Comorbidities, the bi-directional relationship of multiple disorders, have been well documented – especially for patients who suffer from mental illness. Co-occuring depression and heart disease are the major causes of disability worldwide. Unfortunately, mental illness is rarely detected and largely undertreated among patients who are treated for chronic disease, increasing the likelihood of poor overall health. Recently, efforts have been made to better assess depression and anxiety symptoms in the primary care setting in order to contribute to a holistic treatment approach, detect underlying mental illness early, and adjust treatment plans accordingly. Although evidence points to the complex relationship of mental illness and chronic disease, less is known about how mental illness might contribute to the presence of multiple disorders and vice versa. Using 2014 data from the nationally representative Health Information National Trends Survey, the aim of the current study was to test whether a diagnosis for depression or anxiety ("Has a doctor or other health professional ever told you that you had depression or anxiety disorder?") predict other disorders and how symptoms of mental illness contribute to poor overall health. Preliminary results from binary logistic regression analyses indicate a positive relationship between mental illness and the simultaneous presence of heart disease (OR=1.58, 95%CI=1.24-2.01), diabetes (OR=1.89, 95%CI=1.58-2.28), lung disease (OR=2.97, 95%CI=2.43-3.64), and arthritis (OR=2.34, 95%CI=1.99-2.75). Results further suggest that symptoms of anxiety ("over the past two weeks, how often have you been bothered by not being able to stop or control worrying?") in particular decreased a patient's perceived ability to take care of one's own health (OR=.41, 95%CI=.33-.51), reducing the likelihood of engaging in healthy lifestyle choices such as exercise and abstaining from smoking – reinforcing the cycle of poor health. Despite these vulnerability factors, an encouraging finding emerged. Comorbid patients are not less likely to seek professional help for medical issues – highlighting the urgent need for physicians to equip comorbid patients who seek treatment with tools to manage symptoms of mental illness alongside other disorders. Opportunities for improving patient-provider communication for patients managing both chronic disease and mental illness will be discussed.

CONFLICTING PRIMARY LANGUAGE AFFECTS PHYSICIAN-PATIENT RELATIONSHIP IN THE EMERGENCY DEPARTMENT

Brendan Swan, B.S.[1], Melinda Chang, M.S.[1], Chanel Rojas, AA[1], Beatrice Konrad, BA[1], Emily Cea, BS[1], Donald Edmondson, PhD, MPH[2]

[1]Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; [2]Columbia University Medical Center, New York, NY

Communication between physicians and patients during evaluation for acute coronary syndrome (ACS) in the emergency department (ED) is often challenging due to a number of factors. This communication is further complicated if the primary language of the physician does not match that of the patient. It has been shown that effective physician-patient communication is associated with decreased patient anxiety, fewer subsequent PTSD symptoms, and increased patient satisfaction. However, no study has tested whether discrepancy in primary languages of physician and patient negatively impact patient perceptions of communication quality.

We hypothesized that patients who report a different primary language than their ED physician perceive worse communication from that ED physician.

851 participants (mean age, 60.74 (SD, 13.1); gender, 54% female; ethnicity, 57% Hispanic) were enrolled as a part of the Reactions to Acute Care and Hospitalization (REACH) study, which recruits ED patients being evaluated for potential ACS. Participants then reported on the communication received from their ED physician using the physician sub-scale of the Interpersonal Processes of Care Survey (IPCS; 14 items, e.g., How often did the doctor use words that were hard to understand?"), as well as if their primary ED physician appeared to be a native speaker of their primary language. Age, sex, Global Registry of Acute Coronary Events (GRACE) cardiac risk score, and Charlson comorbidity score were included as covariates.

In a linear regression model predicting IPCS physician score [F(5,845)= 2.24, p< .05], physician-patient first language discrepancy was associated with significantly worse perceptions of communication quality (β= .11, p= .002). No other covariates were significantly associated with patient perceptions of communication quality.

Patients who report a different primary language than their ED physician report poorer perception of physician-patient communication. Prior research has shown that poor physician-patient communication is associated with risk for adverse psychological outcomes. Extra effort may be required to ensure that non-native speakers feel informed and cared for by their ED physicians.

DIGITAL STORYTELLING AS A TOOL FOR HEALTH MESSAGING ON AN AMERICAN INDIAN RESERVATION: A DEVELOPMENT PROCESS

Maja Pedersen, M.S.[1], Julia Malich, B.A.[1], Kari Harris, PhD, MPH[1], Brenda Bodnar, BS, RD, CDE[2], Mike Tryon, MS[3], Gyda Swaney, PhD[1], Sonja France, N/A[1], Blakely Brown, PhD, RD[1]

[1]University of Montana, Missoula, MT; [2]Confederated Salish and Kootenai Tribes, St. Ignatius, MT; [3]Salish Kootenai College, Pablo, MT

Introduction:
Digital stories offer a collaborative approach to health messaging, and can raise awareness among viewers on issues presented in stories. This study used an iterative, participatory process to produce and vet digital stories for increasing community awareness about strategies to improve child and family health on an American Indian (AI) reservation.

Methods:
We used a collaborative approach to develop digital story topics and content. This included input from the study leadership team, with members representing a tribal college, a tribal health organization, and a university. Story attributes, such as likability and cultural embeddedness of characters, identification with the storyteller, and language were included to increase influence on viewers' attitudes, beliefs, and behavior change. The advisory board and the tribal health and wellness committee were then engaged in a four-step, iterative process (view, evaluate, prioritize, and revise) to evaluate the story. The survey was adapted from a health promotion digital story evaluation study completed in rural Alaska. The twelve-item, closed ended, Likert-style survey explored community members' perspective on digital storytelling likability, intent to communicate with family and friends about the topics presented, cultural acceptability, and intent to change family health behavior. Viewers were asked to complete a written evaluation, then to share feedback and recommendations on how to make it more likeable, informative, and culturally relevant.

Results/Discussion:
A total of 22 community members viewed and evaluated the digital story. The viewers were mostly female (63%), mostly AI or Alaska Native (63%), and 50% were between the ages of 30-39. They reported liking the story (86%), feeling that it was a good way to learn about improving the health of their families (90%), and 90% felt digital stories are a culturally respectful way to receive health messages. Changes suggested by viewers included different

music, including kids' voices, and adding text to the screen to emphasize the message. Dissemination plans include social media outlets for the tribal college, tribal health organization, and a local hospital. Study findings suggest the four-step, iterative digital story development process may produce an effective health messaging tool for improving community awareness of child health, and that digital storytelling can be a likeable and culturally acceptable tool for health promotion.

ENHANCING SMOKING RISK COMMUNICATIONS: THE INFLUENCE OF HEALTH LITERACY AND MESSAGE CONTENT

Diana S. Hoover, PhD[1], David W. Wetter, Ph.D.[2], Damon J. Vidrine, PhD[3], Nga Nguyen, M.S.[1], Summer Frank, PhD[3], Yisheng Li, PhD[1], Andrew Waters, PhD [4], Cathy Meade, PhD, RN, FAAN[5], Jennifer I. Vidrine, PhD[3]

[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]University of Utah, Salt Lake City, UT; [3]Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma CIty, OK; [4]Uniformed Services University of the Health Sciences, Bethesda, MD; [5]Moffitt Cancer Center, Tampa, FL

Background: For nearly half of United States adults, difficulty with health literacy interferes with the capacity to find, process, and understand health information. Low health literacy is associated with higher smoking prevalence, established predictors of smoking, and relapse following smoking treatment. It has been suggested that risk communications and interventions intended to prevent smoking and promote cessation may not reach those with limited health literacy. Thus, it is critical that smokers with limited health literacy are provided with understandable information about the health consequences of smoking and the benefits of quitting. This study examined the influence of health literacy on smokers' responses to smoking health risk messages manipulated on framing (gain- vs. loss-framed) and emotionality (factual vs. emotional).

Method: Participants (N=402; 66% male; 70% Black; 27% <high school education; 70% < $10,000 total annual household income) were randomized to evaluate one of four sets of smoking health risk messages (factual gain-framed, factual loss-framed, emotional gain-framed, or emotional loss-framed). Multiple linear regression analysis was used to examine main effects of health literacy, message emotionality, and message framing on: 1) risk perceptions, 2) behavioral expectations (i.e., cut down, limit, quit), and 3) risk knowledge. Two-way interactions between health literacy and message emotionality and between health literacy and message framing were examined for these same outcomes.

Results: Smokers with higher health literacy reported significantly stronger risk perceptions and better knowledge retention regardless of message type. A significant main effect emerged for emotionality such that emotional (vs. factual) messages were associated with lower risk perceptions, regardless of level of health literacy. As hypothesized, significant two-way interactions emerged between health literacy and emotionality. Among smokers with lower health literacy, emotion-based messages produced both higher levels of perceived risk

and stronger expectations for quitting, whereas among smokers with higher health literacy, factual messages produced higher levels of these two outcomes.
Discussion: This study provides initial evidence that health literacy plays an important role in influencing how smokers respond to different types of messages. Findings suggest that a "one-size-fits-all" approach to communicating about the health risks of smoking may have limited impact. Thus, one's health literacy should be considered when determining whether smoking risk communications emphasize factual or emotional content.

LUNG SCREENING UNCERTAINTY AND NUMERACY PREFERENCES AMONG CURRENT AND FORMER SMOKERS

Daniel L. Hall, Ph.D.[1], Inga T. Lennes, MD[2], Alaina Carr, BA[3], Justin Eusebio, BA, MA[4], Elyse R. Park, PhD, MPH[5]

[1]Harvard Medical School/MGH/BIDMC, Wellesley, MA; [2]Massachusetts General Hospital Cancer Center, Newton, MA; [3]University of Colorado at Denver, Denvwr, CO; [4]Massachusetts General Hospital, Worcester, MA; [5]Massachusetts General Hospital, Boston, MA

Background: Lung cancer is the leading cause of cancer death in the U.S. and is highly attributable to smoking. Recent guidelines from the National Comprehensive Cancer Network and American Cancer Society recommend ongoing lung screening for current and former smokers (CS and FS) over the age of 55. Recently, Medicare began covering lung screening, but concerns remain about its accuracy and costs. Lack of clarity about screening intent and interpretation could undermine uptake of screening guidelines. This study thus aimed to characterize potential sources of lung screening uncertainty (LSU) and numeracy preferences among CS and FS.

Method: This observational, cross-sectional study examined self-report data obtained from CS and FS undergoing lung screening at a large academic medical hospital. Two items assessed LSU: clarity about purpose for referral (1=Not at all clear, 4=Extremely clear) and perceived accuracy of screening (1=Not at all, 5=Extremely). Numeracy preference was assessed with one item. Bivariate correlations examined demographic predictors of main variables. Group differences were analyzed by independent samples t-tests, Wilcoxon Z-tests, and odds ratios with 2-tailed Fisher exact tests.

Results: Respondents included 169 patients with a smoking history (88, 52.1% CS). CS and FS perceived lung screening to be moderately accurate [M_{total}=3.76, SD=.72]. Mean levels were similar between groups, *p*=.93. Clarity about the purpose for referral was high on average (M_{total} =3.88, SD=.66). Greater clarity was associated with more education (*r*=.31, *p*=.001) and receiving Medicare (*r*=.19, *p*=.048), but not smoking status (Z=1.72, *p*=.09). Preference for numbers in health-related information was associated with years of education (*r*=.25, *p*=.002) and smoking status. Specifically, FS were 2.5 times as likely to prefer numbers in health information compared to CS (P_{FS}=.56, OR=2.51, *p*=.005).

Discussion: We present preliminary evidence that lung screening patients tend to have favorable perceptions of the accuracy of the test and feel they understand the reason for their referral. Values were similar between CS and FS, but varied by insurance and education history. Notably, CS were significantly less likely than FS to favor numeric data. Taken together, findings offer potential targets for interventions aiming to reduce LSU and to tailor communication to suit numeracy preferences in the context of lung screening.

UNDERSTANDING AFRICAN AMERICAN FAMILY HEALTH HISTORY COMMUNICATION: YOUNG ADULT PERSPECTIVES

Sula Hood, PhD[1], Amy Irby-Shasnmi, PhD[2], Hadya Sow, BA (in progress)[1], Kyle Benbow, BA[1], Jasmine Deskins, BA[1], Elizabeth Adams, MPH[1], Lisa Robison, MPH[1]

[1]Indiana University-Purdue University Indianapolis Richard M. Fairbanks School of Public Health, Indianapolis, IN; [2]Indiana University-Purdue University Indianapolis Richard M. Fairbanks School of Public Health, Indianapolils, IN

Background: Family health history (FHH) is the strongest known risk factor for many chronic diseases. Ethnic minorities have been found to have a low awareness of their FHH, which may pose a contributing factor to health disparities. To date, most research seeking to understand FHH sharing within African American families has been limited to the perspective of older adults. However, it is imperative to also gain African American young adults' perspectives, as they function as the ideal recipients of FHH information from older generations.

Purpose: This poster will present findings from a qualitative study designed to understand African American young adults' perspectives regarding FHH sharing.

Methods: We conducted semi-structured individual interviews with African American males and females, ages 21-35. Interview questions assessed each participant's 1) perceptions about the importance of FHH, 2) ability to define the phrase "FHH," 3) knowledge of his or her maternal and paternal family health histories, and 4) perceptions about health communication practices in his or her immediate family, including frequency of health-related conversations and health topics most and least discussed. We also assessed participants' perceived quality of their immediate familial relationships, as well as their interest in learning more about FHH. Demographic characteristics were collected via written survey.

Results: A total of 38 (16 males, 16 females) African American young adults completed interviews. Mean participant age was 28.5. Most participants were single (63.9%), and had a college degree (41.7%) or higher (38.9%). During the semi-structured interviews, most participants indicated that they perceived FHH to be very important, and wanted to learn more about FHH. Most were able to correctly define the phrase FHH. Most participants discussed having knowledge of their FHH, though many seemed to know more about their maternal FHH than their paternal, particularly when they had a strained relationship with their father. Mothers and grandmothers were the most commonly mentioned sources for providing FHH information. Relatives who worked in healthcare were frequently identified as

FHH information disseminators. We observed mixed responses regarding the frequency of health-related discussions within families, as some participants indicated that their families discuss health often, while others indicated that health is rarely discussed. Nutrition was described as a frequently discussed health topic within families, while mental illness was described as health topic that is avoided.

Conclusion: African American young adults value FHH and want to learn more about it. Future efforts should focus on assisting young adults with strategies to collect both their maternal and paternal FHH, and should also provide them with strategies to initiate FHH discussions.

ARE YOU COVERED? EXAMINING HOW KNOWLEDGE OF THE AFFORDABLE CARE ACT INFLUENCES USE OF PREVENTIVE REPRODUCTIVE HEALTH SERVICES

Ashlee Sawyer, MS[1], Eric Benotsch, PhD[2]

[1]Virginia Commonwealth University, RIchmond, VA; [2]Virginia Commonwealth University, Richmond, VA

The Patient Protection and Affordable Care Act (PPACA) expanded access to insurance coverage and health care services for many citizens, and has increased access for women in particular by including preventive reproductive health services as essential health benefits. The current national rates of sexually transmitted infections (STIs) and reproductive cancer diagnoses serve as major areas of concern for women's health and public health. The present study examined how knowledge of the PPACA influences receipt of preventive reproductive health services among women (e.g., STI screening, breast exams). Women aged 18-44 (N=1083) from across the United States completed online questionnaires assessing demographics, insurance status, preventive service use, and knowledge of the provisions of the PPACA. A substantial portion of participants reported using preventive reproductive health services (73.8%, N=799), including pelvic exams, breast exams, well woman's visits, and STI testing. A hierarchical logistic regression was performed to determine the independent relationship between knowledge of the PPACA and use of preventive reproductive health services after controlling for demographic factors (age, racial/ethnic status, relationship status, education level, and income) and insurance status. Knowledge of the provisions of the PPACA focused on preventive health services was associated with use of preventive reproductive health services after controlling for these factors (OR=1.155, 95% CI = 1.021, 1.306, B=.144, SE=.063, $p < .05$). Results indicate that higher levels of knowledge of the PPACA are associated with a greater likelihood of receiving cancer and STI screenings. The current findings provide support for an increase in funds and resources to outreach and education of the general population about the provisions and benefits of the PPACA, as well as individuals' personal health coverage plans.

CAN BIG MEDIA DATA REVOLUTIONIZE GUN VIOLENCE PREVENTION?

John Ayers, PhD MA

http://www.johnwayers.com/, Chula Vista, CA

The scientific method drives improvements in public health, but a strategy of obstructionism has impeded scientists from gathering even a minimal amount of information to address America's gun violence epidemic. We argue that in spite of a lack of federal investment, large amounts of publicly available data offer scientists an opportunity to measure a range of firearm-related behaviors. Given the diversity of available data – including news coverage, social media, web forums, online advertisements, and Internet searches (to name a few) – there are ample opportunities for scientists to study everything from trends in particular types of gun violence to gunrelated behaviors (such as purchases and safety practices) to public understanding of and sentiment towards various gun violence reduction measures. Science has been sidelined in the gun violence debate for too long. Scientists must tap the big media datastream and help resolve this crisis. To demonstrate this value we will present rich analyses of web searches and Twitter posting for one year describing data driven conclusions from these data.

INTERVIEWS OF SUNLESS-ONLY TANNING BUSINESS OWNERS

Jessica Oleski, MA[1], Alexa R. Choquette, N/A[2], Joel Hillhouse, PhD[3], Sherry Pagoto, PhD[1]

[1]University of Massachusetts Medical School, Worcester, MA; [2]UMass Medical School, Bolton, MA; [3]East Tennessee State University, Johnson City, TN

Indoor tanning is a group 1 carcinogen along with tobacco, radon, and arsenic. Fourteen states have passed a ban on indoor tanning in minors and the FDA is considering a ban on indoor tanning at the federal level. A frequently occurring argument against banning indoor tanning is that bans will negatively impact small business owners. A counterargument is that tanning businesses could remain viable by providing non-UV alternatives (i.e., spray/airbrush tanning) to clientele who desire a tan. The purpose of our study was to interview sunless-only business owners about their clientele, reasons for offering only sunless tanning, what their clients like about sunless tanning, and about perceived threats to their business.

Participants were 15 sunless tanning business owners in the New England area including brick and mortar salons (n=10; 5 also offered mobile services) and mobile-only businesses (n=5). On average, owners reported being in business for 5 years (sd=3). None reported ever offering or intentions to offer indoor tanning as a service. The cost of a service ranged from $20-$75, discounts offered for packages. Owners said clients visit them on average 2 times per month (sd=1) and that clients are mostly female ages 20-55. Owners estimated that on average 72% (sd=23, range 20-99) are former indoor tanners and switched to sunless and 26% (sd=29, range 0-90) currently use indoor tanning, which doesn’t include all clients since some may not have used indoor tanning at all. When asked what their clients like about sunless tanning, 86% said clients liked the quality of the product (e.g., color of tan), 73% said clients liked that it took less time than indoor tanning to achieve a tan, and 53% said clients liked that it was a healthy alternative to tanning beds. Threats to business included other sunless-only competition (40%), negative experience with sunless products (e.g., orange color) (20%), UV-based competition (13%), and overhead costs (13%). All owners interviewed supported bans on indoor tanning for minors.

Sunless tanning services appear to attract indoor tanners, former indoor tanners, and never indoor tanners which would seem to be a potentially larger customer base than indoor tanners. Product quality, quicker results than indoor tanning, and lack of health risks appear to be selling points for sunless tanning over indoor tanning.

THE EFFECTS OF AGE AND COMORBIDITY ON THE LIKELIHOOD OF TRAUMATIC BRAIN INJURY PATIENTS HIRING A HEALTH CARE ADVOCATE

Lauren E. McKinley, Student[1], Laura Y. Alcaraz, N/A[1], Symone McKinnon, Bachelors of Arts in Psychology[2], Terry A. Cronan, Ph.D.[1]

[1]San Diego State University, San Diego, CA; [2]San Diego State University, La Mesa, CA

Approximately 1.7 million people experience a traumatic brain injury (TBI) in the United States each year and about 53,000 will die from TBI-related causes. The treatment options for a TBI vary depending on severity. Patients often have complex and continuous treatment plans, especially those who are older and have a comorbid health condition. A health care advocate (HCA) is a trained professional who can help ensure patients optimize their treatment outcomes by providing advisory and supportive services that simplify the navigation of the healthcare system. The present study was conducted to determine whether age and comorbidity (type 2 diabetes) predicted the perceived likelihood of hiring an HCA for those with a TBI. It was hypothesized that being older and having a comorbid health condition would predict a greater perceived likelihood of hiring an HCA. Participants were 441 randomly selected community members, asked to complete a self-report questionnaire. A two (comorbidity) by three (age) between subject's analysis of variance was performed on the mean perceived likelihood of hiring an HCA. A significant main effect was found for age, $F(2, 435) = 5.188$, $p = 0.006$. A post-hoc Gabrielle's test revealed that the perceived likelihood of hiring an HCA was greater for 90 years old than 30 years old ($p = 0.006$) but not 60 years old. No significant differences were detected between 30 years old and 60 years old in the perceived likelihood of hiring an HCA. Comorbidity did not significantly predict the perceived likelihood of hiring an HCA. These results indicate that older individuals who have sustained a TBI report a greater perceived likelihood of hiring an HCA than do younger individuals who have sustained a TBI. These findings may help various health care advocacy organizations identify the specific populations most interested in using their services. Additional research is necessary to determine the ways in which HCAs are able to help individuals who have sustained TBIs receive optimal care and improve their overall wellbeing.

AN EXPLORATION OF SOUTHERN FAITH LEADERS' PERSPECTIVES OF SEXUALITY AND SEXUAL HEALTH TEACHINGS

Latrice Pichon, PhD, MPH[1], Terrinieka W. Powell, PhD[2], Idia B. Thurston, PhD[3], Trisha Arnold, BS[4], Siri A. Ogg, BA, MS[1], Andrea Williams Stubbs, MPA[5], Nicole Becton-Odum, N/A[6]

[1]University of Memphis School of Public Health Division of Social and Behavioral Sciences, Memphis, TN; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]University of Memphis, Memphis, TN; [4]University of Memphis Department of Psychology, Memphis, TN; [5]St. Jude Children's Research Hospital, Memphis, TN; [6]Restoring Lives through Christ, LLC, Meridian, MS

A critical objective of the National HIV/AIDS Strategy is reducing HIV disparities in the South. This paper describes findings from a qualitative study of southern Black faith leaders regarding sexuality and sexual health teachings in their predominantly Black congregations in Memphis, TN. An HIV coalition, faith-based non-profit, and university partnered to conduct four focus groups using a semi-structured discussion guide. Faith leaders, aged 18 or older, who minister to predominantly Black congregations were eligible to participate. Each focus group was transcribed and then two investigators independently coded the data. The final sample included 26 faith leaders with a mean age of 54. A broad range of denominations was represented in the sample with over half being Baptist. Three themes emerged to describe perspectives of sexuality and sexual health teachings among southern Black faith leaders: (1) restricted by scripture, (2) problematic silence, and (3) tackling multiple stigmas. Churches have been involved in HIV prevention efforts for three decades; however, few community-academic partnerships have explored sexuality and sexual health teachings in southern churches using a participatory approach. These results will benefit researchers when developing faith-based interventions and help facilitate HIV prevention efforts in southern churches.

COGNITIVE BEHAVIORAL THERAPY FOR BODY IMAGE AND SELF-CARE IN SEXUAL MINORITY MEN LIVING WITH HIV: A RANDOMIZED CONTROLLED TRIAL

Aaron Blashill, Ph.D. [1], Steven A. Safren, PhD[2], Sabine Wilhelm, PhD[3], Jonathan Jampel, N/A[4], Wade Taylor, PHD[5], Conall O'Cleirigh, PhD[6], Kenneth H. Mayer, MD[7]

[1]San Diego State University, San Diego, CA; [2]Department of Psychology, University of Miami, Coral Gables, FL; [3]MGH/Harvard Medical School, Boston, MA; [4]Clark University, Worcester, MA; [5]Wheelock College, Boston, MA; [6]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [7]Fenway Health, Boston, MA

Objective: Body image disturbance is a distressing and interfering problem among many sexual minority (e.g., gay and bisexual) men living with HIV, and is associated with elevated depressive symptoms, and poor HIV self-care (e.g., antiretroviral therapy (ART) non-adherence). However, no known interventions exist that address body image disturbance and ART adherence among this population. Thus, the current study tested the preliminary efficacy of a newly created intervention: cognitive behavioral therapy body image and self-care (CBT-BISC) for this population.

Methods: The current study was a two-arm randomized controlled trial (N = 44) comparing CBT-BISC to an enhanced treatment as usual (ETAU) condition. Analyses were conducted at post-treatment (3 months post-baseline) and follow-up (6 months post-baseline). The primary outcome was body image disturbance, and secondary outcomes were ART adherence (electronically monitored via Wisepill), depressive symptoms, and global functioning.

Results: At post-treatment, the CBT-BISC condition showed substantial improvement in body image disturbance (B = -13.6, SE = 2.7, 95% CI: -19.0, -8.3, $p < .001$; d= 2.39), depressive symptoms (B = -4.9, SE = 2.8, 95% CI: -10.6, .70, p = .086; d= .87), ART adherence (B = 14.7, SE = 4.9, 95% CI: 5.2, 24.3, p = .003; d= .94), and global functioning (B = 12.3, SE = 3.2, 95% CI: 6.1, 18.6, $p < .001$; d= 2.91). Results were generally maintained, or improved, at 6-month follow-up.

Conclusions: CBT-BISC shows preliminary efficacy in the integrated treatment of body image disturbance and HIV self-care behaviors among sexual minority men living with HIV.

CURVILINEAR ASSOCIATION OF DEPRESSION WITH SEXUAL RISK BEHAVIOR AMONG HIV-INFECTED MEN WHO HAVE SEX WITH MEN

Jacklyn Babowitch, B.S.[1], Peter A. Vanable, PhD[1], Shannon M. Sweeney, PhD[2]

[1]Syracuse University, Syracuse, NY; [2]Le Moyne College, Kirkville, NY

Depression is highly prevalent among HIV+ men who have sex with men (MSM) and may contribute to risky health behaviors. However, research linking depression to sexual risk among HIV+ MSM has yielded mixed findings, and has focused primarily on documenting the linear association of depressive symptoms to elevated rates of unprotected anal intercourse (UAI). In this study, we test the hypothesis that depressive symptoms will show a curvilinear association to UAI, such that depression will be more strongly linked to risky sex in HIV+ MSM with moderate levels of depression. HIV+ MSM recruited during outpatient medical care (*N* = 96*, M* age = 44, 57% Caucasian) completed the Center for Epidemiological Studies – Depression Scale (CES-D) and self-report measures of sexual risk behaviors. The primary study hypothesis concerning the nonlinear association of depression to sexual risk was tested using logistic regression models in which CES-D scores were entered into Model 1, and both CES-D and squared CES-D terms were included in Model 2. Participants reported high levels of depressive symptoms (*M* = 20.15, *SD* = 12.94), and 34% reported at least one instance of UAI in the last three months. Neither model explained any variance in UAI with a primary partner. For encounters involving a casual partner, CES-D scores were not associated with UAI at the last occasion of sex in model 1. However, CES-D (*b* = .28, *SE* = .12, *p* = .02) and squared CES-D terms (*b* = -.005, *SE* = .002, *p* = .04) in model 2 were significantly associated with UAI at the most recent sexual episode. Similarly, CES-D scores were not associated with any instances of UAI for the previous three-months in model 1. However, when CES-D (*b* = .21, *SE* = .09, *p* = .02) and squared CES-D terms (*b* = -.004, *SE* = .002, *p* = .03) were entered into model 2, both were significantly associated with instances of UAI. Further, a comparison of model chi-square values indicated that model 2 fit the data better than model 1 with regard to UAI at the most recent sexual episode (c^2= 2.32, *p* = .13 versus c^2= 7.98, *p* = .02) and for the last three months (c^2= .04, *p* = .53 versus c^2= 7.30, *p* = .03). In this sample of HIV+ MSM, findings confirm a curvilinear relationship between depression and sexual risk-taking. Treating depressed mood in HIV+ MSM may not only improve mental health functioning, but also lead to reductions in sexual transmission risk.

DEVELOPING AND EVALUATING EHEALTH VIDEO TO INCREASE HIV TESTING AMONG HARLEM AREA PATIENTS WHO INITIALLY DECLINE

Ian David. Aronson, Ph.D.[1], Alex S. Bennett, PhD; MPA; MS[2], Honoria Guarino, PhD[3], Lisa Marsch, PhD[4], Theodore Bania, MD,MS[5]

[1]NDRI, Inc., New York, NY; [2]National Development and Research Institutes, Inc, New York, NY; [3]National Development and Research Institutes, Inc., New York, NY; [4]Dartmouth College, Lebanon, NH; [5]Icahn School of Medicine at Mt Sinai, NY, NY

Undiagnosed HIV remains a significant problem in the United States. Many of those most at risk may have limited access to primary care, testing, and related health education. Despite federal recommendations of routine HIV testing in all healthcare settings, many emergency department (ED) patients are not offered HIV testing, and among those who are offered testing far more decline compared to those who accept.

In a recent trial of a tablet-based eHealth intervention designed to increase HIV testing among ED patients who declined HIV tests offered by hospital staff (N=300), roughly 30 percent agreed to an HIV test after watching a brief (< 2 minute) video. The videos were developed in accordance with the Information, Motivation, Behavioral Skills model, and the intervention randomized participants into groups shown different videos to examine which would be more efficacious. Videos depicted either a young, male African American doctor describing the importance of HIV testing to an African American male patient, or a young male African American community member who discloses that he is HIV positive on camera and urges participants to test. Although test rates did not differ by treatment group or participant race, qualitative interviews with patients (n=40) in the Harlem-are hospital where data were collected indicate differing responses to the videos. Most interviewed participants responded strongly in favor of the community member, yet some White and Asian patients used words like “stereotypical” to describe the community member’s appearance (he wore his own clothing in the video and styled himself). African American and Latino participants spoke highly of the community member and largely did not mention his physical appearance. Results indicate patient populations may have very different reactions, by demographic group, to the same intervention video. Further research is warranted to optimize videos to further increase patient acceptance and to better facilitate behavior change (e.g. HIV testing among patients who initially decline) among those most at risk.

IMPAIRED PERFORMANCE ON THE HIV-DEMENTIA SCALE PREDICTS SURVIVAL OVER UP TO THIRTEEN YEARS

Nikhil Banerjee, B.A.[1], Gail Ironson, M.D., Ph.D[1], Bonnie Levin, Ph.D[2]

[1]University of Miami, Coral Gables, FL; [2]University of Miami Neuropsychology Division, Miami, FL

Objective: There is a lack of empirical evidence linking HIV-associated neurocognitive impairment (NCI) with mortality in the era of widespread antiretroviral (ARV) medication availability. This study sought to examine whether global NCI, as defined by the HIV-Dementia Scale (HDS), was associated with mortality among patients predominantly in the midrange of their illness.

Methods: Between 1997 and 2001,210 HIV-positive men and women (M_{CD4} = 323.02 cells/mm^3; M_{age} = 37.69; 72% male; 67% attending some college or more; 31% non-Hispanic White, 35% non-Hispanic African American, and 30% Hispanic) were recruited, administered the HDS, and followed for up to 13 years (1997-2010). Subjects were excluded if they had ever experienced an AIDS-defining illness or had baseline CD4 cell counts outside the range of 150-700 cells/mm^3, in order to capture individuals predominantly in the mid-range of their illness (92% had CD4 cell counts between 150 and 500 cells/mm^3). Subjects were dichotomously classified as either “impaired” (HDS$\leq$10) or “unimpaired” (HDS > 10). Cox proportional hazard regression analysis was used to test whether global NCI predicted survival.

Results: Thirty-six (17%) subjects scored in the impaired range at baseline, and 59 subjects (28%) died during the study’s follow-up period. Participants scoring in the impaired range at baseline were significantly more likely to die during the study period compared with their unimpaired counterparts (HR: 2.06; 95% confidence interval, 1.09, 3.90) controlling for age, sex, race, education, and baseline CD4 cell count, viral load, and antiretroviral medication status.

Conclusion: These findings demonstrate that the HDS can be utilized as brief screening measure that offers potential prognostic utility for assessing mortality risk in HIV-positive adults during the era of AVR availability. Subjects scoring in the impaired range on the HDS faced two times the risk of dying compared with non-impaired subjects during the 13-year study period. This was independent of demographics and key illness variables previously associated with mortality (i.e., disease status and ARV treatment status at study entry). These

data also add to the literature linking NCI with mortality in HIV, especially among patients in the mid-range of their illness, during the era of ARV medication availability.

INCARCERATION, SEXUAL BEHAVIORS, AND HIV INFECTION AMONG WOMEN AT INCREASED RISK OF HIV INFECTION, 20 UNITED STATES CITIES

Akilah Wise, PhD, Teresa Finlayson, PhD, Lina Nerlander, BMBCh, Catlainn Sionean, PhD, Gabriela Paz-Bailey, PhD

Centers for Disease Control and Prevention, Atlanta, GA

Background: Women who are involved in the criminal justice system experience multiple risk factors that increase the likelihood of acquiring HIV infection. We evaluated the prevalence of incarceration and compared behaviors among women with and without a history of incarceration.

Methods: We used data from the 2013 National HIV Behavioral Surveillance system in 20 cities among heterosexuals at increased risk for HIV infection. Participants completed a survey and were tested for HIV infection. We evaluated the association between incarceration and the following past 12 months outcomes: exchange sex, multiple (≥3) casual sex partners, and multiple (≥3) casual condomless sex partners. We also evaluated associations of incarceration with HIV prevalence and with last partner characteristics (ever injected drugs, ever used crack/cocaine, ever incarcerated). Log-linked Poisson regression models, adjusted for demographics and clustered on recruitment chain, with generalized estimating equations were used to estimate adjusted prevalence ratios (aPR) and 95% confidence intervals.

Results: Of 5,154 women, 11% were incarcerated within the previous year, 36% were ever incarcerated but not in the past 12 months, and 53% were never incarcerated. Prevalence of exchange sex (aPR 1.32, 1.20 – 1.46), multiple casual partners (aPR 1.59, 1.2 – 2.1), multiple casual condomless partners (aPR 1.47, 1.07 – 2.03), and HIV infection (aPR 1.66, 1.09 – 2.52) were all higher among recently incarcerated women compared to those never incarcerated. Recently incarcerated women were more likely to have a last partner who injected drugs (aPR 2.05, 1.66 – 2.53), used crack/cocaine (aPR 2.08, 1.79 – 2.41) and had himself been incarcerated (aPR 1.39, 1.29 – 1.50).

Conclusions: Nearly half of women in our study had been incarcerated. Recent incarceration was associated with several sexual risk behaviors and partner characteristics that increase the risk of HIV. Incarcerated women were also more likely to be HIV-positive. HIV prevention, testing, and early treatment among women with a history of incarceration can maximize the effectiveness of the public health response to the HIV epidemic.

LIPODYSTROPHY AND BODY CHANGE DISTRESS IN OLDER WOMEN WITH HIV

Greer A. Raggio, PhD, MPH[1], Gregory Robbins, MD[1], Elyse R. Park, PhD, MPH[1], Sara Looby, PhD[1], Steven A. Safren, PhD[2], Christina Psaros, PhD[3]

[1]Massachusetts General Hospital, Boston, MA; [2]Department of Psychology, University of Miami, Coral Gables, FL; [3]Massachusetts General Hospital/Harvard Medical School, Boston, MA

Background: HIV and some antiretroviral drugs are associated with lipodystrophy, an abnormal redistribution of body fat marked by increased abdominal adiposity and/or loss of subcutaneous fat stores. Other risk factors include older age, genetic factors, and longer treatment duration, making this issue salient to those living with HIV for long periods. Lipodystrophy is associated with body image dysphoria, decreased quality of life, and lower adherence to HIV treatment.

Objectives: (1) To describe body change and related distress, and (2) to examine associations among body change distress, depression, and health among older women living with HIV.

Methods: Data were collected as part of a cross-sectional study examining psychosocial concerns of older women with HIV. Participants (*N*=64) completed a demographic survey and self-report measures of HIV-related body change, depression, and health status. Independent samples *t*-tests and Pearson's *r* correlations were calculated.

Results: Average age was 52.4 years (*SD*=6.3), 58.7% were African American/Black, and 34.9% had < high school education. Mean time since diagnosis was 13.6 years (*SD*=7.3). Among those reporting current HIV treatment (*n*=60), common body changes included increased belt/waist size (57.6%), decreased fat in the buttocks (35.6%) and arms/legs (30.5%), sunken cheeks (29.3%), and fat deposits in the neck (23.7%). Women reporting more body change distress reported significantly more depressive symptoms (*r*=.581, *p*r=.427, *p*=.001). Increases in belt/waist size were significantly associated with higher depression scores (*t*[57]=2.33, *p*=.023).

Conclusions: Fat redistribution, particularly increased abdominal adiposity, was common in this sample of older women living with HIV, and was associated with more severe depressive symptoms. Women endorsing body change distress also noted worse physical pain. It is imperative to develop interventions for this population given the growing number of aging women with HIV and the relation between lipodystrophy and health outcomes. Interventions

that combine aspects of depression/chronic pain management and physical activity promotion may hold promise.

NATIONAL HIV BEHAVIORAL SURVEILLANCE AMONG MEN WHO HAVE SEX WITH MEN IN THE US:A COMPARISON OF WEB-BASED AND VENUE-BASED SAMPLES

Yen-Tyng Chen, PhD[1], Kristina Bowles, MPH[2], Qian An, PhD[2], Elizabeth DiNenno, PhD[2], Teresa Finlayson, PhD[2], Brooke Hoots, PhD[2], Gabriela Paz-Bailey, PhD[2], Cyprian Wejnert, PhD[2]

[1]Centers for Disease Control and Prevention, Decatur, GA; [2]Centers for Disease Control and Prevention, Atlanta, GA

Objectives: To describe the difference in sociodemographic characteristics and risk behaviors between men who have sex with men (MSM) recruited using two different approaches: web-based (WB) and venue-based (VB) sampling.
Methods: We compared the 2012 Web-based HIV Behavioral Survey (WHBS), which recruited MSM online (e.g., direct marketing on Facebook), and the 2011 National HIV Behavioral Surveillance (NHBS), which sampled MSM from physical MSM venues. Chi-square tests were used to compare sociodemographic characteristics. Poisson regression with generalized estimating equations were used to estimate prevalence ratios for each behavioral outcome adjusting for sociodemographic characteristics.
Results: There were 3221 WB and 9256 VB sexually active MSM included in analyses. Compared to the VB sample, the WB sample was slightly older, less likely to be black or Hispanic and from the South, and more likely to have higher income, more education, and health insurance. WB MSM were *more* likely than VB MSM to self-identify as gay/homosexual (aPR=1.05, CI: 1.03-1.07), ever socialize on the Internet (aPR=1.19, CI: 1.15-1.24), have met their last partner online (aPR=2.41, CI: 2.24-2.59), have anal intercourse without a condom with last male sex partner (aPR=1.21, CI: 1.15-1.29). The WB MSM were significantly *less* likely to have multiple male sex partners (aPR=0.92, CI: 0.88-0.96), inject drugs (aPR=0.60, CI: 0.47-0.78), test for HIV in the past 12 months (aPR=0.82, CI: 0.79-0.85), report HIV-negative status (aPR=0.95, CI: 0.93-0.97), receive free condoms (aPR=0.86, CI: 0.81-0.92), and experience physical assault (aPR=0.86, CI: 0.81-0.92) than VB MSM.
Conclusions: WB MSM were less likely to be minority MSM and had higher SES status. We also found differences in sexual and drug using behaviors and HIV testing. The method for recruiting MSM into a behavioral survey should consider the segment of MSM to be reached.

PATIENT-LEVEL BARRIERS AND FACILITATORS OF CERVICAL CANCER SCREENING AMONG HIV-POSITIVE WOMEN IN INDIA

JK Kosambiya, M.D.[1], Vipul Chaudhari, M.D.[1], Apurva Barve, M.A.[2], Janna Gordon, M.S. [3], Ambuj Kumar, M.D., MPH[4], Sukesha Gamit, M.D.[1], Kristen Wells, Ph.D., MPH[5]

[1]Department of Community Medicine (PSM), at the Government Medical College, Surat, Surat, Gujarat, India; [2]University of California, Los Angeles, Los Angeles, CA; [3]SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; [4]Morsani College of Medicine, University of South Florida, Tampa, FL; [5]San Diego State University, San Diego, CA

Although the risk of cervical cancer (CC) is higher in women living with human immunodeficiency virus (HIV), there is no national policy for CC screening in India. Thus, many women living with HIV in India do not get regular CC screening. Based on the Social Ecological Model, this novel qualitative study evaluated patients' and health care providers' perceptions of patient-level factors associated with receipt of CC screening among women living with HIV. Using a standardized guide, in-depth interviews were conducted with 25 women living with HIV (mean age: 37.2 years) and 15 health care providers (mean age: 36.1 years; 66.6% female) recruited from New Civil Hospital in Surat, India. Interviews were audio recorded, transcribed verbatim, translated if necessary, and analyzed using content analysis. Participants noted that women with HIV were generally motivated to stay healthy but had significant gaps in understanding of CC and CC screening. Fear of obtaining the Pap test and its results were also noted by some participants as barriers. Some participants indicated that it was difficult for women to take time away from family, work, or household responsibilities, and this made it difficult to get CC screening. Finally, most interview participants stated that women were very interested in learning more about CC screening. Results obtained from this study, combined with data assessing organizational, interpersonal, community, and societal barriers and facilitators to CC care, will be used to develop intervention strategies to assist women living with HIV in getting CC screening

BEHAVIORAL HEALTH INTEGRATION IN 3 PRIMARY CARE CLINICS: QUALITATIVE EVALUATION & STORIES FROM THE FRONT LINES

Julie E. Richards, MPH[1], Amy K. Lee, MPH[2], Paula Lozano, MD, MPH[2], Carol Achtmeyer, MN, ARNP[2], Emily Williams, PhD, MPH[3], Santino Telles, MA[4], Jessica Ridpath, BA[2], Caldeiro M. Ryan, MD[5], Ludman J. Evette, PhD[2], Rebecca L. Parrish, MSW, LICSW[6], Kathy A. Bradley, MD, MPH[2]

[1]Group Health Research Institute and University of Washington Department of Health Services, Seattle, WA; [2]Group Health Research Institute, Seattle, WA; [3]VA Puget Sound Health Services Research & Development and University of Washington Department of Health Services, Seattle, WA; [4]Group Health, Northgate Medical Center, Seattle, WA; [5]Group Health Behavioral Health Services, Seattle, WA; [6]Group Health Behavioral Health Support Services, Seattle, WA

Background

Health care systems nationwide are implementing routine behavioral health screening, including screening for depression and substance use, in response to mounting evidence supporting benefits of integrating behavioral health in primary care. Between 3/2015 and 3/2016, 3 pilot primary care clinics in a large Pacific Northwest health care system sequentially implemented behavioral health integration [BHI]. This included routine screening and diagnostic assessment for depression, alcohol, marijuana and drug use, and same-day referrals to social workers [LICSWs] for patients with acute care needs (i.e. suicide risk, substance-use issues). Screening rates increased from 14-35% for depression and 5-13% for substance use, prior to BHI, to 60-82% for both, following BHI. This qualitative study evaluated the multi-pronged implementation strategy.

Methods

We used the Greenhalgh Model for diffusion of innovations to assess barriers to and facilitators to behavioral health screening and assessment, two key elements of BHI. The implementation strategy included: use of automated electronic health record [EHR] systems to prompt and document care, partnership between front line clinical operations and a leadership team, and tools that explicitly addressed frontline staff attitudes and skills. Research team members assessed barriers and facilitators to implementation in weekly formative evaluation meetings.

Results

Facilitators of successful implementation included: perceived value of the screening, diagnostic assessments and EHR tools/prompts by clinicians (*Innovation*), hands-on participation in implementation by frontline staff (*Linkage*), and use of LICSWs to provide same-day behavioral health care (*Resources*). Barriers included: fragmented clinic communication and work flow, clinic quality improvement process limitations (*Infrastructure*), and competing priorities for clinicians' time during the patient visit (*Readiness*).

A key facilitator was sharing stories from frontline staff *adopters* with new sites. For example, one MA described, "*When we were first approached about BHI, we all thought 'oh, more paperwork, more work for us…' it turned into this very powerful role, making us feel like it's not just about paperwork, it's us being allowed to get closer to the patient... I am able to be a big part of somebody's betterment. It's rewarding on such a deep level.*" Other stories included identification of heavy alcohol use by a diabetic man at risk of a second foot amputation, and acutely suicidal patients being treated for other common conditions (e.g. influenza, wart removal).

Conclusion

This study identified key facilitators and barriers of BHI implementation in 3 clinics in which these strategies were piloted. Findings were used to refine the implementation strategy for the health care system.

SLEEP PROBLEMS ARE RELATED TO POOR MEDICATION ADHERENCE AMONG YOUNG ADULTS

Lauren Strainge, M.A., Dean Cruess, PhD

University of Connecticut, Storrs, CT

Suboptimal medication adherence is common among individuals with chronic medical conditions, and is also associated with poorer health outcomes, decreased quality of life, and increased morbidity and mortality. For emerging young adults, transition to college and corresponding increases in independence are associated with declines in medication adherence. College students are also likely to report insufficient and significantly disrupted sleep patterns, which has been shown to increase risk for medication non-adherence in middle-aged and older adults. The purpose of this study was to examine the relationship between sleep quality and daily medication adherence among a representative sample of college students. We sampled 785 undergraduates at a large state university (mean age = 18.89; 84% female; 28% non-white) who were prescribed a daily medication (including oral contraceptives) and had them complete an online cross-sectional survey assessing self-reported sleep patterns and medication adherence. Sleep was assessed using the Pittsburgh Sleep Quality Index, and medication adherence was assessed using the Morisky Medication Adherence Scale. Results showed that 78.4% of participants reported ‘fairly bad’ or ‘very bad’ sleep quality over the past month, and 72.6% reported problems with medication adherence. Pearson's correlation coefficients were calculated to determine the relationships between sleep quality, hours of sleep, and daytime functioning with medication adherence. We also conducted a series of hierarchical linear regression analyses predicting medication adherence from each of our sleep variables. Adherence scores were positively correlated with sleep duration ($r = 0.419$, $p < 0.001$), sleep quality ($r = 0.461$, $p < 0.001$), and daytime functioning scores ($r = 0.434$, $p < 0.001$). Longer sleep duration ($b = 0.143$, $p < 0.001$), and greater daytime functioning ($b = 0.099$, $p = 0.007$) significantly predicted better medication adherence, even after controlling for participant age, race, and gender. These results indicate that insufficient sleep and related daytime dysfunction were significant risk factors for poor medication adherence in our college sample. These findings also suggest that interventions that address poor sleep among college students may also have a positive effect on their medication adherence.

ACADEMIC ACHIEVEMENT AND DEPRESSIVE-LIKE SYMPTOMS AMONG ADOLESCENT CAREGIVERS FOR GRANDPARENTS WITH AND WITHOUT DEMENTIA

Gabriel Holguin, BA[1], Ruby Ceullar, BA[2]

[1]California State University San Marcos, san marcos, CA; [2]California State University San Marcos, San Marcos, CA

Alzheimer's disease remains the sixth leading cause of death in the United States, and rates are predicted to increase after age 65. Common symptoms include loss of interest in activities, trouble overcoming difficulties, self-harm, feelings of shame, and cognitive decline. However, little research has explored dementia as a developmental disease and examined the academic abilities and cognitive function of younger individuals who may be genetically predisposed by a family history of dementia. This study seeks to elucidate a link between a family history of dementia and cognitive functioning such as academic performance and depressive-like symptoms among adolescents by comparing those who report caregiving for a grandparent with and without dementia. Adolescents who reported caregiving for a grandparent with (n=19) and without (n=19) dementia, grades 9 through 12, were matched on demographics and were compared for differences in self-reported GPA, perceived stress, shame, and depressive symptoms. A paired samples t-test revealed no academic grade differences between the dementia and control group, p=0.27, nor was there a difference in overall stress or depressive symptoms, p=0.12. Given previous literature linking dementia with trouble overcoming difficulties, loss of interest in activities, and increased self-harm, an analysis of individual items concerning these topics were made. The dementia group (M=3.19, SD=1.28) reported more trouble overcoming monthly difficulties compared to the control group (M=2.13, SD=1.26), p=0.02. They also reported increased loss of interest in usual activities (M=0.94, SD=1.16) compared to the control group (M=0.22, SD=0.55), p=0.01. The dementia group (M=1.72, SD=0.75) showed a trend of increased shame compared to the control group (M=1.33, SD=0.41), p=0.05. Lastly, there was a trend such that the dementia group (M=0.76, SD=1.35) reported more frequent thoughts of self-harm compared to the control group (M=0.06, SD=0.24), p=0.05. These findings suggest that a family genetic predisposition of dementia may increase dementia related symptoms, such as experiencing trouble overcoming daily difficulties and a loss of interest in usual activities, at a younger age. Limitations of the present study notwithstanding, further research to increase our understanding of dementia as a developmental disease that may influence cognition and behavior as early as adolescence is recommended.

