig and cigarette prices increase 1.5x, 2x, and 3x, 17%, 25%, and 39% would quit both while 29%, 43%, and 59% would quit smoking cigarettes (irrespective of e-cig use). At 1.5x (but not 2x or 3x) e-cig price, those with greater e-cig dependence were more likely to quit cigarettes (*OR* = 1.02, *95%CI* = 0.00-1.04, *p* = .03), controlling for cigarette dependence and monthly spending on cigarettes, while e-cig dependence did not predict quitting e-cigs. We also found that at 1.5x and 2x increases in both cigarette and e-cig prices, refillable users, compared to disposable and pre-filled cartridge users, are less likely to reduce or quit using e-cigs (*OR* = 1.35, 1.33, *95%CI* = 1.14-1.60, 1.14-1.56, *p*s = .001, respectively), controlling for covariates. These findings suggest that increases in either e-cig or cigarette prices may lead to increased cessation in all tobacco products, but price increases in e-cigs alone may also lead to more cigarette smoking. What is more, concurrent price increases in both e-cigs and cigarettes may double the rates of cessation in all tobacco products. In addition, the potential impact of price changes on

smoking or vaping behavior may differ across types of e-cigs. Larger studies examining the relations between cost, e-cig type, dependence, and smoking/vaping behavior is needed.

FUNCTIONAL NEUROIMAGING OF BEHAVIORAL SMOKING CESSATION TREATMENT: PRELIMINARY FINDINGS

Andrew T. Fox, Ph.D.[1], Delwyn Catley, Ph.D.[2], Morgan G. Brucks, BA[3], Vlad B. Papa, B.A.[4], Laura E. Martin, Ph.D.[1]

[1]University of Kansas Medical Center, Kansas City, KS; [2]Children's Mercy Hospital & University of Missouri-Kansas City, Kansas City, MO; [3]Hoglund Brain Imaging Center, Mission, KS; [4]Hoglund Brain Imaging Center, Olathe, KS

The dual-systems model of addiction posits that addiction is the result of increased activity in reward-associated brain regions that overrides the decreased activity in cognitive control regions. It is possible that behavioral smoking cessation treatments work by affecting these regions. We hypothesized that cognitive control “practice” would increase activation in the cognitive control regions and decrease activation in the reward regions. 35 subjects were randomized to receive 4-week Cognitive-Behavioral Therapy (CBT) enhanced with scheduled smoking or a 4-week non-smoking-related behavior change intervention. During functional magnetic resonance imaging (fMRI) scans (performed both pre- and post-treatment), subjects passively viewed smoking and non-smoking cues. Analysis based on the 18 subjects (9 per group) who completed treatment and passed motion thresholding showed greater activation to smoking than to nonsmoking cues in dorsolateral and -medial prefrontal areas (typical cue reactivity effect). Comparison across groups and timepoints (pre- and post-treatment) yielded no significant activation differences in *a priori* regions of interest, suggesting that cognitive control practice did not cause detectable brain changes in these areas. Results from behavioral tasks indicated a decrease in impulsive errors in the CBT group but not the control group on a smoking Go/No-go task but no changes in delay discounting were detected in either group. Future research should utilize a stronger cognitive control practice regimen perhaps over a longer time frame.

IMPLICIT THEORIES OF SMOKING AND ASSOCIATION WITH QUIT BEHAVIORS AND INTENTIONS AMONG CURRENT SMOKERS

Chan Thai, PhD, MPH[1], Jennifer M. Taber, PhD.[2], Elise L. Rice, PhD[3], Annette Kaufman, PhD, MPH[4], William Klein, PhD[5]

[1]Santa Clara University, Santa Clara, CA; [2]Kent State University, Kent, OH; [3]National Cancer Institute, Bethesda, MD; [4]Tobacco Control Research Branch, Behavioral Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, National Institutes of Health, Rockville, MD; [5]NCI/NIH, Rockville, MD