CAREGIVER RELATIONSHIPS AND GENERAL SUPPORT RELATED TO DEPRESSIVE SYMPTOMS AND BMI

Monique Griffiths, B.S.[1], Jessica Chiang, Ph.D[2], Shu-Sha Angie Guan, Ph.D[3]

[1]California State University, Northridge, Sunrise, FL; [2]Northwestern University, Evanston, IL; [3]California State University, Northridge, Northridge, CA

Supportive relationships have been associated with decreased risk for poor mental and physical health outcomes (Holt-Lunstad et al., 2010; Oliveira et al., 2013). However, the relationship between specific sources of social support at different developmental time periods and health-related outcomes is less clear. Thus, we examined the linkages between support from caregivers early in life, current social support from friends, and current general support, and makers of physical health (i.e., total-body adiposity as a risk factory for a number of chronic diseases) and mental health (i.e., depressive symptoms) among young adults.

Undergraduate students (N = 103, M_{age}=19.91, *SD*=1.91) from diverse backgrounds (Asian American = 59, Latino = 21, Other ethnicity = 23) reported on their early caregiver relationships (e.g., During childhood and adolescence, my primary caregiver…" was affectionate to me"), current friend social support (e.g., "I could count on my friend when I needed to talk"), and current general support ("I have *someone* who understands my problems"). They also reported on their depressive symptoms (e.g., "you felt lonely"), and height/weight, which was used to calculated body mass index (BMI), a validated indicator of total-body adiposity.

Multiple regression analyses controlling for sociodemographic variables (i.e., ethnicity, parent education, and age) revealed that higher current friend support and general support were associated with lower depressive symptoms (*bs* = -.21, -.26, *SE* = .06, *p* < .001). By contrast, support from primary caregivers early in life was not associated with depressive symptoms (*b* = -.10, *SE* = .08, *p* = .24). When all three forms of relationship were entered into the same model, only general support (i.e, having *someone*), but not support from specific source, was associated with depressive symptoms (*b* = -.20, *SE* = .07, *p* = .01). In terms of physical health, friend and general support were only marginally predictive of BMI (*bs* = -.77, -89, -.26, *SE* = .46, .49, *p* < .10).

These results suggest that having a friend or someone else to rely on from support may decrease risk of depression and perhaps adiposity. Supportive relationships during childhood and adolescence may be less consequential. This may be due to the protective role of social

support in the effects of stress. Stressful events often precede depressive episodes, and support is known to be an effective coping mechanism. Current support may be immediately helpful for dealing with current stress whereas support in the past may be less relevant.

COGNITIVE BEHAVIORAL THERAPY COMBINED WITH PHYSICAL EXERCISE FOR DEPRESSION IN ADULTS WITH CHRONIC ILLNESSES: A META-ANALYSIS

Paquito Bernard, PhD[1], Gregory Moullec, PhD[2]

[1]Université du Québec à Montréal, Montreal, PQ, Canada; [2]Public Health School, University of Montreal, Montreal, PQ, Canada

Interventions combining cognitive behavioral therapy and physical exercise (CBTEx) have been shown to be efficacious at reducing depressive symptoms in various chronic illnesses. The objectives of this review were to systematically examine the absolute efficacy of CBTEx interventions, and then relative to usual care, CBT alone or exercise alone on depressive symptoms reduction in adults with chronic illnesses. Database searches identified randomized controlled trials of people with chronic illnesses (*e.g.*, cancer, heart failure, chronic fatigue) participating in CBTEx interventions compared with control (usual care, waiting list) or active comparators (*e.g.*, exercise, CBT alone). Relevant studies, published before July 2016, were traced through a systematic search of Pubmed, Embase, PsyInfo, Cinahl, SportDiscus and Cochrane Library databases. Standardized mean differences (SMD) were calculated for each intervention arm and control comparison. The pooled SMD associated to CBTEx (19 trials, 2190 participants) was -0.24 (95%CI: -0.43 to -0.06; I^2= 56%). When compared with usual care (11 trials, 1256 participants), the magnitude of effect was greater (SMD = -0.37, [CI: -0.58 to -0.17]); I^2 = 56%). The reduction in depressive symptoms was not statistically different between CBTEx and exercise (SMD = -0.26, [CI: -0.74 to 0.23], 7 trials, 623 participants) or between CBTEx and CBT (SMD = -0.08, [CI: -0.24 to 0.07], 10 trials, 845 participants). Findings suggest a short-term effect of CBTEx on depression in adults with chronic illness. However, CBTEx does not seem to be superior to exercise or CBT alone for decreasing depressive symptoms. Further research should investigate the potential moderators of interventional efficacy, such as participants' adherence, the methodological quality and selected sample characteristics.

DISTRESS INTOLERANCE AS A MODERATOR OF THE BENEFIT OF PHYSICAL ACTIVITY: OUTCOMES FOR DEPRESSION

Kristin Szuhany, M.A.[1], Michael Otto, Ph.D.[2]

[1]Boston University, New York, NY; [2]Boston University, Boston, MA

Negative affect and distress intolerance (DI) are linked to a wide variety of negative health behaviors. For example, DI has been linked to overeating, underactivity, smoking, and illicit drug use behaviors (Otto et al., 2016). There is strong evidence from both laboratory and clinical studies that physical activity (PA) interventions are efficacious for both improving mood and rapidly reducing DI (e.g., Smits et al., 2008), and that PA may have particular efficacy for those with high DI. For example, Smits found that the benefits of a program of PA for smoking cessation were specific to smokers with high DI (measured by anxiety sensitivity; Smits et al., 2016). In the present study, we examine the role of PA as an adjunctive treatment for major depression, and likewise examine whether mood benefits were moderated by baseline level of DI (measured with the Distress Intolerance Index; DII, McHugh & Otto, 2012).

A total of 32 sedentary depressed outpatients (M age=33.7±13.4, 78% female) were randomized to receive 9 sessions of a behavioral activation treatment in combination with either PA (n=15) or a control treatment (stretching; n=17) over the course of 12 weeks. These augmentation strategies involved 6 weekly 30-minute sessions in which participants planned exercise/stretching for the week and received motivational interventions (Otto & Smits, 2011) to improve adherence to their respective regimens.

Analyses indicated the total sample was in the moderate range of depression (27.0±10.2) and distress intolerance (DI; 19.1±8.8) at baseline. Patients reported engaging in 359 metabolic equivalent (MET) minutes of vigorous and moderate intensity exercise at baseline (about 81 minutes of moderate intensity exercise). In a mixed effects linear regression, results indicated that regardless of PA condition, patients improved significantly with treatment ($p < .001$). Also, those in the adjunctive PA condition achieved a significantly greater reduction in DI ($p < .02$). In addition, the degree of benefit was moderated by baseline DII score; those with high DI who were treated with adjunctive PA achieved significantly more mood benefit over time ($p < .01$). These results are consistent with recent findings identifying DI as a transdiagnostic factor that may help explain comorbidity and may moderate the benefits of treatment for conditions ranging from depression and smoking to Type II Diabetes, HIV, and obesity.

GENERAL AND MENTAL HEALTH SERVICE CONNECTION IN POST 9/11 VETERANS

Shadi Gholizadeh, M.Sc., M.S., M.P.H. [1], Caroline A. Thompson, M.P.H., Ph.D. [2], Vanessa L. Malcarne, Ph.D.[3], Autumn Backhaus, Ph.D.[4], Niloofar Afari, PhD[5]

[1]SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; [2]Graduate School of Public Health/San Diego State University, San Diego, CA; [3]San Diego State University, San Diego, CA; [4]Veteran's Administration San Diego Healthcare System and University of California, San Diego, San Diego, CA; [5]University of CA, San Diego & VA San Diego Healthcare System, La Jolla, CA

Despite the relatively high numbers of service-connected injuries among Post 9/11 veterans returning from Iraq and Afghanistan (OEF/OIF), predictors of service connection have only been minimally studied in this group of veterans. The present study aimed to explore differences among service connected and non-service connected OEF/OIF veterans and examine sociodemographic and military predictors of general service connection. Prevalence and predictors of service connection were assessed in 1193 OEF/OIF veterans registering with the VA San Diego Healthcare System. Veterans completed a self-report questionnaire that recorded service history, exposures while in the military, number of deployments, and combat experience. Descriptive statistics and chi-square and t-test analyses were conducted to explore differences in key variables between service-connected and non-service connected veterans. Multivariable logistic regression was used to identify predictors of service connection status. Over one-half of veterans were service connected for at least one condition (n = 641; 53.7%). A smaller subset of veterans (n = 251; 21.0%) were service-connected for at least one mental health condition. Modeling general service connection revealed that career branch was associated with general service connection but concerns about exposures, combat experience, number of deployments, and rank were not. Models for mental health service connection identified that perceived harmful exposures (OR: 1.67; 95% CI: 1.13, 2.45) and career branch (Army compared to Marines OR: 2.32; 95% CI: 1.22, 4.44) were statistically significant predictors. Improved understanding of predictors of service connected disability can inform strategies for prevention of such disabilities and interventions to improve support for returning veterans.

LATINO VETERAN MENTAL HEALTH SERVICE UTILIZATION

James O. E. Pittman, PhD[1], Judith Baer, MSW, PhD[2], Joyce Everett, MSW, PhD[2], Mary Dozier, MA[3], Niloofar Afari, PhD[4]

[1]VA San Diego Healthcare System, San Diego, CA; [2]Smith College, School for Social Work, Northampton, MA; [3]University of California, San Diego, San Diego, CA; [4]University of CA, San Diego & VA San Diego Healthcare System, La Jolla, CA

Latinos represent 18% of the 2.1 million US troops deployed to combat Post 9/11. Since 2001, 56.9 percent of the 1.1 million veterans who used VA healthcare received a mental health (MH) diagnosis. Research has identified disparities in health service utilization between Latinos and non-Latino White individuals. Given these disparities in non-veterans and the need for MH care among Post-9/11 veterans, the purpose of this study was to better understand the MH treatment seeking behavior of Post 9/11 Latino veterans. Aims were to: 1) examine differences in MH service utilization between Latino and non-Latino White veterans; and 2) examine the relationship between potential predictors of MH service utilization by using the Behavioral Model for Health Service Utilization (BMHSU). Previously collected data at VA San Diego Healthcare System were used to examine patterns of MH service utilization in a 740 Post-9/11 veterans with 35% Latino (n = 259) and 65% non-Latino White (n = 481). The sample was primarily male (84.9%) and aged 21 to 67 years (M = 30.48; SD = 7.31). Predisposing, enabling, and need factors from BMHSU were tested as predictors of MH service utilization. Stepwise logistic regression analyses were performed using significant variables from preceding univariate analyses to determine predictors of service utilization. No significant differences in MH symptoms (all p's > .05) or rate of MH service utilization (30.5% vs 29.0%, p = 0.68) between the groups emerged. All BMHSU factors were significantly related to utilization in both groups, but only need predicted utilization in Latino veterans. Further, a positive pain screen made MH service utilization 2.97 times more likely in Latino veterans only. Except for pain, patterns of MH service utilization were similar in both groups of veterans in San Diego. The BMHSU does not seem to fully apply to Latino or non-Latino White Post 9/11 MH care utilization. Findings reinforce VA policy to screen veterans regularly for symptoms of depression, PTSD, TBI, and pain. The relationship between pain and MH utilization in Latino veterans warrants further study.

NEIGHBORHOOD CHARACTERISTICS AND ADOLESCENT SUICIDAL BEHAVIOR

Kristina E. Allen, BA[1], Sidra Goldman-Mellor, PhD, MPH[2]

[1]University of California Merced, Mariposa, CA; [2]University of California Merced, Merced, CA

Prior research suggests that neighborhood characteristics may be related to rates of suicidal ideation and suicide attempt in adolescents, but no study has examined these associations using a comprehensive array of both objective and subjective neighborhood factors. In the current study, we used a population-based sample of adolescents (N=4,615 12-17-year-olds) from the California Health Interview Survey (CHIS 2011-2014) Adolescents' residential addresses were geocoded to the census tract level and linked to objective measures of local violent crime risk, property crime risk, and socioeconomic disadvantage. We also assessed adolescents' subjective perceptions of their neighborhood's safety and neighborhood cohesion. Our outcome variables were any report of past-year suicidal ideation, suicide ideation in the past two months, and past-year suicide attempt, reported by 8.4% of the sample. We found that adolescents who lived in neighborhoods objectively characterized by high levels of violent crime, property crime, or by socioeconomic disadvantage were no more likely than their peers to engage in suicidal behavior. In contrast, adolescents who perceived their neighborhoods to be less safe were 45% more likely to have suicidal ideation in the past year, 42% more likely to have suicidal ideation in the past two months and 40% more likely to attempt suicide in the past year compared to their non-suicidal peers. Further, adolescents who perceived their neighborhoods to be less cohesive were 21% more likely to have suicidal ideation in the past year and 24% more likely to have suicidal ideation in the past two months compared to their non-suicidal peers. In our population-representative adolescent sample from California, only subjective perceptions of neighborhood characteristics appear to be related to risk of suicidal behavior. Individual-level risk factors may exert a more powerful influence on psychologically vulnerable youths

PHYSICAL ACTIVITY AMONG ADULTS WITH PSYCHOTIC DISORDERS: PREFERENCES, BARRIERS AND PERCEPTIONS OF ADVICES

Ahmed Jerome Romain, PhD, Christophe Longpré-Poirier, Medical science, Marc Tannous, Medical science, Amal Abdel-Baki, MD, Msc, FRCPC

University of Montreal Hospital Research Centre, Montreal, PQ, Canada

Introduction: People with serious mental illness are more likely to have a poor lifestyle including high sedentary behaviours and low physical activity (PA). Recent finding acknowledge that PA can be beneficial on several parameters and it has been suggested that considering PA preferences would facilitate its initiation or maintenance. However, few studies assessed the PA preferences of people with serious mental illness. The objective of the present study was to describe the PA preferences of people with serious mental illness.

Methods: Cross-sectional study. Participants with serious mental illnesses were asked to complete several questionnaires about their PA preferences and their preferred context for PA practice.

Results: Among the 114 included participants (men: 60.5%; mean age: 31.94 ± 10.86), 55.3% were physically inactive and 49.5% were overweight or obese. The preferred PA were walking (55.3%), cycling (46.5%) and running (33.3%). Participants did not have preferences on the mode of supervision (37.8%) or preferred supervision by a PA specialist (31.9%). Close to half of participants preferred outdoor PA (46.8%) or did not have preferences (20.7%). The main obstacle to PA was lack of motivation (45.5%). Most of participants highlighted that advices from different mental health professionals were important for them (nutrition: 69.2%; tobacco cessation: 56.1%; PA: 73%) and considered their physical health as important as the improvement of their mental health (64.3%).

Conclusion: These results can be useful to conduct future PA interventions aiming at maintaining PA over the long-term and underline the importance of involving mental health professionals in this process.

PHYSICAL ACTIVITY AND SUICIDE IDEATION AMONG YOUTH: THE ROLE OF PHYSICAL ACTIVITY ENJOYMENT

Chaelin Karen Ra, MPH[1], Adam Leventhal, PHD[2], Genevieve F. Dunton, PhD, MPH[3]

[1]Health Behavior Research, Pasadena, CA; [2]USC, Pasadena, CA; [3]University of Southern California, Los Angeles, CA

Physical activity and suicide ideation among youth: The role of physical activity enjoyment

Background: The suicide rate among children and adolescents in the United States has increased dramatically in recent years. Hence, a growing number of studies have been conducted to understand the underpinnings of suicidal ideation (SI) in youth. A few studies have suggested that engaging in physical activity (PA) may be protective against SI in youth. Yet, inconsistencies in the results of these studies indicate that there may be unexplored factors such as physical activity enjoyment (PAE) that can help us to better understand the mental health benefits of PA in relation to SI. Thus, this study aimed to investigate whether PAE is associated with SI, and whether PAE moderates the association between PA and SI in children.

Methods: This study used baseline questionnaire data from 185 mothers and their children enrolled in the Mothers' and Their Children's Health (MATCH) study. SI was assessed through mothers' reports on the Child Behavior Checklist (CBCL). Minutes per day of moderate to vigorous physical activity (MVPA) was assessed through the child-reported 3-Day Physical Activity Recall (3DPAR), and dichotomized by whether the child met the recommendation of at least 60 minutes per day or not. PAE was assessed through the child-reported Physical Activity Enjoyment Scale (PACES). Multiple logistic regression models were conducted to estimate the likelihood of SI as a function of PAE and engaging in at least 60 minutes of daily MVPA. The interaction of 60+ minutes of MVPA and PAE was included in a subsequent model controlling for age, gender, ethnicity, single parent status and receiving free lunch at school.

Results: MVPA was not associated with SI (OR= 1.782, 0.582-5.452), and PAE was associated with a reduced likelihood of SI (OR=0.485, 0.267-0.883). In the model with the interaction term, the interaction between MVPA and PAE was not significant (OR=0.388, 0.111-1.359).

Conclusion: The enjoyment of physical activity instead of physical activity behavior itself may

be more closely tied to lowered SI among children. Interventions that seek to boost children's enjoyment of physical activity in addition to increasing levels of physical activity behavior may be critical to children receiving the mental health benefits of physical activity, especially among those at risk of suicide.

SEXUAL SATISFACTION, ANXIETY, AND ESTEEM WHILE PRESCRIBED PRE-EXPOSURE PROPHYLAXIS (PREP) AMONG GAY AND BISEXUAL MEN.

Thomas H.F. Whitfield, MA[1], H. Jonathon Rendina, PhD, MPH[2], Christian Grov, PhD, MPH[3], Jeffrey T. Parsons, PhD[4]

[1]The CUNY Graduate Center / The Center for HIV Educational Studies and Training, New York, NY; [2]Hunter College of the City University of New York (CUNY), New York, NY; [3]CUNY Graduate School of Public Health and Health Policy, New York, NY; [4]Hunter College and The Center for HIV Educational Studies and Training, New York, NY

Background: Once-daily PrEP is the most effective biomedical HIV prevention tool currently available. In addition to its protective effects against HIV, PrEP may have other benefits for gay and bisexual men (GBM), including improved mental health. The present study sought to investigate the association between PrEP use and levels of sexual anxiety, sexual esteem, and sexual satisfaction among PrEP users.

Methods: Within a larger U.S. national sample of 1,013 HIV-negative GBM, 580 (57.3%) reported recently engaging in sex with a casual partner. These men provided data on whether they were prescribed PrEP and completed the sexual satisfaction, sexual anxiety, and sexual esteem (multidimensional sexual self-concept) questionnaire.

Results: In total, 70 (12.1%) reported currently being prescribed PrEP and 510 (87.9%) were not currently prescribed. Adjusting for demographic differences (i.e. age, race, income), men currently prescribed PrEP reported more sexual satisfaction ($\beta = 0.30$, $SE = 0.14$, $p = 0.04$) and less sexual anxiety ($\beta = -0.28$, $SE = 0.12$, $p = 0.02$), but were not statistically different with regard to sexual esteem ($\beta = 0.25$, $SE = 0.14$, $p = 0.07$).

Conclusions: These results indicates that there may be benefits to taking PrEP for some GBM that go beyond (but may be due in part to) its protection against HIV acquisition. These findings suggest that being in PrEP may lead to reduced sexual anxiety associated and greater satisfaction though the directionality of these associations may also be reversed. Future longitudinal research is needed to better examine whether the health-protective effects of PrEP may also lead to psychological benefits.

SUPPORT TO KINSHIP CAREGIVERS IMPROVES CHILD BEHAVIOR: RESULTS FROM THE KIN TECH RCT

Kerry Littlewood, Ph.D., MSW[1], Lawrence Cooper, LCSW, MSW[2], Michelle Rosenthal, Ph.D.[3], Liliana Hernandez, MSW, MPP[4], Anne Strozier, Ph.D., MSW[5], Abhishek Pandey, MD[6]

[1]AAJ Research and Evaluation, Seminole, FL; [2]The Children's Home, Inc., Tampa, FL; [3]Data With Purpose, Oakland, CA; [4]US Administration on Children and Families, Washington, DC; [5]University of South Florida, Tampa, FL; [6]University of Arizona, Staten Island, NY

Background: One in 11 of all children and 1 in 5 African American children live with a grandparent at some point before the age of 18. While children raised by grandparents experience more risks of psychological difficulties than children in the general population, especially experiencing trauma at a young age, few studies have examined which interventions can improve psychosocial impairment for children raised by grandparents.

Purpose: This study identified psychosocial impairment using baseline, six month post test, and 12 month follow up self-report data on the Pediatric Symptom Checklist obtained from kinship caregivers enrolled in the KIN-Tech randomized controlled trial funded by the US Children’s Bureau. Descriptives and repeated measures ANOVAS were used to examine mean differences between and within treatment groups (Navigation, Extended Family Support, and Usual Care).

Results: Participants in this study included 1100 female kinship caregivers from low income households (m=$23,000), middle-aged (m=48), unmarried (70%), African American (47%) caring for multiple relative children (65% caring for more than one child). 48% (n=528) of caregivers earned at least a high school diploma. Participants in the navigator and extended family support programs reported a statistically significant reduction in their children’s conduct, anxiety and attention problems [Navigator Program, F(252,3)=3.58, p = .023] [Extended Family Support, F(849,3)=5.14, p = .000]. Participants in the usual care group reported an increase in conduct and anxiety problems, but a decrease in attention problems.

Conclusions: Participants randomly assigned to a kinship navigator program and an extended family support program showed reduction in the conduct, anxiety and attention problems that was significantly different than those assigned to the usual care group. Future studies should explore which specific program components are most beneficial for kinship caregivers

and help promote responsive and competent caregiving for the children living in non-parental care.

THE MENTAL HEALTH SYSTEM IN NORTHERN TANZANIA: PROVIDER PERCEPTIONS OF THE PRESENTATION AND TREATMENT OF MENTAL ILLNESS

Brandon A. Knettel, Ph.D.[1], Janvier Rugira, Ph.D.[2], Florence Tesha, N/A[3]

[1]Duke Global Health Institute, Raleigh, NC; [2]University of Johannesburg, Johannesburg, Gauteng, South Africa; [3]Duke University, Durham, NC

The steady globalization of western models of mental health treatment is causing an influx of practitioners, ideas and resources to developing nations. One such country, the United Republic of Tanzania, is at a crucial stage in the development of its mental health system. As of 2009, there were 18 psychiatrists serving this nation of 51 million people and a gross lack of resources being dedicated to mental health treatment. However, as international organizations shift focus to noncommunicable diseases, there have been some signs of growth in the Tanzanian mental health system, including the establishment of new training programs and professional associations in psychology. As services continue to develop, there is a need for solid foundational research aimed at understanding the unique challenges and strengths of providing mental health care in this context.

We conducted interviews with 29 mental health providers in a variety of treatment settings in northern Tanzania to examine their perceptions of the treatment currently being offered, the characteristics of the patient population, and future directions in mental health treatment. Responses were analyzed using consensual qualitative research (CQR) methodology and offer a nuanced perspective of the characteristics, strengths, and challenges of the Tanzanian mental health system. Participants acknowledged that there is a widespread lack of mental health providers in the region, inadequate resources dedicated to mental health, very little coordination among providers, and major social, logistical, and cultural barriers that prevent all but the most severe patients from seeking or receiving care.

The research provides an important baseline of understanding to inform the ongoing development and improvement of mental health services in the region. In response to the concerns identified, we propose a three-part improvement plan consisting of (1) improving the availability and quality of care via investment in training programs and facilities, (2) Maximize existing resources via task shifting programs aimed at improved coordination of various types of care, and (3) Address barriers to seeking care via public education, stigma reduction, and improved cultural compatibility of care.

USING ECOLOGICAL MOMENTARY ASSESSMENT TO EXAMINE RELATIONS BETWEEN PHYSICAL ACTIVITY AND AFFECT IN ADULTS WITH MENTAL ILLNESS

Chun Nok Lam, PhD Canditate[1], Brian W. Redline, BA[1], Harmony Rhoades, PhD[1], Genevieve F. Dunton, PhD, MPH[1], Benjamin F. Henwood, PhD, MSW[2]

[1]University of Southern California, Los Angeles, CA; [2]University of Southern California, los angeles, CA

Background: Adults with serious mental illness (SMI) engage in limited physical activity, which contributes to significant health disparities and premature mortality in this population. The need for basic research on physical activity mechanisms that can be translated into life style interventions for individuals with SMI is urgent. Individuals with SMI may experience different patterning of emotional experiences than individuals without SMI. This study aims to examine the interrelations between affective states and physical activity among the SMI population.

Methods: This study used ecological momentary assessment (EMA), a real-time data capture strategy to assess subjective positive and negative affective states in free-living setting up to 7 times per day across 4 days from 21 Latino adults diagnosed with SMI. Participants were equipped with an accelerometer which provided an objective measure of their moderate-to-vigorous physical activity (MVPA) during the study period. Multilevel modeling was used to test the bi-directional associations between affective states and MVPA across the day.

Results: Participants (49.0±13.1 years, 76.2% female) engaged in limited MVPA, with only 30.2% engaging in ≥1 minute of MVPA in the 30-minute prior to any given EMA prompt (median MVPA: 2.5 minutes, range 1-28 minutes). Participants who on average reported more positive affect than others in the study had a higher probability in engaging in some MVPA versus no MVPA during the study period. However, among participants who engaged in some MVPA during the study period, reporting more positive affect on average than others was associated with less MVPA on average. In addition, engaging more MVPA than one’s usual in the 30-minutes prior to an EMA prompt was associated with more negative affect at that prompt.

Conclusions: Engagement in more MVPA was generally associated with feeling less positive and more negative affect among individuals with SMI. This finding suggests that the types of physical activity performed in this population (such as active transportation) may not be

perceived enjoyable or pleasant. The results provide new insights into the unmet needs of individuals with SMI and offers new directions for future research.

WE'RE GRAY, GAY AND HERE TO STAY: TRAUMA HISTORY, SOCIAL SUPPORT AS CORRELATES OF RESILIENCY IN LESBIANS AND GAY MEN OVER AGE 50

Bunyong Dejanipont, (BSBME), Kinsie J. Dunham, BA, Mark Vosvick, PhD

University of North Texas, Denton, TX

Traumatic experiences have long-lasting effects, such as the development of psychopathology (Hatzenbuhler, 2009). Lesbians and gay men are more likely to experience trauma (Brown et al., 2011). Further, older cohorts of lesbians and gay men (LG+50) likely have larger cumulative trauma histories (TH; Hash et al., 2013). The dearth of research on TH in LG+50 requires examination of protective factors and trauma outcomes (Brown et al., 2011).

Social support (SS), a protective factor, may increase Resilience among sexual minorities, as it lessens the impact of discriminatory events (Kwon, 2013). Resiliency may be a preferential trauma outcome, as Resiliency is associated with brief dysregulation (Westphal et al., 2007). Additionally, Resiliency is more prevalent in populations that face adversity (Tomac, 2011). As LG+50 face dual discrimination, Resiliency is the ideal outcome in response to a traumatic event. Despite the prevalence of traumatic events for LG50+, little research explores SS and Resiliency. As both are relevant to LG+50, the aim of the current study is to examine the mediating effect of SS (UCLA SSI; Dunkel-Schetter et al., 1986) on TH (THQ; Green, 1996) and resilience (CD-RISC; Connor et al., 2003).

We recruited LG+50 (N = 100; n =71; M_{age} = 59, SD = 5.9), and excluded those who had not experienced a traumatic event. To test for mediation we entered covariates (gender, religiosity and HIV-positive status) into the first block of each analysis. HIV-positive status was the only significant covariate in indirect path a', showing that people living with HIV scored significantly lower on SS (β = -.42, p = .003). In the first step we examined direct relationship c' by regressing TH on Resilience (β = .03, p = .806). Though insignificant, we tested for full mediation. Indirect path a' between TH and SS (β = -.23, p = .039) and indirect path b', SS and Resilience (β = .44, p = .001) were significant. Additional Sobel analysis indicated full mediation (TS = 1.83, p = .003). This suggests SS is a mechanism that may help LG+50 develop Resilience. LG+50 with greater TH did not achieve resiliency, except though SS, reinforcing the importance of this developmentally and socially important mechanism.

ARE SELF-EFFICACY MEASURES CONFOUNDED WITH MOTIVATION? AN EXPERIMENTAL TEST

David Williams, Ph.D.[1], Shira Dunsiger, PhD[2], Jessica Emerson, MS[3], Laura Dionne, B.A.[4], Ryan E. Rhodes, PhD[5], Mark R. Beauchamp, PhD[6]

[1]Brown University School of Public Health, Providence, RI; [2]The Miriam Hospital and Brown University, Portsmouth, RI; [3]Brown University, East Providence, RI; [4]Brown University, Charlestown, RI; [5]University of Victoria, Victoria, BC, Canada; [6]University of British Columbia, Vancouver, BC, Canada

Self-efficacy (SE) is defined as confidence that one can perform a target behavior in the face of various obstacles. SE is highly predictive of a range of health behaviors and is a central construct in many theories of behavior.

Previous authors have argued that standard SE measures may actually tap respondents' motivation rather than their confidence that they can perform the behavior, particularly when the target behavior is under volitional control (e.g., physical exercise). This occurs because respondents tend to interpret the word "can" as willingness when asked whether they, for example, "can exercise even if they are not feeling well". If this is true, then priming respondents regarding the definition of the word "can" or to the contrast between "can" and "will", should increase SE ratings in the absence of any intervention.

In this study, 134 university students (65% female; 55% White) responded to a questionnaire assessing SE for exercise using a standard SE measure, behavioral intentions (BI) to exercise, and their definition of the word "can", as in "I can exercise today even though I am not feeling well". One month later participants were randomly assigned to complete either (a) the same SE and BI questionnaire as at baseline (i.e., control), (b) the same questionnaire but with presentation of each participant's definition of "can" prior to responding to the SE measure (i.e., definition priming), or (c) the same questionnaire but with SE items ("I can exercise . . .") placed side-by-side with BI items ("I will exercise . . .").

Generalized linear models were used to compare groups. Results showed increases in SE responses, relative to controls, for side-by-side ($b=12.08$, $SE=2.70$, $p < .01$), but not definition priming (ns). As expected, there were no effects of side-by-side priming, relative to control, on BI (ns), and the effects of side-by-side priming on SE ratings remained significant even when controlling for BI at times 1 and 2 ($b=8.87$, $SE=2.11$, $p < .01$), thus illustrating that SE ratings were manipulated by the side-by-side priming independent of BI ratings.

The results show that responses to SE items can be increased simply by placing them next to BI items. This suggests that responses to standard assessments of SE do not simply reflect respondents' confidence that they can perform the target behavior, but are confounded by their motivation to perform the behavior. Studies using standard assessments of SE should perhaps be reinterpreted in light of these findings.

COMPARISON OF THE DIAGNOSTIC ACCURACY OF FOUR BRIEF DEPRESSION SCREENING INSTRUMENTS IN OVARIAN CANCER PATIENTS

Shinn Shinn, Ph.D. [1], Cindy Carmack, Ph.D.[1], Kelly Kilgore, B.A. [1], Alan D. Valentine, M.D. [1], Karen Basen-Engquist, PhD, MPH[2]

[1]University of Texas M. D. Anderson Cancer Center, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Objectives: We compared the diagnostic accuracy of 4 depression screening scales, using traditional and alternative scoring methods, to the gold standard Structured Clinical Interview-DSM IV major depressive episode (MDE) in ovarian cancer patients on active treatment.

Methods: At the beginning of a new chemotherapy regimen, ovarian cancer patients completed the following on the same day: the Center for Epidemiological Studies Depression Scale (CES-D), the Beck Depression Inventory Fast-Screen for Primary Care (BDI-FastScreen), the Patient Health Questionnaire-9 (PHQ-9), and a 1-item screener ("Are you depressed?"). Each instrument's sensitivity, specificity, positive predictive value (PPV) and negative predictive value were calculated with respect to major depression.

Results: One hundred and fifty-three ovarian cancer patients were enrolled into the study. Only fourteen participants met SCID criteria for current MDE (9%). When evaluating all patients regardless of whether they were already being treated with antidepressants or not, using a two-phase scoring approach with an alternate cutpoint of 6 on the PHQ-9 had the best positive predictive value (PPV=32%). Using a traditional cutpoint of 16 on the CES-D resulted in the lowest PPV (5%); using a more stringent cutpoint of 22 resulted in a slightly improved but still poor PPV, 7%.

Conclusions:

Using a two-phase scoring method for the PHQ-9, with an alternate cutpoint of 8 resulted in the best diagnostic performance among the four screening instruments. The traditional cutpoint of 16 on the CES-D and the one-item screener were among the worst methods and are not recommended as first-line screening methods in oncological settings.

DEVELOPMENT AND VALIDATION OF AN AGENT BASED MODEL TO EXAMINE NEUROTICISM AND OBESITY

Hilary C. Tanenbaum, MPH, MS, RD[1], Brian Hilton, Ph.D.[2], Kim Reynolds, PhD[2], Bin Xie, PhD[2]

[1]School of Community & Global Health, Claremont Graduate University, Claremont, CA;
[2]Claremont Graduate University, Claremont, CA

The numerous, interacting factors involved in the etiological web of the obesity epidemic warrant examination with modeling methods that can realistically reflect these dynamics. Agent-Based Modelling (ABMs) is one of several complex systems techniques garnering interest among researchers in obesity research. ABMs use computer-generated algorithms to simulate the behavior of individual entities by assigning specific behavior rules, incorporating elements of stochasticity, heterogeneity, and non-linearity. They can also provide a blank canvas to explore potential interventions. Despite recent advances in computer processing and software that have broadened their accessibility, the novelty of this approach in the health field, combined with the wide range of possible techniques, makes navigating ABM construction challenging. Few studies exist that comprehensively explain the development process. A new approach for designing an ABM to examine the linkage between Neuroticism and obesity is presented in this study, providing a detailed description of the process for populating an ABM with real-world data, defining the behavior rules of the agents, structuring the model for future interventions, and validating the model. AnyLogic software (v. 7.6) was used to construct the model with data from two collection points (spanning 13 years) from the National Longitudinal Study of Adolescent to Adult Health (Add Health). The dataset (*N*=9176*)* was segmented by gender and cross-tabulated to define the starting or ending probabilities of weight classes (Under/Normal, Overweight, Obese) by Neuroticism score from the first wave of data collection. The data was randomly split into two equal groups, using half to construct the model, and reserving the rest to verify that no coding or structural errors existed. To validate that the simulated population did not differ significantly from the Add Health dataset, 1000 randomly-seeded Monte Carlo (MC) runs were performed, and a one-sample t-test was used to compare the mean counts in each weight class from the MC runs to the actual dataset means. No significant differences were found for starting weight (Under/Normal: p=0.16, Overweight: p=0.20, Obese: p=0.68), transitioning from starting weight (Under/Normal: p=0.32, Overweight: p=0.44, Obese: p=0.72), or ending weight (Under/Normal: p=0.95, Overweight: p=0.76, Obese: p=0.87), suggesting that the agents accurately reflect the real-world data. With the simulated population established, potential interventions to change Neuroticism scores can be implemented to identify the best feasible

solution for reducing obesity. The ABM construction process presented in this study serves as a modifiable template that may be used to explore relationships among other variables of interest in obesity research.

EDUCATION, HEALTH LITERACY, AND NUMERACY: IMPLICATIONS FOR UNCERTAINTY ABOUT RISK

Erika A. Waters, PhD, MPH[1], Elizabeth Schofield, MPH[2], Caitlin Biddle, MA, MS[3], Jennifer L. Hay, Ph.D.[2], Marc T. Kiviniemi, BA, PhD[3], Yuelin Li, PhD.[2], Kimberly Kaphingst, ScD[4], Heather Orom, PhD[3]

[1]Washington University in St. Louis, St. Louis, MO; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]University at Buffalo, Buffalo, NY; [4]University of Utah and Huntsman Cancer Institute, Salt Lake City, UT

Background: Uncertainty about risk, as operationalized by marking the “don’t know” response option for survey items assessing perceived risk of colon cancer, is related to sociodemographic characteristics (e.g., education), that have been associated with limited knowledge about colon cancer, limited cancer information seeking, and lower engagement in some cancer prevention and detection behaviors. Whether risk uncertainty is also associated with limited health literacy and/or numeracy has been hypothesized but not confirmed.

Objective: To examine whether uncertainty about colon cancer risk and diabetes risk are related to objective and/or subjective health literacy and numeracy.

Methods: Participants were recruited from the GfK Knowledge Networks Internet survey panel and answered questions regarding demographics, objective and subjective numeracy, and objective and subjective health literacy. They also completed items assessing perceived risk of colon cancer ($N = 999$) and diabetes ($N = 893$). Responses to risk perception items were dichotomized according to whether the participant did or did not respond “don’t know.”

Results: Unadjusted analyses indicated that don’t know responding (DKR) for perceived diabetes risk was lower among people with higher objective and subjective health literacy and numeracy ($ps < .05$). DKR for perceived colon cancer risk was lower among people with higher subjective health literacy and numeracy ($ps < .05$), but not higher objective literacy or numeracy. However, after adjusting for education, DKR for diabetes was only associated with subjective health literacy, and DKR for colon cancer was only associated with subjective health literacy and subjective numeracy ($ps < .05$).

Conclusion: Objective measures of health literacy and numeracy do not appear to account for significant variance in DKR above and beyond that accounted for by education. However,

subjective measures of health literacy and numeracy remain unique predictors of DKR. It is possible that these subjective self-report measures assess not only ability, but also confidence in understanding, engaging with, and using health information in a way that relates to people's levels of uncertainty about their risk of disease.

ESTABLISHING CLINICAL CUTOFFS FOR THE SCREENING OF AVOIDANT/RESTRICTIVE FOOD INTAKE DISORDER

Jordan Ellis, MA[1], Hana F. Zickgraf, MA[2], Matthew C. Whited, PhD, Licensed Psychologist[1], Amy T. Galloway, Ph.D.[3]

[1]East Carolina University, Greenville, NC; [2]University of Pennsylvania, Philadelphia, PA; [3]Appalachian State University, Boone, NC

Avoidant/Restrictive Food Intake Disorder (ARFID) is a new DSM-5 diagnosis intended to identify individuals who exhibit clinically significant restrictive eating problems (not primarily accounted for by shape or weight concerns), persistently fail to meet nutritional and/or energy needs, and experience psychosocial difficulties. Recent studies have indicated picky eating (PE; one manifestation of ARFID) can persist into adulthood and is associated with anxiety, depression, and OCD symptomology.

Two brief measures for ARFID symptoms and PE behaviors were recently developed to address a lack of measurement tools. The Nine Item ARFID Screener (NIAS) is a measure of rigid eating behaviors associated with ARFID, and the Adult Picky Eating Questionnaire (APEQ; Ellis et al., 2016) is a multidimensional measure of PE behaviors. The purpose of the current study was to assess the sensitivity and specificity of these measures to detect ARFID and establish a clinically useful cut score.

The current study included two samples: 1.) A general sample of 1219 college students who completed an online survey that included the NIAS and APEQ, and 2.) A sample of 450 adults selected for eating difficulties who completed the NIAS. Participants also completed the ARFID Symptoms Checklist (ARFID-cl). The ARFID-cl assesses cause, duration, and impairment and conforms to DSM-5 diagnostic criteria. It is meant to be used with people who meet a screening criterion. In the general sample 31 (2.5%) college students met criteria for ARFID; 65 (14.4%) in the selective sample.

Receiver Operating Characteristic (ROC) curve analyses were employed to establish cutoff scores for identifying a positive ARFID diagnosis. Area under curve (AUC) indicated that the NIAS ($AUC_{general}$= .87, $p < .001$; $AUC_{selected}$= .80, $p < .001$) and APEQ (AUC = .83, $p < .001$) were good screeners for ARFID. In the general sample, a cutoff of 44 on the APEQ and 24 on the NIAS both demonstrated good sensitivity (0.74) and specificity (0.84; PPV = 0.11; NPV = 0.99).

In the selective sample, a cutoff 28 on the NIAS demonstrated adequate sensitivity (0.71) and specificity (0.68; PPV = 0.69; NPV = 0.70).

The NIAS and APEQ are useful ARFID screeners but higher cutoffs need to be used in selective samples. This finding is likely due to medical and symptom complexity of the participants in the selective sample. Future research should investigate the utility of these measures in detecting symptom changes during treatment.

FEASIBILITY OF USING ECOLOGICAL MOMENTARY ASSESSMENT WITH LOW-INCOME LATINO ADULTS EXPERIENCING SERIOUS MENTAL ILLNESS

Brian W. Redline, BA[1], Chun Nok Lam, MPH[1], Benjamin F. Henwood, PhD, MSW[2], Harmony Rhoades, PhD[1], Stephen Intille, Ph.D.[3], Eldin Dzubur, MS[1], Genevieve F. Dunton, PhD, MPH[1]

[1]University of Southern California, Los Angeles, CA; [2]University of Southern California, los angeles, CA; [3]Northeastern University, Boston, MA

Background: People with serious mental illness (SMI) are more physically inactive and have higher rates of obesity, cardiovascular disease, and premature death compared to the general population. Emerging mobile technologies offer opportunities to examine how unique affective and environmental factors influence weight-related behaviors in this population and develop targeted real-time interventions. However, concerns about poor compliance, unreliable responses, and participant burden present potential barriers to implementation. The aim of this exploratory mixed-methods study was to test the feasibility of using smartphone-based ecological momentary assessment (EMA) methods to examine weight-related behaviors in low-income Latino adults with SMI.

Methods: Twenty-one adults (ages 21-63 years, 76% female, 95% Latino, 48% Spanish-speaking) were recruited from an integrated physical and behavioral healthcare clinic for low-income adults with SMI. After receiving instruction on how to use the study phone, EMA application, and waist-worn accelerometer, participants completed four days of activity, GPS, and signal-contingent EMA monitoring with up to 7 survey prompts per day. EMA surveys measured mood, weight-related behaviors, social and physical context, SMI symptoms, and substance use. Participants returned one week later to complete in-depth interviews that focused on study experience. An interactive GPS map of EMA responses was used to elicit information about how mood and context impacted physical activity using qualitative methods.

Results: Participants completed 82.9% of 520 EMA surveys overall, and provided an average of 3.67 valid days (>10 hrs/day) of accelerometer data. Participants reported being alone immediately before the prompt in 39.7% of surveys, physical activity in the past hour in 15.9% of surveys, psychotic symptoms in the past hour in 4.8% of surveys, and crying spells, poor focus or poor appetite in 10.6% of surveys. Qualitative analysis of follow-up interviews revealed almost half of participants experienced feelings of anxiety or stress using the EMA app. Reasons for reporting feelings of anxiety or stress included feeling a need to stay vigilant

to not miss surveys, lose the phone, or let the battery die, and from limited experience using smartphones.

Discussion: This pilot study demonstrates that although EMA can be effectively used to collect real-time physical activity data in low-income populations with SMI, measures should be taken to minimize undue participant burden due to low technological literacy and pressure to comply that may result in exacerbation of SMI symptoms (e.g., anxiety).

IDENTIFYING BEHAVIORAL PATHWAYS TO SMOKING CESSATION: DECIDE2QUIT RANDOMIZED TRIAL

Mickayla Aboujaoude, B.A. Economics Expected May 2017[1], Arlene S. Ash, PhD[1], Daniel Amante, MPH[1], Rajani Shankar Sadasivam, PhD[2], Thomas Houston, MD, MPH[1]

[1]University of Massachusetts Medical School, Worcester, MA; [2]Univ of Massachusetts Medical School, Worcester, MA

Background: Understanding behavioral pathways through which technology-assisted tobacco interventions support smokers can inform improvements.
Methods: A randomized trial with complete follow-up on 369 smokers had previously demonstrated more quitting (OR = 1.7) among users of an interactive website with motivational messages (enhanced) than for those assigned to the website only. Here we explore patient-reported influences of the intervention on subsequent cessation. After 6 months of website use, we asked if users had quit smoking in the last 30 days and if they agreed using the intervention had influenced 8 smoking cessation behaviors (cutting down; quitting; setting a quit date; using nicotine replacement therapy; using behavioral strategies; making a list of reasons to quit; talking to a doctor; getting support for quitting). We compare perceived influence between randomized groups, and assess six-month cessation rates by each influencing variable, then examine 9 logistic regressions to predict quitting, controlling for age, sex, and baseline readiness-to-quit: 1 regression for each influence item alone and 1 with all 8.
Results: Most were female (63%) over age 45 (65%) and had been thinking of quitting (81.5%) at baseline. Most agreed that the intervention influenced them to cut down on smoking (61%), talk to a doctor (56%), use behavioral strategies (55%), and make a list of reasons to quit (53%). More smokers in the enhanced group endorsed the value of the intervention for each of the 8 questions (differences ranged from 2.8 to 11.8%; only 3 were significant at the $P < 0.05$ level). In the 8 individual regressions, influence on “quitting smoking” was positively associated with quitting (OR 3.01 (95% CI 1.76-5.15)), while influences on “cutting down on smoking” and “using nicotine replacement therapy” were negatively associated (ORs = 0.58 (95% CI, 0.34-0.98) and 0.44 (0.24-0.83), respectively); no other influences were associated with quitting (all $p > 0.20$). Findings from the combined regression were qualitatively similar.
Conclusion: Cutting down to quit is controversial, and was negatively associated with cessation. Our unexpected finding (re: NRT) could be due to residual confounding by severity of addiction, needs further exploration.

MONITORING DAILY EXERCISE FOR 1 YEAR USING SMARTPHONES: VALIDITY OF ECOLOGICAL MOMENTARY ASSESSMENT

Kevin Sundquist, B.S.[1], Ipek Ensari, PhD[1], Jacob Julian, B.A.[1], Karina Davidson, PhD, MASc[2], Matthew Burg, PhD[3], Joseph Schwartz, PhD[1], Keith M. Diaz, PhD[1]

[1]Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; [2]Columbia University Medical Center, New York, NY; [3]Department of Internal Medicine, Yale School of Medicine, New Haven, CT

Background: Accelerometers have been used in research to objectively quantify exercise for over two decades. However, these devices are expensive, are burdensome to participants, and the derivation of exercise bouts from their data is arduous. The purpose of this study was to calculate the agreement between smartphone-based ecological momentary assessment (EMA) and objective accelerometer defined exercise to determine the feasibility of using EMA in lieu of accelerometers in the long term assessment of exercise. **Methods:** Data were collected from an observational study of intermittently exercising, otherwise healthy adults (N=79; 43% male, mean age: 32±9 years) who were studied for 365 days. Smartphone-based EMA self-report of exercise entailed daily end-of-day response to the question: “Did you exercise today for 30 minutes or more at a moderate or vigorous level?” Participants also wore a Fitbit Flex to objectively determine exercise bouts. Within-subject Kappa statistics of agreement were calculated between objectively-determined exercise (24 mins of moderate to vigorous physical activity [MVPA] within 30 minutes) and EMA self-reported exercise. Predictors of agreement (i.e., sex, age) were also examined. **Results:** On average, participants provided 211±91 days of data. The average within-subject Kappa statistic for agreement between objective and self-reported exercise was κ=0.27±0.19 (range: -0.03-0.71). The average within-subject Kappa ranged from 0.16 to 0.27 when the definition of an accelerometer-based exercise bout was varied from 15 to 30 mins (of 30 mins) MVPA. In a multivariable adjusted model, gender was significantly associated with the level of agreement, being higher for women (κ=33.6±0.19) than for men (κ=19.2±0.17). **Discussion:** The agreement between objective (i.e., accelerometer) and self-reported (EMA) measures of exercise was fair. These findings suggest that smartphone-based EMA for long term exercise monitoring in lieu of an accelerometer may be feasible, but does not provide high reliability to an objectively assessed exercise bout.

QUANTIFYING SUN PROTECTION MAINTENANCE AND ENVIRONMENTAL PROMOTERS IN INDIVIDUALS AT RISK FOR MELANOMA

Yuelin Li, PhD., Elizabeth Schofield, MPH, Kristen E. Riley, Ph.D. , Jennifer L. Hay, Ph.D.

Memorial Sloan Kettering Cancer Center, New York, NY

Achieving health behavior maintenance, while a gold standard outcome of behavioral interventions, is difficult to measure accurately and reliably, especially in quantifying the influences of habit and environmental promoters on behavior. We propose a Bayesian Hierarchical Linear Model (HLM) that clearly quantifies both influences.

Ecological Momentary Assessment (EMA) data were collected from 59 first-degree relatives of melanoma patients regarding sun protection behaviors (sunscreen use, shade seeking, hat and protective clothing) and the circumstances (e.g., weather and convenient availability of sunscreen), twice daily (1 pm; 5 pm) over 14 summer days (1,304 total assessments). A Bayesian HLM used random effects to represent habit and environmental promoters for determining whether each person's behaviors were primarily determined by habit or by environmental promoters.

Sunscreen use was influenced by environmental promoters, such as sunny and hot weather (OR=6.44, CI: 3.4,13.1; $p< 0.0001$), and also by person-specific habit (0.286; CI: 0.10,0.73; $p < 0.01$). Each person's habit was independent of propensity to use sunscreen in hot and sunny weather, shown in a non-significant correlation (rho=−0.14, CI: −0.82,+0.70). A gender moderating effect was observed. Sunny and hot weather exerted a greater promoting influence on men's than women's use of sunscreen (OR=3.80, p=0.040), but not when the weather was cool (OR=0.205, p=0.072). Men were less likely than women to wear long sleeve clothing (OR=0.18, p=0.03), more likely to wear a hat (OR=3.6, p=0.05), but equally likely to seek shade. The gender moderating effect was only present in sunscreen use, not the other behaviors. Bayesian HLM yielded a propensity of each person's sun protection behaviors being dictated more by environment than by habit, which showed that women were affected more by weather than habit (73% women vs. 50% men, p=0.096).

In conclusion, sun protection behaviors are mainly a function of weather and other environmental promoters rather than habit. The Bayesian approach to EMA data makes it possible to compare habit and environment in one coherent framework, a option not available by conventional methods. It informs the gender-specific strategies in future interventions.

USING ECOLOGICAL MOMENTARY ASSESSMENT METHODS TO MEASURE STRESS AND WEIGHT-RELATED BEHAVIORS IN HISPANIC POST-PARTUM WOMEN

Sydney G. O'Connor, BA, Jane Wai-Quan Cabison, BS, Wangjing Ke, MA, Carrie V. Breton, ScD, Tracy Bastain, PhD, Genevieve F. Dunton, PhD, MPH

University of Southern California, Los Angeles, CA

Background Excessive gestational weight-gain and post-partum weight retention are associated with an increased risk of lifelong obesity and chronic disease, which disproportionately affects minorities and women of low socioeconomic status. Ecological Momentary Assessment (EMA) methods may provide dynamic and real-time insight on the social and contextual factors influencing weight-related behaviors and obesity risk during this critical period of women’s lives. However, barriers to EMA in this population, including concerns over time demands and participant burden, remain. Thus, this study examined the feasibility and challenges of using EMA methods in low-income, Hispanic post-partum women with young infants.

Methods Twelve low-income Hispanic mothers (mean age: 31 yrs, SD: 7 yrs; 58% Spanish-speaking), of young infants (age range: 6-31 weeks) completed the study procedures. Participants completed up to 5 randomly prompted EMA surveys per day by smartphone across four days. EMA prompting was customized to mothers’ sleep and wake times. EMA surveys assessed stressors, diet, physical activity and sedentary screen behavior. Exit interviews were conducted with each participant to further assess barriers and burden associated with the EMA procedures.

Results Overall, participants responded to 82.05% (range: 0 – 100%) of EMA surveys. Older mothers had higher compliance. Participants reported experiencing one or more stressors in 43.21% of prompts, and “tension with children” (25.6%) and “work at home” (15.4%) were the most frequently reported sources. Across all prompts, the percentages reporting specific weight-related behaviors were as follows: Intake of fruits and vegetables (7.8%), intake of high-calorie, low nutrient foods (25.63%), sedentary screen behavior (44.4%), and engagement in exercise or sports (1.8%). In exit interviews, mothers reported concern over the compatibility of EMA prompting schedule with their variable sleep times.

Discussion This pilot study provides preliminary evidence that EMA methods may be reasonable for use in low-income, Hispanic post-partum women with young infants and multiple competing time demands. Future studies may use EMA to examine time-varying

influences on weight-related behaviors in this population to understand factors contributing to post-partum weight retention.

WHICH CONTROLS VARIABLES DID YOU INCLUDE? DOES IT MATTER? THE CASE FOR UNIFORM CONTROL LISTS IN PUBLIC HEALTH STUDIES

Theodore L. Caputi, N/A

University of Pennsylvania, Washington Crossing, PA

One of the greatest threats to the validity and reliability of public health research is the selective inclusion (or exclusion) of control variables. Most studies include an in-depth explanation of both the model's independent and dependent variables, with only a cursory review -- sometimes as short as half a sentence -- of what other factors were controlled for in the model. However, controls represent major assumptions of the model, and without agreement on those assumptions, even high-quality research can easily be dismissed.

In this session, based on a 2016 publication in the *International Journal of Drug Policy,* I will show how researchers can find two contradictory conclusions simply by selecting a different vector of controls. For example, a recent study connecting strict alcohol policies to methamphetamine use captured media attention from prominent news outlets as the Economist and the Washington Post. And yet, with the addition of just one innocuous and reasonable control, I show that virtually all of the author's significant results disappear.

So how do researchers address this systemic issue? I recommend that expert panels in different disciplines of public health convene to create a list of uniform controls that should be considered in all relevant studies. Peer reviewers should make a point to question authors of the reasoning behind the inclusion or exclusion of those listed controls. This proposal would not coerce authors into including controls they feel are irrelevant -- rather, it would demand that researchers explicate the reasoning for their model's assumptions. In the meantime, I will discuss best practices for choosing appropriate controls in public health studies, based on research from Dr. Gary King.

DEMOGRAPHIC PREDICTORS OF INDIVIDUAL DIFFERENCES IN COPING BEHAVIORS OF SOLDIERS

Ellen P. Merrill, MA[1], Adam J. DiChiara, BS[2], Alan O. Wright, MS, CFS[3], Adrienne Hatch, MS, RD[4], Renee E. Cole, PhD, RDN, LD[5], Susan McGraw, BS[6], Scott J. Mountain, PhD[7], Harris R. Lieberman, Ph.D. [7], Asma Bukhari, PhD, RDN[8]

[1]Cognitive Science and Applications Team, US Army Natick Soldier Research Development & Engineering Center, Sudbury, MA; [2]U.S. Army Natick Soldier Research, Development & Engineering Center, Holliston, MA; [3]Natick Soldier Research, Development, and Engineering Center, North Oxford, MA; [4]Military Nutrition Division, U.S. Army Research Institute of Environmental Medicine, Boston, MA; [5]U.S. Army Research Institute of Environmental Medicine, Natick, MA; [6]US Army Research Institute of Environmental Medicine, Natick, MA; [7]USARIEM, Natick, MA; [8]U.S Army, Bethesda, MD

Background: Most military personnel use dietary supplements (DS) and they are much more likely to use dangerous DS than their civilian counterparts. Given the prevalence and associated risks of DS use, it is important to understand specific trait characteristics of Soldiers when considering these health-related behaviors. *Purpose:* To assess coping behaviors associated with various demographic factors in a sample of active duty U.S. Army Soldiers and how they relate to DS usage. *Methods:* Demographic and behavioral questionnaires were administered to 289 Soldiers (83% male and 17% female, mean age ± SD 28±6y) at 3 installations. The validated Brief Cope Scale (dimensions: self-distraction, active coping, denial, substance use, emotional support, instrumental support, behavioral disengagement, venting, positive reframing, planning, humor, acceptance, religion and self-blame) was used to assess coping behaviors. One-way ANOVAs compared effects of gender, age, education level and marital status on various coping dimensions. A subset of Soldiers (n=128) participated in focus groups to better understand the motivation for use or non-use of DS. *Results:* Seventy-five percent of those sampled were DS users. No significant differences were found between DS users and non-users on coping scale dimensions. Males were more likely than females to use humor (*p*=.02) and acceptance (*p*=.03) while females were more likely to use emotional support (*p*=.02), religion (*p*=.03) and self-distraction (*p*p=.00) and self-distraction (*p*=.03) while older Soldiers were more likely to use religion (*p*=.00). Soldiers with higher levels of education were more likely to use active coping (*p*=.00), emotional support (*p*=.04) and planning behavior (*p*=.00); whereas Soldiers with lower levels of education were more likely to use more behavioral disengagement, self-distraction and denial (*p*=.00) strategies. Married

Soldiers were more likely to use religion (p=.00) while single Soldiers were more likely to use self-distraction (p=.01). In focus groups, Soldiers stated they use DS to address job pressures and meet the performance demands in their military roles to reach short-term goals, despite the known and unknown long-term consequences of DS consumption. *Conclusion:* Younger, less educated and single Soldiers use negative coping styles more frequently and may be more vulnerable to questionable DS claims. Negative coping styles reportedly can increase risk in stressful situations while it has been shown adaptive coping styles, such as emotional support, are protective in such circumstances. Training to encourage positive coping behaviors early in an individual's military career may improve resiliency, facilitate healthful behaviors and provide short and long term benefits.

POSTTRAUMATIC GROWTH AND BIOMARKERS OF CHRONIC STRESS AMONG COMBAT VETERANS OF OPERATIONS ENDURING AND IRAQI FREEDOM

Cara L. Blevins, MA[1], Richard G. Tedeschi, PhD[1], Jeanette M. Bennett, PhD[1], Amy Canevello, PhD[2], Christine Elnitsky, PhD, RN[1]

[1]The University of North Carolina at Charlotte, Charlotte, NC; [2]University of North Carolina, Charlotte, Charlotte, NC

Combat Veterans are at increased risk for cardiovascular disease (CVD) and chronic illness due to in-theater stressors. Growing evidence suggests that experiences of posttraumatic growth (PTG), or positive psychological change in the aftermath of trauma, may convey salutary health benefits; however, the relationship between PTG and Veteran health is currently unknown. The present pilot study sought to elucidate this relationship by examining the influence PTG on levels of inflammation and diurnal cortisol slope in Veterans of Operations Enduring and Iraqi Freedom. We hypothesized that greater levels of PTG would buffer against the adverse effects of stress as indicated by a steeper and more negative cortisol slope and lower levels of C-reactive protein (CRP; mg/L). Participants (*N*=33) focused on their combat experiences when completing self-report measures and provided saliva samples over the course of 2 days to assess CRP and cortisol. Separate hierarchical multiple regression analyses were run to predict CRP and the diurnal cortisol slopes from Day 1 and Day 2 of the study. Consistent with existing theory, significant positive relations were found between PTG and PCL scores ($r(33)=.83$, $p < .001$). The regression models predicting CRP and Day 1 cortisol slope were not significant. The regression model predicting Day 2 cortisol slope revealed a significant positive interaction between PTG and PTSD symptomology ($\beta=.001$, $p < .05$).

Examination of the simple slopes revealed a disordinal interaction between PCL and PTG scores such that the cortisol slope of veterans reporting a greater degree of PTG became increasingly positive as PTSD symptoms increased. Relatedly, the cortisol slope of veterans reporting a low degree of PTG became increasingly negative as PTSD symptoms increased. Results of this pilot study provide preliminary evidence that experiences of PTG may influence how Veterans respond to stress at a physiological level. The positive cortisol slope demonstrated by those Veterans reporting high levels of PTG with greater trauma symptoms may be a reflection of the processes by which one seeks to reconstruct their assumptive worldview in the aftermath of trauma. That those Veterans reporting lower levels of PTG with higher levels of trauma symptoms did NOT demonstrate higher levels of cortisol may indicate a sign of dysregulation or stress desensitization. Future work is warranted before causal assumptions can be made.

PROGRAM OF COMPREHENSIVE ASSISTANCE FOR FAMILY CAREGIVERS: CAREGIVERS PERSPECTIVE ON PROGRAM VALUE

Nina Sperber, PhD[1], Sara M. Andrews, MAT, MPH, RD[2], Jennifer Henius, MSW, LCSW[3]

[1]Veterans Affairs, Durham, NC; [2]VA, Durham, NC; [3]VA, Washington, DC

The Caregivers and Veterans Omnibus Health Services Act of 2010 (P.L. 111-163) directed VA to provide sweeping supports for family caregivers of all Veterans within the Veterans Affairs (VA) health system. This legislation is an innovation in service delivery that acknowledges the important role of family caregivers in health care delivery. Stemming from this legislation, VA caregiver support greatly expanded, with formation of the Program of Comprehensive Assistance for Family Caregivers (PCAFC) and the Program of General Caregiver Support Services, and funding of a Caregiver Support Coordinator (CSC) at every VA medical center (VAMC). PCAFC provides services for caregivers of post-9/11 Veterans seriously injured in the line of duty, including a monthly stipend and required training, and optional services such as health insurance, mental health care, and respite care. We used mixed-methods to assess how caregivers use and value PCAFC services to improve the program's ability to refine and optimize services. We conducted a national web-based survey of caregivers (N=1,407) and semi-structured phone interviews with caregivers from 10 VAMCs (N=50). Caregivers rated all services as helpful, 7.9 to 8.8 on a scale of 1 to 10 ("most helpful"). They rated the stipend highest, valuing it for providing flexibility to be physically present for their Veterans; caregivers also valued trainings for instructing them on how to manage TBI/PTSD symptoms. However, caregivers reported low use of optional services; e.g., only 7% used respite care, with reports that Veterans with TBI/PTSD sometimes have difficulty with strangers in the home. Seventy-five percent of Caregivers reported interacting with their CSCs since joining the program, though for most (57%) less than once a month. A majority (59%) reported obtaining referrals and direct support from their CSC, for example to help navigate the VA health system. Almost two-thirds agreed/strongly agreed that the PCAFC has helped them to feel more confident in caregiving, know about resources to help their caregiving, and support their Veteran's progress and health care engagement. Overall, caregivers valued receiving VA support with particular gratitude for home support, PTSD/TBI symptom management, and assistance with navigating the VA healthcare system. Future work could better evaluate and guide use of optional services to support caregivers and Veterans, especially those with conditions that impose barriers to use.

SMOKING IN U.S. MILITARY PERSONNEL DURING TRANSITION FROM ACTIVE DUTY TO VETERAN STATUS

Chiping Nieh, PhD, CPH[1], James Mancuso, MD, DrPH, MPH[2], Gary D. Gackstetter, DVM, MPH, PhD[3], Marleen Welsh, PhD[1], Teresa Powell, MS[4], Tomoko I. Hooper, MD, MPH[5]

[1]Uniformed Service University of the Health Sciences, Bethesda, MD; [2]USUHS, DPO AE, N/A; [3]Uniformed Services Univ of the health Sciences, Fairfax, VA; [4]Henry Jackson Foundation, San Diego, CA; [5]Uniformed Services University of the Health Sciences, Bethesda, MD

The prevalence of cigarette smoking has been consistently higher in the US military than in civilian populations. Although risk factors for smoking behavior among Service members has been studied, there is a gap in the literature on smoking behavior during transition from active duty military to civilian life. We sought to investigate any change in smoking among those transitioning from military to Veteran status.

Participants in the Millennium Cohort Study (longitudinal study of US military personnel) who separated from service prior to first follow-up or remained in service for at least two survey cycles were included (n=30,996). Using generalized estimating equations, we examined associations between smoking and separation status as well as demographic, military, health behavioral characteristics, and life stressors. Sixteen percent of participants reported smoking at baseline, and 32% subsequently separated from service. Multivariable analysis showed that Service members who separated were significantly less likely to be a current smoker (adjusted odds ratio: 0.89, 95% confidence interval: 0.83-0.95) than those who remained in service. Adjusted odds of smoking increased with higher number of life stressors (1 stressor: 1.05, 1.01-1.10, 2 stressors: 1.12, 1.06-1.19, 3 or more stressors: 1.25, 1.16-1.34 vs. 0 stressor). Higher odds of smoking were also found among those with greater alcohol consumption, being black non-Hispanic, not married, normal weight or underweight, Army, junior enlisted, and screening positive for post-traumatic stress disorder or depression.

In our study, separation from service was protective for current smoking. This finding is interesting as transition out of service might be stressful for some and result in maladaptive coping mechanisms. Although results seem to indicate that staying in the military may facilitate smoking behaviors, since the models were adjusted for life stressors, alcohol consumption, and other risk factors, the effect of separation from service may have been lessened. More research is needed to delineate modifiable risk factors and specific military and Veteran subpopulations for targeted smoking interventions.

SOCIAL SUPPORT AND MASTERY IN THE LINK BETWEEN FUNCTIONAL LIMITATIONS AND NEED FOR HELP AMONG ILL AND INJURED MILITARY MEMBERS

Kimberley Watkins, MA, Jennifer Lee, PhD, Alla Skomorovsky, PhD

Department of National Defence, Ottawa, ON, Canada

Functional limitations (i.e., difficulties in conducting daily tasks) due to illness or injury tend to be associated with a high perceived need for the help of others in performing activities, such as meal preparation or personal hygienic care. However, other variables, such as one's perceived social support and/or feelings of self-efficacy or mastery, may influence this association between functional limitations and perceived need for help.

The present study investigated the moderating roles of social support and mastery in the association between functional limitations and perceived need for help among 164 ill or injured Canadian military members. Participants completed a paper survey measuring various aspects of health, as well as psychosocial variables, including social support and mastery. To assess functional limitations, participants were asked to report the general degree of impairment and frequency of limitations experienced in various tasks. For illness- or injury-related need for help, participants reported the frequency of requiring aid with various activities.

Two moderation analyses were conducted using Hayes' PROCESS macro for SPSS. Each analysis included functional limitations as the independent variable and perceived need for help as the dependent variable, while social support and mastery were included as the hypothesized moderating variables in their respective analyses. Both analyses were significant, and both showed the same effect on the positive association between functional limitations and perceived need for help. Specifically, when social support/mastery was low, this association was much stronger, while at high levels of social support/mastery, there was much less of an association between functional limitations and perceived need. In other words, at low levels of functional limitations, participants at all levels of social support/mastery reported relatively low need for aid. However, when functional limitations were high, those with low levels of social support/mastery reported high need for help while those with high levels of social support/mastery reported low need for help.

Though the patterns were similar, the findings for social support and for mastery may be interpreted differently. The results for social support were as expected: when social support is high, the perceived need for help was low, regardless of functional limitations. For mastery, however, results are potentially concerning, in that participants with high perceived mastery reported a relatively low need for help, even when their functional limitations were high. To the extent that their actual need for help exceeds their perceived need, such participants may be less likely to seek and receive help. The implications of these findings for ill and injured military personnel will be discussed.

THE ASSOCIATION BETWEEN COMBAT AND LATENT TRAJECTORIES OF PHYSICAL WELL-BEING

Ben Porter, PhD[1], Geroge A. Bonanno, PhD[2], Paul D. Bliese, PhD[3], Susan P. Proctor, ScD[4]

[1]Naval Health Research Center, San Diego, CA; [2]Columbia University, New York, NY; [3]University of South Carolina, Columbia, SC; [4]US Army Research Institute of Environmental Medicine, Natick, MA

Combat exposure is associated with an increased risk of adverse mental and physical health conditions. Little research has examined whether trajectories of physical health over time within deployed service members can be separated into distinct classes or patterns and, if so, whether these classes differ by deployment combat exposure experienced. Using the Millennium Cohort Study, this investigation examined physical well-being assessed at four timepoints between 2001 and 2012 among 11 950 (6013 combat-exposed) military service members who deployed between their first and second assessment. Physical well-being was measured using the physical component scale score calculated from the Veterans RAND-36. Latent growth mixture modeling was used to estimate heterogeneous trajectories of physical well-being. Results indicated that five distinct trajectories of physical well-being existed (high-stable, low-stable, improving, delayed declining, worsening). Combat exposure was entered into subsequent models as a known class to compare trajectories of combat-exposed and unexposed service members. The shapes of trajectories between these two groups were highly similar. The high-stable class was the modal class among combat-exposed and unexposed participants (75.6% and 82.2%, respectively). However, chi-squared analyses indicated a larger proportion of service members unexposed to combat were in the high-stable class (*p*p’sp=.45). Results indicate that physical well-being surrounding deployment has several distinct trajectories. However, the shape of these trajectories does not vary much between combat-exposed and unexposed service members. Physical health differences between these groups are likely to be reflected by the larger proportion of participants with poorer physical well-being trajectories.

TRANSLATING EVIDENCE-BASED PRACTICE GUIDELINES INTO PATIENT-CENTERED OBESITY CARE

Jessica A. Lohnberg, Ph.D.[1], Lauren M. Greenberg, Ph.D.[2], Cheryl Bates, M.D.[1], Jessica Y. Breland, Ph.D.[3], Susan Frayne, M.D.[1], Dan Eisenberg, M.D., M.S.[1]

[1]VA Palo Alto Health Care System, Palo Alto, CA; [2]War Related Illness and Injury Study Center, VA New Jersey Health Care System, East Orange, NJ; [3]VA Palo Alto & Stanford University School of Medicine, Menlo Park, CA

Background. Obesity, a leading cause of mortality, morbidity, disability, and rising healthcare costs, affects roughly one-third of the millions of Veterans seeking treatment at VA medical facilities. As such, expanded access to multidisciplinary specialty obesity care, including bariatric surgery, is of paramount importance. New obesity treatment guidelines suggest healthcare providers develop individualized weight loss plans incorporating diet, exercise, and behavioral interventions for all patients, and bariatric surgery for individuals with body mass index (BMI)$\geq$35 kg/m^2. For patients undergoing bariatric surgery, evidence-based clinical practice guidelines recommend multidisciplinary pre- and post-op management. However, little is known about how to implement such programs and whether patients are satisfied with the care. We developed an innovative approach to weight management that provides access to bariatric surgery care for Veterans from multiple VA facilities across the Western US.
Objective. We had two goals: 1) To describe the interdisciplinary MOVE TIME Clinic, which offers a patient-centered approach to weight management before and indefinitely after bariatric surgery in accordance with evidence-based guidelines. 2) To assess patient satisfaction with this clinic.
Methods. As a program evaluation activity, clinic patients (*N*=54 sequential Veterans) completed questionnaires assessing satisfaction with the clinic, satisfaction with functional status as a result of care received, and satisfaction with access to care.
Results. The sample was primarily male (76%), 50-70 years of age (81%), and white (66%). Almost all patients (98%) reported overall satisfaction with the clinic, with a majority (94%) reporting that MOVE TIME improved their quality of life, and with two-thirds (65% of pre-surgery patients and 74% of post-bariatric surgery patients) indicating that their health was better than the previous year. Most said they would recommend the clinic to others (94%).
Conclusion. Given increasing obesity rates and demand for bariatric surgery, access to interdisciplinary specialty care is essential in addressing the rising obesity prevalence among Veterans. MOVE TIME is a novel clinic that provides intensive and accessible patient-centered obesity care and is well-received by Veterans, with high rates of satisfaction and reports of

improved quality of life. This program can serve as a model for how to translate evidence-based obesity and bariatric surgery guidelines recommending multidisciplinary pre- and post-op management into patient-centered clinical practice. Such models are critical given the epidemic of obesity among Veterans and VA's increasing efforts to provide expanded access to multidisciplinary specialty obesity care.

UNDERSTANDING HOW OEF/OIF VETERANS CONCEPTUALIZE HEALTH DURING AND AFTER MILITARY SERVICE

Alicia Sparks, PhD[1], Mira Brancu, PhD[2], Jennifer M. Gierisch, PhD, MPH[3], Meredith Stewart, MPH, CPH[4], Suzanne Maman, MHS, PhD[5], Kristy Straits-Troster, PhD, ABPP[6]

[1]Abt Associates, Silver Spring, MD; [2]Mid-Atlantic VA Mental Illness Research, Education and Clinical Center (VISN 6 MIRECC); Duke University Psychiatry & Behavioral Sciences Department, Durham, NC; [3]Duke Univeristy, Durham, NC; [4]Duke University, Durham, NC; [5]University of North Carolina at Chapel Hill, Chapel Hill, NC; [6]Dept. of Veterans Affairs, Phoenix, AZ

Objectives: Combat veterans returning from Operation Iraqi Freedom and Operation Enduring Freedom in Afghanistan have shown a high prevalence of readjustment problems that impact health behaviors. Approximately 40% of OEF/OIF veterans reported difficulty acclimating to civilian life on returning from deployment (5). Civilian life readjustment issues often manifest in difficulty with social relationships (56%), problems finding or keeping a job (25%), elevated drug and alcohol use (31%), divorce or separation (35%), and increased anger control problems (57%) .This study sought to understand how veterans conceptualize health from active duty to veteran status.

Methods: We conducted in-depth interviews with Operation Iraqi Freedom and Operation Enduring Freedom veterans. Fourteen participants were recruited through the Department of Veterans Affairs Mid-Atlantic Mental Illness Research, Education, & Clinical Center (VISN 6 MIRECC) Database for the Study of Post-Deployment Mental Health. We conducted a qualitative content analysis of telephone interviews that were recorded and transcribed. Codes were reviewed by a cross-disciplinary study team and themes across constructs were analyzed.

Results: We found that health was defined in four categories: Physical and mental health, appearance, and conduct. Participants enumerated challenges in the transition from military to civilian life, including maintaining healthy habits and resisting unhealthy behaviors less prevalent in the military. For the participants in this study, being healthy required either addressing mental health symptoms or being devoid of them, fitting the military appearance expectations of both weight and grooming, and following the conduct expected of them in the military, even while in the civilian world. These four constructs seemed to remain from active-duty service to becoming a veteran, even though participants had more difficulty maintaining

their health as civilians.

Conclusions: Findings from this study have policy implications for improving post-deployment health as well as providing important context for primary care providers working with veterans, their families and peers supporting veterans in efforts to retain healthy habits as civilians. The most important implications are that preventive measures can be taken during the transition from active duty to veteran status that will help maintain or improve a service member's health. Providers working with veterans need to understand what is considered healthy in the military setting and that a veteran's self-perception of their own health might not reflect clinical definitions of health. Providing guidance on maintaining structure in a way that can encourage the continuing of healthy behaviors might be valuable in creating a smoother transition from military to civilian life.

VA TRUST AMONG US ARMY RESERVE/NATIONAL GUARD SOLDIERS WITH SUBSTANCE USE OR MENTAL HEALTH DISORDERS

Jennifer Garcia-Cano, BA & BS[1], D. Lynn Homish, BS[2], Sarah Cercone. Cercone Heavey, MPH[3], Gregory G Homish, PhD[2]

[1]University at Buffalo, San Bernardino, CA; [2]University at Buffalo, Buffalo, NY; [3]State University of New York at Buffalo, Buffalo, NY

VA Trust among US Army Reserve/National Guard Soldiers with Substance Use or Mental Health Disorders

Community Health & Health Behavior, University at Buffalo

Background: Trust in the healthcare system is an important factor in deciding to use healthcare. Long wait times are functional barriers that can negatively impact trust in the healthcare system. This can discourage individuals from seeking treatment. The objective of this study is to examine trust in the VA Healthcare System and to determine if substance use or mental health conditions impact soldiers' trust. Additionally, this work will examine the functional barrier of wait times on the basis of mental vs. physical health role limitations.

Methods: Data are from Operation: SAFETY (Soldiers And Families Excelling Through the Years), an ongoing longitudinal study of US Army Reserve/National Guard Soldiers and their partners. All soldiers were asked about their trust level in the VA Healthcare System. Mental health disorders (PTSD, depression, anger, anxiety) and substance use were also assessed. Soldiers who have had an appointment at the VA were asked about the length of wait time, a factor which could impact trust. We examined differences in wait time on the basis of emotional and physical health role limitations.

Results: At a trend level, trust scores were found to be lower among female soldiers who were currently using drugs or drinking at hazardous levels. Among male soldiers, trust levels were lower among those who were hazardous drinkers. Additionally, male soldiers who had higher anger scores were more untrusting of the VA healthcare system. However, anxiety,

PTSD, and depression were unrelated to trust among both male and female soldiers. In terms of wait times, female soldiers' findings are as one would expect: as functional limitations occurred for either physical or mental health conditions, wait times decreased. However, for male soldiers, functional impairment for either physical or mental health conditions was not related to wait times.

Conclusions: The current results suggest that mental health and substance use issues appear related to less trust in the VA healthcare system. This fact, coupled with structural barriers such as long wait times, could further impact trust and put our soldiers at risk for not receiving treatment.

Supported by R01DA034072 (GGH) & R01DA0340724S1 (GGH).

WOMEN VETERANS' PERCEPTIONS OF VA MENTAL HEALTH CARE

Joya G. Chrystal, MSW, LCSW[1], Cynthia E. Gammage, BA[2], Bevanne Bean-Mayberry, MD, MHS[3], Fay Saechao, MPH[4], Susan Frayne, M.D.[5], Elizabeth M. Yano, PhD, MSPH[2], Alison B. Hamilton, PhD, MPH[6], John E. Zeber, PhD[7], Pamela Smith-Beatty

[1]Department of Veterans Affairs, Health Services Research & Development Center for the Study of Healthcare Innovation, Implementation & Policy, Los Angeles, CA; [2]Department of Veterans Affairs, North Hills, CA; [3]VA Greater Los Angeles, Noth Hills, CA; [4]Center for Innovation to Implementation (Ci2i), VA Palo Alto Health Care System, Menlo Park, CA; [5]VA Palo Alto Health Care System, Palo Alto, CA; [6]VA Greater Los Angeles Healthcare System, Culver City, CA; [7]VA / Baylor Scott & White, Temple, TX

Background: Women Veterans are the fastest growing sector of eligible Veterans Administration (VA) users and are increasingly accessing mental health services.

Objective: To assess women Veterans' perceptions of their VA healthcare and decision–making processes related to healthcare coverage, as well as healthcare experiences within VA.

Design: Nine discussion groups in California, Texas, and Florida across five facilities.

Participants: Women Veteran participants (n=49) currently utilizing VA services.

Approach: Interviews were audio recorded, transcribed and summarized for salient themes. Perceptions of women Veterans' mental healthcare needs and suggestions to improve related services within VA were assessed.

Key Results: Participantswere high utilizers of mental health services (68% saw a mental health provider in past year). The majority had service-connected disability (70%) and used VA exclusively for care (69%), though some dual-coverage participants sought care outside VA for specialty care, such as mental health. Mental healthcare was identified as an area needing improvement, e.g., a supportive infrastructure to better deliver services, including a service climate sensitive to women's needs and stronger patient-provider relationships. Women discussed desired improvements in mental health resources and program areas, including additional individual therapy options, increased appointment duration and frequency, gender-specific trauma-focused therapies, bereavement support, and childcare options during mental

health appointments. Desired improvements in service climate factors include streamlined phone triaging, clarity on patient advocacy support, extended service hours, and provision of transportation. Improvements were also desired in patient-provider relationships such as enhanced communication skills, opportunities for building trust with rotating providers (interns, residents), and ways to address privacy/confidentiality concerns especially for women Veteran employees.

Conclusions: Women Veterans' first-hand perspectives on desired improvements in mental health care provide stakeholders with targeted service areas for infrastructure improvement and greater healthcare engagement. These improvements may improve women Veterans' access to and sustained engagement in care. In an era where Veterans have expanded options for their healthcare coverage, it is incumbent upon the VA to continue to respond to patient-centered feedback on quality of care.

B191 6:00 PM-7:00 PM

"THE FRESHMAN FIFTEEN" AND BEYOND: A META-ANALYSIS

Hannah Lammert, MA[1], Rick LaCaille, PhD[2], Lara LaCaille, PhD[2]

[1]Pacific University, Beaverton, OR; [2]University of Minnesota Duluth, Duluth, MN

The rising rates of overweight and obesity are concerning due to the increased risk for negative health consequences. Not surprisingly, the transition to college is associated with various changes (e.g., increased freedom to food choices, access to unhealthy foods, decreased physical activity, altered life schedules) that may contribute to additional weight gain in students compared to their non-student peers. The *freshman fifteen* is a colloquial term used to specify typical weight gain experienced by students during their first year of college and is concerning given that approximately 30% of college students are considered overweight or obese. The present meta-analysis examined body weight and adiposity changes over the first year as well as to the end of the senior year of college. A search of seven electronic databases resulted in 55 peer-reviewed studies (from 1985 to 2015) for inclusion in the meta-analysis, although only a subset of these were included because of missing data. Using random-effects models to assess change in weight, an overall mean weight gain of 0.74 kg (CI = 0.56 – 0.92, k = 27) was found for freshman year across all students. However, the average weight gain for only those students gaining weight was 3.43 kg (CI = 2.32 – 4.53, k = 4). Comparisons of five studies examining long-term weight change revealed a gain of 2.13 kg (CI = 1.02 – 3.25) by the end of the senior year. Weight change differences between males (1.47 kg; 0.90 – 2.05, k = 10) and females (1.31 kg, CI = 0.86 – 1.76, k = 19) were found during the freshman year and continued through the senior year with gains of 2.89 kg (CI = 0.78 – 4.99) for males and 1.42 kg (CI = 0.69 – 2.14) for females. When sufficient data were available for analysis, the findings with adiposity measurements generally paralleled the weight gain results. Although the research does not support the notion of the *freshman fifteen*, a considerable number of students gain weight in the first year. Cumulative weight gain throughout college is notable and of continued concern because of the potential harmful health behaviors and patterns that may carry into adulthood. These findings highlight the need for greater focus being paid to developing targeted strategies to prevent weight gain throughout students' experiences with college.

A DYNAMICAL SYSTEMS MODEL FOR UNDERSTANDING HOW THE INTRAUTERINE ENVIRONMENT AFFECTS FETAL GROWTH IN AN INTERVENTION CONTEXT

Mohammad T. Freigoun, BS in Chemical Engineering[1], Penghong Guo, Master in Chemical Engineering[2], Daniel E. Rivera, PhD[2], Emily Hohman, PhD[3], Abigail Pauley, MS Exercise Science[4], Danielle Symons Downs, Ph.D.[5], Jennifer S. Savage, PhD[6]

[1]Arizona State University, Mesa, AZ; [2]Arizona State University, Tempe, AZ; [3]Center for Childhood Obesity Research, University Park, PA; [4]Penn State University, Bellefonte, PA; [5]The Pennsylvania State University, University Park, PA; [6]Penn State University, University Park, PA

BACKGROUND: The underlying mechanism for how maternal perinatal obesity and intrauterine environment influence fetal development remains largely unknown. Dynamical systems modeling is used to develop a fetal growth model within the context of an intervention to manage gestational weight gain (GWG) that illustrates how maternal GWG and the intrauterine environment influences fetal growth and ultimately, infant birth weight.

METHODS: The Healthy Mom Zone (HMZ) intervention is an individually-tailored, intensively adaptive intervention aiming to manage weight gain among overweight/obese pregnant women (OW/OBPW). Intensive longitudinal data (ILD) is collected daily (weight, physical activity, self-reported dietary intake) and bi-weekly/monthly (sleep, eating/physical activity self-regulatory behaviors) using *mHealth* tools. ILD is also collected on indicators of fetal growth (six ultrasound scans per participant) and stress (bi-weekly urine). OW/OBPW (*N=30*) will be randomized to treatment and control groups from approximately 8-36 weeks gestation. Relying on this data and a previously developed maternal weight gain model, the parameters of a system of differential and algebraic equations based on the First and Second Laws of Thermodynamics are estimated to obtain a predictive model for fetal weight gain.

RESULTS: Estimated models from four completed participants allow contrasting model predictions to available measurements of fetal weight and placental volume. These models point to an acceptable goodness-of-fit (within the standard deviation of the measurements) obtained from a semi-empirical approach relying on fixed parameter values available from the literature (energy densities and efficiencies) with adjustable parameters estimated from the data (fetal growth rate, back-calculated energy intake, and selected conversion factors). Model enhancements (an improved equation for placental volume) and simplifications (a single first-order differential equation for fetal weight) are obtained from this analysis, in contrast to earlier models. The overall result is a parsimonious system of equations that

reliably predicts maternal GWG and fetal weight gain based on a sensible number of assessments.

CONCLUSION: Dynamical systems modeling developed from ILD on fetal growth is feasible. Findings from our dynamical models can be used in future studies to explore the underlying mechanisms for how maternal perinatal obesity "programs" fetal development, related metabolic disorders, and later obesity. Use of these models can inform the development of intensively adaptive interventions for preventing childhood obesity.

A NOVEL STEPPED-CARE APPROACH TO WEIGHT LOSS: THE ROLE OF SELF-MONITORING AND HEALTH LITERACY IN TREATMENT OUTCOMES

Jennifer Selensky, B.S.[1], Robert Carels, Ph.D., MBA[1], James J. Rossi, MA[1], Chelsey Solar, M.S./Ed.S[1], Reid Hlavka, B.A.[2], Emily Hefner, Student[3]

[1]East Carolina University, Greenville, NC; [2]East Carolina University, Winterville, NC; [3]East Carolina Universtiy, greenville, NC

Objectives: The aims of the current study were twofold: 1) examine the effectiveness of an innovative three-step, stepped-care behavioral weight loss treatment, and 2) examine factors that contribute to poor weight loss outcomes and the need for more intensive treatment.

Methods: The total sample for the study consisted of 53 individuals (87% female; 62% Caucasian, 34% African American, 4% Asian/Pacific Islander) with M_{BMI}=35.6, SD_{BMI}=6.4. Participants were recruited through a faculty and staff listserv email at a large southeastern university and through a community newspaper with the advertisement of a free weight loss program. A three-step, stepped-care treatment approach was implemented over six months. Step 1 included the Diabetes Prevention Program manual adapted for self-administration and the use of a Fitbit Zip® device with the associated application/website to self-monitor their diet, physical activity, and weight loss progress. Participants who were unsuccessful at achieving predetermined weight loss goals received stepped-up treatments in 2-month increments beginning at month 2. The stepped progression included the addition of meal replacement at Step 2 and individual counseling concurrent with meal replacement at Step 3. We assessed for contributing factors to poor weight loss outcomes using the following measures: The Newest Vital Sign, Center for Epidemiological Study of Depression, Universal Measure of Bias – FAT, Weight Bias Internalization Scale, and the Binge Eating Scale.

Results: Non-stepped and once-stepped participants lost a clinically significant amount of weight (8.7% and 6.0% weight loss over 6 months, respectively), while twice-stepped participants lost an insignificant amount of weight (1.0% weight loss over 6 months). Twice-stepped participants were significantly lower in health literacy (p = .03) and self-monitoring frequency (p = .02).

Conclusions: In this investigation, approximately 60% of the participants were able to lose a clinically significant amount of weight utilizing a minimally intensive intervention with little additional support. Regular self-monitoring and high health literacy proved to be significant correlates of weight loss success.

A SCHOOL-BASED HEALTH CENTER OBESITY PREVENTION PROGRAM

Robin Whittemore, PhD, APRN, FAAN[1], David Collett, MA, MAT, RN[2], Sangchoon Jeon, PhD[3]

[1]Yale University, School of Nursing, Orange, CT; [2]Yale University School of Nursing, New Haven, CT; [3]Yale University, West Haven, CT

Background: Approximately 34% of youth are overweight or obese. School-based health centers represent a system of care for providing health education and obesity prevention programs. The purpose of this study was to describe the obesity-risk behaviors of youth 5-12 years of age and the feasibility of a school-based health center obesity prevention program that was initiated by the school.

Methods: A one-group pre-post design was used to evaluate an obesity prevention program promoting 9 hours of sleep, 5 fruits and vegetables, less than 2 hours of screen time, 1 hour of physical activity, and 0 sugar-sweetened beverages/day. The program consisted of interactive health education provided by nurses during lunch; lesson plans provided to teachers; weekly health messages in morning announcements; and posters, bulletin boards, and newsletters for parents. Data were collected on obesity-risk behaviors with established measures by parents of youth 5-9 years and by students 10-12 years of age. BMI was calculated from height and weight measures. Descriptive statistics and t-tests were used.

Results: There were a total of 345 youth whose parents did not opt-out of the program evaluation. At the time of enrollment, youth in the school were 52% male, with 56% white non-Hispanic, and 48% of students eligible for free lunch. At baseline, 44% of youth were overweight or obese, 80% of youth ate < 5 servings of fruits/vegetables per day, with a mean of 2.7 days/week of moderate-vigorous exercise. The program was challenging to implement with competing responsibilities of nurses and teachers. The program did not improve obesity-risk behaviors over time and BMI increased significantly over time ($p < .01$)

Conclusions: High rates of overweight/obesity and poor health behaviors continue to be evident in youth of diverse race/ethnicity. School-based obesity prevention programs are challenging to implement. Designated program staff, family involvement, and school health policies may be necessary to ensure success with implementation and improvement in youth outcomes.

AN ECOLOGICAL MOMENTARY ASSESSMENT STUDY OF INTERNAL AND EXTERNAL WEIGHT STIGMA EVENTS IN A WEIGHT LOSS TREATMENT SEEKING SAMPLE

James J. Rossi, MA[1], Chelsey Solar, M.S./Ed.S[1], Jennifer C. Selensky, Bachelor of Science[1], Reid Hlavka, B.A.[2], Robert Carels, Ph.D., MBA[1]

[1]East Carolina University, Greenville, NC; [2]East Carolina University, Winterville, NC

Objectives: This study sought to explore temporal relationships between experiences of internal and external weight stigma and mood and coping in real time using ecological momentary assessment (EMA). Furthermore, we sought to explore cross sectional differences in binge eating, levels of internalized weight bias and lifetime history of experienced stigma between those individuals who reported instances of weight stigma during a 2-week pre-weight loss intervention EMA study and those who did not.

Methods: 51 BWL participants completed EMA assessments of weight stigma events as well as their emotional and coping responses. Participants were asked to report external instances of weight stigma, including hearing inappropriate/rude comments about their weight, encountering structural or physical barriers in their environment, or internal experiences or personal reminders that “made [you] feel bad about your weight” (eg. trying on clothes, looking in the mirror, etc.). Participants also completed random prompt entries assessing mood at various times not related to weight stigma events. In addition participants completed measures at baseline including the Binge Eating Scale (BES), Weight Bias Internalization Scale (WBIS) and the Stigmatizing Situations Inventory (SSI).

Results: 30 of 51 participants reported 80 instances of experienced weight stigma over the course of two weeks. The majority of stigma experiences were personal reminders of one’s weight (74%). Given the limited amount of observations per participant, responses were aggregated and between subjects differences were analyzed between those who reported weight stigma over the two week study period and those who did not. In those that experienced weight stigma, stigmatizing experiences were associated with lower levels of positive emotion (less happy $t(27)=6.75$, $p < .01$, less inspired $t(27)=4.51$, $p < .01$, less relaxed $t(28)=4.07$, $p<.01$) and higher levels of negative emotion (more depressed $t(27)=3.04$, $p=.01$, more ashamed $t(27)=2.61$, $p=.02$ and more frustrated $t(26)=-2.92$, $p=.01$). Participant coping style was also related to mood. Isolation and avoidance was significantly associated with higher levels of feeling depressed ($r=.40$, $p<.05$), feeling ashamed (r=.52, $p < .01$), and was inversely associated with feeling happy ($r=-.38$, $p < .05$). Furthermore, there was an inverse association between positive self talk and feeling numb ($r=-.37$, $p < .05$). Participants

reporting any weight stigma event over the two week study period were more likely than non-reporters to evidence higher levels of experienced lifetime weight stigma *t*(34.8)=2.54, *p*=.02, internalized weight bias *t*(53)=2.87, *p* < .01 and binge eating t(50)=2.71, *p* < .01.

Discussion: This study suggests that stigmatizing experiences have momentary impacts on psychological well-being and coping among participants with overweight and obesity.

AUTONOMY SUPPORT BY ROMANTIC PARTNERS IS ASSOCIATED WITH DECREASED CONTROLLED REGULATION FOR WEIGHT LOSS AMONG HIGH BMI WOMEN

Katelyn M. Gettens, M.A.[1], Noemie Carbonneau, Ph.D.[2], Theodore A. Powers, PhD[3], Richard F. Koestner, PhD[4], Amy A. Gorin, Ph.D.[1]

[1]University of Connecticut; Institution for Collaboration on Health, Intervention, and Policy, Storrs, CT; [2]University of Quebec in Trois-Rivieres, Trois-Rivieres, PQ, Canada; [3]University of Massachusetts Dartmouth, N Dartmouth, MA; [4]McGill University, Montreal, PQ, Canada

Background: Self-Determination Theory and ecological models strongly suggest that provision of autonomy support (AS) by existing social networks engenders successful health behavior change. This dual-study analysis examined the impact of romantic partners' autonomy support on women's reasons for weight control, particularly the extent to which women felt pressured or controlled to lose weight. **Methods:** *Study 1* participants (n=159) were couples from the general population (M_{ageM}= 44.1±13.1; M_{ageF} = 43.63±12.1 years; M_{BMI} = 26.5±5.3kg/m^2; 97.8% Caucasian; 61% married). Men self-reported their provision of autonomy support (AS). Controlled regulation (i.e., more externally motivated reasons for weight loss) was measured using the Regulation of Eating Behaviors Scale and was regressed onto: Step 1, women's mean-centered BMI and men's mean centered provision of AS; and Step 2, the product term for the women's BMIxMen's AS interaction. *Study 2* participants (N=62; 79% female, 86% Caucasian; M_{ageF} = 47.3±11.3 years; M_{BMI}= 36.7±6.2 kg/m^2) were females in a behavioral weight loss intervention that included modifications of the home environment. Participants completed perceived AS and Sallis Support Scales in reference to their partners' support. Controlled regulation (measured using the 12-item Treatment Self Regulation Questionnaire) was regressed onto: Step 1, women's mean-centered baseline BMI and increase in men's AS from baseline to 18 months; and Step 2, the product term for the women's baseline BMI×Men's increase in AS interaction. **Results:** *Study 1:* Women's BMI×partners' provision of AS interaction was significant (p = .0001). For high BMI women, men's provision of AS was negatively and significantly related to women's controlled regulation (p = .0002). *Study 2:* Men's increase in AS was marginally related to a decrease in women's controlled regulation (β = -.241, p = .064). Addition of the two-way interaction term (women's baseline BMI x partner's increase in AS) significantly increased explained variance ($F(1, 57) = 8.551$, p = .005, $\Delta R^2 = .123$)). Simple slopes analyses indicated that when women's baseline BMI is high, men's increase in AS is significantly related to decreased controlled regulation among women over 18 months (t(57) = -3.3361, p = .0015)). **Conclusion:** Greater

provision of autonomy support from male romantic partners, as rated from both male and female perspectives, is associated with decreased controlled regulation, and is particularly influential among the highest BMI women. Lower controlled motivation is expected to be associated with better emotional regulation and superior outcomes. Our results indicate that this pattern is reflected both in the general population and within a weight loss intervention.