Background: Implicit theories of smoking (ITS) refer to people’s beliefs about whether smoking behavior is something that is changeable (incremental belief) or fixed (entity belief). A recent study found that current smokers are more likely to hold entity beliefs than former or never smokers. However, the role of ITS in quit behaviors and intentions remains unexplored. The three aims of this study of current smokers were to assess how ITS relates to 1) attempts to quit in the past 12 months, 2) having called a quit line, and 3) intentions to quit in the next 6 months. **Methods:** The Health Information National Trends Survey (HINTS) is a nationally representative, cross-sectional mail survey of all civilian, non- institutionalized adults aged 18 or older in the United States. It tracks trends in the American public’s need for, access to, and use of health-related information and health behaviors, perceptions, and knowledge. Analyses were conducted using data from three iterations of HINTS, collected between 2013-2015, with a total of 1,579 smokers. Data were submitted to logistic regression analyses with ITS regressed on 1) attempts to quit in the past 12 months, 2) having called a quit line, and 3) intentions to quit in the next 6 months. **Results:** Controlling for sociodemographic variables, analyses indicated that greater incremental beliefs were marginally significantly associated with higher likelihood of having tried quitting in the past 12 months than not having tried (β=.26, p=.06) and with higher likelihood of having called a quit line than not (β=.50, p=.09). Greater incremental beliefs were significantly associated with intending to quit in the next 6 months (β=-.27, p=.02). There was a significant interaction effect between ITS and past quit attempts; those with greater incremental beliefs who had not tried quitting in the 12 months were more likely to report that they intended to quit in the next 6 months than those who had tried (β=.51, p=.01). **Conclusions:** These findings suggest that for current smokers, greater incremental beliefs are associated with higher likelihood of having attempted to quit in the past 12 months, having called a quit line, and intending to quit in the next 6 months. For current smokers who have attempted unsuccessfully to quit in the past year, those with greater incremental theories have a lower likelihood of considering

quitting in the next 6 months while those who have not tried quitting in the past year have a greater likelihood of considering quitting in the next 6 months. Current findings may be used to inform campaigns to motivate and sustain smoking cessation among current smokers through cultivating incremental beliefs that their smoking behavior can change.

LITTLE CIGAR AND CIGARILLO PERCEPTIONS AND USE AMONG AFRICAN AMERICAN YOUTH AND YOUNG ADULTS

Kari-Lyn K. Sakuma, PhD, MPH[1], Maddison M. Greaves, MS[2], Jessica Seifert, MPH[3], Lyzette Blanco, PhD MPH[4], Pebbles Fagan, PhD, MPH[5], Monica Wilson, PhD[6], Jamie Q. Felicitas-Perkins, MPH[7], Dennis R. Trinidad, PhD, MPH[8]

[1]Oregon State University, CPHHS, Corvallis, OR; [2]Oregon State University, CPHHS, Philomath, OR; [3]Oregon State University, Corvallis, OR; [4]Claremont Graduate University, Lakewood, CA; [5]Fay W. Boozman College of Public Health, University of Arkansas for Medical Sciences, Little Rock, AR; [6]National University, San Bernardino, CA; [7]Claremont Graduate University, Claremont, CA; [8]UC San Diego, La Jolla, CA

Background: African Americans disproportionately suffer from tobacco-related diseases. Little cigar and cigarillo (LCC) use has increased in African American youth populations and may play a role in observed health disparities.

Objectives: We examined the data for patterns of LCC use to identify reasons for use, health perceptions, and celebrity and advertisement social influences.

Methods: Individual in-person interviews were conducted among a community sample of continuation high school and vocational school students in southern California. Participation was limited to those who had ever tried at least one tobacco product, self-identified as African American, and were between the ages of 14-26 (n=28). We analyzed themes related to health perceptions, reasons for use, and social influences including marketing exposure.