COLD FEET AT THE THRESHOLD OF WEIGHT LOSS TREATMENT: PRE-RANDOMIZATION DROPOUT AMONG THOSE ELIGIBLE AND CONSENTING TO TREATMENT

Sara A. Hoffman, B.A.[1], Christine Pellegrini, PhD[2], Angela Fidler Pfammatter, PhD[1], Amanda Paluch, PhD[3], Linda M. Collins, PhD[4], Bonnie Spring, PhD[5]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]University of South Carolina, Columbia, SC; [3]Northwestern University, Feinberg School of Medicine, Chicago, IL; [4]Penn State, University Park, PA; [5]Northwestern University, Chicago, IL

A minority (10-20%) of those screened for weight loss treatment research reach randomization to a study condition. Among those eligible and consenting to participate, we examined differences between individuals who dropped out prior to and those who proceeded on to randomization. Our aim was to understand bias and limitations to generalizability arising from late-stage pre-randomization study withdrawal. Participants were Chicago-area residents with a BMI of 25-40 who indicated interest in a weight loss study, attended an orientation session, gave informed consent, and were deemed eligible. All were offered 6 months of treatment with a smartphone app and calls from a health coach. Each participant was randomized to a combination of other helpful strategies to augment treatment; there was no inactive group. These analyses compared consented eligible individuals who proceeded to be randomized and begin treatment ("Randomized"), versus those who chose not to proceed ("Non-Randomized"). Individuals were compared on age, BMI, smartphone type (Android vs. iPhone) and self-reported exercise coded from 0 (do not exercise or plan to) to 5 (exercise 4+ days a week). We hypothesized that Randomized participants would have more motivation and fewer barriers to weight loss (i.e., older, lower BMI, more likely to report regular exercise) than Non-Randomized participants. We also examined differences in smartphone ownership (iPhone vs. Android). Study candidates who attended an orientation session and consented as of December 2016 [n=931, *m*age=36.51 yrs, *m*BMI=31.88 kg/m^2] were examined. Of these, 519 were Randomized and 412 were Non-Randomized. Independent-samples t-tests and Chi-square showed Non-Randomized participants were younger (*M*=33.96, *SD*=10.75) than Randomized (*M*=38.55, *SD*=10.81; p < .001). Non-Randomized (M=2.74, *SD*=.97) versus Randomized (*M*=2.96, *SD*=1.07) participants were less likely to exercise (*p*=.001). The groups did not differ on BMI (*p*=0.7) or smartphone type (*p*=.21). Treatment-seeking eligible and consenting weight loss volunteers who drop out prior to randomization tend to be younger and report less exercise than those who persist through randomization, but do not differ on BMI. Future studies should be aware of selective potential for dropout among these participants during screening and engage in participant-

centered retention methods. By further exploring these characteristics, researchers may enhance generalizability of weight loss study findings.

EFFECTIVE RECRUITMENT CHANNELS IN AN ONGOING SOCIAL MEDIA WEIGHT LOSS TRIAL FOR UNIVERSITY STUDENTS

Jessica Whiteley, PhD[1], Meghan Mavredes, MPH[2], Jamie Faro, MS[3], Laura L. Hayman, PhD, RN, FAAN, FAHA[4], Melissa Napolitano, PhD[5]

[1]UMass Boston, Boston, MA; [2]The George Washington University, Washington, DC; [3]University of Massachusetts Boston, Newton, MA; [4]University of Massachusetts Boston, Boston, MA; [5]The George Washington University, Washington DC, DC

Examining the effectiveness of recruitment strategies utilized in intervention studies may lead to more efficient and cost effective recruitment strategies for future trials. University students initiated or completed an online screener to determine eligibility for a weight loss trial. Following initial online consent, students were asked to indicate how they heard about the study: email, flyer/poster, Facebook post, Facebook advertisement, in-person event, friend, other. A total of 898 (23.25±4.01 years old, 42% non-white, BMI 28.6±6.4 $kg^{.}m^{-2}$) students indicated how they heard about the study. Most participants (92.5%, n=831) indicated they heard about the study from only one source with the following rank order among the choices: email (77%, n=690), flyer/poster (16%, n=142), “other” (4.3%, n=39), a friend (4.0%, n=36), in-person event (3.7%, n=33), Facebook post (3.5%, n =31), and Facebook ad (0.7%, n=6). Approximately 13% (n=116) were randomized into the trial (22.26±3.5 years old, 54% non-white, BMI 31.7±3.87 $kg^{.}m^{-2}$). Among those randomized, most participants continued to indicate that they heard about the study from only one source (87%). The ways in which participants heard about the study were more distributed but retained their rank order: email (64.7%, n=75), flyer/poster (28.4%, n=33), “other” (8.6%, n=10), a friend (6.0%, n=7), in-person event (3.4%, n=4), Facebook post (2.6%, n =3), followed by a Facebook ad (0.9%, n=1). Results indicated that emails, either in the form of blast emails or emails distributed by professors, clubs, or organizations, were the most successful as well as cost effective method for reaching university students. It is recommended that researchers track and monitor recruitment efforts in real time so that they may realize increased cost effective participant yields in ongoing trials while also collecting useful data to inform recruitment efforts and cost estimates for future trials.

EFFECTS OF HIGH-INTENSITY INTERVAL TRAINING ON WEIGHT LOSS AND BODY COMPOSITION IN OBESE POST-MENOPAUSAL WOMEN

Joan A. Grossman, Registered Dietitian[1], Danielle Arigo, Ph.D., Licensed Psychologist[1], Jessica L. Bachman, PhD, RD[2]

[1]The University of Scranton, Scranton, PA; [2]University of Scranton, Scranton, PA

Many women experience weight gain as a result of menopause. Exercise can mitigate weight gain and associated cardiometabolic risks. This study examined the impact of high-intensity interval training (HIIT) among obese, sedentary, post-menopausal women in a 16-week behavioral weight loss program. Participants (*n*=11, M_{AGE}=59, M_{BMI}=*32*.0 kg/m^2) were assigned to one of two exercise groups (HIIT vs. Endurance). The HIIT group (*n*=6) engaged in 15 minutes of daily resistance exercises (DVD guided), progressing to a total of 75 minutes weekly. The E group (E; *n*=5) engaged in 15-50 minutes of aerobic exercise (e.g., brisk walking) at 65% of age-predicted HR_{Max}, progressing to a weekly total of 250 minutes. All participants wore a wristband physical activity monitor and were prescribed a restricted diet (1200-1500 calories). Measurements completed at baseline, mid- and end program included body composition (BC), body weight (BW), % body fat (%BF), fat mass (FM), fat-free mass (FFM), and anthropometric measures (size of waist, abdomen, hips, thigh, biceps). All participants received weekly behavior change information through an online platform and attended both weekly weigh-ins and monthly treatment group meetings. Across groups, average weight loss was 11.9 pounds (6.7% of baseline BW); average total inches lost was 22.4. Both groups significantly decreased waist circumference (*ps*F[2,8]=33.83, *p*F[2,8]=85.44, *p*F[2,8]=5.07, *p*=0.04). The HIIT group also showed a slight decrease in mean calories consumed and W/H ratio. Meanwhile, the E group showed an overall decrease in BMI; FFM and W/H ratio did not show significant change. Findings suggest that, relative to endurance exercise, HIIT may be more effective for weight loss and body composition change among obese, sedentary, post-menopausal women. Consequently, there is need for large-scale tests of the benefit of HIIT for reducing disease risk in this population.

EXAMINING THE DOSE-RESPONSE RELATIONSHIP IN THE VETERANS HEALTH ADMINISTRATION'S MOVE!® WEIGHT MANAGEMENT PROGRAM

Stephanie H. Chan, MPH[1], Susan D. Raffa, PhD[2]

[1]Department of Veterans Affairs, Bedford, MA; [2]Department of Veterans Affairs, Durham, NC

BACKGROUND: Clinical practice guidelines recommend intensive, multicomponent behavioral interventions for individuals who are obese or overweight with an obesity-associated condition. For more than a decade, the Veterans Health Administration (VHA) has offered MOVE!, an evidence-based comprehensive lifestyle intervention designed as a series of sessions.

OBJECTIVE: To inform VHA policy and planning, this VHA-wide study examines the relationship between MOVE! participation and weight outcomes.

DESIGN: A longitudinal observational study of Veterans across VHA who participated in the MOVE! Weight Management Program.

PARTICIPANTS: Veterans who initiated their most recent episode of weight management with MOVE! between 2004 and 2014 were included in this study.

MAIN MEASURES: Weight measurements were abstracted from VHA electronic health records. The primary outcome was the proportion of Veterans with clinically relevant weight loss. The predictor of interest was number of MOVE! contacts during the 12 months following MOVE! initiation.

KEY RESULTS: The cohort consisted of 237,577 Veterans (87.4% male; mean age 54.4 years), who had, on average, 5.3 contacts in the 12 months following initiation. Veterans with between 2 and 5 contacts had the same odds of achieving clinically relevant weight loss as Veterans with only one contact (Adjusted OR:1.00, 95%CI:0.98,1.03). Veterans with between 6 and 9, 10 to 13, 14 to 17, and 18 or more contacts had significantly higher odds of clinically relevant weight loss (Adjusted OR:1.17, 95%CI:1.13,1.20; Adjusted OR:1.53, 95%CI:1.47,1.59; Adjusted OR:1.84, 95%CI:1.74,1.94; Adjusted OR:2.21, 95%CI: 2.12, 2.31, respectively)

CONCLUSIONS: Veterans with 6 or more MOVE! contacts in the year following treatment initiation were significantly more likely to achieve clinically relevant weight loss than those with 1 contact, with participation increasing odds of clinically relevant weight loss. Further

characterization of key predictors of weight loss is needed to understand how contact frequency may modify weight change and associated implications for increasing engagement.

KNOWLEDGE AND AWARENESS OF METABOLIC RISK IN UNIVERSITY STUDENTS

Meghan Mavredes, MPH[1], Loretta DiPietro, PhD, MPH[1], Laura L. Hayman, PhD, RN, FAAN, FAHA[2], Samuel J. Simmens, PhD[3], Jessica Whiteley, PhD[4], Melissa Napolitano, PhD[5]

[1]Milken Institute School of Public Health, The George Washington University, Washington, DC; [2]University of Massachusetts Boston, Boston, MA; [3]George Washington University, Washington, DC; [4]UMass Boston, Boston, MA; [5]The George Washington University, Washington DC, DC

Background. The prevalence of young adults having one or more components of metabolic syndrome, (MetS); i.e., increased abdominal adiposity, high blood pressure, high fasting blood glucose, high triglycerides, body mass index [BMI] overweight/obese, is increasing. Understanding knowledge and awareness of risk is likely an important first step in preventing the numerous chronic conditions associated with MetS, including cardiovascular disease, diabetes, and stroke. ***Purpose.*** We examined the knowledge of metabolic risk in a sample of university students with BMIs in the overweight or obese range. ***Methods.*** Students (N=177; 79.7% female; age 22.1±3.6 years; BMI 31.7±3.6 kg/m^2) completed a 5-item measure assessing knowledge of metabolic risk, and self-perception or awareness of metabolic risk including knowledge of blood pressure, cholesterol, and blood glucose. ***Results.*** The majority (68.4%, n=121) of participants had never heard of the term metabolic risk, with 66% of obese (n=68) and 71.6% overweight (n=53) reporting being unfamiliar with the term. There were no significant differences in knowledge of metabolic risk by BMI status, sex, age, or academic year. Of those individuals who had prior knowledge of metabolic risk, 53.6% reported they were not concerned with their own metabolic risk factors. The majority of all participants reported knowing their blood pressure (66.1%) and having blood work done to measure cholesterol (52.0%), but only 41.7% reported ever having blood work to measure glucose levels. ***Conclusions.*** Although participants reported having components of MetS evaluated, a large proportion of students did not recognize the term metabolic risk, despite having elevated BMIs in the overweight and obese range. This disconnect is an important area of risk communication and information dissemination. Implications of these findings will be discussed such as leveraging university healthy lifestyle programming to educate young adults about metabolic risk and the benefits of forming long-term healthy eating and physical activity behaviors.

METABOLIC SYNDROME MARKERS AND PHYSICAL ACTIVITY IN OBESE WITH AND WITHOUT PRADER-WILLI SYNDROME

Kelsey McAlister, Student[1], Daniela A. Rubin, Ph.D.[2], Koren L. Fisher, Assistant Professor[2], Marilyn C. Dumont-Driscoll, M.D., Ph.D.[3]

[1]California State University, Fullerton, Pasadena, CA; [2]California State University, Fullerton, Fullerton, CA; [3]University of Florida Gainesville, Gainesville, FL

Introduction: Metabolic syndrome (MS) is defined as a group of cardiovascular and diabetes risk factors that occur simultaneously. Prader-Willi Syndrome (PWS) is a genetic disorder associated with obesity. To date, only one study showed that MS could be a health risk in PWS. In youth, physical activity (PA) is negatively associated to MS; however, youth with PWS appear to participate in less PA than other youth. Thus, the purpose of this study is to examine the relationship between MS and moderate-to-vigorous PA (MVPA) in youth with PWS compared to youth with non-syndromic obesity (OB).

Methods: Participants were 21 youth with PWS (ages 10.7 ± 2.6; 12 males, 9 females; body fat= 46.0 ± 8.9%) and 34 youth with OB (ages 9.6 ± 1.0; 17 males, 17 females; body fat= 45.4 ± 6.4%). MS markers (body mass index (BMI), blood pressure, triglycerides, high-density lipoprotein, and glucose) were obtained in each child and evaluated using the adolescent adaptation of the National Cholesterol Education Program. Accelerometry was used to measure MVPA for eight consecutive days. Cut-points formed by Evenson et al. (2008) defined MVPA. Chi-square analyses and independent t-tests compared frequency of meeting the MS criteria and differences in MS severity between PWS and OB youth, respectively. A median-split separated participants into four groups (PWS low PA, PWS high PA, OB low PA, OB high PA). An ANOVA determined differences in MS severity in relation to MVPA with a Bonferroni post hoc. Significance was set at $p < 0.05$.

Results The frequency of presenting BMI and glucose as a risk factor was lower in PWS (61.9% and 14.3%, respectively) than in OB (91.2% and 44.1%, respectively) (BMI χ^2=6.952, $p < 0.01$; glucose χ^2=5.247, $p < 0.05$). MS severity was lower in PWS (0.10 ± 0.81), than in OB (0.77 ± 0.63, $p < 0.01$). The PWS high PA youth had lower MS severity scores (-0.01 ± 0.71) than the OB low PA youth (0.83 ± 0.52, $p < 0.05$). There were no other significant differences.

Conclusion: The results indicate that the presence of PWS may have protective effects against MS risk factors in youth with obesity. The evidence also suggests PA may have a role in MS severity in youth with PWS and non-syndromic obesity. Further research should evaluate the role of exercise interventions on MS risk factors in youth with PWS.

PARENTING PROFILES ACROSS OBESITY-RELATED BEHAVIOURS THAT SUPPORT ADOLESCENTS' HEALTH BEHAVIOURS

Louise C. Masse, PhD[1], Nicole S. Carbert, MSc Candidate[1], Kevin Lu, MPH[1], Patti-Jean Naylor, PhD[2], Heather McKay, PhD[3], Lucy Le Mare, PhD[4], Rhona Hanning, PhD[5]

[1]School of Population and Public Health/University of British Columbia/BC Children's Hospital Research Institute, Vancouver, BC, Canada; [2]School of Exercise, Physical and Health Education/University of Victoria, Victoria, BC, Canada; [3]Department of Orthopaedics and Family Practice/Centre for Hip Health and Mobility/University of British Columbia, Vancouver, BC, Canada; [4]Faculty of Education/ Centre for Research on Early Child and Health Education (CRECHE)/Simon Fraser University, Burnaby, BC, Canada; [5]School of Public Health and Health Systems/University of Waterloo, Waterloo, ON, Canada

Objective: The family environment is important in shaping adolescent health behaviours. Parents can influence these behaviours directly through specific parenting practices (e.g., rules or routines). Further research is necessary to explore the extent to which parents use more supportive practices with respect to influencing health behaviours. We used qualitative methods to explore parenting practices in relation to adolescent health behaviours (physical activity (PA), nutrition, and screen time behaviours).

Methods: We conducted 28 semi-structured interviews with parents of grade 7 students (March-May 2016) in Surrey, British Columbia, Canada [68% mothers; ethnicity diverse: 11% Chinese, 32% South Asian, 14% Southeast Asian, 25% White; 54% had income < $60,000]. We asked open-ended questions regarding the environmental and behavioural factors that influence their child's health behaviours. Interviews were recorded and transcribed verbatim.Two staff and the principal investigator transcribed and coded the first five interviews, while the remaining interviews were coded and reconciled by two staff. A conceptual framework that grouped parenting practices under structure, control, and responsiveness guided our analyses. We used Nvivo 11 for all analyses.

Results: Parenting practices predominantly related to structure and control were observed across all health behaviours; differences also emerged across health behaviours. For PA, adolescent behaviours were structured using practices such as co-participation, modeling, and access/availability. In some cases, parents controlled their child’s PA by pressuring them to enroll in activities that they were not interested in. Other parents were responsive to their child and used practices such as encouragement, involvement, and autonomy support to

influence their child’s activity. In contrast, screen time and nutrition behaviours were structured through expectations (e.g., rules). As parents experienced difficulty in achieving certain behaviour for screen time, they sometimes resorted to controlling practices such as bribes or discipline. With nutrition, we identified more permissive practices. Parents acknowledged certain expectations around eating, but noted difficulty in maintaining these expectations both for their child and themselves.

Conclusions: Our findings suggest that parenting practices differ across adolescent health behaviours. They provide insight into the complexity of ensuring that parents utilize supportive practices—an aspect that needs to be emphasized in current interventions to encourage healthy behaviours.

POSITIVE EMOTIONS AND EATING IN OVERWEIGHT ADULTS

Abby Braden, PhD, Tanya Watford, MS, Elizabeth Emley, BS

Bowling Green State University, Bowling Green, OH

Background: Recently, there has been increased interest in examining positive emotions as triggers for eating. Studies have concluded that eating in response to positive emotions may be a greater problem in normal or underweight samples than overweight samples. However, eating in response to positive emotions is frequently reported by overweight adults. The current study aimed to identify the positive emotions that trigger eating in this sample, and to examine differential associations of eating in response to positive vs. negative emotions with demographic and health outcomes.

Methods: Overweight adults (n = 188; BMI = 33.17 ± 6.98; age = 41.78 ± 13.61; 64.9% female) were recruited using Amazon Mechanical Turk. Eating due to positive and negative emotions was assessed with the Emotional Appetite Questionnaire (EAQ). Body mass index (BMI) was calculated from self-reported height and weight. Mental health symptoms (i.e., depression, anxiety, and somatization) were measured with the SCL-90R. Mean scores were calculated to identify positive emotions that most commonly trigger eating. Next, correlational analyses examined relationships between positive and negative emotional eating and outcomes.

Results: Of the positive emotions assessed, happiness was the eating trigger most commonly reported ($M = 5.2$, $SD = 1.7$). Of the 15 total emotions assessed, happiness was the fourth most common emotion reported to trigger eating, after boredom, loneliness, and depression. Eating due to positive emotions was unrelated to BMI, gender, and depressive symptoms, but significantly related to symptoms of anxiety ($r = .15$, $p < .05$) and somatization ($r = .15$, $p < .05$). Eating due to negative emotions was significantly associated with greater BMI ($r = .19$, $p = .01$), female gender ($r = .19$, $p = .01$), and symptoms of depression ($r = .32$, $p < .001$), anxiety, ($r = .22$, $p < .001$), and somatization ($r = .19$, $p = .01$).

Conclusions: Happiness frequently triggers eating in overweight adults. Despite this, eating due to positive emotions was unrelated to BMI, gender, and depressive symptoms, whereas eating due to negative emotions was significantly related to BMI, female gender, and a range of mental health symptoms. Among overweight/obese adults, eating due to positive emotions may be less problematic, as it is less closely related to weight and depressive symptoms than eating due to negative emotions.

RACIAL/ETHNIC REPRESENTATION IN LIFESTYLE WEIGHT LOSS INTERVENTION STUDIES IN THE UNITED STATES: A SYSTEMATIC REVIEW

Christina Haughton, MPH[1], Valerie J. Silfee, PhD[1], Monica Wang, PhD[2], Andrea Lopez-Cepero, BS, MHSN[1], David Estabrook, MPH[1], Christine Frisard, MS[1], Milagros C. Rosal, PhD[1], Sherry Pagoto, PhD[1], Stephenie Lemon, PhD[1]

[1]University of Massachusetts Medical School, Worcester, MA; [2]Boston Univeristy, Boston, MA

Objective: Despite efforts to enhance inclusion, underrepresentation of minorities in research has been documented. The primary aim of this review was to evaluate representation of racial/ethnic sub-group members in behavioral weight loss interventions conducted among adults in the United States. The secondary aims were to assess recruitment and study design approaches to include racial/ethnic groups and the extent of racial/ethnic sub-group analyses conducted in these studies.

Methods: PubMed, PsycInfo, and Medline were searched for behavioral weight loss intervention trials conducted in 2009-2015 using keywords: weight, loss, overweight, obese, intervention and trial.

Results: The majority of the 87 studies reviewed included a majority White sample. Across the included studies, 61% of participants were White, 18% were Black/African American, 9% were Latino/Hispanic, 2% were Asian and 1% were American Indians. An additional 7.8% were categorized as “other”. Nine of the 87 studies enrolled exclusively minority samples. More than half (59.8%) of the studies did not report an intention, approach or specific site/location to recruit a sample that was racially or ethnically diverse. Of the 54 studies that included more than one racial/ethnic group, 8 included sub-group analyses of weight loss outcomes by race/ethnicity.

Conclusions: Lack of adequate representation of racial and ethnic minority populations in behavioral trials limits the generalizability and potential public health impact of these interventions. Given persistent racial/ethnic disparities in obesity in the U.S., the high morbidity, mortality, and economic costs associated with obesity and obesity-related conditions among racial/ethnic minority groups, findings from this review emphasize the need to maximize representation of some underrepresented racial/ethnic groups in behavioral lifestyle weight loss trials.

REWARD-RELATED EATING IN OBESE AND LEAN ADULTS: A MULTIMETHOD CHARACTERIZATION

Angela Wackerly, BFA[1], Kirstin Aschabacher, PhD[1], Kinnari (Nina) Jhaveri, BA, MBA[2], Carlos Almeida, BS[1], Alison R. Hartman, BA[3], Samantha Schleicher, BA[1], Cindy W Leung, ScD MPH[1], Suneil Koliwad, MD PhD[4], Elissa S. Epel, PhD[3], Ashley E. Mason, PhD[1]

[1]University of California San Francisco, San Francisco, CA; [2]University of Southern California, San Francisco, CA; [3]University of California, San Francisco, San Francisco, CA; [4]University of California San Francisco - School of Medicine, San Francisco, CA

Reward-Related Eating in Obese and Lean Adults: A Multimethod Characterization

Background: An obesity phenotype characterized by high reward-related eating (RRE) may be optimally assessed by combining self-report, neurocognitive, and biological measures. Consciously experienced symptoms of enhanced drive to eat can be assessed using the Reward-based Eating Drive (RED) scale. Less conscious dimensions of RRE may be characterized using neurocognitive assessments of selective attention to food cues. Moreover, selective attention to food cues may differ in a fasted state versus after glucose ingestion, because glucose (a primary source of fuel for the brain) can facilitate cognitive function.

Hypotheses: Compared to lean controls, participants with obesity will exhibit higher self-reported symptoms of RED (H1), and greater glucose-induced enhancement of selective attention to food cues (H2). Across all participants, greater blood glucose increases will correlate positively with glucose facilitation of selective attention (H3).

Methods: Participants with obesity (n=11) and lean controls (n=12) completed the RED scale before completing the N-Back neurocognitive assessment. The N-Back employed food and non-food stimuli, and participants completed it both in a fasted state, and 50 minutes after drinking 75g of glucose (Glutol). We assayed blood glucose before and 50 minutes after Glutol consumption. We calculated selective attention to food cues as the difference between food and non-food stimuli in 2-back correct identifications on the N-Back. We defined glucose facilitation of selective attention as the increase in correct ‘food’ relative to ‘non-food’ identifications from pre- to post-glucose ingestion.

Results: Participants with obesity had significantly higher RED scores (H1) and greater glucose facilitation of selective attention to food cues compared to lean controls (H2; all *p*’s *< .05).*

Greater increases in blood glucose correlated with greater increases in selective attention to food cues in the whole sample (H3; *r*=.51, p=.01).

Conclusions: People with obesity are more likely to have higher RED scores and greater attentional biases toward food, which characterize reward-related eating (RRE). Used in concert, self-report, neurocognitive, and blood glucose measures may comprise a brief battery that can identify individuals with high RRE. The RRE phenotype may contribute to a “vicious cycle” of overeating and resultant obesity.

STRESS IS ASSOCIATED WITH WEIGHT CIRCUMFERENCE IN HISPANIC ADULTS

Mary Kate Clennan, B.S.[1], Erin N. Etzel, Ph.D.[2], Judith R. McCalla, PH.D.[3], Patrice G. Saab, Ph.D.[1]

[1]University of Miami, Coral Gables, FL; [2]Presbyterian Medical Group, Albuquerque, NM; [3]University of Miami, Department of Psychology, Coral Gables, FL

Introduction:
Waist circumference is a commonly used indicator of abdominal obesity. Individuals with abdominal obesity are at a greater risk for metabolic syndrome, cardiovascular disease and diabetes. Similarly, evidence also shows that greater perceived stress is related to poorer health outcomes. Moreover, perceived stress and waist circumference have been shown to be related as individuals often engage in unhealthy weight behaviors in response to stress. Minority groups may be particularly vulnerable because they are at an increased risk for abdominal obesity and higher stress levels. As there is little research on the link between perceived stress and waist circumference in minorities, the current study investigated this relationship in a sample of Hispanic adults *controlling for health behaviors.*

Methods:
The Heart Smart exhibition at the Miami Science Museum educated museum visitors about the importance of a heart healthy lifestyle. The exhibition invited visitors to take simple personal measurements (e.g., waist size and self-reported habits) using the exhibition's interactives. Visitors received personalized feedback, and, after consenting, could anonymously contribute their information to a research database. The exhibition reached a large sample of Hispanic adults in South Florida. Data from 12,272 consenting Hispanic visitors (18-90 years old; 59.6 % female) were analyzed in the cross-sectional analysis.

Results:
A multiple regression analysis showed that gender, age, perceived stress, fruit consumption, vegetable consumption, soda consumption, and physical activity accounted for significant variance in waist circumference (M = 32.85, SD = 6.94), adjusted $R^2 = .133$, F (2, 12,264) = 270.69, $p < .001$. Results indicate that, controlling for covariates, for every one-point increase in stress level, waist circumference increased by .17 inches 95% CI [.05, .28], p = .005. Interestingly, squared semi-partial correlations indicate that perceived stress explained just as much variance in waist circumference as health behaviors.

Discussion:
The current study’s findings show that higher stress levels are related to greater waist circumference in Hispanic adults, controlling for age, gender, and health behaviors. This is consistent with the view that stress hormones (i.e., cortisol) contribute to the accumulation of abdominal fat. These findings have important clinical implications. Stress reduction techniques are often briefly introduced in most evidence-based weight loss protocols designed to improve nutrition and increase activity. The present findings underscore the value of devoting additional attention to stress management strategies when implementing behavioral weight loss interventions.

THE IMPACT OF WEIGHT ON PSYCHOLOGICAL FUNCTIONING: THE ROLE OF WEIGHT DISCRIMINATION AND INTERNALIZED WEIGHT BIAS

Krystal Waldo, Ph.D.[1], MacKenzie R. Peltier, MA[2], Melanie Roys, MS[3], Aaron F. Waters, B.S.[4], Renee Laurent, B.S.[5], Robert Troups, B.S.[6], Amy Copeland, PhD[3]

[1]Pittsburgh VA Healthcare System, Pittsburgh, PA; [2]Louisiana State University, New Haven, CT; [3]Louisiana State University, Baton Rouge, LA; [4]Louisiana State University, San Anselmo, CA; [5]Louisiana State University, Destrehan, LA; [6]LSU, Baton Rouge, LA

Obesity rates in the United States (U.S.) continue to rise with approximately 34.9% of adults considered obese and an additional 34% that are overweight. In addition to several health problems, obese individuals report greater psychological distress and are at a higher risk for experiencing negative psychological effects. With the increased prevalence of obesity, there has also been a rise in weight-based discrimination and weight bias in the U.S. The present study examined if weight bias internalization mediated the relationship between weight-based stigmatizing experiences and psychological functioning. Non-treatment seeking overweight and obese participants (*N* = 112) completed several questionnaires including the Weight Bias Internalization Scale (WBIS), Stigmatizing Situations Inventory (SSI), and Brief Symptom Inventory (BSI). Participant's height and weight was also measured to determine body mass index (BMI). As predicted, weight-based stigmatizing experiences was found to be a significant predictor of internalized weight bias, and weight-based stigmatizing experiences was a significant predictor of psychological functioning. Results indicated that the direct effect of weight-based stigmatizing experiences on psychological functioning was significant, indicating that weight-based stigmatizing experiences also affects psychological functioning in ways independent of internalization. Consistent with expectations, the indirect effect of weight-based stigmatizing experiences on psychological functioning was significantly greater than zero, indicating that individuals who have weight-based stigmatizing experiences were, on average, 0.040 units higher in their likelihood of experiencing psychological distress as a result of the effect of internalized weight bias. These results support the predicted hypothesis that weight bias internalization would mediate the relationship between weight-based stigmatizing experiences and psychological functioning. Results provide evidence for significant relationships between internalized weight bias and weight-based stigmatizing experiences and psychological functioning, as well as support the predicted hypothesis that weight bias internalization mediates the relationship between weight-based stigmatizing experiences and psychological functioning. Recommendations for future research based on these findings will be discussed.

THE USE OF THE LIFESTYLE QUESTIONNAIRE FOR WEIGHT MANAGEMENT TO IMPROVE WEIGHT MANAGEMENT COUNSELING.

Christopher Anderson, PhD[1], Ryan Roberts, Undergraduate Student[2]

[1]Utah Valley University, orem, UT; [2]Utah Valley University, Alpine, UT

Abstract

Background: Productive counseling sessions for weight management in clinical settings can be challenging due to time-restraints and health-care providers' lack of comfort with counseling. Patients often feel frustrated due to a history of unsuccessful weight loss attempts which leads to hopelessness in future attempts. An instrument is needed to facilitate short and effective counseling sessions and to provide specific feedback to increase patients' likelihood of success. The *Lifestyle Questionnaire—Weight Management* (LQ-WM) is a brief instrument (27 items) regarding behavioral and emotional patterns and also estimates patients' likelihood of success quantitatively based upon responses by research participants. The instrument was recently piloted and showed concurrent validity in predicting weight loss success. The current investigation expanded the sample size, adjusted several items, and re-validated its ability to concurrently predict weight loss success. **Method:** 529 participants engaged in a weight loss attempt completed an online questionnaire covering their demographics, behavioral patterns, and weight management outcomes. Participants were recruited from college classes and a popular social networking site. **Results:** A *Lifestyle Score* was computed for each participant based upon their responses to healthy and unhealthy behavioral patterns. The average *Lifestyle Scores* between participants reporting successful weight management (n=300) versus unsuccessful weight management (n=228) were significantly different (m=28.6 & m=15.4, $p < .001$). Participants whose lifestyle score was in the top 10% had a significantly higher rate of reporting weight loss success versus those in the bottom 10% (83.8% & 35.7%, respectively. $p < .001$). **Discussion and Conclusion:** The *Lifestyle Score* from the LQ-WM showed concurrent validity in predicting weight loss success but with a larger and more diverse sample than the pilot study. The LQ-WM may provide utility in clinical scenarios to facilitate brief, yet effective, counseling interactions which provide the patient with specific feedback on their behavioral patterns and their likelihood of success. However, future research should investigate the performance of the LQ-WM longitudinally, use clinical samples, and employ more objective weight management measures besides self-report. The LQ-WM has the potential to facilitate more effective counseling interactions between providers and patients.

WEIGHT STIGMA AND WEIGHT CYCLING IN YOUNG ADULTS WITH OVERWEIGHT/OBESITY

Samantha N. Martinez, M.A. , Gabriela Bolivar, M.A. , Sylvia Herbozo, Ph.D., Serena D. Stevens, MA

Loma Linda University, Loma Linda, CA

The negative effects of weight stigma on psychological and physical health in individuals with overweight/obesity are well documented. Less is known about weight stigma and weight cycling, especially among young adults who report high levels of weight stigma. The current study examined the influence of weight stigma on weight cycling in an ethnically diverse sample of young adult women with overweight/obesity. Participants were 91 young adult women (41.7% ethnic minority) aged 18 to 30 (*M* = 20, *SD* = 5.62), with an average body mass of 29.03 (*SD* = 3.80). Within the sample, 46.4% of participants indicated weight cycling at least one time. A hierarchical multiple regression analysis was used to determine the influence of weight stigma on weight cycling, controlling for age and ethnicity. The regression model accounted for a significant proportion of the variance in weight cycling frequency, $R^2 = .13$, $F(7, 83) = 1.81$, $p < .05$. Ethnicity was a significant independent predictor of frequency of weight cycling for Asian Americans, such that on average, Asian Americans reported 0.69 fewer incidence of weight cycling than Caucasians, $p < .05$. Weight stigma significantly predicted weight cycling, such that as the frequency of weight stigma increased by one-unit, there was a 0.17 increase in frequency of weight cycling, $p < .05$. These results suggest that young adult women with overweight/obesity who experience higher rates of weight stigma have an increased incidence of weight cycling. In addition, Asian Americans appear to be less susceptible to weight cycling compared to Caucasians. Future studies should examine weight stigma and factors associated with weight cycling to further inform interventions for obesity.

A FIRST LOOK AT MILD TRAUMATIC BRAIN INJURY (MTBI) SYMPTOM FREQUENCY AMONG U.S. FIREFIGHTERS

Victoria Torres, B.A.[1], Michelle Pennington, B.A.[2], Marc Kruse, Ph.D.[3], Nathan Kimbrel, Ph.D.[4], Sara Dolan, PhD[5], Suzy B. Gulliver, Ph.D.[2]

[1]University of Mississippi, Oxford, MS; [2]Baylor Scott and White Health, Waco, TX; [3]Austin Fire Department, Austin, TX; [4]Durham VAMC, Waco, TX; [5]Baylor University, Waco, TX

Rushing into burning buildings and performing daring acts of bravery, fighting fire is a dangerous profession. Yet, over 1 million firefighters serve communities across the United States. The National Fire Protection Agency (NFPA) estimates that 65,880 U.S. firefighters were injured in the line of duty in 2013 alone. Often described as a ‘silent epidemic’, traumatic brain injury (TBI) has been observed in military, athletic and pediatric populations. However, gathering epidemiological data has been challenging due to debate on an adequate definition, differences in study methods and comorbidities. A recent statewide population-based survey by Whiteneck and colleagues (2016) revealed that out of 2701 adult Colorado residents, 37.7% reported a head injury but no TBI, 36.4% reported mild traumatic brain injury (mTBI) and 6.0% reported moderate-severe TBI. Further, an estimated 5.3 million Americans are currently living with a TBI-related disability (Langlois, Rutland-Brown, & Wald, 2006). However, the frequency of TBI among firefighters is completely unknown. Our anonymous Qualtrics survey of career firefighters (N = 60) reveals a first look at firefighter mild traumatic brain injury (mTBI) frequency. Due to the risky nature of their profession and their likely former athletic and military participation, we hypothesized that prevalence of post-concussive syndrome (PCS) symptoms and mTBI are inflated among firefighters. Basic descriptive statistics were analyzed using SPSS statistical software package. In conjunction with fire service, the majority of participants were Caucasian males between the ages of 27 and 67 (90.0% male; 80.0% Caucasian; M = 41.64; SD = 9.36). Though much debate has centered on an adequate definition of traumatic brain injury, we classified mTBI symptoms using the World Health Organization’s (WHO) preliminary screening criteria: a) loss of consciousness (LOC) for 30 minutes or less, b) posttraumatic amnesia for less than 24 hours and c) confusion or disorientation after sustaining an injury to the head resulting from external physical forces. Our initial review of lifetime head injury events revealed that 36.8% endorsed LOC for 30 minutes or less, 44.1% endorsed loss of memory, and 57.4% endorsed feeling dazed and confused after sustaining an injury to the head. Altogether 61.8% met lifetime criteria for one of the aforementioned mTBI symptoms. 25.0% of participants endorsed currently experiencing post-concussive symptoms that they thought might be related to injuries

experienced either in their career as a firefighter, athletic or military participation. Though no cure for TBI is available, useful treatments for TBI-related symptoms are readily available.Results from this study suggest further research in this area is warranted to inform development and improvement of firefighter policies and procedures.

SUN PROTECTION BEHAVIORS AMONG MALE HISPANIC OUTDOOR LABORERS

Adrienne Viola, MPH[1], Jerod Stapleton, Ph.D.[2], Michele Oschner, Ph.D.[3], Germania Hernandez, N/A[4], Louis Kimmel, BA[4], Daniel Giovenco, Ph.D., MPH[5], Shawna Hudson, Ph.D.[6], Denalee O'Malley, MD, MPH[7], Carolina I. Lozada, MPH[8], Elliot Coups, PhD[9]

[1]Rutgers Robert Wood Johnson Medical School, Lawrenceville, NJ; [2]Rutgers Cancer Institute of New Jersey, East Brunswick, NJ; [3]Rutgers School of Management and Labor Relations, New Brunswick, NJ; [4]New Labor, New Brunswick, NJ; [5]Columbia University- Mailman School of Public Health, New York, NY; [6]Department of Family Medicine, Research Division; Director of Community Research, New Brunswick, NJ; [7]Department of Family Medicine and Community Health, Research Division Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; [8]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; [9]Rutgers, The State University of New Jersey, New Brunswick, NJ

Introduction: Individuals who work outside are at increased risk for skin cancer due to exposure to the sun’s ultraviolet (UV) radiation. Hispanic individuals in the United States are over-represented in several outdoor occupations that have high UV exposure. Little is known about the sun protection practices of Hispanic individuals who work outdoors. In this project, we examined Hispanic day laborers’ sun protection knowledge, beliefs, behaviors, and barriers.

Methods: 175 Hispanic men (47% Mexican, 26% Honduran; *M* age 35.1) were recruited at local outdoor locations where day laborers commonly congregate in New Brunswick, NJ. Participants were eligible if they were male, self-identified as Hispanic or Latino, and reported working outside in the past 3 months or the previous summer. Participants completed a 15-20 minute pencil and paper or interviewer administered survey in Spanish or English. Questions focused on demographic factors as well as sun protection knowledge, beliefs, behaviors, and barriers.

Results: Overall, knowledge of skin protection and skin cancer was modest (*M* = 3.9 correct items out of 7, *SD* = 1.11). Participants were most frequently incorrect (97%) about the recommended sun protection factor (SPF) of sunscreen. More than 90% of participants somewhat/strongly agreed that it was “important to protect my skin from the sun while working outdoors” (91%) and “if I don’t protect myself from the sun while working outdoors, my skin will be damaged” (93%). Only 11% of the sample felt that “there’s not much you can do to lower your chances of skin cancer." The reported rate of often or always engaging in sun protection behaviors when working outside was as follows: sunscreen, 17%; staying in the shade, 10%; wearing a wide-brimmed hat, 13%; wearing a long-sleeved shirt, 44%; wearing long pants, 89%. The top barriers to wearing sunscreen were forgetting to apply it and not knowing what kind to use. The top barriers for not wearing long pants and a long-sleeved shirt as well as wearing a wide brimmed hat were that they were too hot and uncomfortable to wear.

Conclusions: Hispanic day laborers do not sufficiently engage in many sun protection behaviors while working outdoors, despite believing in the importance of skin protection. Participants reported several factors that hinder their ability to engage in sun protection behaviors during outdoor work. Future research is needed to facilitate engagement in sun protection behaviors in this at-risk population.

THE PROVISION OF CLERGY HEALTH RESOURCES BY FAITH-BASED ORGANIZATIONS IN THE UNITED STATES

Benjamin Webb, PhD, CSCS[1], Scherezade Mama, DrPH[2], Jonathon Kirby, BS[1]

[1]Southern Illinois University Edwardsville, Edwardsville, IL; [2]The Pennsylvania State University, University Park, PA

The percentage of clergy classified as obese is reported to be as high as 41%. Additionally, clergy are disproportionately affected by several chronic diseases. Provision of health resources should be a priority for faith-based organizations (FBOs) that employ clergy, but little is known about the extent to which clergy health is prioritized and addressed among FBOs. The purpose of this study was to describe practices related to promoting clergy health among a national sample of FBOs. A total of 154 administrators from the largest religious denominations in the U.S. completed questionnaires on their beliefs and practices regarding clergy health promotion. Stress (64.7%), obesity (45%), and lack of exercise (41.2%) were identified as the top health-related issues facing clergy. The most commonly offered health-related resources were health insurance (86.7%), an employee wellness benefit provided by health insurance provider (61.3%), a health-related newsletter (61.3%) and a website with general health information (61.3%). Lack of financial resources (61.3%), lack of trained staff (46.7%) and lack of interest from clergy (47.4%) were cited as the most common barriers to providing health resources for clergy. Respondents indicated that their FBOs encourage clergy to lead healthy lives (91.2%), be physically active (65.4%), eat healthy (62.3%), and avoid smoking (66.9%). Although a majority of respondents thought that clergy must adhere to a healthy lifestyle to effectively encourage their congregation to do the same (88.5%), very few (29.4%) respondents thought clergy were prepared to be good role models for health to their parishioners. Additionally, few respondents (37.3%) thought their clergy were ready to face the challenges of health-related self-care while in ministry, with 78.0% indicating that clergy need more training related to health and prevention of chronic disease. Respondents indicated that the most appropriate ways for clergy to receive health education were through online training (41.9%) and special events (30.1%). The results of this study highlight potential priorities (e.g., stress, obesity, exercise, and education) and modes of delivery (e.g., online training) for FBOs interested in providing or enhancing resources aimed at promoting the health of clergy. Further research is needed to determine whether the provision of health-related resources is associated with more positive health and behaviors among professional clergy.

A SYSTEMATIC REVIEW OF SOCIAL SUPPORT AND PAIN IN PATIENTS WITH RHEUMATOLOGIC DISEASE

Emily Rose San Diego, BA[1], Karina R. Aguilar, BA[2], Rina S. Fox, PhD, MPH[3], Erin L. Merz, PhD, MPH[4]

[1]California State University, Dominguez Hills, Costa Mesa, CA; [2]California State University, Dominguez Hills, Wilmington, CA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]California State University, Dominguez Hills, Carson, CA

Background: Pain is a significant quality of life concern in patients with rheumatologic disease. A biopsychosocial conceptualization of pain is widely accepted, with perceived social support being recognized as a potentially important factor in understanding pain in this population. The aim of this study was to summarize the empirical evidence of the link between social support and pain in rheumatology patients.

Methods: PRISMA guidelines were used to conduct the systematic review. Keyword searches of pre-defined terms of the PsycINFO and PubMed/MEDLINE databases were conducted. A standardized tool was used to extract and record study-level data. Social support was classified into four taxonomies (overall, emotional, instrumental/tangible, informational). Weighted correlations were aggregated using random effects models across each social support type.

Results: Of the 411 screened articles, 27 studies met the inclusion/exclusion criteria (N = 4,069). The majority was comprised of patients with rheumatoid arthritis, although osteoarthritis, lupus, and fibromyalgia were also represented. The pooled effect sizes from cross-sectional analyses suggested a small inverse association with pain for overall social support (r = -.15, 95% CI: -.09, -.21), emotional social support (r = -.18, 95% CI: -.09, -.18), and instrumental/tangible support (r = -.14, 95% CI: -.08, -.19). There were insufficient studies to evaluate the relationship between pain and informational social support, or any longitudinal relationships. Studies were most limited by substantial heterogeneity in the measurement of social support and pain, ambiguities with regard to how measures were used and reported, cross-sectional designs, and representativeness of the samples.

Conclusions: The results suggest that rheumatology patients with greater social support report lower pain, although the effect is small. These findings are consistent with research on the health benefits of social support in numerous populations.

PAIN EXPERIENCES AND PAIN MEDICATION USE AFTER SPINAL CORD INJURY: RELATIONSHIP WITH RISK OF MORTALITY

Jillian Clark, M.A.[1], James S. Krause, PhD[2], Yue Cao, PhD[2]

[1]University of Missouri-Kansas City, San Diego, CA; [2]Medical University of South Carolina, Charleston, SC

Spinal cord injury (SCI) has long been associated with diminished longevity, particularly among those with more severe SCI. Lower income, less education, tobacco use, binge drinking, prescription medication use, physical health conditions (e.g., heart disease), and secondary conditions (e.g., pressure ulcer surgeries, depressive symptoms) have been associated with increased risk of mortality in SCI. Pain is a common secondary condition after spinal cord injury; however, there is no prior literature that examines pain and pain-related factors in relation to mortality in SCI. The current study examined the roles of pain intensity, pain interference, and pain medication use with risk of mortality, while controlling for biographic, injury, socioeconomic, and health factors.

Participants (n = 2535) with spinal cord injury, identified through records at a specialty hospital in the southeastern United States, completed self-report questionnaires. Predictor variables assessed included: patient characteristics (e.g., demographics and injury), health indicators (e.g., pressure sores, hospitalizations, broken bones, amputations, depressive symptoms, pain intensity, and interference of pain on daily functioning), and frequency of pain medication use. The outcome variable, mortality, was identified using the National Death Index and the Social Security Death Index.

There were 335 deceased participants who had an average of approximately 38 survival months, compared to approximately 73 months for those alive. The final stage of a three-stage hierarchical multivariate model (i.e., stage 1 = patient characteristics, stage 2 = health indicators, and stage 3 = pain medication use) using Cox proportional hazards modeling indicated that being male (HR = 1.42), and having greater injury severity (HR = 3.06) were risk factors for mortality, whereas, having a four-year college degree or higher was a protective factor (HR = .64). With the exception of pain interference, pain intensity, and having a broken bone, all other health indicators were predictive of increased risk of mortality. Those who reported daily use of pain medications were 61% more likely to be deceased compared to those who don’t use pain medication (HR=1.61).

Frequency of prescription pain medication use was significantly related to risk of mortality, even after controlling for all other predictors. It is important for providers to be cognizant of the potential contributory effects of pain medication use on mortality in individuals with SCI.

THE EFFECTS OF AN ANTI-INFLAMMATORY DIET IN THE REDUCTION OF PAIN SUBJECTIVITY AMONG VETERANS WITH CHRONIC PAIN

Jay T. Wiles, M.A. in Clinical Psychology[1], Melody Mickens, Ph.D.[2], Ka Wong, Registered Dietician[2], Meghan Rooney, Psy.D.[2]

[1]Regent University, Richmond, VA; [2]Hunter Holmes McGuire VA Medical Center, Richmond, VA

Background:
Research has suggested a direct link between poor diet, systemic inflammation, and increased reports of subjective pain (Minihane et al., 2015). Newer approaches to pain management have incorporated behavioral treatments and a focus on managing biopsychosocial aspects of pain. Participants included in this study were veterans at VA medical Center who were actively involved in a multimodal, self-management integrative pain clinic. One aspect of this integrative clinic included following an anti-inflammatory diet, which targets the elimination of pro-inflammatory foods (i.e., pain inducing) and introduction of anti-inflammatory foods (i.e., pain reducing).

Methods: Participants (*N*=78) were predominately African-American (58%)male (70%) Veterans with a mean age of 56 years (*SD* = 10.66) who completed an 8-week anti-inflammatory diet group led by a registered dietician and licensed psychologist. One third of participants (*N* = 30) had completed data for pre-and post measures. Veterans completed the Pain Catastrophizing Scale (PCS) and Pain Outcomes Questionnaire (POQ) at intake and during the final group. Paired T-tests were conducted to assess differences between pre and post measures. Outcomes included total PCS scores, PCS subscale scores (Rumination, Magnification, and Helplessness), POQ total score, and POQ subscales (Pain, Mobility, Activities of Daily Living, Vitality, Negative Affect, and Fear).

Findings:When comparing pre-and post-group data, participants who completed the anti-inflammatory group had lower scores on the following subscales: PCS Helplessness, t(29) = 2.08, *p* < .05, POQ Mobility, t(29) = 3.08, *p.01, POQ Vitality, t(29) = 2.14, pp* < .05. No significant racial or gender differences were identified on outcome variables.

Conclusions: Results of the study suggest that multiple areas of pain subjectivity were significantly influenced after an 8-week anti-inflammatory diet group. While most veteran participants were involved in multiple treatment modalities for chronic pain management during the time of the group, this research suggests that diet modification, specifically the

incorporation of an anti-inflammatory diet, may play a significant role in pain reduction amongst veterans with chronic pain. Use of an anti-inflammatory diet may prove as an effective adjunctive treatment to pharmacological and other non-pharmacological management of pain, as well as help to improve overall quality of life and well-being.

Jackson Foundation, Rockville, MD; [4]Henry M Jackson Foundation, Rockville, MD; [5]Henry M. Jackson Foundation, Kansas City, MO; [6]Henry M. Jackson Foundaion, Rockville, MD; [7]YogaMedics, Huntington Woods, MI

Background: To optimize treatment selection for patients with chronic pain, data must show why and for whom particular modalities are most effective. The present study examines the role of pre-treatment psychosocial characteristics on the effects of an 8-week yoga program for chronic lower back pain (cLBP) in a military health setting.

Methods: Participants (N=68) were randomized to a control group or the Restorative Exercise and Strength Training for Operational Resilience and Excellence (RESTORE) yoga group. The Patient Reported Outcomes Measurement Information System (PROMIS) was administered at baseline (BL), mid-treatment, and post-treatment (PT). Participants were stratified into “risk” groups (e.g. 1 SD from the norm on PROMIS scales) for Sleep Disturbances, Social Functioning, and Pain Interference. The independent and interactive effects of time, treatment, and risk groups on Physical Functioning were examined with generalized estimating equations. Sequential Bonferroni post-hoc tests compared group differences in BL to PT Physical Functioning changes for each treatment x risk group.

Results: From BL to PT, the control group retained BL Physical Functioning levels, across all risk groups. Participants in the RESTORE group with above average BL Sleep Disturbances and Pain Interference scores reported significant increases in Physical Functioning, while those in the RESTORE group with average scores did not change. Participants in the RESTORE group with below average Social Functioning retained BL Physical Functioning levels, while those with average Social Functioning reported increases from BL to PT.

Conclusions: For military service members with cLBP, yoga may be most helpful for individuals with elevated sleep difficulties and pain interference, but adequate social support. Given the

high prevalence of sleep disorders among service members, coupled with the need to combat the opioid epidemic with integrative pain management strategies, yoga is a promising avenue of treatment for cLBP. Future research is needed to determine whether preparatory interventions targeting social support can bolster functioning improvements in yoga-based therapies, as well as compare treatment moderators across other integrative pain treatments. By identifying and leveraging research regarding treatment moderators, providers can match the best-fitting treatments with each patient, increasing the likelihood of treatment success.

A SYSTEMATIC REVIEW OF ADHERENCE TO RCTS INVOLVING PHYSICAL ACTIVITY INTERVENTIONS TARGETING THREE CHRONIC DISEASES

Sean P. Mullen, PhD, Tiffany Bullard, B.S.

University of Illinois at Urbana-Champaign, Urbana, IL

The medical community has accepted physical activity as an effective behavioral medicine for the prevention and treatment of a variety of diseases and chronic conditions. Chronic conditions may vary in the extent to which they impact self-regulatory skills necessary for initiating and maintaining a physical activity program. However, insufficient evidence is available to make comparisons across chronic conditions regarding adherence to structured physical activity interventions overall, or across different settings. To explore potential differences, we conducted a systematic review and quantitative summary of randomized controlled trials using physical activity or exercise as a treatment for one of three chronic diseases. A total of 33 peer-reviewed scientific articles published between 2000 and 2016 (via PsychInfo, PubMed, CINAHL, Clinical Key, SCOPUS, and hand-picked articles) met our inclusion criteria (i.e., randomized controlled trial, at least one trial arm consisted primarily of aerobic and/or strength training, lasted three or more months, reported % of sessions or made data available). We targeted three clinical populations, i.e., cardiovascular disease [CVD] (n=10), diabetes (n=10), and cancer (n=13), and data from all studies were included in our analyses. Authors from 54.5% of identified studies confirmed data. Adherence rates varied considerably across samples: 85.03% (SD=13.77%), 77.76% (SD=14.56%), and 66.94% (SD=24.52%), respectively. Dropout rates showed a similar pattern (10.60%, 12.15%, and 12.42%, respectively). Interestingly, overall, adherence for center-based trials (75.00%[SD=21.77%]) did not differ from home-based trials (77.42%[SD=17.89%]). Although few differences emerged, substantial variability exists across studies and within each of the targeted conditions. Moreover, these findings imply that the average patient is not receiving 25% of their prescribed physical activity treatment. These findings underscore the need for novel approaches to maximize the reach and treatment uptake of structured physical activity interventions. It is important to note that many of these interventions preceded the "tech boom" and it is possible that mobile health technologies could be incorporated in an effort to increase participation motivation. Additionally, screening patients' self-regulatory capacity at the onset of intervention may facilitate touch points for “mini-interventions” designed to enhance their trial experience and optimize treatment adherence.

ACCULTURATION, PHYSICAL ACTIVITY AND SEDENTARY: ASSOCIATION OF ANTHROPOMETRIC VALUES IN A BINATIONAL MEXICAN POPULATION.

Katia Gallegos Carrillo, PhD MSc[1], Lourdes Baezconde-Garbanati, PhD, MPH, MA[2], britni R. belcher, PhD, MPH[3], Genevieve F. Dunton, PhD, MPH[3], Jonathan Samet, MD[3]

[1]University of Southern California, Glendale, CA; [2]University of Southern California, Department of Preventive Medicine, Institute for Health Promotion and Disease Prevention Research, Los Angeles, CA; [3]University of Southern California, Los Angeles, CA

Introduction: Increases in acculturation influence several health behaviors and can be a challengeamong individuals of Mexican origin. This pattern has been shown in large population studies based on people living in Mexico when compared to those living in the U.S. The current study examined the influence of acculturation on the association between physical activity, sedentary behaviors, and anthropometric measures of Mexicans and Mexican-Americans living in the U.S. and Mexicans living in Mexico.

Methods: We examined data from two national surveys, the National Health and Nutrition Examination Survey (NHANES) 2011-2012 and the National Health and Nutrition Survey of Mexico (ENSANUT) 2012. Using the self-reported moderate to vigorous physical activity (MVPA) and sedentary behavior (SB), we calculated 4 exclusive categories: a) physically active and low sedentary, b) physically active and high sedentary*,* c) physically inactive and low sedentary, and d) physically inactive and high sedentary. Anthropometric measures were body mass index (BMI) and waist circumference (WC). Acculturation was assessed through a combination of ethnicity, birth place, and country of residence: Mexican born & living in Mexico, Mexican born & living in the US and Mexican-American born & living in the US. Multiple linear regression models were conducted independently for BMI and WC, for each of the four exclusive categories of MVPA and SB, with acculturation as the independent variable. The models were adjusted by sociodemographic variables and health risk conditions.

Results: Among Mexicans living in the U.S., those “physically active and low sedentary” had a BMI 1.47 kg/m^2 higher, compared with Mexicans living in Mexico. The association remained significant after adjusting for sociodemographic factors and health risk conditions ($p= 0.028$). Mexican-Americans living in the U.S. who were categorized as “physically inactive and high sedentary” had higher BMI values 3.96 kg/m^2 ($p< 0.001$), than their Mexican counterparts living in Mexico or in the US, statistical significant in adjusted models. Even among those with the lower risk “physically active and low sedentary” group, the Mexicans and Mexican-

Americans living in the U.S. had higher WC values compared to Mexicans living in Mexico (p=0.01 and p=0.008 respectively).

Conclusion: According to these results, acculturation plays a role in the relationship between MVPA and sedentary behaviors and adiposity measures in adults, participants more acculturated have higher values of BMI and WC, even in categories of lower risk as physically active and less sedentary. However, more research is needed to understand the underlying mechanisms (e.g. dietary changes, occupation type) driving these relationships.

ACCURACY OF LED-BASED HEART RATE MONITORING ON WRIST-WORN ACTIVITY TRACKERS

Lisa Cadmus-Bertram, Ph.D.[1], Emily Wirkus, MPH[1], Keith Thraen-Borowski, Ph.D.[2], Ronald Gangnon, Ph.D.[1], Jessica Gorzelitz-Liebhauser, MS[3]

[1]University of Wisconsin - Madison, Madison, WI; [2]Loras College, Dubuque, IA; [3]University of Wisconsin-Madison, Madison, WI

BACKGROUND: Some wearable activity trackers now use light-emitting diode (LED) sensors to monitor HR during both rest and exercise. Unlike traditional monitors requiring a separate chest strap, wrist-worn models are unobtrusive and are appropriate for continuous long-term wear. By providing objective feedback on exertion, they may help individuals achieve federal physical activity guidelines. The objective of this study was to determine the validity of the HR monitoring function on wrist-worn activity trackers at rest and during moderate-intensity activity.

METHODS: This study used four wrist-worn trackers (Fitbit Charge, Fitbit Surge, Mio Fuse, and Basis Peak) with LED-based HR monitoring capability. Participants were 40 healthy adults aged 30-65 years. Participants were connected to an electrocardiogram (ECG) and the four trackers (two per wrist; location randomized). While sitting, participants' resting HR was recorded from each of the devices at 1-min intervals for 10 min. Next, participants exercised on a treadmill until their HR reached 65% of maximum HR. Once the targeted HR was achieved, participants exercised for an additional 10 min, with HR measured from each device at one-minute intervals. Analyses were performed in R.

RESULTS: Participants were 49.3 years of age (SD=9.5) with a body mass index of 25.1 kg/m^2 (SD=3.9); 50% were female. At both rest and 65% MHR, bias was minimal for all four trackers (range: -2.5, 2.8). At rest, the Fitbit Surge was most precise [device variance: 0.3; repeatability over 10 measurements: 1.3(LoA: -2.0,1.4)], the Fitbit Charge HR and the Mio Fuse were somewhat less accurate, and the Basis Peak was the least accurate [device variance: 7.0; repeatability: 6.1(LoA: -11.9,17.4)]. At 65% MHR, bias remained minimal but all devices exhibited substantially more error than at rest. The Mio Fuse performed the best [device variance: 7.4; repeatability: 7.5(LoA: -14.0,17.5)]. Position on the wrist (first vs. second position nearest to hand) did not affect accuracy.

CONCLUSIONS: At rest, all trackers produced relatively unbiased measures with high precision for some models. During moderate-intensity activity, the trackers still produced measurements with low bias, albeit with less precision. The data suggest that while

commercial activity trackers are not error-free, they may be accurate enough for general health promotion purposes, particularly if they are effective in motivating participants to engage in more moderate-vigorous vs. light-intensity activity. These devices also have the potential to provide individuals with a useful, unobtrusive tool that could be a feasible and convenient method of at-home continuous HR monitoring. More data are needed to address the accuracy of consumer-based trackers during vigorous-intensity activities.

BEING ACTIVE IN PREGNANCY: THEORY-BASED PREDICTORS OF PHYSICAL ACTIVITY AMONG PREGNANT WOMEN

Kyra Hamilton, PhD[1], Martin S. Hagger, PhD[2]

[1]Griffith University and Menzies Health Institute Queensland, Brisbane, Queensland, Australia; [2]Curtin University, Perth, Western Australia, Australia

Objective: Although regular physical activity is recommended for pregnant women and has been associated with a range of physical and psychological benefits, research indicates that compared to pre-pregnancy, antenatal physical activity often reduces or ceases completely. The aim of the current study was to apply an integrative theoretical model to identify the motivational and social cognitive factors that predict physical activity participation in pregnant women. **Methods:** Participants were pregnant women aged 18 years and older (N=207, Time 1; M_{age} = 30.03, SD_{age} = 4.49). The study used a prospective-correlational design with a one week follow-up. At Time 1 (T1), participants completed an initial questionnaire assessing intrinsic motivation from self-determination theory, social cognitive constructs from theory of planned behaviour, and self-control from self-control theory. Demographic variables were also collected. At Time 2 (N=117, T2), participants completed a follow-up questionnaire assessing their self-reported physical activity behaviour in the previous week. **Results:** A well-fitting structural equation model, controlling for baseline age, BMI, and gestation age, accounted for 73% and 42% of the variance in intention and physical activity behaviour, respectively. There was a significant indirect effect of intrinsic motivation on intention mediated by attitude and perceived behavioural control, and significant direct effects of intention, perceived behavioural control, and self-control on physical activity behaviour. **Conclusions:** Current findings fill a knowledge gap in the empirical literature on the multiple processes that guide physical activity behaviour in pregnant women and add to the cumulative evidence advocating the use of integrative models in explaining health behaviour. The findings of the current study indicate important potential routes to behavioural performance that researchers and practitioners can use to ensure the design of future physical activity interventions for pregnant women that are efficacious in eliciting behaviour change. Future behavioural interventions aiming to promote physical activity during pregnancy, a period when physical activity levels typically decline, should consider the multiple processes advocated in the integrative model as necessary for motivated action.

CHANGES IN PSYCHOSOCIAL FACTORS WITH PARTICIPATION IN A COLLEGE PHYSICAL ACTIVITY CLASS: AN EXAMINATION BY RACE/ETHNICITY

Melissa Bopp, PhD, Zack Bopp, MPH, Michele Duffey, MS

Pennsylvania State University, University Park, PA

Participation in physical activity declines with the transition to college but can be combated with participation in college physical activity (PA) classes. The impact of these classes on PA-related psychosocial factors could help with long-term maintenance of PA. Limited research has addressed how PA classes impact different student groups, therefore the purpose of this study was to examine how participation in a college PA class could impact PA-related psychosocial factors by race/ethnicity. Methods: Students enrolled in a college PA class were recruited to participate in an online survey at the beginning and end of their class. The survey included: demographics, PA participation, PA enjoyment, self-efficacy and exercise goal setting. Change from pre to post was calculated. T-tests examined differences in the change in psychosocial factors by race/ethnicity. Pearson correlations examined the relationship between a change in PA and psychosocial factors separately by race/ethnicity. Regression analyses predicted change in vigorous PA. Results: Students (n=838) were predominately Non-Hispanic White (NHW; n=634, 81.6%) and female (n=451, 57.7%). At baseline NHW students were more vigorously active than ethnic minority group (EMG) students (p=.004), had higher PA enjoyment (p < .001), PA self-efficacy (p < .001) and greater exercise goal-setting behavior (p < .001). At follow up EMG students had a greater change in moderate (p=.02) PA, PA enjoyment (p < .001) PA self-efficacy (p < .001) and exercise goal setting (p < .001) than NHW students. Among NHW, a change in vigorous PA was related to a change in PA enjoyment (r=0.16, p < .001), self-efficacy (p=0.15, p < .001) and exercise goal-setting (r=0.19, p < .001). For EMG students, a change in vigorous PA was associated with a change in PA enjoyment (r=0.67, p < .001), PA self-efficacy (r=0.42, p < .001) and exercise goal setting (r=0.37, p < .001). Among NHW students, psychosocial factor changes predicted 4.5% of the change in vigorous PA (p < .001) with PA enjoyment changes as a significant predictor (B=1.01, p=.04) while the regression model predicted 18.8% of the change in vigorous PA for EMG students with PA enjoyment (B=0.92, p=.05) and self-efficacy (B=1.97, p=.03) changes as significant predictors. Conclusion: College PA classes offer an opportunity to instill lifetime skills for active lifestyles, though may be received differently by race/ethnicity. Further research should examine how tailoring could impact this relationship.

DAILY EXERCISE PRESCRIPTIONS ARE MORE INTUITIVE THAN WEEKLY EXERCISE PRESCRIPTIONS: IMPLICATIONS FOR GUIDELINE DEVELOPMENT

Zachary Zenko, PhD, Dan Ariely, PhD

Duke University, Durham, NC

Exercise guidelines recommended by scientific and governing bodies are typically framed as a “weekly” amount. For example, the guidelines from the American College of Sports Medicine, US Department of Health and Human Services, and National Health Service each include recommended minimum durations of aerobic activity per week, not per day. However, recent evidence suggests that reframing exercise requirements into daily amounts may be beneficial (Peetz et al., 2011). Understanding the most effective framing of exercise guidelines is important for creating exercise guidelines that will lead to superior behavioral outcomes (e.g., increased adherence). **Purpose:** This study was designed to determine if people intuitively create daily, rather than weekly, exercise prescriptions. **Methods:** Participants were recruited at the North Carolina State Fair; 381 people (57% woman, mean age: 34.37 ± 15.05 years) followed instructions and were included in the analysis. First, each participant described the person they felt closest to (“friend”, 58.5% woman, mean age: 38.42 ± 17.40 years, 65.1% normal weight) and then created an exercise prescription that their friend would be “(1) most likely to adhere to, (2) most likely to keep track of, and (3) most likely to benefit from.” To create the exercise prescriptions, each participant entered the number of minutes of aerobic exercise that the friend should do per [frequency] and then chose a frequency (day, week, or month). The frequently chosen was hypothesized to represent the intuitive framing of the exercise prescription (i.e., daily, weekly, or monthly). **Results**: Most participants recommended an amount of exercise per day (86.9%) rather than per week (12.6%), suggesting that daily exercise is more intuitive than weekly exercise ($p < .001$). This result was replicated on the Internet in a sample of 124 participants (50.8% woman, mean age: 38.30 ± 12.41 years), with the majority (76.6%) of participants recommending daily exercise ($p < .001$). **Conclusion:** These data suggest that recommending minimum durations of exercise “per day” may be more intuitive than recommending minimum durations of exercise “per week”. Future investigators should determine if daily exercise prescriptions are (1) more memorable and (2) result in better adherence than weekly exercise prescriptions. These data can inform the development of future exercise guidelines that may be more intuitive and more likely to be completed.

DEVELOPMENT AND RELIABILITY OF A STREETSCAPE OBSERVATION INSTRUMENT FOR INTERNATIONAL USE: MAPS-GLOBAL

Kelli L. Cain, MA[1], Carrie M. Geremia, BA[2], Terry L. Conway, PhD[1], Lawrence D. Frank, PhD[3], James E. Chapman, MA[4], Eric Fox, BA[4], Anna Timperio, PhD[5], Jenny Veitch, PhD[5], Delfien Van Dyck, PhD[6], Hannah Verhoeven, MS[6], Rodrigo Reis, PhD[7], Alexandre Augusto, BA[8], Ester Cerin, PhD[9], Robin Mellecker, PhD[9], Ana Queralt, PhD[10], Javier Molina-García, PhD[10], James F. Sallis, PhD[11]

[1]University California San Diego, San Diego, CA; [2]UCSD, San Diego, CA; [3]University British Columbia, Seattle, WA; [4]UD4H, Seattle, WA; [5]Deakin University, Burwood, Victoria, Australia; [6]Ghent University, Ghent, N/A, Belgium; [7]Washington University in St. Louis, Saint Louis, MO; [8]PONTIFÍCIA UNIVERSIDADE CATÓLICA DO PARANÁ, Curitiba, Parana, Brazil; [9]The University of Hong Kong, Pokfulam, N/A, Hong Kong; [10]Universitat de València, Valencia, N/A, Spain; [11]University of California, San Diego, San Diego, CA

Objective: Relationships between several built environment factors and physical activity and walking behavior are well established. MAPS-Global is an observational streetscape audit instrument developed for international use with inter-observer reliability evaluated in several countries.

Methods: MAPS-Global was developed by compiling common concepts across 8 pedestrian and biking audit tools from numerous countries, including the original MAPS instrument which was developed in the US. Inter-rater reliability data were collected in neighborhoods selected to vary on GIS-derived macro-level walkability in 5 countries (Australia, Belgium, Brazil, Hong Kong-China, and Spain). MAPS-Global assessments (n=407) were completed along a 0.25 mile route from a residence toward the nearest non-residential destination, and a commercial block was also rated for each residence. Two raters in each country rated each route independently. A tiered scoring system was created that summarized items at multiple levels of aggregation, and positive and negative valence scores were created based on the expected affect on physical activity. Intraclass correlations (ICC's) were computed for scales using oneway random models.

Results: Overall, 89.2% of individual items, subscales and overall summary scores showed excellent agreement (ICC> .75); 7.2% showed good agreement (ICC=0.60-0.74); and 3.6%

showed fair agreement (ICC=0.40 to 0.59). Two items were too rare to compute ICC's. The median ICC was .94 with a range of .54-.99. Aesthetics and social characteristics showed lower ICC values than other constructs but the scales were still in the excellent range.

Conclusion: Evaluation of inter-observer reliability of MAPS-Global in 5 countries indicated virtually all items and scales had "good" or "excellent" reliability. The results demonstrate that trained observers from multiple countries were able to reliably conduct observations of both residential and commercial areas with the new MAPS-Global instrument. This instrument can now be used to collect comparable microscale data across countries to identify strengths and weaknesses of activity-supportive environments, identify microscale correlates of physical activity, and evaluate changes in built environments, especially those designed to improve physical activity and health.

DEVELOPMENTAL TRAJECTORY PATTERNS OF VIGOROUS-INTENSITY PHYSICAL ACTIVITY FROM AGE 5 TO 19 YEARS: IOWA BONE DEVELOPMENT STUDY

Soyang Kwon, PhD[1], Kathleen F. Janz, EdD[2], Elena M. Letuchy, MS[2], Steven M. Levy, DDS[2]

[1]Lurie Children's Hospital of Chicago, Chicago, IL; [2]University of Iowa, Iowa City, IA

Background: At a population-level, physical activity decreases during childhood and adolescence; however, the developmental trajectory of physical activity is not homogeneous. In addition, researchers have hypothesized that at the same absolute volume, vigorous-intensity physical activity (VPA) may effect health outcomes differently than moderate- and vigorous-intensity physical activity (MVPA). A group-based trajectory analytic approach enables data to identify district trajectory patterns of an outcome of interest. This approach is a critical step in understanding differential effects of VPA and MVPA across the developmental years. Using the group-based trajectory approach, the authors have previously identified distinct developmental patterns of MVPA and sport participation from age 5 to 19 years.

Objective: We aimed to identify diverse trajectory patterns of daily minutes spent in VPA from age 5 to 19 years and examine the associations of these patterns with sex and sport participation trajectory.

Methods: Participants were Iowa Bone Development Study (IBDS) cohort members. They were asked to wear an ActiGraph accelerometer for four or five days at approximate ages 5, 8, 11, 13, 15, 17, and 19 years. Vigorous-intensity was defined as ≥4,012 ActiGraph counts per minute. VPA minutes from multiple assessment days were averaged. Sports participation was assessed using a questionnaire every six months. Group-based trajectory analysis was used to identify diverse patterns in VPA and sport participation.

Results: Based on the data from 537 IBDS participants (50% male, 95% White), four VPA trajectory patterns were identified: Group 1 (7.2%) = increasing from approximately 10 minutes/day at age 5 to approximately 35 minutes at age 19; Group 2 (75.3%) = consistently low below 10 minutes/day (unhealthy VPA pattern); Group 3 (13.7%) = increasing during preadolescence and decreasing during adolescence; Group 4 (3.8%) = consistently high above 20 minutes/day. The sex distribution was significantly different across the four groups (proportions of males: 66% in Group 1, 40% in Group 2; 90% in Group 3, and 85% in Group 4; $p < 0.01$). Compared to youth who dropped out of sport participation, youth who maintained sport participation were more likely to be in Group 1 or Group 4, as opposed to Group 2 ($p < 0.01$).

Conclusion: In our 14-year longitudinal follow-up, three-fourths of the participants followed an unhealthy VPA pattern. This study suggests that females may be missing distinct health benefits associated with VPA during the growing years. Research on health consequences, such as obesity, related to these VPA patterns should follow.

MERITORIOUS AWARD WINNER

DIFFERENTIAL EFFECTS OF THE COMPANY OF MOTHERS VERSUS FATHERS ON PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOR IN BOYS AND GIRLS

Eldin Dzubur, MS, Sydney G. O'Connor, BA, Gayla Margolin, Ph.D., Genevieve F. Dunton, PhD, MPH

University of Southern California, Los Angeles, CA

Background: The company of parents is thought to increase children’s level of physical activity and decrease sedentary behavior. These effects, however, may differ for boys and girls. For example, compared to mothers, fathers have a stronger influence on their daughter’s physical activity. However, prior studies examining the role of parental influence on children’s physical activity and sedentary behavior have been limited by retrospective recall, and the failure to concurrently measure activity and social context. The aim of this study was to determine whether children's physical activity and sedentary behavior levels varied across different types of parental contexts (i.e., mothers, fathers, or both parents).
Methods: Children (N=192, ages 8-12, 53% female) wore accelerometers and answered Ecological Momentary Assessment (EMA) survey prompts by smartphone up to 7 times a day for 8 days. Each EMA survey prompt assessed whether one, both, or neither parents were present. Accelerometer data were used to summarized minutes of moderate-to-vigorous physical activity (MVPA) and sedentary behavior (SB) across the 30-minute window prior to each EMA prompt. Separate multilevel models were used to examine main effects of type of parental company girls’ and boys’ physical activity, disaggregating variance (between-subject [BS] and within-subject [WS]) and adjusting for age and ethnicity.
Results: WS findings show that girls engaged in more SB when neither parent was present than when they reported being with their mother or both parents (WS, z's=2.60 and 2.38, respectively; p's < 0.05). Overall, BS findings show that girls who reported being with their father more often than being with their mother, with neither parent, or with both parents, engaged in more MVPA (BS, z's=-3.63, -2.92, and -2.78, respectively; p's < 0.01). Additionally, boys who reported being with their mother more often than with neither parent or with both parents, engaged in less SB (BS, z's=-2.60 and -2.25; respectively, p's < 0.05).
Discussion: The findings are consistent with prior research suggesting that spending more time with fathers may promote physical activity to a greater extent in girls than boys. The results indicate that reporting being with mothers more frequently may reduce sedentary behavior more in boys. However, girls were less sedentary when concurrently with mothers or both parents. Future interventions targetting sedentary behavior and physical activity may

seek to vary or prioritize the amount of time spent with each parent differently for boys and girls.

EFFECTS OF A COMMUNITY-BASED EXERCISE PROGRAM ON PHYSICAL FUNCTION AND EXERCISE-RELATED OUTCOMES IN OLDER ADULTS

Susan S. Levy, Ph.D.[1], Katie J. Thralls, M.S., C.S.C.S.[2], Kari Carmody, MPH[3], Taylor B. Krippes, MS[1]

[1]San Diego State University, San Diego, CA; [2]San Diego State University/University of California, San Diego; Joint Doctoral Program, San Diego, CA; [3]Aging and Independence Services of San Diego County, San Diego, CA

Fostering healthy aging reduces risks of diminished function and loss of independence. Exercise programs for older adults have led to improved function, yet few have been integrated into services provided by state and related agencies serving older adults. Community exercise programs have confirmed feasibility in their delivery and acceptance by older adults, yet many lack controlled studies examining their efficacy on desired outcomes. This study examined the efficacy of a community-based exercise program, using a controlled design.

Participants (N=169) were recruited from senior centers served by the County Area Agency on Aging, who offered exercise classes in 21 centers. Intervention participants (n=87, M_{age}=73.3±8.5) were recruited from new classes starting at 7 centers. Controls (n=82, M_{age}=74.9±7.7) were recruited from matched sites not offering classes. Classes emphasized physical function related to activities of daily living (ADL), met twice weekly, and were taught by trained instructors. Exercises were low-impact and focused on proper execution of movement, core stabilization, strength, balance, flexibility, and aerobic fitness. Validated measures of

physical function, exercise self-efficacy, and exercise behavior (outside of class) were administered at baseline and 6 months.

Mixed design ANOVAs revealed significant improvements in upper body strength ($p < .001$) as measured by the arm curl (24% increase), lower body strength ($p < .001$) as measured by the 30-second chair rise (21% increase), aerobic endurance ($p < .001$) as measured by the 6-minute walk (8% increase in distance), and mobility ($p < .004$) as measured by the 8-ft up and go (8% decrease in time) in the exercise, but not control group over time. Significant increases in exercise self-efficacy ($p < .002$) and moderate/vigorous intensity activity ($p < .05$), and days

of muscular-based training ($p < .005$) were found in the exercise group but not controls. No significant changes ($p > .05$) were found in flexibility training in either group.

These findings support the efficacy of a County-wide disseminated exercise program in improving ADL-related function, and exercise-related outcomes in older adults. Building an evidence base for community delivered programs should provide impetus for increasing dissemination through involvement of appropriate state and national agencies. This will increase the impact of programs on a growing population of older adults, and foster healthy aging initiatives.

INTRINSIC MOTIVATION FOR EXERCISE AND PATTERNS OF HEALTH BEHAVIORS

Elise L. Rice, PhD[1], Chan Thai, PhD, MPH[2], Rebecca A. Ferrer, PhD[3], Annette Kaufman, PhD, MPH[4], William Klein, PhD[5]

[1]National Cancer Institute, Bethesda, MD; [2]Santa Clara University, Santa Clara, CA; [3]National Cancer Institute, Rockville, MD; [4]Tobacco Control Research Branch, Behavioral Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, National Institutes of Health, Rockville, MD; [5]NCI/NIH, Rockville, MD

The value of intrinsic motivation (IM; being driven by enjoyment to engage in a behavior) for sustainable exercise has been documented in prior research. Given that most Americans fall short of physical activity (PA) guidelines, it is crucial to understand the prevalence of IM for PA. These analyses extend previous work by examining the relationship between IM and exercise in a nationally representative sample, identifying moderators of that relationship, and exploring whether IM for exercise is related to other health behaviors. The current study utilized the Health Information National Trends Survey (HINTS; 2012-2014). Respondents (*N*=7,307) indicated how much “getting enjoyment from exercise” influenced why they would start or continue exercising regularly. They also reported on their patterns of PA, sedentary behavior, fruit and vegetable (F&V) consumption, and sunscreen use, as well as their height, weight, and smoking history. As expected, respondents’ IM was associated with more PA in a typical week (β=62.07, p < .01). However, that association was moderated by gender and BMI, such that the relationship between IM and PA was weaker among women (β=-46.65, p=.02) and those with higher BMI (β=-4.01, p=.02). Additionally, IM was associated with less sedentary behavior (β=-0.33, p < .01), although that relationship was moderated by self-reported physical health, such that the link was stronger among those who reported that their general health was poor (β=0.30, p=.01) and those who reported having been diagnosed with a medical condition (β=0.30, p=.02). Finally, IM for exercise was also associated with other health behaviors, even controlling for PA, including: F&V consumption (β=0.55, p < .01), sunscreen use (β=0.13, p < .01), and non-smoker status (β=-0.16, p=.03). Collectively, these findings suggest that although IM for exercise is a robust statistical predictor of self-reported heath behavior – even beyond the domain of PA – its predictive power is variable. Although further study is needed, these results suggest opportunities to tailor IM-based interventions to participants, which could potentially impact the broader lifestyle beyond the immediate target behavior.

LATENT CLASS ANALYSIS OF FACTORS ASSOCIATED WITH EXERCISE DEPENDENCE AND EATING PATHOLOGY

Brian Cook, PhD, Steven Kim, PhD

California State University Monterey Bay, Seaside, CA

Background: Exercise dependence is a multifaceted maladaptive pattern of exercise attitudes, cognitions, and behaviors that result in significant health detriments. Specifically, it has been identified as a key factor that may mediate the relationship among exercise and related psychopathology (e.g., eating disorders, behavioral addiction, etc.). Several factors have been associated with exercise dependence with and without comorbid psychopathology. However, few studies have included multiple factors that may clarify individual differences among exercise dependence. Classifying profiles of factors associated with exercise dependence and related eating pathology may identify individual differences that could allow for tailored interventions to maximize exercise-related benefits. Thus, the purpose of this study was to examine profiles of factors associated with exercise dependence and eating pathology. **Method:** Participants (N=1374; mean age = 28.24, SD = 10.20, 65.4% female) completed an online survey that included the Leisure-time Exercise Questionnaire (LTEQ), Exercise Dependence Scale (EDS), Positive and Negative Affect Schedule, Behavioral Inhibition/Behavioral Activation Scales (BIS/BAS), and the Eating Disorders Examination-Questionnaire (EDEQ). Latent class analysis was used to classify latent groups. We used multiple imputations to account for uncertainty for missing data then selected a final model which minimizes Bayesian Information Criterion to balance between model fit and simplicity. **Results:** Analysis identified four distinct profiles: group 1 (36%) displayed high levels of EDEQ, LTEQ, negative affect (NA) and EDS; group 2 (17%) displayed high EDS, LTEQ, BAS, and positive affect (PA), and low EDEQ scores; group 3 (22%) displayed high EDEQ, BIS, and NA, and low EDS scores; group 4 (25%) displayed low scores for all variables. **Discussion:** Results of this study suggest that relationships among exercise dependence, eating pathology, temperament, and affect may be more heterogeneous than previously conceptualized. This study may inform researchers and clinicians on how to identify who may benefit from exercise interventions, factors that should be considered when using exercise as behavioral medicine, and identifying risk for exercise-associated pathology.

OVERALL EFFECTIVENESS OF INTERVENTIONS TO INCREASE PHYSICAL ACTIVITY IN AFRICAN AMERICAN WOMEN: A META-ANALYSIS

Brittany Miller, BA[1], Anne Moyer, Ph.D.[2]

[1]Stony Brook University, East Setauket, NY; [2]Stony Brook University, Stony Brook, NY

African American women have one of the lowest physical activity rates and highest obesity rates in the United States. Consequently, they are at increased risk for and suffer disproportionately from related illnesses, such as cardiovascular disease and diabetes. Researchers have developed and tested interventions to increase physical activity in African American women, but their effectiveness lacks consistency, particularly over time. Two meta-analyses, utilizing pre-intervention and post-intervention data, were conducted to examine the overall effectiveness of physical activity interventions in African American women. Three bibliographic databases were searched, and nine studies were included in the final meta-analysis. The samples of the nine studies ranged from $N = 13$ to $N = 447$ African American women. The mean age ranged from $M = 21.2$ to $M = 60.1$ years. Intervention length ranged from 1.5 to 6 months. Five of the nine studies had data extracted from self-report measures, while the other four had data extracted from a monitoring device. The interventions included a range of components, including exercise training, motivational interviews, group exercise sessions, problem-solving to overcome exercise barriers, group sessions addressing exercise benefits, and pedometer use. The first meta-analysis extracted the baseline physical activity measurement as pre data and the end of the study physical activity measurement as post data. The second meta-analysis extracted the baseline physical activity measurement as pre data and the last physical activity measurement taken as post data. The meta-analyses yielded moderate aggregate effect sizes of $r = 0.52$ and $r = 0.49$, respectively. The results suggest that interventions significantly increase engagement in physical activity, but those effects may be slightly less strong in the long term. Additionally, whether the intervention design was individual-based, group/community-based, or a mix of the two was found to be a significant moderator in the second meta-analysis. Interventions targeting African American women are a promising way to increase the rate of physical activity in this population, however, it may be beneficial for researchers to focus on how to maintain their effects over time. Improving the long-term effects of these physical activity interventions may be helpful in addressing related health disparities negatively impacting African American women.

PERCEIVED NEIGHBORHOOD ENVIRONMENT AND PHYSICAL ACTIVITY AMONG AFRICAN AMERICAN WOMEN IN RURAL NORTH CAROLINA:

Mary L. Greaney, PhD, MPH[1], Alyssa Platt, MA[2], Dori Steinberg, PhD, RD[2], Erica Levine, MPH[2], Perry Foley, MPH, MSW[3], Gary G. Bennett, PhD[4]

[1]University of Rhode Island, Kingston, RI; [2]Duke Global Health Institute, Durham, NC; [3]OCHIN, Inc., Milwaukie, OR; [4]Duke University, Durham, NC

Background/purpose: More than 75% of Black women living in the US are overweight or have obesity, and more than 50% are not meeting current guidelines for physical activity. The potential effects that the built environment and community have on physical activity behaviors of Black women living in rural areas have not been thoroughly researched. To address this gap, we conducted a cross-sectional secondary analysis of baseline data from The Shape Program to explore how participants' perception of their environment influenced physical activity and sedentary time.

Methods: The Shape Program, a randomized control trial of a weight gain prevention intervention implemented in community health centers in rural North Carolina, was designed for socioeconomically disadvantaged Black women who are overweight or have obesity. Participants' perceptions of their environment were assessed using item from the Boehmer & Brownson instrument (e.g., seeing billboards encouraging physical activity, seeing trees along community streets, presence of sidewalks). The sample for the current study included participants with 10+ valid days of accelerometer data and valid survey data for perceived environment variables (n=159; 81.2% of Shape participants). Accelerometer data were aggregated into 1- minute bouts of moderate to vigorous physical activity (MVPA) and minutes of sedentary time. Assessed Boehmer & Brownson items were entered into an exploratory factor analyses, a Scree test was conducted, and identified factor scores were entered into log-linear ordinary least squares regression models examining MVPA and sedentary time.

Results: Participants had an average of 52 minutes (median = 34) of MVPA and 663 minutes (SD=173.2)/day of sedentary time. The exploratory factor analyses and Scree test identified 4 distinct perceived environmental factors: 1) facility of travel; 2) community aesthetic; 3) physical activity messaging, and 4) existing physical activity facilities. After adjusting for covariates, a 1 SD change in factor score for "community aesthetic" was associated with a

26.5% (95% CI: 7.9% - 45.1%) higher level of MVPA when measured. None of the examined factors correlated with sedentary activity.

Conclusion: Among this sample of socioeconomically disadvantaged Black women, none of the examined factors were associated with sedentary time and only “community aesthetic” was associated with physical activity. Our results suggest that no other environmental or community variables influenced physical activity.

POST-EXERCISE AFFECTIVE RESPONSE: EXAMINING DIFFERENCES BETWEEN REGULAR AND INFREQUENT EXERCISERS

Margarita Sala, BS[1], David Rosenfield, PhD[2], Austin S. Baldwin, PhD[2]

[1]Southern Methodist University, Dalas, TX; [2]Southern Methodist University, Dallas, TX

Background: Exercise-related affect is a critical factor in understanding why some people exercise regularly and others do not. The vast majority of people report an improvement in core affect after exercise (i.e., “feeling better”), and although it is reasonable to expect that “feeling better” after exercising would reinforce exercise behavior, fewer than half of U.S. adults exercise regularly (Centers for Disease Control Prevention, 2013). It is important to examine the influence of post-exercise affect on exercise because post-exercise affect may play a unique role in influencing future exercise. The purpose of this study was to determine the extent to which specific *post*-exercise affective states (i.e., positive affect, negative affect, fatigue, calmness, relief) differ between regular and infrequent exercisers, thereby elucidating the “feeling better” phenomenon.

Methods: Regular (N = 32; > 75 minutes per week of vigorous exercise) and infrequent exercisers (N = 25; < 30 minutes per week of vigorous exercise) completed a 10-minute bout of vigorous exercise on a treadmill and reported their affective states at various time points during the bout and during a 30-minute post-exercise period.

Results: Consistent with previous findings, both regular (p = .004) and infrequent exercisers (p < .001) reported an improvement in core affective valence after the exercise bout (i.e., “feeling better”). However, infrequent exercisers reported a higher decrease in negative affect (p = .01) as well as a greater sense of relief (p = .003) immediately post-exercise than regular exercisers. Relief was more strongly correlated with changes in negative affect (r = .38) than with changes in positive affect (r = -.12). Regular exercisers reported a higher increase in positive affect (p = .01) immediately post-exercise than infrequent exercisers. Finally, there were no differences in post-exercise fatigue and calmness.

Implications: Both regular and infrequent exercisers experienced increases in core affective valence immediately post-exercise. However, for infrequent exercisers, “feeling better” appears to be due to a decrease in negative affect and a greater sense of relief immediately post-exercise. This study demonstrates how post-exercise affective states systematically differ between regular and infrequent exercisers, thereby elucidating the “feeling better” phenomenon

PSYCHOSOCIAL FACTORS AS MODERATORS OF ASSOCIATIONS BETWEEN BUILT ENVIRONMENT AND ADOLESCENTS’ ACTIVE TRANSPORTATION

Terry L. Conway, PhD[1], Xiaobo Wang, PhD[2], Kelli L. Cain, MA[3], Lawrence D. Frank, PhD[4], Brian E. Saelens, PhD[5], Carrie M. Geremia, BA[6], Jacqueline Kerr, PhD, MSc[7], Karen Glanz, PhD, MPH[8], Jordan A. Carlson, PhD, MA[9], James F. Sallis, PhD[1]

[1]University of California, San Diego, San Diego, CA; [2]Zhengzhou University of Light Industry, Zhengzhou, Henan, China (People's Republic); [3]University California San Diego, San Diego, CA; [4]University of British Columbia, Vancouver, BC, Canada; [5]University of Washington, Seattle, WA; [6]UCSD, San Diego, CA; [7]Department of Family Medicine and Public Health, UC San Diego, La Jolla, CA, USA, La Jolla, CA; [8]University of Pennsylvania, Philadelphia, PA; [9]Center for Children's Healthy Lifestyles & Nutrition, Kansas City, MO

Objective: Factors across different levels of influence (e.g., individual and environmental) may relate to active transport physical activity (PA) of adolescents, but the multiple levels are seldom studied concurrently. The primary aim here was to examine individual-level psychosocial variables as moderators of associations between objective built environment measures and adolescents’ reported active transport PA.

Methods: Mixed-effects regression models were examined in the Teen Environment and Neighborhood (TEAN) observational study (N=928, 12-16 year old adolescents). An index of active transportation to/from school and neighborhood destinations was the dependent variable. Explanatory constructs explored were from psychosocial and objective built environment domains. Seven psychosocial measures related to PA (self-efficacy, enjoyment, athletic ability, decisional balance, barriers to PA in the neighborhood, social support from peers and family) were self-reported by adolescents. Objective built environment measures included a neighborhood walkability index and count of nearby parks and recreation facilities derived from Geographic Information System (GIS) procedures, and an environmental audit of streetscape quality (MAPS tool). Covariates included demographic characteristics and study design factors.

Results: Three of 21 interactions were related to the active transportation index (p’s < 0.10): self-efficacy X GIS walkability index, barriers to PA X MAPS streetscape score, and self-efficacy X GIS count of parks and recreation facilities. Each interaction showed a synergistic pattern of higher active transport scores among adolescents with the combination of activity-supportive

built environment and pro-physical activity psychosocial characteristics. All 3 objective environment measures and 3 psychosocial variables (self-efficacy, social support from peers, and enjoyment of PA) also had significant positive main effects with active transportation (*p*'s < 0.056).

Conclusion: Results provided modest support for the ecological model principle of interactions across levels of influence, highlighted the importance of built environment and psychosocial factors in facilitating or hindering adolescents' active transportation, and suggested that strategies for improving adolescents' active transportation may be most effective when targeting multiple levels of influence in ecological models.

PSYCHOSOCIAL PREDICTORS OF PHYSICAL ACTIVITY CHANGE AMONG COLLEGE STUDENTS IN AN OBESITY PREVENTION TRIAL

Danielle Arigo, Ph.D., Licensed Psychologist[1], Paul Rohde, Ph.D.[2], Heather Shaw, Ph.D.[2], Eric Stice, Ph.D.[2]

[1]The University of Scranton, Scranton, PA; [2]Oregon Research Institute, Eugene, OR

Accumulating evidence shows the importance of moderate-to-vigorous physical activity (MVPA) for maintaining a healthy body weight, particularly among those at risk for weight gain. At present, however, little is known about psychological barriers to maintaining MVPA in at-risk groups. As obesity prevention programs involve multiple behavior changes, identifying individuals who specifically are unlikely to adopt or maintain MVPA in this context could improve weight control outcomes. In the present study, we examined predictors of MVPA in an obesity prevention trial targeted toward college students at risk for weight gain (n = 364; 72% female, M_{BMI} = 23.4 kg/m^2). Based on their proposed relations to self-regulatory abilities, predictors of interest were impulsiveness, cognitive dissonance regarding unhealthy behaviors, and perceived sociocultural pressure to be thin. Participants were randomly assigned to one of three intervention conditions and completed assessments at pre- and post-intervention, and at 6- and 12-month follow-ups. These assessments included measured height and weight, self-report measures of psychosocial experiences, and four days of waistband accelerometer wear. Of the total variability in MVPA minutes per day over 12 months, only 33% was attributable to between-person differences; across conditions, participants decreased their total MVPA minutes per day during this time (B = -5.48, p < 0.01). Baseline self-report scores for both impulsiveness and cognitive dissonance regarding unhealthy behaviors negatively predicted MVPA over time. Participants with elevated baseline impulsiveness scores (B = -7.36, p = 0.04) and dissonance scores (B = -3.89, p = 0.05) began the study with more MVPA minutes, but showed sharper declines over time. These differences (~5-30 minutes over four days) represent 3-22% of recommended MVPA per week. Sociocultural pressure was not related to MVPA change (B = -1.56, p = 0.36). Targeted MVPA-focused intervention for students who show elevated impulsiveness and cognitive dissonance may improve both MVPA and weight control outcomes for these individuals over the long term.

RELIABILITY OF ACTIVITY MONITORS FOR TRACKING STEPS AND ESTIMATING ENERGY EXPENDITURE DURING A GRADED MAXIMAL TREADMILL TEST

Bradley J. Kendall, B.A., M.S.[1], Bryanne Bellovary, M.S.[2], Neha Gothe, MA, MS, PhD[3]

[1]Wayne State University, Grosse Pointe Park, MI; [2]University of New Mexico, Albuquerque, NM; [3]Wayne State University, Detroit, MI

Background: Due to the increased awareness of the importance of exercise and physical activity (PA), individuals are more interested in their ability to track steps and energy expenditure (EE). It is expected that individuals as well as employers, insurers, and clinicians will begin to use activity monitors (AMs) more frequently in order to address health behaviors. To date, there have been mixed findings on the accuracy of various AMs during exercise and PA. Therefore, the purpose of this study was to (1) assess the accuracy of EE estimation and step tracking abilities of six AMs in relation to indirect calorimetry and hand counted steps and (2) assess the accuracy between high and low fit individuals.

Methods: Fifty participants (mean age: 25.84±8.10 years) wore the Basis watch, Fitbit Flex, Polar FT7, Jawbone, Omron pedometer, and Actigraph during a maximal graded treadmill test. Correlations, intra-class correlations (ICCs), and one-sample t-tests determined accuracy and agreement between AMs and criterions.

Results: All AMs were significantly correlated with the hand counted steps (overall ICC=0.994, $p < 0.001$, CI 95%=0.991-0.996). One sample t-tests revealed that the Omron, Fitbit, and Actigraph showed agreement with the steps standard ($p>0.05$), while the Basis and Jawbone significantly underestimated steps ($p < .05$). All fitness trackers were significantly correlated with the metabolic cart (overall ICC=0.934, $p < 0.001$, CI 95%=0.856-0.968). One sample t-tests revealed that no device showed agreement with the metabolic cart ($p>0.05$). When split by fitness categories, the low fit group showed better correlations compared with the high fit group. One sample t-tests revealed the Actigraph and Omron showed agreement to indirect calorimetry in the low fit group while the Polar FT7 and Basis watch showed agreement in the high fit group.

Conclusions: The Omron, Fitbit, and Actigraph were reliable for measuring steps. AMs were more reliable for measuring EE at low intensity exercise compared to high intensity. Future research on reliability of these devices as well as manufacturing and development of new AMs should account for the greater metabolic demand of higher intensity activities in order to improve EE estimates.

RESPONSE PATTERNS AND PREDICTORS OF COMPLIANCE TO ECOLOGICAL MOMENTARY ASSESSMENT: RESULTS FROM THE MOVINGU STUDY

Matthew Kwan, PhD[1], Chloe Bedard, B.HSc.[1], Scott Veldhuizen, MSc[2], John Cairney, PhD[3]

[1]McMaster University, Hamilton, ON, Canada; [2]Brock University, Hamilton, ON, Canada; [3]University of Toronto, Hamilton, ON, Canada

Background: The transition out of high school represents a major life transition often associated with significant declines in physical activity behaviors (Bray & Born 2004; Kwan, et al., 2012). To date, the extant literature is largely based on cross-sectional or infrequent longitudinal designs, and are limited in our understanding of contextual and intra-individual factors impacting physical activity during this transitory time. Ecological momentary assessment (EMA) is an intensive data capture method that can address these limitations (Shiffman et al., 2008). The purpose of the current study was to describe the utility of EMA data in a sample of first-year university students, and to examine several time invariant and time-varying predictors of EMA compliance. **Method:** Current sample included 96 recent high school graduates (*M*age=18.30 $\underline{+}$.54;males=45%), whom were asked to wear a wrist-worn accelerometer and to complete EMA prompts 7x/day for a period of five days (Wed through Sun). Each prompt included a very-brief questionnaire assessing context, acute feeling and mood states, and social cognitions. **Results:** Overall, 68% of the sample met the minimal acceptable compliance (answered $\underline{>}$3 prompts on >3 days), of which only 26% were considered to have excellent compliance (answered $\underline{>}$5 prompts for >4 days). Results of logistic regression did not find any time-invariant factors being related to compliance; however, findings from the mixed effects logistic model indicates that there was a significant time of day (Coefficient= -5.10 SE=.75, pDiscussions: Overall compliance to EMA prompts were modest in our current sample, thus it was important to investigate for potential non-response biases. While socio-demographic or behavioural factors did not predict response compliance, our results found prompts being sent in the afternoons/early evenings were more likely to be answered compared to mornings and later evening. Findings also showed linear response pattern decline, suggesting that participants either became less inclined to respond over time or less likely to respond on weekend days. Understanding factors related to EMA compliance is an important step to recognize the potential biases for this data-intensive sampling strategy, and current findings suggest that future EMA studies may require a smaller sampling frame for the emerging adulthood population.