Results: Specific LCC brands, like Swishers and Phillies, were associated with marijuana use. Reasons for use were embedded in the context of LCC use only and LCC use mixed with marijuana. Initiation of LCC use was commonly associated with significant life events, including coming of legal age, and social influences such as friends or family. Stress relief, relaxation, and escapism was frequently reported reasons for LCC use, both modified with marijuana and unmodified. Participants often reported their patterned/habitual LCC use, although addiction was not always recognized. Participants stated that LCCs saved costs because they are less expensive than cigarettes and last longer. Particularly with Black & Mild (B&M) cigars, participants described processes of rationing to be cost-effective and prolong the “head change” experience. Whether discussing LCCs as unmodified, modified with

marijuana, or the B&M brands, LCC use was not dependent on social settings. Cigarettes were perceived negatively, especially in comparison to LCCs. Truth Campaign advertisements influences their health beliefs related to cigarettes but not for LCCs. Other than point-of-sale, few other pro-tobacco advertisements for LCCs were reported. When asked about celebrity use, participants (n=18) specifically noted rappers, as social influences on LCC use.

Implications: Understanding reasons for use, how LCCs are used, the influence of social and physical environments, and the legalization of marijuana are important to address LCC use. Further understanding of how interventions and policies curtail the effect of socio-environmental influences on LCC use is warranted.

REDUCING THE HARM OF SMOKING AMONG HOMELESS SMOKERS IN A RANDOMIZED CONTROLLED TRIAL TARGETING CESSATION

Olamide Ojo-Fati, MD[1], Janet Thomas, PhD[2], Susan A. Everson-Rose, MPH, PhD[3], Rachel Isaksson. Vogel, Ph.D.[1], Gbenga Ogedegbe, MD[4], Kola Okuyemi, MD, MPH[1]

[1]University of Minnesota, Minneapolis, MN; [2]University of Minnesota, Mpls, MN; [3]University of Minnesota Medical School, Minneapolis, MN; [4]New York University Langone Medical Center, New York, NY

Background: Despite reduction in cigarette smoking in the general US population, smoking rates and related morbidity remain high among poor and underserved individuals, especially homeless adults. An estimated 70% of homeless adults smoke cigarettes. Many factors may contribute to the high smoking rates among homeless adults, including quality of life and other psychosocial factors, such as depression, anxiety and stress. These factors influence poor adherence and lack of self-efficacy to adopt behaviors that lead to better health outcomes. We conducted a randomized controlled trial (RCT) to enhance smoking cessation in a community of homeless persons who smoke. Only 7% of participants quit smoking by 26-week follow-up but many reported smoking less even if they had not quit. The focus of this secondary analysis was to examine predictors of smoking reduction, which is an important intermediate step toward complete cessation.

Methods: Data are from a RCT comparing standard care (nicotine replacement therapy; NRT) with standard care plus motivational interviewing among homeless smokers interested in quitting smoking. Smoking reduction was defined as at least 50% reduction in self-reported number of cigarettes smoked (past week) at 26-week follow-up visit compared to baseline. Those who did not complete the follow-up visit were assumed to have not reduced smoking. Demographic, psychosocial, tobacco-related, substance abuse and treatment adherence measures were compared between those who did and did not reducing smoking by 50%.

Results: Participants (N=430) were homeless, current cigarette smokers, predominantly Black (56.3%), male (74.7%), and, on average, 44.4 years old (SD=9.9). Most were unemployed (90.5%) and completed at least a high school education or equivalent (76.7%). A total of 268 (62.3%) participants reduced smoking by ≥50%; this included 32 who quit smoking. In multivariate analysis, smokers randomized to the intervention group (OR=1.59, 95% CI, 1.04-2.42) and those who smoked menthol cigarettes (OR=1.88, 95% CI, 1.06-3.32) were more likely to report reduced smoking by 26 weeks. Participants adherent to NRT at the end of

treatment were more likely to reduce/quit smoking (OR=2.08, 95% CI, 1.35-3.22) as were older smokers (OR=1.02, 95% CI, 1.00-1.05, for each year of age) and those with increased baseline depressive symptoms (OR=1.05, 95% CI, 1.02-1.09, for PHQ9≥10 versus < 10).