RESULTS OF THE GUIDELINES FOR EXERCISE IN MULTIPLE SCLEROSIS (GEMS) PROJECT: A FEASIBILITY RANDOMIZED CONTROLLED TRIAL

Brynn Adamson, MS[1], Yvonne C. Learmonth, PhD[2], Dominique Kinnett-Hopkins, B.S. [1], Maria Bohri, BS[3], Robert W. Motl, PhD[4]

[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]University of Illinois, Urbana, IL; [3]University of Illinois at Urbana-Champaign, Washington, DC; [4]University of Alabama at Birmingham, Birmingham, AL

There is increasing recognition that exercise is an efficacious strategy for managing many consequences of multiple sclerosis (MS), yet this population engages in less exercise than the general population, and other chronic disease populations. The poor uptake of exercise among persons with MS might be associated with the lack of emphasis on translational and feasibility research. Additionally, most exercise studies completed in this population are center-based and supervised, and not easily translated into practice and widespread adoption. We conducted a randomized controlled trial in order to examine the feasibility of a 4-month, home-based exercise training program based on recent, MS-specific physical activity guidelines. Feasibility was assessed based on the four domains of process (e.g., recruitment), resource (e.g., monetary costs), management (e.g., personnel time requirements), and scientific outcomes (e.g., treatment effect). We recruited persons with mild-to-moderate MS who were randomized into an intervention or a wait-list control condition. Participants in the intervention condition received exercise equipment (i.e., a pedometer, resistance bands, DVD, training manual, calendars, and logbook), video coaching calls via Skype^{TM}, and newsletters based on principles of Social Cognitive Theory. Participants in both conditions completed home-based assessments before and after the 4-month period. Ninety-nine persons with MS were assessed for eligibility, and 57 were randomized. Fifty-one persons completed the study (90%). Total costs of the study were US$5331.03. Personnel time to conduct the study totaled 263 hours. Participants in the intervention group complied fully with 71% of all exercise sessions. There was a statistically significant time by group interaction on Godin Leisure-Time Exercise Questionnaire scores (F=6.94, P η_p^2 = 0.12); there was a moderate increase (d≥0.5) in self-reported exercise behavior for the intervention participants. Qualitative surveys and interviews indicated overall satisfaction with all aspects of the intervention. These results support the feasibility, efficacy and acceptability of a home-based exercise intervention based on the physical activity guidelines and supplemented with behavioral strategies for adults with mild-to-moderate MS. This is an important step towards providing adequate and

appropriate resources that can aid in the adoption of exercise behavior among adults with MS.

REVISED MODEL FOR PREDICTING ATTRITION FROM EXERCISE

Jason D. Cohen, B.S.[1], Tiffany Bullard, B.S. [1], Daniel Palac, MA[2], Arthur Kramer, Ph.D.[3], Edward McAuley, PhD[4], Sean P. Mullen, PhD[1]

[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]University of Illinois at Urbana-Champaign, Champaign, IL; [3]Northeastern University, Boston, MA; [4]University of Illinois at Urbana Champaign, Urbana, IL

Exercise behavior maintenance is challenging, particularly for people with many barriers. It would benefit researchers and practitioners to have an accurate method to identify individuals exhibiting characteristics associated with a high likelihood of dropout from an exercise trial. Using brief measures, serving as proxy measures of poor self-regulatory functioning, Mullen et al (2013) provided initial evidence for such a “profile for attrition from exercise” based on 4 variables (i.e., memory complaints, self-efficacy for overcoming barriers to exercise, left leg balance time, and stairs down time) in a sample of older adults (65+) involved in an exercise trial. In the current NHLBI funded study (n=133 middle-aged adults, 45-64 years; 3 values were imputed for 4 participants using EM algorithm imputation), we replicated the original model using discriminant function analysis (DFA); note the perceived memory item was taken from a different scale and a longer, 60s balance assessment was used. The DFA found that 71.3% were correctly classified vs. 72.22% of the original sample, however the memory complaint item was a non-significant discriminating variable (p=.68). Self-efficacy for overcoming barriers (66.74 vs. 56.14), left leg balance time (38.46s vs. 30.32), and stairs down time (5.61s vs. 6.65) all differentiated ($p < .05$) "completers" from "dropouts," respectively. Upon re-examination of theory and research, and given the age difference between samples, a revised model was tested. Current physical activity level (3-day average Fitbit step count) replaced memory complaints and the revised model (imputed data showed similar results, in parentheses) correctly classified 72.1% (71%) of the total sample (Wilk's Λ = .84, X^2 (4) = 22.57, $p < .01$, eigenvalue = .20, canonical correlation = .41). Classification results determined that the new model accurately classified 74% (72%) of those who remained for the entirety of the exercise trial, as well as 66.7% (69.7%) of those who officially requested to withdraw from the study or discontinued contact. These findings support using a brief battery for identifying middle-aged and older adults who may need some additional support to enhance their self-regulatory skills.

SLEEP DURATION AND ITS EFFECT ON DAILY MVPA

Janine Nguyen, N/A [1], Chrisanta Tomaneng, N/A [2], Margaret Schneider, PhD[3]

[1]University of California, Irvine, Orange, CA; [2]University of California, Irvine, Winchester, CA; [3]University of California, Irvine, Irvine, CA

Background: Although physical activity is a key factor to a healthy lifestyle, much of today's youth are not getting the recommended amount of physical activity. Only 24.8% of adolescents in the U.S. engage in at least 60 minutes per day of moderate to vigorous physical activity (MVPA) and it is suspected that sleep duration may influence activity. Findings have been inconclusive with respect to this relationship.

Methods: Middle school students (N=182, mean age = 11.06 years) participated in this study. MVPA was objectively monitored for seven days with an ActiGraph. During the same 7-day period, sleep data were collected using a self-report log that documents wake and sleep time. Participants also completed a test of cardiorespiratory endurance (VO2peak) and a depression inventory and were assessed for height and weight to determine Body Mass Index percentile (BMI). Correlational and regression analyses assessed the relationship of average sleep duration with average minutes of MVPA per day.

Results: The participants' average sleep time was 9.55 hours per night (SD = 0.52 hours) and average MVPA was 49.05 minutes/day (SD = 22.47 minutes). After removing participants with incomplete data, correlation analysis (N = 151) showed no association between sleep and activity ($p > 0.05$). Results were the same for both males and females and for teens with relatively low versus higher scores on a depression inventory, and the association remained non-significant after controlling for VO2peak and BMI.

Conclusions: Average sleep duration had no correlation with average MVPA in this study, suggesting that young adolescents' participation in physical activity is not influenced by their usual amount of sleep. It is possible, however, that unmeasured aspects of the environment such as parental control of time to bed may have influenced self-reported sleep duration, thus obscuring the sleep-activity relationship. Using an objective measure of sleep duration would strengthen future studies.

THE RELATIONSHIP BETWEEN SELF-EXPANSION AND FITBIT-MEASURED PHYSICAL ACTIVITY: DAILY DATA ACROSS 4 WEEKS

Xiaomeng (Mona) Xu, PhD[1], Samantha J. Tupy, M.A.[2], Ashley L. Miller, B.S. in Psychology[3], Danielle Correll, BS[4], Rick Tivis, MPH[5], Claudio R. Nigg, PhD, FSBM[6]

[1]Idaho State University, Pocatello, ID; [2]Idaho State University, Chubbuck, ID; [3]University of Oregon, Eugene, OR; [4]University of Colorado Colorado Springs, Colorado Springs, CO; [5]Idaho State University, Meridian, ID; [6]University of Hawaii, Honolulu, HI

Physical activity (PA) is related to the prevention of chronic diseases, however most Americans do not engage in sufficient PA. Translational research promoting PA behavior and adherence is recommended. One novel factor associated with health behaviors and adherence is self-expansion. The self-expansion model states that people are intrinsically motivated to enhance abilities to achieve goals by increasing perspectives, identities, and resources. Self-expanding activities are characterized by novelty, excitement, and interest or challenge (e.g., hobbies). Self-expansion has been associated with better outcomes in behavioral weight loss, including greater self-reported PA. This study is the first to investigate the link between self-expansion and objective PA and their relationship on a daily basis (past research has only examined pre-post). Community participants (n= 50, 72% female, 88% white, M_{age} = 39.96, SD_{age} = 12.14) completed baseline assessment, wore a Fitbit One$^{\text{TM}}$ and completed a daily survey for 4-weeks, and completed follow-up. Participants were not given PA directions as this was not an intervention. Retention was 100% and compliance was 99.29% for wearing the Fitbit and 96.86% for completing the 28 daily surveys. Baseline measures included general self-expansion (M = 74.12, SD = 15.5, max possible 98) and PA-specific self-expansion (M = 62.92, SD = 18.54, max possible 91). Daily surveys included short versions of the general and PA-specific self-expansion scales. Across the 4-weeks, participants averaged 8589 daily steps (SD= 5151). Baseline general self-expansion did not significantly predict steps taken over the 4-weeks, however baseline PA-specific self-expansion did ($t(48)$= 2.06, $p < 0.05$). At the daily level, repeated measures analyses showed that steps taken was significantly correlated with both general (rs .14-.17, ps ≤.01) and PA-specific self-expansion (rs .40-.49, ps < .001) across the 4-weeks. This data implies that self-expansion (particularly PA-specific self-expansion) may be a promising avenue to pursue for promoting PA. Additionally, the association with day-to-day variation of PA suggests that self-expansion may be well suited for real-time interventions.

URBAN YOUTH'S PHYSICAL ACTIVITY EXPERIENCE, PHYSICAL ACTIVITY LEVELS, AND USE OF SCREEN BASED MEDIA DURING LEISURE TIME

Hui Xie, Ph.D[1], Linda Caldwell, PhD[2], Jason Scott, Ph.D.[3]

[1]California State University Northridge, Northridge, CA; [2]Penn State, University Park, PA; [3]University of Tennessee-Knoxville, Knoxville, TN

Urban Youth's Physical Activity Experience, Physical Activity Levels, and Use of Screen Based Media During Leisure Time

Introduction: Physical activity (PA) and sedentary behaviors are two important factors associated with childhood obesity. However, there is no guarantee that participation in PA will lead to decreased sedentary behaviors. If youth do not obtain positive experiences from PA, they may seek desirable experiences from sedentary activities, implicating the need for studying youth's affective responses to PA. Therefore, this study examined the relationships between youth's positive PA experience (LTPA-E), PA level (LTPA-L), and use screen-based media (LTUS) during leisure time.

Methods: The sample consists of 305 7th and 8th graders (47% female) from 4 schools in an urban, under-resourced area in the US. 90% to 95% of students in those schools were African or Latino Americans. LTPA-L was measured by asking participants to recall their LTPA in the last 7 days via 18 questions that addressed 3 domains: walking, jogging, and other physical activity. LTPA-E was measured by 5 items (e.g., *When you are doing physically active things in your free time, how often do you enjoy it*). Items were aggregated into 3 parcels for LTPA-E and LTPA-L. Three types of LTUS were included: watching TV/movie, using computer/Internet, and non-active videogame. Two questions (one for weekday use and the other for weekend use) were used to measure each type of LTUS and were aggregated. Multiple-group structural equation models were used to examine the relationships between LTPA-E, LTPA-LE and each type of LTUS for males and females.

Results: The measurement models had a good fit (non-significant χ^2; RMSEA = .045 to .051) and were equivalent across genders. The path coefficients were also equivalent between two genders except for the relationship of LTPA-E to LTUS-videogame. LTPA-E had a significant positive effect on LTPA-L. LTPA-L in turn had a significant effect on LTUS-TV/movie, but not on LTUS-computer/Internet and LTUS-videogame. LTPA-E directly had a significant negative effect on LTUS-videogame (only for males) and LTUS-computer/Internet.

Conclusion: LTPA-E predicts LTPA-L, and has an influence on LTUS-computer/Internet and LTUS-videogame that is independent of LTPA-L. The effect of LTPA-E on LTUS-TV/movie is mediated by LTPA-L. The findings suggest PA experience has an important role in promoting PA and thwarting use of screen based media among youth.

VARIABILITY IN SLEEP AND PHYSICAL ACTIVITY RELATED TO BMI AMONG HEALTHY ADULTS

Stephanie A. Hooker, M.S., M.P.H.[1], Laura C. Bouchard, M.S.[2], Kelly Glazer. Baron, PhD, MPH, CBSM[3]

[1]University of Colorado Denver, Denver, CO; [2]University of Miami, Coral Gables, FL; [3]Rush University Medical Center, Chicago, IL

Objectives: Variability in health behavior is receiving increased attention as a marker of health and health outcomes. However, little is known about the relationships between variabilities among different health behaviors and how these relate to measures of health, such as body mass index (BMI). This study assessed the relationship between variability in sleep and physical activity (PA) and tested the relationship between variability and BMI in a sample of healthy participants.

Method: Healthy participants with at least 6.5 hours habitual sleep duration were recruited from the greater Chicago area (N=75) as part of a larger study of circadian timing and health. Participants wore Actiwatch Spectrum wrist bands and SenseWear arm bands for 7 consecutive days to provide daily data on sleep duration (hours per night) and PA (minutes >3 METS). Linear regression analyses were used to assess the relationships among sleep and PA variabilities as well as BMI. Analyses controlled for age and sex.

Results: Two thirds of this sample were female (66%) with an average age of 26.8 years (*SD*=7.6). Participants had an average sleep duration of 6.7 hours (*SD*=1.5) and engaged in PA for an average of 147.2 minutes (*SD*=87.8) per day. Average BMI was 23.5 (*SD*=4.2). Sleep variability was not related to PA variability (*p*=0.71). Greater sleep variability was related to shorter sleep duration (*r*=-0.30, *p*=0.002). In contrast, greater PA variability was related to greater PA duration (*r*=0.73, *p*s>0.18). There was a significant interaction between PA variability and average PA related to BMI (*p*=0.021). At low levels of average PA, greater PA variability was related to lower BMI, whereas lower PA variability was related to greater BMI. At high levels of average PA, variability was unrelated to BMI.

Conclusion: Among healthy adults, variability was related to total levels of each behavior but variabilities in sleep and PA were not correlated. Results suggest that PA variability may be more related to health among those who are less active. Further research is needed to clarify relationships among variability in health behaviors in relation to cardiometabolic outcomes, such as BMI.

WALK AND ROLL TO SCHOOL

Carolyn C. Johnson, PhD MS, John Marmion, MPH

Tulane University School of Public Health and Tropical Medicine, New Orleans, LA

Background: Safe Routes to School (SRTS) is a federally-funded program partnering with states for the purpose of increasing community health by making walking and biking to schools safe for the nation's children. SRTS Louisiana funded a Tulane Prevention Research Center project in partnership with Bike Easy.

Purpose: To implement and evaluate safety education classes for elementary schoolchildren, assess attitudes of parents about children walking and biking to school, develop a crossing guard manual and provide safety equipment to school crossing guards for the purpose of increasing the number of children biking and walking to school.

Method: Bike Easy provided two one-hour courses "Safe Steppers" and "Bicycling Skills 123"to 4th and 5th graders in 10 New Orleans public schools. Classes were interactive with practice with bikes and helmets. Post-surveys were administered. Brief surveys were distributed to parents via the children. The crossing guard manual was developed through a literature search and review of manuals from other states.

Results: A total 335 4th and 5th graders completed the bike quiz and 332 completed the walking quiz. The bike training was the more successful with 15 of 19 classes obtaining a class mean of >70% correct responses, while only 5 of 19 classes achieved the same for the walking quiz. Parental response was low (14%). More than 50% of those responding lived more than 2 miles from school and child transport was via school bus or private vehicle (bus=65%; car=24%; walk=10%; public transit=1%). Generally, parents were not in favor of children walking or biking to school with distance to school being the most frequently identified barrier (53%), and sidewalk quality (20%), traffic (16%), and time (14%) also being cited as barriers. The crossing guard manual has been completed and is under review by the state.

Conclusions: Although the education classes were interactive and fun, learning from the walking class was limited and, though better for the biking class, was still not optimal. While these education classes probably will not contribute to increased walking and biking to schools because of the attitudes and barriers cited by parents, improving the safety of children wherever they bike and walk is a worthwhile public health effort.

FAMILY COHESION, BURDEN, AND HEALTH-RELATED QUALITY OF LIFE AMONG PARKINSON'S DISEASE CAREGIVERS IN MEXICO

Stephen K. Trapp, PhD[1], Melissa M. Ertl, BA[2], Susana Gonzalez Arredondo, Lic[3], Yaneth Rodriguez Agudelo, Dr[4], Juan Carlos C. Arango-Lasprilla, PhD[5]

[1]University of Utah, Salt Lake City, UT; [2]University at Albany, State University of New York, East Greenbush, NY; [3]Student, México, Distrito Federal, Mexico; [4]Instituto Nacional de Neurologia, mexico, Distrito Federal, Mexico; [5]Ikerbasque. Basque Foundation for Science., Bizkaia, Pais Vasco, Spain

Family cohesion is a known predictor of health-related quality of life (HRQOL) for family caregivers (CG) of someone with Parkinson's disease. Unfortunately, CG tend to experience numerous psychosocial stressors that can lead to CG burden and diminished HRQOL. Although past research illustrates these relations within samples in the US, little is known about the role of CG burden on the association between family cohesion and CG HRQOL in Mexico. The present study examines whether CG burden mediates the relation between family cohesion and HRQOL among Parkinson's disease CG in Mexico.

Method

The sample consists of family caregivers (N = 102; M_{age} = 50.34, SD = 14.02; 77% women, 23% men) of patients with Parkinson's disease from Mexico City, Mexico.

Outcome measures of the study include aggregate factors of mental and physical HRQOL from the SF-36 Health-Related Quality of Life (Ware, Snow, Kosinski, & Gandek, 2000). The Family Adaptability and Cohesion Evaluation Scale-Fourth Edition (FACES-IV; Olson, 2010) assessed family cohesion, and the Zarit Burden Inventory (Zarit, Orr, & Zarit, 1985) measured perceived burden.

Results

Perceived burden was hypothesized to mediate the relation between family cohesion and mental and physical HRQOL among caregivers. Results indicated that family cohesion significantly predicted perceived burden (b = -5.77, SE = 1.47, p = .0002 for the mental HRQOL model and b = -5.90, SE = 1.80, p = .002 for the physical HRQOL model), and that perceived burden was a significant predictor of mental (b = -.80, SE = .13, p < .0001) and physical HRQOL (b = -.73, SE = .13, p < .0001). Family cohesion, which significantly predicted mental HRQOL (b

= 6.98, *SE* = 2.23, *p* = .002), was no longer a significant predictor of mental HRQOL after controlling for perceived burden (*b* = 2.38, *SE* = 2.05, *p* = .25), consistent with full mediation. In terms of physical HRQOL, family cohesion remained a significant predictor, *b* = 6.88, *SE* = 2.31, *p* = .004, providing evidence of partial mediation. Approximately 14% of variability in mental HRQOL (R^2 = .14) and 10% in physical HRQOL (R^2 = .10) were accounted for by the predictors. Indirect effects were tested using bootstrap estimation with 1000 samples. Indirect coefficients were significant for mental (*b* = 4.60, *SE* = 1.56, 95%CI = 1.99, 8.04) and physical HRQOL (*b* = 4.33, *SE* = .2.04, 95%CI = 1.00, 8.92).

Conclusion

Identifying contributing factors to improved HRQOL among Parkinson’s CG is critical. Family CG are vulnerable to experiencing health deterioration. Present study findings provide support that caregiver burden is an intermediary variable for the relations between family cohesion and HRQOL among Mexican CG. Understanding these factors provides an opportunity to intervene and improve HRQOL of CG in this area. Important cultural implications will be discussed.

INSTILLING THE ART OF HAPPINESS IN COMMUNITY DWELLING OLDER ADULTS

Elizabeth M. Orsega-Smith, PhD, Steve Goodwin, PhD, Katie Greenawalt, BS, Jennie Turner, BS, Erica Rathie, Student

University of Delaware, Newark, DE

The population of older adults is increasing exponentially as we know that by 2030 older adults will comprise 20% of the population. As the US population ages, late life depression becomes more of a public health problem. Depression is associated with increased mortality and decreased physical, cognitive and social functioning, which can impact the ability to maintain independence which is important to overall well-being.

Methods:

The Art of Happiness is an 8-week intervention based on the teachings of the Dalai Lama with the goals of enhancing happiness levels and overall mental well-being in older adults. The pilot program was conducted at 3 senior centers with 90 minute classes that examined a different weekly topic including; (1) defining happiness, (2) stress management, (3) reflecting on happiness, (4) compassion and human connection, (5) forgiveness, (6) transforming suffering, (7) mindfulness, and (8) humor. Participants were provided with *The Art of Happiness* by the Dalai Lama as well as a journal to complete homework assignments. Each session included lecture and discussion portions with homework that focused on that week's topic. Pre and post questionnaires were used to assess participant gratitude, life satisfaction, depression, stress, mindfulness, arousal states, subjective happiness, and general demographic and health information.

Results:

The 31 participants who completed the course were mostly married (43.8%), female (87.5%) and Caucasian (91%) with an age range of 53-93 years of age (mean age= 74 years). Paired t-tests (pre and post program measures) showed significant improvements in participant's subjective happiness (p

Conclusion:

This suggests that it is possible to influence the older adults' frame of mind in terms of outlook on life and improving quality of life. These types of programs which influence positive mental health in the older adult population may be a mechanism by which to improve the overall well- being in the older adult population

PHYSICAL ACTIVITY, SELF-REPORTED PHYSICAL FUNCTIONING AND QUALITY OF LIFE IN STROKE SURVIVORS

Erin Snapp, MS[1], Bradley J. Kendall, B.A., M.S.[2], Neha Gothe, MA, MS, PhD[3]

[1]Wayne State University, Dearborn, MI; [2]Wayne State University, Grosse Pointe Park, MI; [3]Wayne State University, Detroit, MI

Background

Stroke is the third leading cause of death in the United States and the leading cause of disability among its survivors. Recent reviews in this population have shown that regular physical activity (PA) can lead to improved quality of life (QOL), functional capacity and mobility among stroke survivors. The goal of this study was to examine the relationship between PA levels in stroke survivors and their satisfaction with life (SWL) and overall physical functioning (PF).

Methods

Participants consisted of 31 stroke survivors who were at least 6 months post-stroke (mean age:61.97±11.17). PA was measured using an Actigraph accelerometer that was worn by participants during waking hours for 7 days. Using NHANES cut-offs, PA data was categorized by counts per minute as sedentary (0-100), light (101-2019), and moderate to vigorous (MV; ≥2020). The 36 Item Short Form Health Survey (SF-36) was used assess overall PF and the Satisfaction with Life Scale (SWLS) was used to asses perceived SWL.

Results

Correlation and regression analyses showed that light PA was correlated with SWLS (r=.404, p =.03, β=.40) and SF-36 PF (r=.454, p =.01, β=.45). MVPA was not significantly correlated with SWLS (p=.12) but was significantly correlated with SF-36 PF (r=.49, p =.009, β=.53). Sedentary time was not significantly correlated with either self-report measure.

Conclusion

Light PA consistently predicted self-reported PF and SWL in stroke survivors. MVPA was predictive of PF but comparable with light PA which may be more effective to adopt and maintain for this population.   Future research should examine light PA based interventions such as stretching and strengthening, yoga, tai-chi etc., and their efficacy in improving QOL among stroke survivors.

THE INFLUENCE OF DIET, SLEEP AND PHYSICAL ACTIVITY ON WELL-BEING - PERCEPTIONS AND BEHAVIORS

Sandra Jane. Winter, PhD, MHA[1], Tia Rich, Ph.D., M.A., M.S.W.[2], Erin Avery, M.S., B.S.[3], Haley Hedlin, PhD[4], Vidhya Balasubramanian, MS[4], Catherine Heaney, PhD, MPH[5]

[1]Stanford University School of Medicine, Palo Alto, CA; [2]Stanford School of Medicine, Stanford, CA; [3]Stanford Prevention Research Center, Santa Cruz, CA; [4]Quantitative Sciences Unit, Department of Medicine, Stanford University, Palo Alto, CA; [5]Stanford Prevention Research Center, Stanford, CA

Background: The association between health behaviors and chronic diseases is well documented. Less well researched is the association between health behaviors and perceived wellbeing. This study examined the perceived influence of diet, sleep and physical activity on wellbeing and associations between self-reported behaviors and perceived wellbeing.

Methods: Participants were mainly older, well-educated women (n=222, mean age=59.2±0.7, years of education=16.7±0.2, women=90%) who reported good, very good or excellent health (88.3%) and wellbeing (91%). For the previous two weeks, participants reported: 1) the perceived influence of diet, sleep and physical activity on their wellbeing (none, positive or negative influence) and 2) measures of these behaviors.

Results: The reported influences of these behaviors on wellbeing were: diet : none=48%, positive=27%, negative=26%; sleep: none=38%, positive=27%, negative=35%; physical activity: none=64%, positive=16%, negative=20%. Comparing the groups of participants who reported no influence, positive influence or negative influence of these behaviors on their wellbeing, there were statistically significant differences in the reported behaviors by group. Those reporting a negative influence of these behaviors on wellbeing also reported eating more desserts and processed food daily and sleeping fewer minutes per night compared to those reporting no or a positive influence of these behaviors on wellbeing: mean servings of desserts/day (none=1.6±1.9, positive=1±1.3; negative=3.1±4.1; p

Conclusion: More than half of the participants in this study reported that diet and sleep positively or negatively influenced their wellbeing, and over one third reported that physical activity positively or negatively influenced their wellbeing. There was no association between reported physical activity and the influence of physical activity on wellbeing, but eating more

servings of desserts and processed foods per day and sleeping fewer minutes per night were negatively associated with perceived wellbeing.

WELLNESS IN WOMEN: LONG TERM FREEDOM FROM A DIAGNOSIS OF INVASIVE BREAST CANCER

Winnifred B. Cutler, Ph.D.

Athena Institute for Women's Wellness, Chester Springs, PA

Overestimates of health risks can impair decision-making and paradoxically reduce wellness. Records of 2,305,427 screened-symptomless women were used to estimate their risk of being diagnosed with invasive breast cancer over their next 25 years, and determine the percentage of women actually likely to remain free of invasive breast cancer.

Prior estimates of breast cancer incidence started with "Diseased Women' from cancer registries and used census population estimates. Our study intentionally did neither, thereby increasing accuracy in determining the likelihood of a woman's living free of breast cancer.

Method: Our systematic review identified 19 peer-reviewed published studies of 2,305,427 women meeting 5 stringent criteria. Incidence of first invasive breast cancer was estimated using logistic regression based on follow-up duration

Results: Over 25 years of follow-up, an estimated 94.55% of women will remain breast cancer-free (95% CI: 93.97, 95.13). The mean cumulative incidence rate of first invasive breast cancer increased by 0.2% for each year of follow-up (95% CI: 0.17, 0.23; $p < 0.01$; $R^2 = 0.90$). There was no evidence of an age-related increase; but there was evidence of a higher rate for those who became menopausal through surgery.

Conclusion: The vast majority (99.75%) of asymptomatic peri and postmenopausal women will not be diagnosed with invasive breast cancer each year, and 95% will live well – free of a diagnosis of invasive breast cancer. For those who avoid the 7 known risk factors for being diagnosed with breast cancer an even higher percentage will live free of invasive breast cancer.

Weight gain, inadequate exercise, excess alcohol, and inadequate solar radiation generating vitamin D deficiencies are the 4 major risks factors well documented to increase the risk of breast cancer. Hormonal declines following menopause and several specific hormonal therapy regimens are also associated with increased risk. Converging evidence suggests that we should now add mammography itself to our list of hazards.

Ever more sensitive scanning is increasingly likely to detect very early stage cancers, 30-50% of which we now know would be self-limiting and benign. However, once detected, such cancers usually prompt treatment and expose women to unnecessary iatrogenic harms.

The apparent success of screening depends heavily on inclusion of cases where treatment was directed at breast cancer that was most likely to never develop to clinical significance. Like prostate cancer, as many as 50% of women develop non-life threatening breast cancer before they die. Overestimates of one’s risk of developing deadly invasive cancer fuel this excessive fear and detrimentally drive women’s decision to undergo regular mammography screenings. A broad convergence of recent research shows that these decisions paradoxically compromise wellness.

ACCULTURATION MODERATES THE EFFECTS OF POSITIVE EMOTIONALITY ON THE CORTISOL AWAKENING RESPONSE IN MEXICAN AMERICAN ADULTS

Antonio Garcia, M.A., Deborah Mangold, Ph.D.

The University of Texas at San Antonio, San Antonio, TX

Mexican Americans face unique acculturation-related stressors that affect the neurohormonal stress response. Previous research has shown that Mexican Americans with greater Anglo orientation evidence an attenuated cortisol awakening response (CAR) and that stress associated with the acculturation process may render some Mexican Americans more susceptible to adverse health outcomes. The tendency to experience positive emotions is a personality trait with particular relevance for examinations of resilience to the adverse effects of stress in this underserved minority group. Numerous studies have demonstrated a strong relationship between stress-induced alterations of the hypothalamic-pituitary-adrenal (HPA) axis and certain negative health outcomes, and suggest that extraversion is an important factor promoting psychological adaptation and resilience to the adverse effects of stress. Additional evidence suggests that highly resilient individuals proactively cultivate positive emotionality, a key facet of extraversion, by strategically eliciting positive emotions through the use of humor, relaxation techniques, and optimistic thinking. However, to our knowledge, no studies have examined the relationship between the tendency to experience positive emotions and the CAR in Mexican Americans.

In the current study, the effects of positive emotionality and acculturation on the CAR were examined in adults of Mexican descent. Salivary cortisol samples were collected at awakening and 30, 45, and 60 minutes thereafter, on two consecutive weekdays from 89 healthy Mexican American adult males (43) and females (46), ages 18 to 38 years. Results of general linear mixed modeling (GLMM) showed that lower positive emotionality was associated with an attenuated CAR. Stronger Anglo orientation was also associated with an attenuated CAR. Follow-up analyses showed that in Mexican Americans with strong Mexican orientation, positive emotionality was associated with a robust CAR, whereas in Mexican Americans with moderate or strong Anglo orientation, CAR was attenuated, and positive emotionality showed no effect. The current findings suggest that in less acculturated Mexican Americans with strong connections to traditional cultural values and behaviors, positive emotionality functions as a buffer against stress-induced alterations in the CAR. However, in more acculturated Mexican Americans with fewer connections to cultural values and traditions, the tendency to experience positive emotions may not be an effective buffer against stress-induced alterations in the CAR. It is possible that participation in cultural traditions and

behaviors facilitates a social milieu responsive to positive emotionality, fostering resilience to stress-induced alterations in the CAR.

HISPANIC ETHNICITY AND PRIMARY CARE UTILIZATION AMONG MILLENNIALS

Hannah Kimmel, BA, MPH '17

Brown University School of Public Health, Providence, RI

Background: Hispanics are the largest ethnic minority in America, and experience racial health disparities on outcomes for various health measures. Using a primary care provider minimizes some of these outcome disparities. Persons aged 18-34 years old (“Millennials”) occupy an age range more likely to be uninsured than older and younger individuals. Implementation of the Affordable Care Act (ACA) in 2010 sought to increase preventive primary care access and utilization. There exists a gap in the literature of Millennial primary care utilization by ethnicity after the ACA.

Objective: This study examines the characteristics of primary care utilization among Millennials, exploring differences in this utilization by Millennial ethnicity.

Methods: Data are collected from the 2011-2012 National Health and Nutrition Examination Survey (NHANES). This study accounts for complex survey design and uses bivariate analysis and multivariate logistic regression to assess the relationship between ethnicity and routine health care utilization habits. Primary care utilization is defined as routine care provided at a doctor’s office, clinic, or Health Maintenance Organization (HMO).

Results: Among Millennials (N=1,794), Hispanics (N=397) have 1.75 times (95% CI 1.25, 2.46) the odds of not utilizing primary care compared to Non-Hispanic Whites. This relationship is not significant after adjusting for gender, citizenship status, health insurance status, and education level (OR 1.04; 95% CI 0.731, 1.48). Hispanic Millennials are 2.63 times (95% CI 1.64, 4.21) more likely to be uninsured than Non-Hispanic Millennials holding citizenship status, gender, and education level constant.

Conclusion: The unadjusted results of Millennial routine care utilization habits show Hispanic Millennials are 1.75 times as likely to not use primary care when compared to Non-Hispanic White Millennials. When adjusting for insurance utilization, this difference is no longer significant. This reinforces previous findings of health care utilization and access disparities by race and ethnicity, even among Millennials. This could explain the difference in primary care utilization among these two groups.

OUTCOMES OF ELEMENTARY AND MIDDLE SCHOOL REFUSERS IN JAPAN

Mari Saito, M.D.[1], Alan Lefor, Ph.D.[2], Yutaka Kikuchi, M.D.[1]

[1]Haga Red Cross Hospital, Mouka, Tochigi, Japan; [2]Department of surgery, Jichi Medical University, Shimotsuke, Tochigi, Japan

Background: Japan's modern education system is built on the principle that every child has equal educational opportunity. All schools are the same so every child gets the same education. However, children who are unwilling to attend school have few options to continue their education. In 2015, the Education Ministry reported that school refusers represent at least 1.5% of elementary and middle school aged children, but detailed data is unavailable. We provided behavioral approaches to school refusers and aim to describe the outcomes of elementary and middle school aged school refusers who received therapy at our institution.

Methods: Data were extracted from medical records of children with insurance codes including "school refusal", "psychogenic reaction" or "somatoform disorders". Data were analyzed if they underwent psychological therapy because of prolonged physical symptoms related to school activities or because of prolonged school refusal.

Results: A total of 118 children (boys, n=53) underwent therapy at a mean age of 12y. The most frequent concomitant physical symptoms were headache and digestive symptoms (nausea, vomiting, abdominal pain) related to school activities. The common trigger for school refusal was fear of other classmates, such as being talked about behind their back or being excluded from class activities. Of these, 31 (26%) were diagnosed with borderline mental retardation or a developmental disorder including autism spectrum disorder, attention deficit hyperactivity disorder and Asperger syndrome. Half of children improved after a mean of 10 months of cognitive-behavioral therapy and resolving problems with classmates. Twenty-three (21%) children quit psychological therapy at an average of 7 months and 87% had continued difficulty attending school. Children who quit therapy tended to be absent from school for longer periods, be totally absent from school and have a previous history of stopping therapy.

Conclusion: Most school refusers are triggered by difficulties with other classmates. They had headaches and digestive symptoms related to school activities, however, one-half had a good response to psychological therapy within a year. School refusers who did not have a good

response after 7 months of therapy, had decreased compliance with appointments and poor outcomes.

SOCIOCULTURAL AND ENVIRONMENTAL INFLUENCES ON BRAZILIAN MOTHERS' BELIEFS & PRACTICES RELATED TO CHILD FEEDING & WEIGHT STATUS

Ana Cristina. Lindsay, DDS, MPH, Dr.PH[1], Sherrie Wallington, PhD[2], Mary L. Greaney, PhD[3], Maria Helena Hasselmann, RN, PhD[4], Marcia Maria Tavares Machado, N/A[5]

[1]University of Massachusetts Boston, Boston, MA; [2]Georgetown University Medical Center, Lombardi Comprehensive Cancer Center, Rockville, MD; [3]University of Rhode Island, Kingstom, RI; [4]Institute of Nutrition, Rio de Janeiro, Rio de Janeiro, Brazil; [5]PROFESSOR OF UNIVERSITY FEDERAL OF CEARA, FORTALEZA, N/A, Brazil

Background: Length of residence in the United States (US), changes in dietary and physical activity behaviors, and economic and social barriers contribute to high childhood obesity rates among children from immigrant families in the US. Brazilians comprise a fast-growing immigrant population group in the US, yet little research has focused on health issues affecting Brazilian children in immigrant families. Understanding sociocultural and environmental influences on parents' beliefs and practices related to child feeding and weight status is essential to altering obesity trends in this group.

Methods: Qualitative study consisting of five focus groups with a convenience sample of 29 Brazilian immigrant mothers.

Results: Analyses revealed that the sociocultural and environment transitions faced by Brazilian immigrant mothers' influence their beliefs and practices related to child feeding and weight status. Additionally, acculturation emerged as a factor affecting mothers' feeding practices and their children's eating habits, with mothers preferring Brazilian food environments and that their children preferring American food environments. Mothers viewed themselves as being responsible for promoting and maintaining their children's healthy eating and feeding behaviors, but changes in their social and cultural environments due to immigration and the pressures and demands of raising a family in a new country make this difficult.

Conclusions: Health promotion interventions to improve healthful eating and feeding practices of Brazilian children in immigrant families must account for social and cultural changes and daily life demands due to immigration as well as potential variation in the levels of acculturation between mothers and their children.

MERITORIOUS AWARD WINNER

THE ROLE OF RABBIS IN DECISION-MAKING ABOUT BRCA TESTING AMONG ORTHODOX JEWISH WOMEN

Haeseung Yi, MPA[1], Meghna Trivedi, MD[2], Rivka Starck, PsyD[3], Alejandro Vanegas, MS[2], Raven David, MS[2], Isaac Schechter, PsyD[3], Rita Kukafka, DrPH, MA[2], Katherine Crew, MD, MS[2]

[1]Columbia University, Edgewater, NJ; [2]Columbia University Medical Center, New York, NY; [3]Institute for Applied Research & Community Collaboration, Monsey, NY

BACKGROUND The prevalence of founder mutations in the BRCA1 and BRCA2 genes is 1 in 40 among Ashkenazi Jews. Despite the potential benefits of BRCA testing to inform cancer screening and risk-reducing surgeries, there are still concerns about adverse psychological and social consequences, which may vary by cultural and religious backgrounds. Orthodox Jews often consult with Rabbinic and communal authorities in medical decision-making, which is consistent with their religious values. The aim of this study was to examine whether Rabbis have a role in medical decision-making about BRCA genetic testing among Orthodox Jewish women.

METHODS We applied a mixed-methods approach to analyze quantitative survey data and qualitative transcripts. We distributed a survey via community-based and religious email listservs in Upper Manhattan in New York City. We collected data on demographics, breast cancer risk factors and religious/cultural factors influencing a decision to undergo BRCA genetic testing. Survey participants were re-contacted to participate in two focus groups separated into single (n=8) and married (n=10) women. The sessions were audio-recorded and transcribed. For the qualitative approach, a content analysis was conducted using Atlas.ti software. The Scott’s Pi value for the inter-rater reliability of two coders was 0.7091.

RESULTS Of 505 Orthodox Jewish women invited to participate in the survey study, 269 (53%) completed the survey. The median age was 25 years (range, 19-86) and 67% identified as Modern Orthodox. Sixty-six percent stated that they were moderately to very likely to consult a Rabbi to make a significant medical decision. However, less than half (46%) thought that their Rabbi was moderately to very medically informed. When making an important medical decision, 88% replied that they were moderately to very likely to seek advice from a primary doctor/family physician and 43% said that they would consult with a Rabbi or Rebetzin (Rabbi’s wife). Themes that emerged from qualitative analysis confirmed the results we obtained from the survey. While some participants said that they would consult a Rabbi, some preferred discussing health decisions with their doctors. By analyzing the transcripts, we

found that Orthodox Jewish women tend to seek medical advice from Rabbis especially for the halachic implications (Jewish law or code of ethics).
CONCLUSION A key finding from our study is that Rabbis and health professionals influence medical decisions about genetic testing in the Orthodox Jewish population. Therefore, educating Rabbis on the medical aspects of BRCA genetic testing, including cancer risk and risk reduction strategies, will be crucial. We believe that education and decision support tools for both Rabbis and health professionals will be important to disseminate information on BRCA testing in the Orthodox Jewish community.

UNDERGRADUATES' DESIGNATED ORGAN DONOR STATUS ON THEIR DRIVER'S LICENSE: AGE, RACE/ETHNICITY, GENDER, AND RELIGION MATTER

Cheryl Albright, PhD, MPH[1], Kara Saiki, MPH[2], Lynne Wilkens, DrPh[2], Ashley M. Biddle, MA[2], David Devine, MS[2], Misty Pacheco, DrPH[3], Pamela Smith, APRN, RNFA, FNP-BC[4]

[1]Univeristy of Hawaii at Manoa, Honolulu, HI; [2]University of Hawaii, Honolulu, HI; [3]University of Hawaii at Hilo, Hilo, HI; [4]Hawaii Pacific University, Kaneohe, HI

On average, 22 people die each day waiting for an organ transplant and over half of the 119,967 people on the U.S. transplant waiting lists are ethnic minorities. Specifically, the proportion of Asian, Native Hawaiian, Pacific Islanders (**ANHPI**), on waiting lists exceeds their representation in the general population; thus, the need for ANHPI organ donors is high. The iDecide Hawaii Project was designed to educate ANHPI undergraduates about the decision to be a Designated Organ Donor (**DOD**) on their next (often an "adult" 21+ years of age) driver's license. The project used a gamified online eHealth intervention (e.g., Instagram, YouTube) to both educate and engage undergraduates in issues surrounding DOD status and incentivized student organizations to be DOD advocates via pledge contests with cash prizes. From 2014-2016, 2,138 students completed baseline surveys before the intervention was launched (M_{age}= 22.8 years ± 5; 76% female; 15% Hispanic, 3% African American, 4% American Indian/Alaska Native, 32% Asian, 17% Native Hawaiian/Pacific Islander, 31% White, and 9% multiracial (largely Asian/White). One-third (35%) were Protestants, 24 % Catholic, and 28% were not religious or were Agnostics/Atheists. Of those who had a driver's license, 59.6% were already a DOD; but, DOD rates were significantly lower for students with a < 21year license (57%) versus those with 21+ year license (63%) (p = 0.006). There were also differences by age with 58% of 18-24y/o, 59% of 25-29y/o, and 68% of 30+ y/o being a DOD (p = 0.0001). Significantly more females (62%) were DODs than males (54%; p = 0.003). There were significant differences by race with 74% of Whites, 56% of Native Hawaiians/Pacific Islanders, 44% of Asians, and 65% of multiracial persons reporting being a DOD on their license (p=0.0001). There were significant DOD differences within Asians: Filipinos= 38%, Koreans=62%, Japanese=63%, Asian/White multiracial= 70% (p=0.001). There were significant differences by religion with 53% of Protestants, 46% Catholics, and 62% not religious/Agnostics reporting being DODs on license (p=0.0001). Thus, prevalence of DOD was higher for students who were older, female, not religious, or White; but, within Asians, DOD prevalence ranged from 38% to 70%. Changes in knowledge, attitudes and

actions/engagement of both DODs and non-DODs exposed to our eHealth, gamified intervention will be assessed via post-test surveys. Moderator analyses will determine any differential impact by age, race, gender or religion. Engagement in the gamified eHealth intervention varied by site and contest; but, hundreds of undergraduates entered the DOD pledge contests and the Instagram picture contests that followed an organ donation-related theme. Examples of contest winners will be displayed.

ASSOCIATIONS BETWEEN PHYSICAL ACTIVITY, SEDENTARY BEHAVIOR, AND SLEEP HABITS AMONG AN ATLANTIC CANADIAN COHORT

Cynthia C. Forbes, PhD[1], Vanessa DeClercq, PhD[2], Melanie Keats, PhD[1]

[1]Dalhousie University, Halifax, NS, Canada; [2]Atlantic PATH, Halifax, NS, Canada

Background: Lack of sleep and poor sleep quality has been linked to many poor physical and mental health outcomes. Engaging in regular PA has been linked to changes in sleep circadian rhythms, thermogenic regulation, body weight, physical fitness, anxiety, depression, and pain; any of which could be a possible mechanism by which PA impacts sleep. The goal of this study was to determine any associations between physical activity or sedentary behaviour (SB) and sleep duration or quality among a cohort of Atlantic Canadians.

Methods: 31,173 participants, aged 35-69 years, living in Atlantic Canada (Nova Scotia, New Brunswick, Newfoundland & Labrador, and Prince Edward Island), completed a series of assessments. Domain-specific physical activity and sedentary behaviour was assessed using the International Physical Activity Questionnaire-Long Form (IPAQ). Sleep duration and sleep quality were measured with two items; first asking participants to report in hours and minutes "On average, how many hours per day do you usually sleep, including naps?" and then, "How often do you have trouble going to sleep or staying asleep?" on a 5-point scale from "never" to "all the time". Objective measures were used in Physical Activity Level (PAL) calculations if available; in cases where they were not, self-report measures were used.

Results: 18,258 participants had both PA measures and sleep data. PAL computation revealed 59.7% of the sample was inactive with a further 14.5% in the 'low active' category. 25.7% of the sample were considered 'active' or 'very active'. Participants averaged 5.8 hours of SB per day with most of the sample sedentary between 4-7 hours per day (37.7%). Most (65.5%) reported getting between 7-9 hours of sleep per night with an actual average of 7.2 hours per night. Most of the sample reported having sleep troubles 'some of the time' or less frequently (77.5%). As sleep duration increased, the percentage of those inactive also increased. U-shaped trends emerged with sleep disturbances either 'none of the time' or all of the time' at higher levels than 'some of the time' among those classified as very active. An inverse linear relationship was found for sleep quality and SB.

Conclusion: As sleep duration increased, so did the proportion of those classified as inactive. This is contrary to research that shows a u-shaped relationship between sleep duration and PA. Results also showed that a higher proportion of those who slept more than 11 hours and

had sleep disturbances ‘all the time’ were those who were sedentary for more than 7 hours. There is less research on SB’s link to sleep quality but what literature there is indicates a link similar to PA. More research is needed to confirm a link between SB and sleep duration and quality.

ASSOCIATIONS OF CHRONOTYPE WITH ALCOHOL AND MARIJUANA USE IN A NATIONAL SAMPLE OF U.S. HIGH SCHOOL STUDENTS

Denise Haynie, PhD, MPH[1], Daniel Lewin, Ph.D.[2], Kaigang Li, PhD[3], Leah Lipsky, PhD[4], Danping Liu, PhD[1], Joseph Bible, PhD[1], Ronald J. Iannotti, PhD[5], Bruce Simons-Morton, EdD, MPH[4]

[1]National Institute of Child Health and Human Development, Bethesda, MD; [2]Children's National Health System, Washington, DC; [3]Colorado State University, Fort Collins, CO; [4]NICHD, Bethesda, MD; [5]The CDM Group, Inc, Bethesda, MD

Changes typifying adolescence have profound effects on adolescent sleep patterns with implications for health and well-being. Research has demonstrated relations between poor sleep quality and increased alcohol use. Preferred sleep period, or chronotype, has emerged as potentially useful in understanding this association. This study examined adolescents' chronotype in association with alcohol and marijuana use.

Data come from the NEXT Generation Study, a national cohort of US 10thgrade students (2009-10). Latent class analysis using data from the first 3 years of the study (W1-W3) identified chronotype classes by preference for 1) earlier sleep period (21%), 2) later sleep period (16%) and 3) middle sleep period (61%). W3 weekday and weekend sleep durations were categorized as short (< 7 hours per night), inadequate (7-8 hours), optimal (8-9.5 hours) and long (> 9.5 hours). Logistic regression models examined the associations of chronotype class and W3 sleep duration with W3 30-day alcohol and marijuana use. Models adjusted for design variables, gender, race/ethnicity, and W2 substance use.

Participants (n=2168) were 59% (weighted) female, 62% white, 13% African American, and 19% Hispanic. 30-day reports of W3 alcohol use were: 38% any use, 27% binge drinking, 25% drunk, and 7% blackout from alcohol; 19% reported any W3 30-day marijuana use. In adjusted logistic regressions, compared to members of the mid-type class, the early chronotype class had lower odds of drinking (odds ratio=0.48, 95%CI=0.32-0.71), binging (OR=0.44, CI=0.29-0.67) or being drunk (OR=.0.37, CI=0.23-0.61); the late chronotype class had higher odds of binging (OR=1.87, CI=1.17-2.99) and being drunk (OR=1.68, C=1.06-2.67). Odds of marijuana use were lower for those reporting long sleep duration on unscheduled days (OR=0.44,CI=0.29-0.67); marijuana use was not associated with chronotype.

Three distinct classes of chronotypes were identified in US adolescents, with late chronotype associated with alcohol use but not marijuana use, which was positively associated instead with long sleep duration. Research is needed to differentiate the psychosocial, behavioral and biological causes of associations between chronotype, sleep duration and substance use.

ASSOCIATIONS OF MULTIPLE SLEEP PROBLEMS WITH AFFECTIVE AND COGNITIVE VULNERABILITIES

Catherine Rochefort, MS[1], Erin Koffel, PhD[2], Michael Chmielewski, PhD[1]

[1]Southern Methodist University, Dallas, TX; [2]Minneapolis VA Health Care System, Mineapolis, MN

Recently, there have been calls for additional research examining the combined influence of cognitive and affective factors on sleep problems. Past research has demonstrated that increased rumination is associated with poor sleep, but less research has examined other cognitive vulnerabilities. Furthermore, although studies have examined the influence of depression/anxiety (as broad classes) on sleep, very little research has examined the association of specific symptoms of depression/anxiety with sleep problems. This is an important limitation because depression and anxiety are heterogeneous constructs comprised of multiple symptoms, each of which might demonstrate differential associations with sleep problems. In this cross-sectional study, college students (N = 611) completed measures assessing a variety of sleep problems (sleep quality [WHIIRS], daytime sleepiness [ESS], and insomnia [IDAS]), cognitive vulnerabilities (trait rumination [RSQ], automatic thoughts [ATQ], fear of negative evaluation [BFNE], dysfunctional attitudes [DAS]), and ten symptoms of depression and anxiety (IDAS, with items referencing sleep removed). Results indicated that cognitive vulnerabilities (including rumination) demonstrated limited incremental validity over symptoms of depression and anxiety for all sleep problems (ΔR^2 = .00 - .02). In contrast, the depression and anxiety symptoms demonstrated significant ($p < .01$) incremental validity over and above all of the cognitive vulnerabilities for each sleep problem (WHIIRS: ΔR^2 = .10; ESS ΔR^2 = .09, IDAS ΔR^2 = .35). Interestingly, each sleep problem was predicted by different symptoms of depression and anxiety, indicating unique associations between specific types of sleep problems and specific symptoms. Given that between 15 – 56% of the variance in sleep problems was accounted for by symptoms of depression and anxiety, our results suggest that they are more important for sleep problems than cognitive vulnerabilities, which appear to have limited influence across the included sleep problems. Because quality sleep is integral to physical and mental health in clinical and nonclinical populations, sleep interventions may need to place more emphasis on improving affect.

INFANT SLEEP TRAINING AND MATERNAL HEALTH BEHAVIORS

Megan Clarke, Ph.D.[1], Amy A. Gorin, Ph.D.[2], Jennifer Selensky, B.A.[3]

[1]University of Connecticut, West Hartford, CT; [2]University of Connecticut; Institution for Collaboration on Health, Intervention, and Policy, Storrs, CT; [3]University of Connecticut, Storrs, CT

Background: Women are vulnerable to excess weight gain and retention during their childbearing years. This study explored the relationships between infant sleep training, maternal physical activity levels, and weight loss during the first postpartum year by comparing mothers who reported successfully sleep training their infants with those who did not. Group differences were examined in 1) quantity of maternal sleep, 2) quantity of infant sleep, 3) maternal physical activity and weight loss, 4) psychosocial variables including postpartum depression and perceived social support and 5) mothers' preference for potential weight loss and infant sleep training interventions.

Methods: Mothers of 6-12 month old infants (N=150, M_{age}=32.24, M_{BMI}=27.07) were recruited with study flyers both online and in the community. Participants completed questionnaires online, including item 8 from the Paffenbarger Activity Questionnaire, the Postpartum Depression Screening Scale, and the Brief Infant Sleep Questionnaire. Participants also answered questions about how they had engaged with various sleep training methods with their infants. Two groups were established: Sleep Trainers were those who endorsed successfully sleep training their infants, and Non-Sleep Trainers who did not endorse the item. Data was analyzed using chi-square and independent t-tests.

Results: Sleep Trainers slept more than Non-sleep Trainers ($p < .05$) and woke up significantly fewer times overnight ($p < .01$). The children of Sleep Trainers also slept significantly more overnight (p < .01), and their mothers reported higher levels of perceived social support ($p < .05$). There were no significant group differences in physical activity levels, but differences in weight retention approached significance ($p = .10$) with mothers who successfully sleep trained indicating that they were closer to their prepregancy weight. Mothers in both groups endorsed the highest level of interest in online interventions. Non-Sleep Trainers were

significantly more likely to express interest in potential sleep training interventions, with most expressing interest in an online format.

Discussion: These results suggest that interventions targeting postpartum weight retention should take the mother-infant dyad into account in study design. Infant sleep modification presents a possible target for intervention with potential benefits for both mothers and infants.

INFLUENCES OF INSOMNIA SUBTYPES ON SUBSEQUENT ANXIETY AND DEPRESSION: A POPULATION-BASED LONGITUDINAL COHORT STUDY

Ping-Jen Chen, MD[1], Shih-Feng Weng, PHD[2], Ming-Ping Wu, MD, PHD[3], Chung-Han Ho, PHD[3], Charles Lung-Cheng Huang, MD[3], Jhi-Joung Wang, MD, PHD[3], Ya-Wen Hsu, PHD, MPH[4]

[1]Chi-Mei Medical Center, Tainan, Taiwan, Tainan, Tainan, Taiwan (Republic of China); [2]Kaohsiung Medical University/Department of Healthcare Administration and Medical Informatics, Kaohsiung, Kaohsiung, Taiwan (Republic of China); [3]Chi-Mei Medical Center, Tainan, Tainan, Taiwan (Republic of China); [4]Chia Nan University of Pharmacy & Science, Tainan, Tainan, Taiwan (Republic of China)

Background: Though prior studies have investigated the associations between insomnia and mental health, research assessing the causal relationships using population-based study with long-term follow-up is still lacking.

Objective: To examine the causal influences of insomnia on the onset of depression only, anxiety only, depression or anxiety, and depression and anxiety during the 4-year follow-up.

Methods: Participants were identified from the National Health Insurance enrollees in Taiwan during 2002~2009. The study included 19,273 subjects with insomnia (52.1±16.0 years old) and 38,546 matched subjects without insomnia (51.2±16.0 years old).

Results: Compared with non-insomniacs, insomniacs had a higher risk of developing anxiety only [adjusted hazard ratio (HR) =8.83, 95% CI=7.59-10.27)], depression only (adjusted HR=8.48, 95% CI=6.92-10.39), either anxiety or depression (adjusted HR=9.90, 95% CI=8.83-11.1), as well as both anxiety and depression (adjusted HR=17.98, 95% CI=12.65-25.56). When breaking down into insomnia subgroups, individuals with a relapse of insomnia (adjusted HR=10.42-26.80) had the highest risk of anxiety only, depression only, either anxiety or depression, and both anxiety and depression, followed by persistent insomnia (adjusted HR=9.82-18.98) than remission of insomnia (adjusted HR=4.50-8.27) in comparison to the non-insomniacs. When comparing the 4-year cumulative incidence between insomniacs to non-insomniacs for anxiety only, depression only, either anxiety or depression, and both anxiety and depression, we found that the relapse group (p-value for log-rank test

Conclusions: Insomnia is a strong predictor for developing depression and anxiety. Patterns of insomnia should be monitored to help treating and controlling subsequent psychiatric disorders.

SLEEP AND HEALTH BEHAVIORS AMONG AFRICAN AMERICAN CONGREGATION MEMBERS

Natasha Aduloju-Ajijola, PhD, MPH, CHES[1], Jannette Berkley-Patton, PhD[2], Carole Bowe Thompson, BS[3], Kelsey Christensen, MA[4], Alexandria G. Booker, M.A.[5], Sheila Lister, B.S.[4], Nia Johnson, B.A.[6], Therese Ruhland-Petty, MA[7]

[1]University of Missouri-Kansas City School of Medicine, Kansas City, MO; [2]University of Missouri-Kansas City, Kansas City, MS; [3]Community Health Ressearch Group/School of Medicine/University of Missouri-Kansas City, Kansas City, MO; [4]University of Missouri-Kansas City, Kansas City, MO; [5]University of Missouri-Kansas City, Raytown, MO; [6]University of Missouri- Kansas City, Kansas City, MO; [7]University of Missouri- Kansas City, Des Moines, IA

Sleep disorders are often comorbid with a broad range of medical and psychiatric conditions that have a negative impact on health, mood, and quality of life. African Americans (AAs) report higher rates of extreme sleep behaviors, including hypersomnia and hyposomnia, and are at an increased risk for related consequences, including cardiovascular disease, diabetes mellitus, and respiratory issues. Research has demonstrated that there is a reciprocal relationship between sleep and these health issues–thus, health conditions impact sleep and sleep subsequently impacts health outcomes. The Black church is an integral part of the AA community, as AAs have the highest rate of church attendance compared to all other racial and ethnic groups in the United States. The Black church has the ability to address health concerns affecting members, as well as their communities through outreach ministries. However, previous studies have not examined the sleep behaviors of AA church-affiliated persons. The purpose of the current study was to examine the demographic, social, and health factors associated with lack of sleep among AA church-going populations. This study used baseline data from Project FIT (Faith Influencing Transformation), a health promotion intervention piloted in AA faith-based settings. The study participants (N = 352) were predominantly female (n = 240, 69.4%), with an average age of 53.6 years (SD = 13.1). Results showed that 30% of participants had less than 6 hours of sleep a night, 70% received 6 to 10 hours of sleep a night, and 1% received over 10 hours of sleep a night. Findings indicated that income (r=.159, p=.008), stress levels (r=-.163, p=.007), and gender (r=.140, p=.017) were significantly correlated with sleep. In addition, diagnoses of heart disease (r=-099 p=.067) and polycystic ovarian syndrome (r=.160, p=.008); previous screening for mental health (r=-.159, p=.018) and level of education completed (r=.176, p=.004) were also significant sleep predictors. Linear regression analyses revealed that income (β =.155, p=.020), polycystic ovarian syndrome (β =.165, p=.012), stress levels (β =-.120, p=.068), and gender (β =.133, *p*=.039) together were able to predict sleep behavior. Sleep behaviors and their subsequent impact on health should be further explored among the African American church-going populations.

SLEEP PROBLEMS IN A LARGE SAMPLE OF CANCER PATIENTS BEFORE INITIATING TREATMENT

Eric S. Zhou, PhD[1], Karen Clark, MS, MS[2], Christopher Recklitis, PhD. MPH[3], Richard A. Obenchain, N/A[4], Matthew Loscalzo, LCSW[5]

[1]Dana-Farber Cancer Institute, Boston, MA; [2]City of Hope, Carlsbad, CA; [3]Dana-Farber Cancer Institute/Harvard Medical School, Boston, MA; [4]City of Hope National Medical Center, Pasadena, CA; [5]City Of Hope-National Medical Center, duarte, CA

Background: Sleep problems are common in adult cancer patients and have significant health consequences. However, few studies have examined multiple disease sites, or captured sleep function at the critical time post-diagnosis, but prior to initiating treatment. This study sought to address these limitations by exploring the prevalence of sleep problems and its correlates in a large sample of cancer patients.

Methods: 5,702 cancer patients (67.5% female; 76.9% White, 17.2% Asian, 5.5% Black) completed a routine electronic distress screen, including a question on sleep problems, following diagnosis and prior to initiating cancer treatment. Patients across 8 different cancer diagnoses (breast, gastrointestinal, gynecological, head and neck, hematological, lung, prostate, urinary) were included. Patients endorsing “Severe” or “Very Severe” sleep problems-related distress were classified as having a sleep problem.

Results: 12.5% of patients reported sleep problems, though significant differences in the proportion of patients with sleep problems were seen across diagnoses (4.3-13.8%; $p < .001$), with prostate cancer patients least likely and gastrointestinal cancer patients most likely to experience sleep problems. Logistic regression analyses indicated demographic factors (lower household income and female gender; not race, education, or marital status) were associated with greater prevalence of sleep problems. A logistic model adjusted for demographic variables revealed anxiety and depression, but not concerns about potential treatment-related side effects, were associated with sleep problems ($p < .001$).

Conclusions/Implications: A sizeable proportion of cancer patients already report major problems with their sleep, before any treatment has occurred, and this is an issue across racial groups and educational levels. Key demographic and mood factors are associated with sleep problems. This can have important implications for identifying and treating patients at greatest risk for sleep problems during a vulnerable period early in their cancer trajectory.

SLEEP, RESILIENCE, AND PSYCHIATRIC DISTRESS IN UNITED STATES MILITARY VETERANS

Jaime M. Hughes, PhD, MPH, MSW[1], Christi S. Ulmer, PhD[2], Susan N. Hastings, MD, MHS[2], Jennifer M. Gierisch, PhD, MPH[3], Mid-Atlantic VA MIRECC Workgroup, .[4], Matthew O. Howard, PhD[5]

[1]Center for Health Services Research in Primary Care, Durham VA Health Care System, Cary, NC; [2]Center for Health Services Research in Primary Care, Durham VA Health Care System, Durham, NC; [3]Duke Univeristy, Durham, NC; [4]Durham VA Health Care System, Durham, NC; [5]UNC School of Social Work, Chapel Hill, NC

Sleep problems are a common symptom of several mental health conditions, including depression, PTSD, and anxiety. However, roughly two-thirds of Veterans without an active mental health diagnosis also complain of poor sleep. Left untreated, sleep problems may be associated with psychiatric distress that could contribute to a subsequent mental health diagnosis. Few studies have examined the clinical correlates of sleep problems in Veterans without current mental health diagnoses. Identifying risk and protective factors related to poor sleep and increased psychiatric distress could strengthen pertinent prevention efforts. Research suggests psychological resilience, defined as positive stress-coping ability, protects against poor mental health outcomes in Veterans exposed to stress or trauma. However, the relationship between sleep and resilience has not been previously studied. Utilizing data from the Study of Post-Deployment Mental Health, a volunteer research registry housed at the Mid-Atlantic VA's Mental Illness Research, Education, and Clinical Center, this research examined the demographic, health, sleep and resilience characteristics of post-9/11 military Veterans with one or more deployments who did not meet past-month criteria for a DSM-defined Axis I mental health disorder (N=1,117). Hierarchical linear regression and moderation analyses were used to examine the relationship between poor sleep quality (Pittsburgh Sleep Quality Index) and psychiatric distress (Global Symptom Index, Symptom Checklist-90) and to test whether psychological resilience (Connor-Davidson Resilience Scale) moderated this relationship. Results revealed Veterans with poor sleep quality had worse physical and psychological health, lower resilience, and endorsed more lifetime traumatic events. Controlling for health and demographic characteristics, poor sleep quality was associated with greater psychiatric distress [F (5, 1111) = 84.7, R^2=0.159, $p < 0.0001$]. Both factors of resilience – adaptability and self-efficacy – were found to have a significant buffering effect between poor sleep quality and greater psychiatric distress (p's < 0.05). Additional research is needed to better understand the relationship between sleep and resilience in Veterans, and how

interventions targeting each may help to curb psychiatric distress and ultimately reduce risk of subsequent mental health diagnoses.

ARE THERE RACIAL DISPARITIES IN THE SOCIAL INTEGRATION/MORTALITY ASSOCIATION?

Steven D. Barger, PhD[1], Bert N. Uchino, PhD[2]

[1]Northern Arizona University, Flagstaff, AZ; [2]University of Utah, Salt Lake City, UT

Objective: Social integration, as indicated by being married, having recent contacts with other people, participating in group activities, etc., is strongly and inversely associated with mortality. However, there is little data evaluating whether this association is consistent across racial groups. **Method**: In a representative US sample we examined the presence and form of the association of social integration with all-cause mortality within non-Hispanic Blacks (n = 4,201) and non-Hispanic Whites (n = 20,217). Vital status was ascertained ten years following the baseline assessment. Social integration scores ranged from zero to eight. The two lowest categories were combined and this single social integration variable was entered as a predictor in Cox regression models. We statistically controlled for age, sex, chronic disease prevalence, received emotional support, socioeconomic status (education, employment, home ownership) and smoking. **Results**: After multivariate adjustment social integration was inversely related to ten-year survival for both groups. Among Whites each unit increase in social integration was associated with a 10% reduced risk of dying over ten years, hazard ratio [HR] = 0.90, 95% confidence interval [CI], 0.87-0.92. A similar association was observed among Blacks, HR = 0.92, 95% CI, 0.86-0.98. There was no evidence of heterogeneity across the two hazard estimates (z = -0.64, p = 0.52). **Conclusions**: These data provide evidence that the social integration/mortality association is evident for both Whites and Blacks.

CHRONIC DISEASE PREVENTION AND TREATMENT AMONG MEXICAN MIGRANTS: FINDINGS FROM A BINATIONAL PROJECT

Xiao Zhang, PhD[1], Gudelia Rangel, PhD[2], Eduardo Gonzalez-Fagoaga, PhD[3], Melbourne Hovell, PhD[4], Sylvia Guendelman, PhD[5], Ana Martinez-Donate, PhD[6]

[1]University of Wisconsin-Madison, Verona, WI; [2]El Colegio de la Frontera Norte, San Antonio del mar, Baja California, Mexico; [3]Comisión de salud fronteriza méxico- estados unidos, San Diego, CA; [4]San Diego State University, San Diego, CA; [5]University of California-Berkeley, Berkeley, CA; [6]Drexel University, Philadelphia, PA

Background: Circular Mexican migrants represent a socioeconomically disadvantaged population and are more likely to experience limited access to health care in both the U.S. and Mexico.The situation may worsen if the new administration implements stringent immigration and health policy reforms that target immigrants. Guided by the Andersen health care utilization model, this study aims to 1) examine the levels of preventive and treatment services receipt for chronic diseases, including hypertension, hypercholesterolemia and diabetes, across the migration phases; and 2) identify predisposing, enabling, and need factors that were associated with the receipt of preventive and treatment services for each migration phase, among Mexican migrants that converged in the border city of Tijuana, Mexico.

Methods: We used data from a 2013 cross-sectional survey of Mexican migrants conducted as part of Project Migrante, a binational collaboration between the U.S. and Mexico (N=2115). Based on spatial trajectories and migration history, Mexican migrants were categorized into five migration phases: pre-departure, return, transit, destination, and interception. We conducted multiple logistic regressions to model receipt of preventive and treatment services for chronic diseases within each migration phase and to compare receipt levels across migration phases.

Results: Overall, 23.0% of Mexican migrants represented by our sample self-reported at least one type of chronic diseases. The age- and gender-standardized prevalence rates of any preventive services receipt ranged from 23.0% among return migrants to 29.2% among transit migrants; and the standardized rates of any treatment services receipt among those with any chronic diseases ranged from 39.5% among migrants in the interception phase to 54.5% among those in the destination phase. After statistical adjustment for other factors, destination (AOR=1.49) and interception migrants (AOR=1.84) were more likely to receive preventive services than their pre-departure counterparts. In contrast, receipt of treatment

services did not vary significantly across migration phases. Different sets of predisposing, need, and enabling factors were associated with the receipt of preventive and treatment services for different migration phases.

Conclusion: Mexican migrants had suboptimal levels of receipt of preventive and treatment services for chronic diseases across all migration phases. Tailored intervention programs should be provided to Mexican migrants at different migration phases to increase health care receipt and reduce the burden of chronic diseases.

COUPLE EMOTION REGULATION SKILLS AND PARTNER SUPPORT OF PHYSICAL ACTIVITY IN ADULTS WITH OSTEOARTHRITIS

Cynthia M. Khan, PhD[1], Christine Rini, PhD[2], Robert F. DeVellis, Ph.D.[2], Ida J. Griesemer, BA[1], Kent M. Lee, MA[2], Mary Altpeter, PhD, MSW, MPA[3], Leigh F. Callahan, PhD[4]

[1]University of North Carolina at Chapel Hill, Carrboro, NC; [2]University of North Carolina at Chapel Hill, Chapel Hill, NC; [3]UNC at Chapel Hill, Chapel Hill, NC; [4]University of North Carolina, Chapel Hill, Chapel Hill, NC

Physical activity is crucial to management of osteoarthritis (OA). Even small increases in activity can improve health and well-being. Getting social support for physical activity (e.g., encouragement, working together) from a partner is a robust predictor of physical activity, making it a potentially useful target for couples-focused interventions to promote OA management. Yet, social support involves complex, skill-based interpersonal interactions, so partner support for physical activity is most likely to be beneficial when both members of a couple have adequate support-related skills. We propose that benefits of partner support depend on the emotion regulation skills of both members of couples (i.e., ability to understand their own and each other's emotions and respond adaptively to discordance). In 169 couples that included a person with OA (PWOA) who was insufficiently active and wanted to increase activity and that person's partner (Partner), we investigated associations between couples' emotion clarity (i.e., their ability to understand their own emotions) and partner support received by PWOA after a couples-focused OA and physical activity class. We hypothesized that the association between PWOA emotion clarity and partner support would be moderated by partner emotion clarity. After controlling for PWOA gender, findings from hierarchical linear regression analyses partially supported our hypothesis: PWOA emotion clarity was positively associated with positive partner support for physical activity ($\beta = .25$, $p = .029$) when partners had better emotion clarity. However, when partners had poorer emotion clarity, PWOA emotion clarity was not associated with positive partner support ($\beta = -.10$, $p = .349$). PWOA emotion clarity was negatively associated with partner unsupportive behaviors (e.g., criticism, minimizing the importance of physical activity; $\beta = -.20$, $p = .010$), but this association was not moderated by partner emotion clarity ($\beta = .02$, $p = .842$). Findings suggest that efforts to leverage partner support to promote PWOA physical activity may be optimized by helping each couple member attain or improve emotion regulation skills such as emotion clarity.

FORGIVENESS & GRATITUDE VS. SHAME DUE TO HETEROSEXISM & DEPRESSION IN OLDER GAY MEN AND LESBIANS

Tosha Griggs, Student

Center for Psychosocial Health Research, Lake Dallas, TX

Older lesbians and gay men (LG) are at greater risk for depression and shame due to heterosexism (SDH) because of a lifetime of victimization (Fredriksen-Goldsen et al., 2013). SDH is associated with negative mental health outcomes, is positively correlated with age and more prevalent in older LG that live alone (Meyer, 1995; Grossman, D'augelli & O'connell, 2002). However, forgiveness of others may help older LG combat depression and shame because forgiveness is empowering (Cass, 1984). According to Cass (1984) forgiveness of others is associated with self-acceptance and lower mental distress (Kim & Enright, 2014). Forgiveness of others is also associated with increased gratitude and greater life satisfaction (McCullough, Tsang & Emmons, 2004). Gratitude is associated with positive mental health (Snyder & McCullough, 2000) and lower depression (Musick & Wilson, 2003). Through a minority stress (Meyer, 2003) lens, we hypothesize that SDH is positively associated with depression, forgiveness of others and gratitude are negatively associated with depression and that SDH, forgiveness of others and gratitude account for a significant proportion of variance in depression. Participants (M_{age} = 58.99, *SD*= 6.48) were 50% gay men, 50% lesbians and self-identified as 68% European American, 17% African American and 15% other ethnicity. A hierarchical regression analysis (*F* [10, 89] = 7.12, $p < .001$) indicated that, in aadition to gratitude (β=-.34, $p < .001$) and forgiveness of others (β=-.22, $p < .05$), being single (β=.42, $p < .001$) was also a significant predictor, accounting for approximately 38% of the variance in depression (adjusted R^2=.38, $p < .001$).

Our findings suggest that depression is positively associated with SDH and negatively associated with gratitude and forgiveness of others. SDH is negatively associated with gratitude and forgiveness of others. Being single is negatively associated with forgiveness of others and positively associated with SDH. Because depression in older adults is associated with a decrease in physical, social and cognitive function and increased mortality (Blazer, 2003), therapeutic priorities should focus on the aspects of life to be thankful for, while encouraging older LG to use forgiveness as a coping strategy to counteract SDH and depression.

GENDER DIFFERENCES: IMPACT OF VIOLENCE EXPOSURE ON DRUG USE AND HIV RISK BEHAVIORS AMONG YOUNG ADULT AFRICAN AMERICANS

Forough Saadatmand, PhD[1], Roderick Harrison, PhD[2], Jennifer Bronson, PhD[3], Deanna Crouse, MHS[4]

[1]Howard University, College of Medicine, Department of Pediatrics and Child Health, Washington, DC, N/A; [2]2M Research Services, LLC, Reston, VA; [3]Office of Justice Program / Department of Justice, Laurel, MD; [4]Howard University / College of Medicine / Dept. of Pediatrics and Child Health, Washington, DC, DC

BACKGROUND: This presentation provides baseline preliminary analysis of data collected in a longitudinal study from 440 African Americans young adults ages 18-25 living in Washington DC. OBJECTIVE: One component of the study is designed to test the effects of social and environmental stressors such as exposure to community violence (including homicide) on alcohol, tobacco and other drug (ATOD) use and sexual risk behaviors that may render African American young adults more vulnerable to contracting HIV/AIDS**.** The objective here is to understand how exposure to violence impacts ATOD use and HIV risk behaviors, and to determine if the strengths of the associations vary based on violence type and gender. METHODS: We first conducted a factor analysis of the exposure to community violence scales to identify domains or types of violence. We then conducted a series of regression analyses to assess the various community violence types (e.g., witnessing a murder) on the dependent variables representing ATOD use, and knowledge and perception of HIV risk factors. RESULTS: Our data showed that as children, 33% of the participants reported seeing a parent get hit by another parent or a boyfriend/girlfriend, and 42% said someone close to them was murdered. As adults, 66% have seen other people using or selling drugs in real life, and 36% have actually been asked to get involved in aspects of selling or distributing illegal drug. Women and men differed in the types of violence to which they were likely to have been exposed. Women were significantly more likely to have been exposed to personal violence and attacks, which explained a mean of 75 percent of the total variance in lifetime ATOD use and age of first ATOD use for women. Men, in contrast, were more likely to have been direct victims of violence. Experiencing gun use or seeing violent deaths explained 51.6 percent of the total variance for men and 69 percent of the total variance in the model for male marijuana use. CONCLUSION: The results suggest that a large percentage of young African American adults are exposed to community violence, that community violence has a strong impact on ATOD use and HIV risks behaviors, and that African American women and men are exposed to different kind of community violence.

GREEN SPACES AND GROCERY STORES: URBAN ENVIRONMENTAL DETERMINANTS OF WEIGHT AMONG MEXICAN-AMERICAN YOUTH

Dorothy McLeod, MA, Amy Bohnert, PhD, Catherine DeCarlo Santiago, PhD

Loyola University Chicago, Chicago, IL

Latino children have the highest rates of obesity of any racial/ethnic group in the U.S. (Ogden, Kit, Carrol, & Flegal, 2014), and are therefore at increased risk for the many negative sequelae of child obesity. Several studies have demonstrated that neighborhood factors, such as the distance to or density of grocery stores or other food outlets, as well as the distance to or density of green spaces and parks, are associated with obesity and related risk factors among Latino youth (e.g. Chaparro et al., 2014, Hsieh et al., 2014). Studies of these relations among Latino youth have suggested that these factors may be differentially impactful by gender (e.g., Hsieh et al., 2014). This study will examine these neighborhood factors and their impact on obesity among Mexican-origin immigrant youth, and whether these effects have differential significance for girls and boys.

Data were collected in the homes of 104 Mexican-origin immigrant families with a child aged 6-11 years (*M*=8.91, *SD*=1.34), in which at least one parent was a first-generation immigrant and whose household income fell at or below 150% of the poverty line. A sample of 89 participants with valid zBMI data was used for initial analyses. Parents provided child/family demographic information. Anthropometric measurements were used to calculate child zBMI based on CDC growth charts (Kuczmarski et al., 2002). Address data was used to plot the participants' home locations in a Geographic Information System (GIS). Data derived from the City of Chicago Public Data Portal were used to plot grocery store and park locations. ArcGIS was used to conduct geospatial analyses of participants' home locations and their relation to the stated neighborhood factors.

There was substantial variation in child zBMI (*M*=1.01, *SD*=1.07). Overall, 44.9% of children were normal weight, 14.6% were overweight, and 40.4% were obese, demonstrating a heavier sample than the overall US Hispanic child population (Ogden et al., 2014). A map of participants' locations and weight statuses revealed no geographic clustering of participants falling into the overweight or obese categories. Contrary to previous research, preliminary analyses revealed that proximity to the nearest park was negatively associated with zBMI, such that the greater distance between the participant's home and the nearest park, the lower the participant's zBMI (β=-.07, *p*=.01). However, there was no direct association between proximity to grocery stores and child weight. These preliminary findings suggest that home distance to parks and green spaces may have unique effects among this population.

Future analyses will confirm this finding by examining density of parks and grocery stores (rather than distance) and will explore the moderation effects of gender on these relations.

HEALTH-RELATED SELF-EFFICACY: THE ROLE OF SOCIAL SUPPORT IN CANCER, DISABILITY, AND MULTIMORBIDITY

Kelly D. Blake, ScD[1], Devlon Jackson, PhD, MPH[2], Anna Gaysynsky, MPH[3], Erin Kent, PhD[4], Neetu Chawla, PhD, MPH[5], Danielle Blanch-Hartigan, PhD, MPH[6], Lila J. Finney-Rutten, PhD, MPH[7]

[1]Behavioral Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, National Institutes of Health, Bethesda, MD; [2]University of Maryland, College Park, College Park, MD; [3]ICF International, Bethesda, MD; [4]National Cancer Institute, Rockville, MD; [5]Kaiser Permanente Northern California, Oakland, CA; [6]Bentley University, Waltham, MA; [7]Mayo Clinic, Rochester, MN

Background: Self-efficacy consistently has been shown to play a role in health behavior, and social support is associated with health-related self-efficacy. Our study provides population estimates of disability, multimorbidity, social support, and health-related self-efficacy in adults ever diagnosed with cancer and adults with no cancer history, and examines the relationship between social support and health-related self-efficacy in the context of cancer, disability, and multimorbidity. **Methods:** Data were from the National Cancer Institute's cross-sectional Health Information National Trends Survey (HINTS) 4, Cycle 2 (2012-2013). Multivariable logistic regression models were employed to assess the probability that cancer, cancer plus the presence of any disability, cancer plus the presence of any comorbid condition, and social support are independently associated with two measures of health-related self-efficacy (confidence in ability to take care of own health, confidence in ability to get advice about cancer) in the overall sample (N=3,266) and the subsample of individuals ever diagnosed with cancer (N=422). **Results:** Those with a cancer diagnosis and cancer plus a comorbid condition were no more or less likely to be confident that they could take care of their health or get advice or information about cancer compared to those never diagnosed with cancer or those without cancer and multimorbidity (OR 0.93, CI 0.66-1.32 and OR 0.71, CI 0.49-1.04, respectively). In contrast, those who had been diagnosed with cancer and also experienced a disability were significantly less likely to report being confident in their ability to take care of their health (OR 0.30, CI 0.16-0.56). Social support was independently and significantly associated with health-related self-efficacy: those reporting that they had some type of social support (emotional, informational, instrumental) were more than twice as confident on both measures of health-related self-efficacy across all health conditions under

study. **Conclusion:** Social support may play an important role in bolstering health-related self-efficacy among cancer patients, particularly in the context of multimorbidity and disability.

PRESSURE ULCER DEVELOPMENT AMONG ETHNICALLY DIVERSE, COMMUNITY DWELLING ADULTS WITH SPINAL CORD INJURY

Lucia I. Florindez, MA[1], Florence Clark, Phd, OTR/L, FAOTA[2], Mike Carlson, PhD[2]

[1]University of Southern California, Burbank, CA; [2]University of Southern California, Los Angeles, CA

Background:

Medically serious pressure ulcers (MSPUs) are the most prevalent secondary complication for individuals with a spinal cord injury (SCI), compromising physical health and quality of life.

Purpose:

The objective of this study was to identify the life circumstances that lead to MSPU development while people with SCI participated in a lifestyle-based pressure ulcer prevention program, and to provide recommendations for future intervention design.

Methods:

This study entailed summarizing baseline co-morbidity data and a qualitative thematic analysis of 1800 treatment notes from the Pressure Ulcer Prevention Study (PUPS), a randomized controlled trial evaluating the efficacy and cost-effectiveness of a multifaceted lifestyle-based intervention in reducing incidence of MSPUs. Participants were ethnically and socio-economically diverse community-dwelling adults with SCI recruited from a major rehabilitation facility in Los Angeles County. Of the 83 participants enrolled into the 12-month PUPS intervention, 25 developed an MSPU during the course of the intervention and are the focus of this sub-study.

Results:

In total, 25 patients enrolled in the intervention developed 40 unique MSPUs. Analysis of data from eligible PUPS participants revealed themes that captured the range of circumstances that led to MSPU development during study participation. The six factors that describe MSPU development are as follows: 1) circumstances unrelated to the intervention, 2) lack of rudimentary knowledge pertaining to wound care, 3) equipment and supply issues, 4) co-morbidities, 5) non-adherence to prescribed bed rest, and 6) passivity.

Conclusions:

Many factors may contribute to the development of MSPUs in ethnically diverse adults with SCI. These conditions, especially when compounded by limited financial resources, seemed to have undermined the effectiveness of a multifaceted intervention program. Several programmatic modifications have potential for increasing the intervention's effectiveness for individuals similar to those in the sample we studied, including a focus on addressing equipment needs, and tailoring the intervention to the health literacy levels of participants.

Funding and Acknowledgements:

This work was supported by grant R01HD056267 from the National Center for Medical Rehabilitation Research (NCMRR) within the Eunice Kennedy Shriver National Institute of Child Health & Human Development, National Institutes of Health to the University of Southern California. Sincere thanks to members of the PUPS Study Team.

RELATIONSHIP BETWEEN CROSS-CULTURAL AND SEXUAL MINORITY SPECIFIC-CULTURAL COMPETENCE: A STUDY OF HEALTHCARE PROVIDERS

Joanne G. Patterson, MSW, MPH[1], Jennifer M. Jabson, PhD, MPH[1], Charles Kamen, PhD, MPH[2]

[1]University of Tennessee, Knoxville, TN; [2]University of Rochester Medical Center, Rochester, NY

Background: Cross-cultural competence (CCC) improves health care providers' (HCPs) skills for providing culturally competent healthcare to racial/ethnic minority patients. It is not known how CCC relates to HCPs' cultural competence in treating sexual minority patients (lesbian, gay, and bisexual patients; SMP). Given the pervasive influence of homophobia and heterosexism, associations between CCC and SMP specific cultural competence (SMPCC) may be moderated by HCPs' attitudes about SMP.

Methods: HCPs recruited from a Southeast region completed a self-report questionnaire including measures of CCC, SMP-specific cultural competency (SMPCC), and attitudes toward SMP. Descriptive statistics were calculated on each measure. Nested multivariable linear regression was calculated to test for associations between CCC and SMPCC. Attitudes toward SMP were tested as a moderator of this relationship. Analyses were adjusted for HCP age, number of years of practice, prior sexual minority training, and gender.

Results: Mean SMPCC scores ($\bar{x}$ = 2.47, SD = 0.54) indicated low SMPCC whereas mean CCC scores ($\bar{x}$ = 2.88, SD = 0.32) indicated average CCC. Mean attitudes toward SMP scores ($\bar{x}$ = 14.84, SD = 2.16) indicated neutral attitudes toward treating SMP. CCC was associated with SMPCC; for every unit increase in CCC, SMPCC increased 1.72 units (b = 1.72, t(17) = 4.27, p < .001). HCP attitudes about SMP moderated the association between CCC and SMPCC (b = 0.23, t(17) = 2.28, p = .04).

Discussion: While CCC and SMPCC were generally associated, HCPs' attitudes toward SMP moderated this association. At high CCC, HCPs evidenced high SMPCC regardless of attitudes toward SMP. At low CCC, HCPs with negative attitudes towards SMP had significantly lower

SMPCC than HCPs with positive attitudes toward SMP. It is unclear whether negative attitudes towards SMP exacerbate low CCC, leading to significantly lower SMPCC, or whether positive attitudes towards SMP make providers more competent in caring for these patients, even in the context of low CCC. Future research should examine HCPs' experiences with CCC and SMPCC, elements of CCC associated with SMP cultural competency, and how HCPs reconcile attitudes toward SMP with CCC and provision of SMPCC.

ROLE OF RACIALIZED POLICE VIOLENCE IN REDUCING BLACKS' MENTAL HEALTH: #BADGEONBLACK CRIMES

Aerielle Allen, M.A.[1], Blair T. T. Johnson, Ph.D.[2], Mora A. Reinka, M.S.[3]

[1]University of Connecticut, Cromwell, CT; [2]University of Connecticut, Storrs, CT; [3]University of Connecticut, Manchester, CT

Research has shown that members of stigmatized groups experience chronically high levels of stress and poor health due to experiences of prejudice and discrimination. Experiencing racialized police violence and police (mis)conduct arguably raise stress levels among marginalized individuals. While these incidents usually directly involve only a few people, they are not isolated events. Social media and national media attention allows such events to affect communities across the country, not just those directly involved. As such, racialized policing events are potentially a major concern to public health, especially for those who are most similar to the victims. Using data from the Center for Disease Control's Behavioral Risk Factors Surveillance System, the current study examines how the Michael Brown and Eric Garner incidents related both to Black and White individuals' mental health. These events are of particular interest because they gave national attention to the Black Lives Matter activist movement, which has provided a platform to campaign against violence and racism targeting Black people. Results demonstrated that in the thirty days following the shooting of Michael Brown in Ferguson, MO, there were significant increases in the mean number of days Missouri residents aged 18-24 and 35-44 reported stress, depression, or overall poor mental health, compared to those polled outside the state, p=.009. Within Missouri, Black respondents also reported an increase in the mean number of days they experienced poor mental health, compared to Whites, p<.01. Similar trends emerged regarding the death of Eric Garner in Staten Island, NY. Thirty days following Garner's death, New York respondents aged 25-34 reported more stress, depression, or overall poor mental health compared to residents of other states, $p < .01$. Although not significant, similar trends were seen for respondents not living in New York. Mirroring the Michael Brown analyses, Black respondents in New York also demonstrated an increase in the mean number of reported days where they experienced poor mental health, compared to White New Yorkers, $p < .01$. Additional analyses examine trends for mental health one year following each event and limitations and implications are discussed.

UNDERSTANDING THE SOCIAL DETERMINANTS OF HEALTH IN UNDERSERVED COMMUNITIES

Alexa J. Meinhardt, Department of Biological Sciences, University of Delaware, Newark, DE[1], Jaclyn M. Natalone, Department of Biological Sciences, University of Delaware, Newark, DE[2], Maggie Norris Bent, MPA[3], Mia A. Papas, PhD[4]

[1]University of Delaware, Lititz, PA; [2]University of Delaware, Dix Hills, NY; [3]Westside Family Healthcare, Wilmington, DE; [4]Value Institute, Christiana Care Health System, Newark, DE

There is growing recognition of the strong correlation between social determinants and community health outcomes. Despite efforts to address these issues, Delawareans living in underserved communities continue to experience poor health outcomes. The *Healthy Neighborhoods Project,* a partnership between Westside Family Healthcare and the Delaware Center for Health Innovation, provides a formal approach for organizations to develop and implement strategies that improve community health. As part of the community planning process, a neighborhood-level community needs assessment was conducted in the urban areas of Wilmington and Claymont, Delaware to identify the strengths and resources available within specific neighborhoods. Guided by the precede-proceed model, this investigation helped communities prioritize their health targets and determine barriers that hinder meeting these targets. A survey was administered to residents in the communities to understand concerns from a local perspective, and a resource library was developed that identified all available community health promotion activities. Activities were divided into themes including maternal/child health, chronic disease prevention/management, and mental health/addiction. Programs were divided among these themes, with 255 locally available programs and an additional 56 that could be accessed statewide. The locations of each program were mapped using a Smartsheet feature that allows for visualization of programs by theme. Community health indicators for the Wilmington and Claymont neighborhood revealed poor health outcomes with an increased prevalence of obesity (29.7%), smoking (18.9%) and infant mortality (6.9 per 1,000 live births). Although there are many programs targeting the Wilmington and Claymont neighborhood, community health indicators are poor. It is important to understand how this community utilizes health promotion programs and determine current unmet needs. Understanding the social determinants of health from a unique community-based perspective will aid in developing health promotion programs to successfully meet the goals of this initiative.

DO LONELINESS AND SELF-ESTEEM ALTER THE INFLUENCE OF SELF-AFFIRMATION ON STRESS RECOVERY?

Lauren Hofschneider, B.A.[1], Mikaela Grimm, B.A.[2], Hong Di Wang, Student[1], Katlyn King, Student[3], Kallie Ochiai, Student[1], Paula Ong, Student[1], Marie Cross, B.A., M.A.[1], Sarah Pressman, Ph.D.[1]

[1]University of California, Irvine, Irvine, CA; [2]University of California, Irvine, San Juan Capistrano, CA; [3]University of California, Irvine, Newport Beach, CA

Recent research has illustrated that self-affirmation can ameliorate damaging physiological stress responses. What has gone unstudied, however, is the possibility that some individual differences interact with forms of affirmation to determine whether these benefits are present or absent. Since self affirmation often focuses on esteem enhancement and affirming on important social relationships, we examine the relationship between trait loneliness (an important determinant of social perceptions) and self-esteem in the context of different forms of affirmations and how these variables relate to physiological stress recovery. One hundred and ten undergraduates (59% female, Mage=19.4) were randomly assigned to one of three conditions: a non-social self-affirmation group (n=33) who wrote about an important personal value, a social self-affirmation group (n=42) who wrote about an important relationship, or a control group (n=35) who wrote about daily activities. Participants then completed two stress tasks (a speech and a math task). Blood pressure was recorded approximately every two minutes during the study. Trait self-esteem and loneliness were assessed via self-report at baseline. Within the non-social self-affirmation condition, both self-esteem, $b = .494$, $t(28) = 2.215$, $p = .035$, and loneliness, $b = -.627$, $t(28) = -2.963$, $p = .006$, significantly predicted recovery diastolic blood pressure after controlling for age, sex, and ethnicity. Within the social self-affirmation condition, only loneliness significantly predicted recovery diastolic blood pressure after controlling for age, sex, and ethnicity, $b = -.622$, $t(37) = -2.44$, $p = .02$. Within the control condition, neither self-esteem nor loneliness predicted recovery diastolic blood pressure. Neither self-esteem nor loneliness predicted recovery systolic blood pressure in any of the conditions. The different rates of diastolic blood pressure recovery indicate that the benefits derived from self-affirmation exercises may be contingent upon psychosocial variables. For example, individuals who report being more lonely may benefit from affirming the existence of strong social relationships, and individuals who report higher levels of self-esteem may benefit from affirming the existence of strong personal values. Future research incorporating self-affirmation manipulations should focus on

investigating similar individual differences because they may play an important role in how stress interventions work.

EXPERIENCES AND IMPACTS OF STRESS RELATED TO PARENTING CHILDREN WITH LEARNING DISABILITIES: A QUALITATIVE ANALYSIS

Emma Chad-Friedman, BA[1], Karen Kuhlthau, PhD[2], Jacqueline Proszynski, BA[1], Thomas Muzzonigro, BA[1], Elyse R. Park, PhD, MPH[1]

[1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital, boston, MA

Background: There is growing literature on the increased levels of parental stress associated with caring for children with learning disabilities (LD). High levels of parental stress are associated with clinical depression, low levels of self-efficacy in caregiving, maladaptive parenting practices, decreased social support, and poor perceived health. This qualitative study explored the perspectives of parents of LD and experts working with these parents to identify 1) sources and impacts of parental stress, and 2) resources available to parents; this study also informed development of a targeted mind-body resiliency program for parents of children with LD.

Methods: From June-July 2016 individual and focus group in-depth interviews were conducted with 5 clinicians, 2 organizations and 4 focus groups of parents of children with LD (N=25). Content analyses were conducted using NVivo 11 software; reliability of kappa = 0.93 was achieved.

Results: Results from expert and parent interviews demonstrated high levels of parental stress associated with caring for children with learning disabilities. Sources of stress were primarily navigating the educational system to advocate for the child's needs and communicating with other parents, family members, and the child. Both parents and experts identified impacts of stress on emotional and physical exhaustion, strained familial relationships, and social isolation. Experts identified heightened guilt and concerns about stigma as main stressors, whereas parents additionally revealed being burdened by feeling misunderstood. Experts identified many informational resources available to parents, but most parents were not aware of these resources. Moreover, no skills-based psychosocial programs were revealed.

Conclusions: Parents caring for children with LD experience high levels of stress, particularly affecting relationships, leading to high levels of social isolation. Parents also utilize few emotional or informational support systems. A skills-based resiliency intervention could provide useful skills for parents to manage their stressors and provide support to their children and family.

FINDINGS OF A MIND-BRAIN-BODY INTERACTION STUDY OF HYPERTENSION IN BLACK MEN

Linda Oakley, PhD

University of Wisconsin-Madison, Madison, WI

Findings of a Mind-Brain-Body Interaction Study of hypertension in Black Men. PROBLEM Hypertension, a well characterized inflammatory illness response to the stress of racialized social and economic inequities, is a prevalent population health problem in Black men. AIM We assessed the interaction of mind, brain, and body factors with racial stress and blood pressure in community Black men. METHODS Over 3 study visits, 2-3 weeks apart, a diverse sample of right-handed, adult Black men (N = 20), age 24-64, completed surveys and were assessed for biomarkers of stress reactivity. Participants responded to self-report measures of daily racial micro-aggressions, civilian Post Traumatic Stress, resilience, positive thinking, daily life stress, depression, childhood stress, incarceration, days of poor physical-mental health, and interoception (self-awareness and self-observation of body sensations). At visit 2 Electroencephalography (EEG), using a 19-sensor cap, was used to produce 2 10-minute (eyes-open/ closed) maps of brain electrical activity (frequency and aptitude). Following the EEG, participants were assessed for heart rate variability (HRV) using a 3-lead computerized electrocardiogram (ECG) program and completed measures of positive and negative affect and daily spirituality. A brief third study visit was used to obtain a venous blood sample to test non-fasting plasma level of high sensitivity C-reactive protein (hs-CRP), body weight, and digital blood pressure readings. ANALYSES Structural equation modeling (SEM) is used to estimate parameters of racial social stress related to mind-brain-body interaction and hypertension. The brain score used in the model is the EEG estimate of Left-Right prefrontal cortex asymmetry (F3 minus F4) or greater left (social challenge) relative to right (social threat) reactivity to perceived social rejection. Body variables in the model are the RMSSD (Square Root of the Mean Squared Difference between Adjacent Normal to Normal Beat Intervals) estimate of HRV and plasma hs-CRP as an estimate of autonomic nervous system interaction linking cognitive perception and blood pressure. RESULTS Our results present a SEM test of mind-brain-body x environment interaction of stress related hypertension in adult Black men. DISCUSSION Findings are discussed relative to their contributions to symptom science and neurofeedback training in stress self-management for Black men.

HAIR BIOMARKERS AMONG MIDDLE-SCHOOL CHILDREN IN RELATION TO SCHOOL STRESS AND ASTHMA

Eyal Oren, PhD, MS[1], Erika Barrett, MPH[1], Julia Fisher, MS[2], Dean Billheimer, PhD[1], Mark L. Laudenslager, PhD[3], Lynn B. Gerald, PhD, MSPH[1]

[1]University of Arizona, Tucson, AZ; [2]Arizona BIO5 Institute, Tucson, AZ; [3]University of Colorado Denver Anschutz Medical Campus, Aurora, CO

Background: Children and adolescents with chronic exposure to disruptive events have prolonged physiological and health consequences. Given the extensive time spent at school, it is possible that school social and physical environments strongly impact students through the effects of stressors such as school-based conflict, discrimination and violence, as well as academic and social demands. There has been little research examining the role of chronic school stress and asthma status on hair biomarkers among low SES children and adolescents.

Methods: In this feasibility study, 52 children were recruited from a large, low socioeconomic status, majority-Latino middle school. On two study visits, participants completed a self-report questionnaire including perceived chronic school stressors (CASE), asthma outcomes, and demographics and provided hair samples to test for cortisol and dehydroepiandrosterone (DHEA). We examined the effects of predictors on cortisol and DHEA. A separate linear mixed model was run on outcome variables for each predictor of interest. Each model included the given predictor and visit as fixed effects and participant as a random intercept.