Conclusions: In this study, more than 7 times the number of participants reduced as quit completely. The intervention helped participants reduce their smoking but further research is needed to understand additional factors that predict reduction in the goal towards achieving cessation among homeless smokers.

RESPONSIVENESS OF YOUNG ADULTS TO STATE CIGARETTE EXCISE TAXES BY PSYCHOLOGICAL HEALTH

Allison M. Schmidt, MPH[1], Shelley D. Golden, PhD, MPH[2], Nisha C. Gottfredson, PhD[3], Kurt M. Ribisl, PhD[4], Susan Ennett, PhD, MSPH[5]

[1]Gillings School of Global Public Health, UNC Chapel Hill, Chapel Hill, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]UNC Gillings School of Global Public Health, Chapel Hill, NC; [4]UNC, Chapel Hill, NC; [5]Gillings School of Global Public Health, Chapel Hill, NC

Purpose: While smoking has significantly decreased among the general population in the past several decades, significant decreases in smoking have not been observed among those with poorer psychological health. One of the most effective tobacco control strategies to reduce smoking is raising cigarette prices through taxation to lower demand and consumption. However, we do not know whether this strategy is equally effective among young adults with poorer psychological health, a group with an especially high smoking rate of over 36%. The current research tests whether diagnosis of a psychiatric condition or amount of psychological distress affect the relationship between state cigarette tax rates and smoking over the period of young adulthood.

Methods: Repeated measures data of young adults' aged 18-30 smoking behavior and demographic information across years 2007, 2009, 2011, and 2013 were drawn from the Panel Study of Income Dynamics. Quarterly state tax data from the CDC's State System were linked to individual cases on state membership and interview date. Two outcomes were modeled: smoking status (current smoking: yes/no) using logistic regression and smoking amount among smokers (number of cigarettes per day) using linear regression. State-level fixed effects models were used to account for unobserved time-stable state characteristics that may affect taxes and smoking.

Results: Independent effects of psychological health were found such that poorer psychological health was associated with increased likelihood of being a current smoker and smoking greater numbers of cigarettes. However, few interaction effects of psychological health and taxes were found.

Conclusions: In many cases, psychological health did not affect the impact of taxes, suggesting that tax policies do not seem to be exacerbating a disparity in tobacco use. However, the effects of tax on smoking status and amount within individuals across young adulthood were small in general. These findings suggests that other intervention approaches should be explored to prevent and reduce smoking within individuals, in particular young adults with poorer psychological health, who are at increased risk of smoking at all and smoking more over time.

SELF-EFFICACY IN SMOKING RESTRAINT, BUT NOT MOTIVATION, PREDICTS POSTPARTUM SMOKING RESUMPTION AMONG WOMEN

Lisa J. Germeroth, Ph.D.[1], Rebecca Emery, MS[1], Rachel P. Kolko, PhD[2], Rachel H. Salk, PhD[3], Yu Cheng, PhD[1], Michele D. Levine, PhD[4]

[1]University of Pittsburgh, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]University Of Pittsburgh, Pittsburgh, PA

Introduction: Women commonly quit smoking during pregnancy, but most resume smoking within the first year postpartum. Low motivation to remain quit from smoking and low self-efficacy in maintaining abstinence are two factors that may contribute to resumption of smoking behavior postpartum. The present study assessed motivation and self-efficacy to stay quit as predictors of initial smoking lapse and full-blown relapse through 1 year postpartum. **Methods:** Three hundred pregnant, recently quit smokers (*M* age = 24.99, *SD* = 5.64 years) participating in one of two postpartum relapse prevention interventions completed a prenatal baseline session and follow-up sessions 12, 24, and 52 weeks postpartum. Participants completed measures of motivation to remain quit (Reasons for Quitting Questionnaire), self-efficacy in refraining from smoking (Self-Efficacy Questionnaire), and a Timeline Follow-Back interview of any smoking since delivery. The primary outcomes, time to lapse and time to relapse, were determined by counting the number of days between delivery and (a) the first day at least 1 cigarette was smoked (lapse) and (b) the first day of 7 consecutive days of smoking (relapse). **Results:** Cox regression analyses, adjusted for treatment group, number of weeks quit at baseline, age, race, and education, indicated that women with higher self-efficacy in refraining from smoking were less likely to lapse than women with lower self-efficacy at each postpartum follow-up (e.g., Week 52: HR = 0.99, 95% CI = 0.97-1.00, p = .01). Self-efficacy, however, did not predict relapse, and motivation was not predictive of time to lapse or relapse at any point through 52 weeks postpartum (all *p*s between .23 and .98). **Conclusions:** Self-efficacy in refraining from smoking consistently predicted smoking lapse through 1 year postpartum. This finding suggests that the efficacy of postpartum smoking cessation efforts may be improved by focusing on increasing prenatal self-efficacy to remain quit, especially given the stress of raising a child. Motivation did not provide unique predictive value, and further work is needed to understand how prenatal self-efficacy and motivation may interact to influence postpartum smoking behavior.

UNDERSTANDING ADOLESCENT E-CIGARETTE USERS: ATTITUDES, BELIEFS, AND SOCIAL NORMS

Jennifer P. Alexander, MSW, MPH[1], Peyton Williams, N/A[2]

[1]RTI International, Takoma Park, MD; [2]RTI International, Research Triangle Parl, NC

Background: Despite the rapid rise in youth using e-cigarettes, few studies have assessed knowledge, attitudes, and beliefs among youth who are regular users of these products. This study qualitatively explored reasons for initiation and current use, understanding of health effects, and social norms among users.

Methods: Four focus groups with 42 adolescents ages 14-17 were held in 2 cities. Participants were split into younger (ages 14 and 15) and older (ages 16 and 17) age segments and self-identified as regular users of e-cigarette products by indicating that they used these product every day or some days in the past 30 days. Focus groups were transcribed, coded, and analyzed using NVivo10.

Results: Youth reported enjoyable first experiences with e-cigarettes. Younger groups said that they were most interested in trying e-cigarettes because of flavors and because friends were using them. Most of these younger users reported that their first use of an e-cigarette was their first experience with a nicotine-containing product. Older youth reported that they were most interested in trying e-cigarettes because of the ability to perform tricks and for social aspects. Most used e-cigarettes with friends for the first time and continued use most often in social settings. Flavors, tricks, and social influences were the three most frequently mentioned reasons for continued use. Younger users shared devices and e-liquid with friends, often using devices belonging to older siblings, family members, or friends. Older users are more likely to choose and own their own device and buy their own e-liquid. Users overwhelmingly preferred tank devices. Youth were well-educated on nicotine and the health effects of nicotine, but younger users in particular were unsure whether their e-cigarette contained nicotine. Using an e-cigarette has not changed how participants felt about cigarettes – they think cigarettes are “gross” and “dirty”. Additionally, using an e-cigarette has not made exclusive use participants more curious to try a combustible; participants mentioned the commercials and anti-tobacco messages they’ve seen and heard. Overwhelmingly, e-cigarettes were seen by participants as having fewer negative health effects than combustible cigarettes, even while participants agreed that health effects of e-cigarettes are not yet known. Participants reported very little peer stigma to using e-cigarettes and limited negative reaction from family members, who often viewed e-cigarette use by

participants as acceptable when in comparison to potential or existing combustible cigarette use.

Conclusion: While youth enjoy using e-cigarettes, especially the flavors and ability to perform tricks, they are also aware of the negative health effects of nicotine and have heard very little about negative health effects. Findings regarding parental reactions to youth e-cigarette use and youth social norms should be considered when designing behavioral and educational interventions to prevent use by youth.