Results: High overall school stress was reported, with slightly increased stress during the second visit (P=0.103). On the second visit, which corresponded to final school examinations, average cortisol (marginal mean 4.0 vs. 6.5, $P < 0.001$), but not DHEA (marginal mean 14.5 vs. 15.7, P=0.316), was significantly higher. Neither overall stress, nor any of ten domain-specific stress questions were correlated with higher cortisol or DHEA levels. Self-reported asthma status was also not correlated. Females showed significantly lower cortisol (4.4 vs. 6.4, P=0.049) but not DHEA (14.9 vs. 15.3, P=0.858) than males.

Discussion: Middle-schoolers reported high perceived school stress, but questionnaire responses did not correlate with hair biomarker measures. Chronic stress may induce hyporesponsiveness of the hypothalamic-pituitary adrenal axis and result in a blunted cortisol response. This preliminary study demonstrated feasibility of collecting hair biomarkers in a school setting and lower reported levels among females but found no correlation with self-

reported measures. Future research can examine these associations in larger samples among asthmatic children, to better understand mechanisms mediating chronic stress and asthma relationships.

SELF-ENHANCEMENT AND EMOTIONAL EXPERIENCE AMONG PATIENTS WITH THALASSEMIA AND MULTIPLE SCLEROSIS

Shaima Almahmoud, MA[1], Karin Coifman, PhD[2]

[1]Kent state University, kent, OH; [2]Kent state University, Kent, OH

Self–enhancement (SE) is the tendency toward overly optimistic or unrealistic self-serving biases. It has been shown to be a useful disposition under circumstances of extreme diversity with different populations such as patients with chronic illnesses (e.g., HIV; Stein et al., 2011; cancer; Zsuzsanna et al., 2012). While SEers show resilience and good adjustment in managing threatening events, SE has potential social costs too (Bonnano et al., 2002). For example, SEers have difficulty forming or maintaining friendships (Fraley & Bonanno, 2004; Yan & Bonanno, 2015), which may conflict or undermine the benefits. Although there is evidence of regulatory benefits to SE following threatening situations, little is known about the beneficial effects of SE on different emotion response dimensions (especially emotion facial behavior). This study examines emotional responses in a sample of chronically ill adults (Thalassemic/MS patients). Thalassemia: an inherited blood disorder causing severe anemia that may lead to frequent complications due to transfusion-transmitted infections and iron overload (Galanello & Origa, 2010). Multiple Sclerosis (MS): a kind of autoimmune disease—usually diagnosed between 20-50—, which involves abnormal response of the body's immune system against the central nervous system leading to unpredictable exacerbations (Goretti et al., 2010).Participants were 27 adults with transfusion-dependent thalassemia, 41 adults with MS, 73% female. Mean age= 35, SD= 8.86 years. They were recruited from medical centers in the Northeastern USA.They completed questionnaires and were interviewed in private in the medical exam room or in the lab. Multiple regression analyses, controlling for psychological distress, age, and disease burden were conducted to examine whether SE could significantly predict positive or negative affect or facial behavior and how the nature of the relationship between SE and emotion changed as a function of the type of illness. Results showed that higher SE was associated with lower levels of psychological distress, r=-0.38, p=.001 and higher reported positive affect, r=0.47, p < .001 across both samples. There was an interaction of SE with the patient group when predicting negative and positive facial emotion, β=.32, p=.04, β=-.39, p=.004, respectively. Moreover, there was an interaction of SE with the patient group when predicting close informant's social attributes and the availability of the close informant to the participant, β=.27, p=.05, β=.43, p=.002, respectively. These results indicate the importance of illness history in the development and influence of self-enhancing biases and show that SE has different impacts on the regulatory responses of emotion.

THE ACCURACY OF BRIEF STRESS MEASURES IN PREDICTING ILLNESS

James Amirkhan, Ph.D.

California State University Long Beach, Long Beach, CA

Medical and psychological theories indicate stress to be an etiological factor in a variety of illnesses; therefore, stress measures hold promise for the prediction of imminent pathology. However, most stress measures are too lengthy to be used for rapid diagnosis, and too cumbersome to be imposed on distressed individuals. The present study examined two brief measures, the popular 10-item Perceived Stress Scale (PSS-10) and the recently published 10-item Stress Overload Scale-Short (SOS-S), in terms of their accuracy in identifying symptomatic persons. A demographically diverse sample (*n* = 249) was drawn from two different community sites, which were purposefully selected to yield a wide range of stress levels. Survey packets included the PSS-10, the SOS-S, and the Patient Health Questionnaire (PHQ-15), which assesses somatic symptoms common to physical and psychiatric disorders, in counterbalanced orders. Participants completed these packets on site, with full anonymity of response. Partial correlations showed PSS-10 and SOS-S totals to inter-correlate, and to correlate significantly with PHQ-15 symptoms. However, a test comparing the magnitude of these correlations revealed the SOS-S to be a significantly stronger predictor of PHQ-15 scores than the PSS-10. Next, categories were constructed from stress scores to divide participants into High Risk vs. Low Risk groups for each measure. ANOVA tests showed significant differences in the number of symptoms reported across risk categories for the PSS-10 and for the SOS-S. In short, both total scores and categorical scores, on both short stress measures, worked to differentiate highly symptomatic from other participants. It was concluded that brief stress scales, which are well suited to urgent situations and/or distressed victims, are indeed viable diagnostic tools for assessing the risk for stress sequelae. Moreover, having been tested in a general population at community venues, the PSS-10 and especially the SOS-S appear to be good choices for use across a broad demographic spectrum and a variety of contexts.

THE ROLES OF STRESS EATING AND MINDFULNESS IN THE RELATIONSHIP BETWEEN RECENT LIFE STRESSORS AND INDICATORS OF OBESITY RISK

Elizabeth Cotter, PhD[1], Nichole Kelly, PhD[2]

[1]American University, Washington, DC; [2]University of Oregon, Eugene, OR

Research has established a link between stress and increased risk for obesity. This study examined whether stress eating mediates the relationship between recent life stressors and indicators of obesity risk, including body mass index (BMI) and waist circumference. We also explored whether mindfulness moderates the relationship between recent life stressors and stress eating. Cross-sectional data were examined from 4963 adults in the Midlife in the U.S. study (MIDUS II). Hierarchical regression analyses indicated that recent life stressors were associated with higher BMI and waist circumference, even after controlling for age, race, gender, education level, and annual household income. Using a nonparametric bootstrapping approach, we found that stress eating partially mediated the association between recent life stressors and BMI/waist circumference. Both recent life stressors and mindfulness were independently associated with stress eating; however, their interaction was not significant. These results provide further evidence of the contributions of psychosocial factors to obesity risk and suggest that stress reduction and mindful eating techniques might be beneficial components to obesity-related interventions.

A COMPARISON OF TRAUMATIZED AND NON-TRAUMATIZED INJURED PATIENTS WHO SCREENED POSITIVE FOR HEAVY DRINKING

Dylan Richards, BS[1], Emmanuel Sequeira, BS[2], Craig Field, PhD, MPH[1]

[1]Latino Alcohol and Health Disparities Research (LAHDR) Center, Department of Psychology, The University of Texas at El Paso, El Paso, TX; [2]Latino Alcohol and Health Disparities Research (LAHDR) Center, The University of Texas at El Paso, El Paso, TX

Health care settings are regularly accessed by non-treatment-seeking heavy drinkers. Thus, Screening, Brief Intervention, and Referral to Treatment (SBIRT) has been implemented as a public health approach to address the unmet need for alcohol treatment. The purpose of the current study was to examine potential differences between two groups of heavy drinking trauma patients: those who experienced their injury as traumatic and those who did not experience their injury as traumatic.

Exploratory analyses were conducted using baseline data from a multisite randomized controlled trial of brief intervention to reduce drinking in the trauma care setting. Participants were 596 injured patients from three urban Level I trauma centers who screened positive for heavy drinking. Participants completed questionnaires that assessed sociodemographics, injury history, and alcohol-related variables. Univariate analyses were conducted to assess potential differences between traumatized and non-traumatized patients. Statistical differences between the groups included gender ($\chi^2[1] = 7.55$, $p < .01$), ethnicity ($\chi^2[3] = 27.95$, $p < .001$), intent of injury ($\chi^2[1] = 8.19$, $p < .01$), and readiness to change alcohol use ($\chi^2[2] = 7.91$, $p < .05$). A multivariate logistic regression (0 = non-traumatized; 1 = traumatized) assessed potential predictors of injury-related trauma. Correlates that met the criteria of $p < .25$ in the univariate analyses were simultaneously entered into a logistic regression model. Gender ($OR = 0.46$, $\beta = -0.78$, $p < .01$ [reference group was female]) and identification as African American and Hispanic ($OR = 2.70$, $\beta = .99$, $p < .001$ and $OR = 3.14$, $\beta = 1.14$, $p < .001$, respectively) were statistical predictors in the model.

The results of the current study suggest that women and ethnic minorities were more likely to experience their injuries as traumatic. Admission to a trauma care center provides an opportunistic moment for alcohol intervention, and those who experience an injury as traumatic may be more receptive to healthy behavior change. Understanding the characteristics of traumatized and non-traumatized patients provides insight into potential avenues for tailoring intervention.

CHARACTERISTICS OF COMORBID MARIJUANA USE AND INTERNET GAMING DISORDER

Travis Hyke, B.A. [1], Charlotte Beard, M.S.[2], Amie Haas, Ph.D.[3]

[1]Palo Alto University, Sunnyvale, CA; [2]Palo Alto University, Milpitas, CA; [3]Palo Alto University, Palo Alto, CA

The current study explored the association between Internet Gaming Disorder (IGD) and comorbid marijuana use. Internet gaming addictions are highly prevalent in adolescents, affecting about 3% of persons under age 20 (Muller at al., 2015, Ferguson, Coulson, & Barnett, 2011). Similar etiological pathways have been found between IGD and substance use addictions, with both disorders linked to negative psychosocial consequences (Van Rooij et al., 2014) and co-occurrence (Castro-Calvo et al., 2016). In particular, IGD appears to co-occur with substances that are expand the user’s sensory experience, like marijuana, and it has been posited that behavioral addictions like IGD activate cannabinoid receptors in the brain (Lopez-Moreno et al., 2008) and comorbid use has been linked to IGD severity (Van Rooij et al., 2014). However, few studies have provided more analysis of marijuana use among individuals with IGD. The present study sought to explore two primary hypotheses concerning Internet gaming and marijuana use: i) individuals who use marijuana while playing internet games would show more IGD symptoms than those who abstained while gaming and ii) individuals who reported using marijuana to enhance gameplay would have an increased severity of IGD symptoms related to mood modification. Concurrent cannabis and video game users (*n* = 68, **63**% male) were recruited from Amazon's Mechanical Turk as part of a larger study related to Internet gaming and substance use. Participants completed a survey that included questionnaires regarding domains of IGD, substance use, and psychological functioning. As expected, individuals with simultaneous use had significantly greater IGD scores relative to conjoint users (t (61) = -2.94, p < .01). Overall frequency of marijuana use and using marijuana to enhance gaming experience failed to predict IGD (F(1, 61) = 2.35, p = 0.13 and F(1, 61) = 2.59, p = 0.11, respectively). This study provides preliminary evidence that the link between marijuana use and IGD can be differentially affected by how and when individuals administer marijuana. The present study has implications for future treatment of comorbid behavioral and substance use addictions, as when and how individuals are using both can help inform evidence-based treatment.

EPIDEMIOLOGY OF SUBSTANCE USE AMONG YOUNG AFRICAN AMERICAN WOMEN IN NEW ORLEANS, LOUISIANA

Aubrey S. Madkour, PhD[1], Gretchen Clum, PhD[2], Norine Schmidt, MPH[2], Carolyn C. Johnson, PhD MS[2], Patricia Kissinger, BSN, MPH, PhD[2]

[1]Tulane University, New Orleans, LA; [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA

Background: While studies exist describing differences in substance use across racial/ethnic and gender groups, patterns of substance use and for correlates of substance use for late adolescent African American women are not well understood.

Purpose: Few studies have examined the epidemiology of substance use among young African American women, including potential correlates of substance use patterns within this group.

Methods: Young African American women, ages 18-19 yrs, were recruited from a community college, historically black universities, and community sites to participate in a randomized controlled trial for online teen pregnancy prevention. At baseline participants reported lifetime and past three-month alcohol, marijuana and other illicit drug use. Respondents also reported indicators of health and well-being, characteristics of sexual partnerships, and family background characteristics. Latent class analysis (LCA) and multivariable multinomial logistic regression determined the association between potential risk factors and latent classes of substance use.

Results: Of 459 participants, 60% reported drinking alcohol, 24% reported binge drinking, and 32% reported marijuana use in the past three months. LCA results suggested four latent typologies of substance use: recent abstainers (31%), recent drinkers (30%), marijuana users (8%), and polysubstance users (31%). In multivariable analyses, factors found to be significantly associated with increased risk of substance use was higher maternal education, early sexual initiation, and having a recent male sexual partner.

Conclusions: A substantial proportion of late African American adolescents exhibited one or more recent substance use behaviors, with nearly a third evidencing use of two or more substances. Future analyses should examine how substance use behaviors change over time, as well as the consequences of longitudinal patterns of use for this group.

EXAMINING CHARACTERISTICS AND CLINICAL TREATMENT OF SMOKERS IN A SUBSTANCE USE DISORDER TREATMENT CLINIC

Julie C. Gass, PhD, MA[1], David H. Morris, Ph.D.[2], Jamie Winters, PhD[3], Joseph VanderVeen, PhD[4], Stephen Chermack, Ph.D.[5]

[1]VHAWNY Center for Integrated Healthcare, Buffalo, NY; [2]Veteran Affair Ann Arbor Healthcare System, Ypsilanti, MI; [3]VA Ann Arbor Healthcare System & University of Michigan, Ann Arbor, MI; [4]Ann Arbor VA Healthcare System, Canton, MI; [5]University of Michigan/VA Ann Arbor, Ann Arbor, MI

Individuals with a substance use disorder (SUD) diagnosis are more than twice as likely to smoke cigarettes as the general population. Emerging research has suggested that treating a substance use disorder simultaneously with tobacco use leads to a higher rate of treatment success for both substances. Despite this, substance use treatment protocols tend not to focus on tobacco use; in fact, traditional substance use treatments discourage patients from attempting to quit smoking. One rationale is that patients may not be motivated to quit smoking. In the current study, data from Veterans enrolled in outpatient treatment for a SUD were examined to assess for general characteristics of smokers as compared to non-smokers as well as to examine motivation to quit smoking. Baseline (i.e., pre-treatment) data from 278 Veterans were used. Charts of smokers in the SUD clinic (SUDC) were reviewed to assess how smoking is handled by SUDC providers, and if smokers to attempt cessation. Of 278, 163 SUDC patients reported that they currently smoke cigarettes (M = 16.3 cigarettes per day, SD = 11.1). Smokers in the clinic reported greater general impairment than nonsmokers, $F(1,248)=10.2$, $p=.002$, as well as greater specific impairment: Physical Problems, $F(1,258)=14.8$, $p=.000$; Interpersonal Problems, $F(1,262)=6.7$, $p=.010$; Intrapersonal Problems, $F(1,260)=7.2$, $p=.008$, and Social Responsibility, $F(1,262)=16.5$, $p=.000$. Smokers in the sample were marginally more anxious than their non-smoking counterparts as measured by the GAD=7, F(1,254)=3.8, p=.053, though they were not significantly more depressed (p=0.193). On a 1-10 scale, smokers reported moderate levels of importance (M=5.4, SD=3.1), readiness (M=5.6, SD=3.2), and confidence (M=5.0, SD=3.0) regarding quitting smoking. Review of smokers' medical records reveal that while SUDC providers assess tobacco use at intake (90%) and offer treatment (86.5%), a substantially small portion of smokers attempt cessation (41.1%) while enrolled in SUDC. No patients enrolled in smoking-specific treatment in SUDC with a behavioral health provider, though 78 patients did obtain nicotine replacement or another smoking cessation medication (41% were prescribed by a SUDC provider).These preliminary analyses demonstrate that, contrary to the belief that treatment-seeking

substance users are not motivated to quit smoking, Veterans were at least moderately ready to quit smoking while they were enrolled in substance use treatment though a majority do not attempt to quit smoking. Further, there is evidence that those who are smokers have greater impairment caused by substance use, suggesting that this subgroup is of particular high need. Specific treatment recommendations will be discussed, including how behavioral health providers in SUD clinics may be better able to capitalize on patients' moderate motivation to quit at intake.

INITIATION INTO INJECTION DRUG USE AND CROSS-BORDER MIGRATION AMONG PEOPLE WHO INJECT DRUGS IN TIJUANA, MEXICO

Claudia Rafful, MSc, PhD candidate[1], Maria Luisa Mittal, MD[2], Jason S. Melo, BS Public Health[3], Dan Werb, PhD[4], Andy Guise, PhD [3]

[1]UCSD, La Jolla, CA; [2]University of California San Diego, La Jolla, CA; [3]University of California San Diego, San Diego, CA; [4]University of California, San Diego, La Jolla, CA

Background: People who inject drugs (PWID) play a key role in facilitating the entry of others into this behavior. In Tijuana, Mexico, recent findings suggest that the initiating of others into injecting is associated with reporting short-term residence (i.e., 1-5 years) in the United States. However, the nature of the association between cross-border migration and injection initiation of others and own remains unexplored. **Methods:** *Preventing Injecting by Modifying Existing Responses* (PRIMER, NIDA DP2-DA040256-01) is a mixed methods multi-site study assessing social and structural factors associated with PWID initiating others into drug injection. For the present qualitative study, PWID enrolled since 2011 in a prospective cohort study in Tijuana (*Proyecto El Cuete IV*, NIDA R01-DA019829)were purposively sampled for the qualitative component of PRIMER according to sociodemographic factors and drug use behaviors indicating their initiation of others into injection drug use. Semi-structured interviews were performed during June- August 2016, which explored the context and characteristic of individuals' own injection initiation events as well as their initiating others into drug injection. Thematic analysis was used to develop recurring and significant categories in the data. **Results:** Twenty-one participants were interviewed (women=8, men=13) with a median age of 40 years (Interquartile Range: 36 – 46). Migration between Mexico and the United States was core in participant narratives on their own and others injection initiation. The majority of participants that lived in the United States (66.7%) reported that they had initiated their injection drug use there. Migration from Mexico to the United States was linked to participants' own initiation into injecting, which seems to be related to the normalization of injection in social networks as well as underlying social and economic alienation and marginalization. Additionally, participants reported on a 'moral code' whereby the initiation of others into injecting was highly stigmatized. However, participants also reported that increases in economic, social and physical insecurity after returning to live in Mexico made them more susceptible to initiating others. **Conclusion:** This is the first study to qualitatively investigate the initiation of injection drug use in Mexico. Migration stressors appear key to individuals' own initiation and their initiation of others. Further research is needed to analyze the social normalization and expansion of injection drug use among migrant populations in

the Mexico-U.S. border in order to address the unacceptably high burden of injection-related harms among this vulnerable population. The impact of migration should be considered within binational injection prevention and social programs.

MEDICAL MARIJUANA DISPENSARY ROLL-OUT: BASELINE MEASURES OF MARIJUANA USE AMONG ADULTS AND YOUTH IN HAWAII FROM 2010-2014

Codie M. Garza, B.S.[1], Claudio R. Nigg, PhD, FSBM[2]

[1]Office of Public Health Studies/University of Hawaii at Manoa, Honolulu, HI; [2]University of Hawaii, Honolulu, HI

BACKGROUND: Medical marijuana has been legal in Hawaii since 2000. Dispensaries became legal in 2015, were permitted as of July 2016, and are expected to open in December 2016. With rates of prescription drug use without a prescription stable in Hawaii, monitoring and prevention of non-medical marijuana use should be a focus among these changes in access.

PURPOSE: To provide baseline marijuana use among adults and youth in Hawaii prior to the launch of dispensaries.

METHODS: The National Survey on Drug Use and Health data regarding adult and youth marijuana use for years 2010-2014 was examined. Rates for past year and past month marijuana use are presented for youth (12–17), young adult (18–25), and adult (26+).

RESULTS: Youth marijuana use remained stable from 2010-2014. Past year use rates were: 2010–2011: 14.95% [95%CI: 12.54–17.73], 2011–2012: 16.6% [95%CI: 14.04–19.54], 2012–2013: 15.33% [95%CI: 12.82–18.23], 2013–2014: 13.9% [95%CI: 11.61–16.57]. Past month use rates were: 2010–2011: 8.29% [95%CI: 6.54–10.46], 2011–2012: 9.69% [95%CI: 7.74–12.06], 2012–2013: 9.55% [95%CI: 7.69–11.81], 2013–2014: 7.65% [95%CI: 6.04–9.65].

Young adult marijuana use remained stable from 2010-2014. Past year use rates were: 2010–2011: 29.53% [95%CI: 25.87–33.47], 2011–2012: 31.51% [95%CI: 28.05–35.19], 2012–2013: 31.27% [95%CI: 27.69–35.09], 2013–2014: 27.32% [95%CI: 23.75–31.2]. Past month use rates were: 2010–2011: 17.58% [95%CI: 14.65–20.95], 2011–2012: 18.15% [95%CI: 15.42–21.25], 2012–2013: 18.84% [95%CI: 15.94–22.13], 2013–2014: 15.87% [95%CI: 13.07–19.14].

Adult marijuana use remained stable from 2010–2014. Past year use rates were: 2010–2011: 8.79% [95%CI: 7–10.97], 2011–2012: 10.14% [95%CI: 8.17–12.53], 2012–2013: 10.35% [95%CI: 8.28–12.87], 2013–2014: 10.13% [95%CI: 8.18–12.48]. Past month use rates were: 2010–2011: 5.13% [95%CI: 3.86–6.8], 2011–2012: 5.69% [95%CI: 4.31–7.48], 2012–2013: 6.91% [95%CI: 5.28–8.99], 2013–2014: 6.68% [95%CI: 5.12–8.66].

CONCLUSIONS: The data suggests a fairly low level of use in youth and adults but higher use in young adults. Relatedly, other data indicates young adults have the lowest perception of great risk about marijuana use. With recreational marijuana use illegal in Hawaii and change in access to come, it is vital to monitor marijuana use.

MEN'S AND WOMEN'S PERCEPTIONS OF TREATMENT OUTCOMES IN A CLINICAL TRIAL OF INJECTABLE OPIOIDS FOR SEVERE OPIOID USE DISORDER

Heather Palis, BA, MSc, Kirsten Marchand, BSc, Eugenia Oviedo-Joekes, PhD

University of British Columbia, Vancouver, BC, Canada

Background: Studies of opioid use disorder and clinical trials of treatments for severe opioid use disorder consistently suggest that treatment outcomes rarely differ by gender. The present study aims to explore whether men and women have differing perceptions of treatment effectiveness.

Methods: Baseline characteristics and six-month treatment outcomes were analysed by gender. Participants were asked to share their reasons for perceived treatment effectiveness. A thematic analysis was carried out using an inductive approach and themes and relationships across participant comments were developed using the strategy of constant comparison.

Results: Women in treatment presented with a number of vulnerabilities as compared to men. These included higher rates of HIV (22.6% vs. 11.4%), having ever engaged in sex work (83.9 % vs. 22.1%), and significantly worse health. After six months of treatment, the only outcome that differed by gender was physical health, with men having a significantly better score. Themes surrounding perceptions of treatment effectiveness were similar for men and women, the most common of which were improved health and improved quality of life, however men's and women's descriptions surrounding these themes differed.

Conclusions: The collection of participant perceptions of effectiveness provides an opportunity for understanding the patient experience that cannot be revealed with the use of standardized tools and researcher defined health measures. The systematic use of information collected from participants' perceptions of effectiveness has strong clinical significance, and can work to ensure clinical practice is designed in a way that can effectively meet individual patient needs.

SOCIAL DESIRABILITY BIAS AND SELF-REPORTS OF MENTAL HEALTH, DRUG USE, AND HEALTH SERVICE UTILIZATION AMONG SUBSTANCE USERS.

Carl A. Latkin, Ph.D, Melissa Davey-Rothwell, Ph.D, Karin Tobin, Ph.D

Johns Hopkins School of Public Health, Baltitmore, MD

Social desirable response bias may lead to inaccurate self-reports and erroneous study conclusions. We examined the relationship between social desirability bias and self-reports of substance use, mental health, and health service utilization among a community sample of 591 inner-city substance users who were enrolled in a behavioral change intervention to address HIV risk behaviors and depressive symptoms. The study was conducted Baltimore, Maryland from 2009-2013. Modified items from the Marlowe-Crowne Social Desirability Scale were included in the survey, which was conducted face-to-face and using Audio Computer Self Administering Interview (ACASI) methods. Less than half (44%) the participants were female, 54% had less than 12 years of education, 61% reported main partners. The median age was 45 and 95% reported that they had been unemployed within the last six months and 24% homeless. There were highly statistically significant differences in levels of social desirability response bias by levels of depressive symptoms, drug user stigma, subjective health status, recent drug use, and size of social networks. There were no associations between health service utilization measures and social desirability bias. In multiple logistic regression models, even after including the CES-D, as a measure of depressive symptomology, social desirability bias was associated with drug use stigma, drug use duration, and network size. We also found that social desirability bias was not associated with enrollment in prior research studies, indicating that "professional subjects" do not appear to provide more socially desirable responses. These findings suggest that social desirability bias is associated with key health measures. These associations are not primarily due to depressive symptoms and research methods are needed to reduce social desirability bias. Such methods may include the wording and prefacing of questions, clearly defining the role of "study participant", and assessing and addressing motivations for socially desirable responses.

YOUNG ADULTS RIDING WITH A MARIJUANA-, ALCOHOL-, AND DRUG-IMPAIRED DRIVER

Kaigang Li, PhD[1], Elizabeth Ochoa, B.A[2], Federico E. Vaca, MD, MPH[3], Bruce Simons-Morton, EdD, MPH[4]

[1]Colorado State University, Fort Collins, CO; [2]Colorado State University, Fort collins, CO; [3]Yale University School of Medicine, New Haven, CT; [4]NICHD, Bethesda, MD

Purpose: Examine the prevalence and correlates of young adults riding with an impaired driver (RWI) due to marijuana (MJ), alcohol (ALC), or illicit drug (ID).

Methods: Data were from the NEXT Generation Health Study waves 4 and 5 (W4&5 [2013-14], 1 and 2 years after high school, with N=1979 at W4 and N=2142 at W5). W5 data was specified for ALC-, MJ-, and ID-related RWI in a vehicle that was driven by a young or older adult. Multinomial logistic regressions estimated the association of W5 substance-specific RWI with W5 binge drinking, MJ use, and environmental status variables (i.e., school-, residence-, and work- status). Overall W4 RWI and demographic variables were included.

Results: The prevalence of W5 RWI was 33% (n=694). Specifically, 17% of participants reported riding with a young ALC-impaired driver and 4% with an older ALC-impaired driver; 21% reported riding with a young MJ-impaired driver and 2% with an older MJ-impaired driver; and 5% reported riding with a young ID-impaired driver and 0.7% with an older ID-impaired driver. The adjusted models included residence and work status separately so two adjusted odds ratios [OR] were reported. W4 RWI was associated with W5 ALC- (OR=2.6-4.3, p < .05).

Conclusion: The results show that RWI is prevalent in young adults two years after high school, with 33% of participants reporting RWI at least once in the past year. MJ-related RWI prevalence was greater than ALC-related prevalence, and occurred more often with an impaired young driver than with an impaired older driver. MJ use was associated with all ALC-, MJ-, and ID-related RWI. The findings support the reduction of early RWI, substance use, and heavy drinking as strategies to reduce impaired driving in young adults.

AURORA SMOKING AND HEALTH SURVEY: A COMMUNITY-BASED SURVEY ON STRESS, COPING AND SMOKING STATUS

Patricia Valverde, PhD MPH[1], Kathleen Garrett, MA[1], Robert McGranaghan, MPH[2], Natalie Slopen, ScD[3], Margaret A. Chesney, PhD[4], Arnold Levinson, PhD MJ[1]

[1]Colorado School of Public Health, Aurora, CO; [2]Colorado School Of Public Health, Aurora, CO; [3]School of Public Health, University of Maryland College Park, College Park, MD; [4]UCSF School of Medicine, Menlo Park, CA

SIGNIFICANCE: The community-academic partnership project was designed to assess smoking patterns, coping skills, knowledge, motivation to quit smoking and barriers to cessation including chronic life stressors in a low socioeconomic status (SES) population. We hypothesized that stress levels would be similar among smokers and non-smokers and coping self-efficacy would be associated with smoking status. METHODS: The cross sectional survey respondents were English and Spanish speaking adult smokers and non-smokers recruited through recreation centers, a local food bank program, multi-unit housing complexes and a public library in the targeted neighborhood. The survey instrument included validated measures and a stress instrument of 6 domains comprised of life stressors, stress related to work, relationships, neighborhood, unfair treatment and finances. Each stress domain score was standardized into a Z-score distribution. Coping was measured using the Coping Self-Efficacy instrument. RESULTS: A total of 405 individuals were surveyed including 295 current smokers (72.8%) and 110 non-smokers (27.2%). Respondents were 48% male, 42.6% African American and 31.4% Hispanic and 45.8% were single and only 11% of the population completed college or higher. Three fourths of the respondents were not working. The majority had some type of health insurance (79.4%) with most reporting Medicaid as their insurance (72.4%). Most respondents smoked cigarettes (95.6%) compared to cigars (8.8%). A third of respondents reported smoking their first cigarette within five minutes of waking up (35.4%). Regarding past quit attempts, respondents who did use evidenced based treatments reported NRT (26.6%), and QuitLine (18.3%) use. Those more likely to be smokers were men with less than college education and non-Latinos. Those experiencing higher levels of stress due to discrimination were at higher odds (aOR 1.82, 95% CI 1.25-2.67) of being a smoker than those with lower stress levels after controlling for demographic and other stress variables. Higher levels of stress across the 6 stress domains were associated with smoking (aOR 1.37 95% CI 1.07-1.76) even after adjustment. Those with higher levels of coping self-efficacy were more likely to be non-smokers (OR 0.99 95% CI 0.985-0.996). CONCLUSION: Different types of stressors and the coping skills to handle them are an under-researched area

for smoking cessation interventions. Assisting the low SES smoker to quit and adhere amidst chronic stressors will be essential to further reduce smoking prevalence.

CIGARETTE SMOKING AND ELECTRONIC CIGARETTE VAPING PATTERNS AS A FUNCTION OF E-CIGARETTE FLAVORINGS

Mark Litt, PhD[1], Valerie Duffy, PhD[2], Cheryl Oncken, MD[3]

[1]University of Connecticut Health Center, Farmington, CT; [2]University of Connecticut, Storrs, CT; [3]University of Connecticut School of Medicine, Farmington, CT

Objective: The present study examined the influence of flavoring on the smoking and vaping behavior of cigarette smokers asked to adopt e-cigarettes for a period of six weeks.

Methods: Subjects were 88 current male and female smokers with no intention to stop smoking, but who agreed to substitute e-cigarettes for their current cigarettes. Upon intake, subjects were administered tests of taste and smell for e-cigarettes flavored with tobacco, menthol, cherry, and chocolate, and were given a refillable e-cigarette of their preferred flavor or a control flavor. Subjects monitored their daily cigarette smoking for 1 week, and were then asked to adopt e-cigarettes for a period of 6 weeks. Subjects completed daily logs of cigarette and e-cigarette use and were followed each week.

Results: Analyses over days indicated that, during the 6-week e-cigarette period, cigarette smoking rates dropped from an average of about 16 cigarettes/day to about 7/day. E-cigarette flavor had a significant effect on smoking, such that the largest drop in cigarette smoking occurred among those assigned menthol e-cigarettes, and the smallest drop in smoking occurred among those assigned chocolate and cherry flavors. These results were confirmed by weekly CO readings. E-cigarette vaping rates also differed significantly by flavor assigned, with the highest vaping rates for tobacco and cherry flavored e-cigarettes, and the lowest rates for those assigned to chocolate. These results persisted regardless of preferred flavor, whether the subject was a menthol smoker, or the level of nicotine in the e-cigarette.

Conclusions: The findings suggest that adoption of e-cigarettes in smokers may influence smoking rates, and that e-cigarette flavorings can moderate this effect. E-cigarette vaping rates are also influenced by flavorings. These findings may have implications for the utility of e-cigarettes as a nicotine replacement device, and for the regulation of flavorings in e-cigarettes for harm reduction.

ELECTRONIC NICOTINE DELIVERY SYSTEM (ENDS) USE DURING SMOKING CESSATION: A QUALITATIVE STUDY OF 40 OKLAHOMA QUITLINE CALLERS

Katrina Vickerman, PhD[1], Laura Beebe, PhD[2], Gillian Schauer, PhD, MPH[3], Brooke Magnusson, MA[1], Brian King, PhD, MPH[4]

[1]Optum Center for Wellbeing Research, Seattle, WA; [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [3]Centers for Disease Control and Prevention, Office on Smoking and Health, Atlanta, GA; [4]Office on Smoking and Health, Centers for Disease Control and Prevention, Atlanta, GA

Objectives: Approximately ten percent (40,000 each year) of U.S. quitline enrollees who smoke cigarettes report current use of Electronic Nicotine Delivery Systems (ENDS); however, little is known about callers' ENDS use. Our aim was to describe why and how quitline callers use ENDS, their beliefs about ENDS, and the impact of ENDS use on callers' quit processes and use of FDA-approved cessation medications.

Design: Qualitative interviews conducted 1-month post-registration. Interviews were recorded, transcribed, double-coded, and analyzed to identify themes.

Setting: Oklahoma Tobacco Helpline

Participants: 40 callers aged ≥18 who were seeking help to quit smoking, were using ENDS at registration, and completed ≥1 program calls.

Results: At 1-month post-registration interview, 80% of callers had smoked cigarettes in the last 7 days, almost two-thirds were using ENDS, and half were using cessation medications. Nearly all believed ENDS helped them quit or cut down on smoking; however, participants were split on whether they would recommend cessation medications, ENDS, or both together for quitting. Confusion and misinformation about potential harms of ENDS and cessation medications were reported. Participants reported using ENDS in potentially adaptive ways (e.g., using ENDS to cut down and NRT to quit, and stepping down nicotine in ENDS to wean off ENDS after quitting) and maladaptive ways (e.g., frequent automatic ENDS use, using ENDS in situations they didn't previously smoke, cutting down on smoking using ENDS without a schedule or plan to quit), which could impact the likelihood of quitting smoking or continuing ENDS use.

Conclusions: These qualitative findings suggest quitline callers who use ENDS experience confusion and misinformation about ENDS and FDA-approved cessation medications. Callers also use ENDS in ways that may not facilitate quitting smoking. Opportunities exist for quitlines to educate ENDS users and help them create a coordinated plan most likely to result in completely quitting combustible tobacco.

IDENTIFYING PREDICTORS OF SMOKING IN THE SMOKEFREE.GOV ADULT TEXT-MESSAGING SMOKING CESSATION PROGRAM

Kara P. Wiseman, MPH, PhD[1], Kisha I. Coa, PhD, MPH[2], Augustson Erik, PhD, MPH[3]

[1]National Cancer Institute, Bethesda, MD; [2]ICF International, Rockville, MD; [3]National Cancer Institute, Rockville, MD

Background: Text-based smoking cessation programs are effective, however, many users fail to initiate their quit attempt or quickly relapse. A more thorough understanding of predictors of early failures can help inform program changes targeted to improving treatment outcomes. **Methods**: Items were included on the program registration page of a cessation text program to assess: time to first cigarette, cigarette cravings, frequency of smoking reminders, frequency around smokers, external and internal motivation to quit, confidence in the quit attempt, and long-term intention to be smoke free. Associations between each characteristic and smoking status were evaluated using logistic regression modeling (n=6226). Two outcomes were considered: smoking on the quit day (yes/no) and smoking one week into the quit attempt (yes/no). Smoking on the quit day was included in all models of smoking at one-week. **Results**: Three user characteristics were associated with smoking on the quit day. Users who smoked within five minutes, or between six and 30 minutes of waking up were 1.63 and 1.54 times more likely to smoke on their quit day, respectively compared to users who smoked after more than 30 minutes (95% CIs: 1.20–2.21, 1.14–2.10). Compared to users who had low confidence in their quit attempt, users with high confidence or some confidence were 50% and 40% less likely to smoke on their quit day, respectively (ORs: 0.50, 0.60; 95%CIs: 0.33-0.75, 0.40-0.89). Users who had low long-term smoke free intention were 1.79 times more likely to smoke on their quit day compared to those with high long-term intention (95%CI: 1.11-2.88). Two user characteristics were associated with smoking at one-week. Users who were often around smokers were 2.04 times more likely to smoke at one-week compared to users who were infrequently around smokers (95%CI: 1.36-3.09). Users who reported high external motivation to quit smoking were 1.52 times more likely to smoke at one-week compared to users with low external motivation to quit (95%CI: 1.04-2.23). **Conclusions**: Within a short time window, the predictors of smoking differed, which suggests that the relevance of specific messages might change over the course of the quit attempt. Quit success might be increased if messages early in a program focus on preparing users for withdrawal symptoms, and building confidence in quitting, and by saving messages about handling cravings and maintaining motivation to stay smoke free until after the quit day.

IMPULSIVITY AND ALTERNATIVE TOBACCO USE AMONG YOUNG ADULT NON-DAILY SMOKERS

Kristin Brikmanis, BA, Angela Petersen, PhD, Neal Doran, PhD

University of California, San Diego, La Jolla, CA

Introduction: Impulsivity has been prospectively associated with cigarette smoking behaviors among young adults, but little is known about how impulsivity affects alternative nicotine and tobacco product (ANTP) use. One possibility is that impulsive individuals find nicotine particularly reinforcing, and thus may be vulnerable to rapid progression of tobacco use. The purpose of the present study was to examine the association between impulsivity and ANTP use over time.

Method: Participants (n = 392, 52% male) aged 18-24 were recruited for a longitudinal study of tobacco use. Eligibility criteria included non-daily cigarette smoking for ≥ 6 months with no history of daily smoking. Five components of impulsivity (lack of premeditation, lack of perseverance, sensation seeking, and negative and positive urgency) were measured at baseline, and participants reported recent tobacco use at baseline and follow-ups at 3, 6, and 9 months. Assessments were conducted online or via mobile app.

Results: Across the 4 assessments, 37-55% of participants reported recent ANTP use. Frequency of use did not vary significantly over time. Sensation seeking and lack of premeditation prospectively predicted frequency of ANTP use, such that participants higher in those aspects of impulsivity used ANTPs more often. This association did not change over time.

Conclusion: Findings suggest a high prevalence of ANTP use among young adult non-daily smokers. Data also indicated that those who lack premeditation and/or are prone to sensation seeking may be more likely to use ANTPs.

JOB SEEKING SMOKERS: SCREENING & ELIGIBILITY IN A TOBACCO TREATMENT TRIAL

Beatriz Anguiano, B.A[1], Anna Epperson, PhD[2], Nicole E. Anzai, BS[3], Adrienne Lazaro, BS[4], Judith J. Prochaska, PhD, MPH[3]

[1]Stanford University, Oakland, CA; [2]Stanford Prevention Research Center, Palo Alto, CA; [3]Stanford University, Stanford, CA; [4]Stanford Prevention Research Center, Palo, CA

Background/Objective: While the US adult smoking prevalence has declined greatly over the past 4 decades, disparities exist for those with less education, lower socioeconomic status, and the unemployed. In California, 1.4 million adults are unemployed and seeking work and 16% are smokers, compared to 12% of employed Californians. Our prior research has found unemployed smokers have a significantly lower likelihood of reemployment and a lower hourly wage compared to nonsmoking jobseekers. The current study summarizes screening and recruitment strategies of the Total IMPACT study, a randomized controlled trial testing a smoking cessation intervention for unemployed smokers with the objective of increasing abstinence and aiding re-employability.

Methods: Jobseekers presenting to three Employment Development Departments (EDD) in the San Francisco Bay Area were approached about the study and screened for eligibility. Pro-active face-to-face recruitment and reactive methods (e.g., flyers) were used and reasons for ineligibility and refusals were coded. Eligibility criteria included unemployed < 2 years, currently job seeking, smoking > 1 cigarette per day, with a carbon monoxide breath reading > 7 ppm, able to read and write in English, and currently residing in the Bay Area.

Results: Of the 1,934 adults approached between October 2015 and August 2016, 37% were current smokers (n = 720). Those ineligible were nondaily smokers (23%), currently employed (23%), or non-job-seeking (16%). Among eligible smokers (n = 231), 67% declined. Key reasons for declining enrollment were the length of time needed to complete the study (21%) and lack of interest (67%). To date, 144 participants have enrolled into the study. Participants are predominantly men (73%) and ethnically/racially diverse with 52% non-Hispanic African American, 30% non-Hispanic White, 8% Hispanic, and 4% Asian/Pacific Islander. Among those eligible, men were more likely to enroll than women (43% vs. 29%) and African American individuals were more likely to enroll than other ethnic/racial groups (49% vs. 38%), p-values < .05.

Conclusions: While integrating a tobacco cessation intervention into EDD settings offers

opportunity for reach and engagement of under-served and racially/ethnically diverse smokers, recruitment is challenging and points to the need for flexibility in criteria (i.e., broadening to include nondaily smokers) and minimizing study time demand.

METHODS OF CESSATION AND ROLE OF ELECTRONIC CIGARETTES AMONG CURRENT AND FORMER SMOKERS: A CROSS-SECTIONAL SURVEY OF US ADULTS

Pratibha Nayak, PhD[1], Terry Pechacek, PhD[1], Joanna-Grace Manzano, MD[2], Michael Eriksen, ScD[1]

[1]Georgia State University, Atlanta, GA; [2]The University of Texas MD Anderson Cancer Center, Houston, TX

Background: Electronic cigarettes (EC) are increasingly used by smokers as cessation or harm reduction tools without FDA approval. We examined smoking cessation methods of current and former smokers, EC use with nicotine, perceived influence on craving, and attitude toward continued use of EC.

Participants: Nationally representative 2015 cross-sectional survey of U.S. adults. Respondents were current (n=1,280) and former smokers (n=341; within five years of quitting cigarette use).

Methods: Main exposure was EC use to substitute for or complement cigarettes. Outcome measures were weighted adjusted odds ratios (AOR) for successful quitting based on reported smoking status.

Results: The most commonly reported method to quit smoking was gradually reducing cigarettes among current smokers (64%) and completely giving up cigarettes among former smokers (80%). Respondents who reported having tried switching completely to EC while trying to quit were more likely to report having a successful quit attempt compared to those who did not [AOR=1.53, 95% confidence interval [CI], 1.07-2.19]. Respondents who had completely switched to EC during their last quit attempt were more likely (AOR=2.81, 95%CI, 1.28-6.15) to report having a successful quit attempt. Compared to respondents who did not use EC as cigarette substitutes, those who did were less likely to report a successful quit attempt (AOR=0.33, 95%CI 0.17-0.64). About 100% of current and 95% of former smokers who used EC daily included nicotine. Almost 35% of current smokers and 80% of former smokers reported that EC helped reduce cigarette cravings. Daily EC users intend to use EC for a long time.

Conclusions: Switching completely to EC may help smokers successfully quit; however, using EC to substitute for some cigarettes was less likely to support quitting. Thus, EC use during quit attempts may have positive and negative effects on population trends in quitting.

PSYCHOLOGICAL FACTORS AMONG COPD PATIENTS: RELATIONS WITH SMOKING STATUS AND COPD SYMPTOM IMPACT

Amanda Mathew, Ph.D., Susan Yount, Ph.D., Allison Rogowski, M.S., Neil Shea, M.D., Ravi Kalhan, M.D., M.S., Brian Hitsman, Ph.D.

Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Chronic obstructive pulmonary disease (COPD) is a tobacco-related disease associated with several comorbid conditions, including elevated rates of depression and anxiety. Psychological factors that commonly underlie nicotine dependence, depression, and anxiety may represent novel treatment targets, but have not yet been examined among COPD patients. We assessed three psychological factors – anxiety sensitivity (AS; fear of anxiety-related sensations), distress intolerance (DI; inability to withstand distressing states), and anhedonia (Anh; diminished sense of pleasure or interest) – in relation to smoking status, COPD symptom impact, and negative response to COPD symptoms.

Methods: We conducted a single-session laboratory assessment with 40 COPD patients (20 current smokers and 20 former smokers). All participants completed self-report measures of psychological factors (Anxiety Sensitivity Index, Distress Intolerance Index, and Snaith-Hamilton Pleasure Scale, respectively), COPD symptom impact (COPD Assessment Scale), response to COPD symptoms (Breathlessness Catastrophizing Scale), and general anxiety and depression symptoms (PROMIS-Depression and Anxiety short forms).

Results: Participants were older adults (66.7 ± 6.8 years; 21 men, 19 women) with moderate levels of COPD symptom impact (CAT score 16.6 ± 6.7). Current vs. former smokers reported higher levels of AS (19.0 vs. 9.9; *p*=.01) and marginally higher levels of DI (16.1 vs. 11.5; *p*=.07). In univariate regression models, AS, DI, and Anh were each associated with greater COPD symptom impact (*β*'s .31-.64; all *p's*β's .36-.67; all *p's*β=.36, *p*=.03) and breathlessness catastrophizing (*β*=.31, *p*=.04) after adjusting for general depression and anxiety symptoms.

Conclusion: Preliminary findings show that AS and DI are higher among current vs. former smokers and all three psychological factors are positively associated with COPD symptom impact and negative response to symptoms. AS showed unique associations with COPD functioning even after adjusting for general depression and anxiety symptoms, perhaps because it specifically indexes risk for negative reactions to bodily sensations such as shortness of breath. AS may be an important target for behavioral interventions to improve symptom burden and quality of life among COPD patients.

RACIAL AND GENDER DIFFERENCES IN SMOKING, SECONDHAND SMOKE AND RELATED FACTORS FROM THE 2009 CALIFORNIA HEALTH INTERVIEW SURVEY

Katrina Obieta, MPH(c), Hee-Soon Juon, PhD

Thomas Jefferson University, Philadelphia, PA

Background: Lung cancer is the number one cause of cancer-related death in the U.S. and worldwide. Overall lung cancer incidence and mortality rates have decreased for all races over the past 20 years, however, racial differences still persist. When looking at smoking rates by race, Asians and Hispanics have the lowest prevalence of smoking. The data is consistent in that Asians and Hispanics also have the lowest lung cancer incidence and mortality rates. When these racial groups are further divided by ethnic subgroups, however, there are large disparities in trends for lung cancer between subgroups. Particularly, large disparities persist in Asian American ethnic groups. The purpose of this study is to examine the prevalence of current smokers and secondhand smoke by race, Asian American ethnicity, and gender. The study also examines the risk factors for smoking.

Methods: We used data from the 2009 California Health Interview Survey (CHIS) and performed univariate analysis to examine racial/ethnic and gender differences in prevalence of current smokers as well as racial differences in prevalence of secondhand smoke exposure. We also looked at related factors for smoking among residents of California. A multivariate logistic regression model was conducted with weighted analyses using svy from STATA version 13.

Results: Among 47,614 California adults, the prevalence of current smokers was 13.57% (95% CI 12.83-14.34%). American Indian / Native American (26.64% 95% CI 18.61-36.58) and African Americans (16.22%, 95% CI 13.55-19.3%) had the highest rate of current smoking while Asian Americans had the lowest among all races (10.58%, 95% CI 8.45-13.17%). When Asian Americans are disaggregated, however, rates of prevalence are different among subgroups. Among Asian Americans, Vietnamese (30.96%, 95% CI 16.1-51.17), Korean (20.37%, 95% CI 9.13-39.42%), and Filipino (19.35%, 95% CI 12.13-29.42%) men and highest prevalence rates for current smokers. In Asian American women, Korean (19.74%, 95% CI 10.26-34.6%) have the highest prevalence of smokers. Asians had the highest prevalence of secondhand smoke exposure (10.39%, 95% CI 8.12-13.19%), measured by whether or not smoking was allowed in the home, of all the races. In multivariate analysis, factors associated with current smoking were acculturation, gender, age, general health perception, marital status, education, and alcohol consumption.

Conclusion: Results dispel the notion that Asian Americans are not high risk groups ideal for intervention programs. This has a significant implication in increasing awareness of lung cancer screening since lung cancer screening rates are low in Asian Americans despite high smoking prevalence in certain ethnic groups. Moreover, the study shows that both men and women in specific Asian American groups can greatly benefit from culturally integrated cessation programs.

SUPPORTING SMOKERS WHO ARE NOT PREPARED TO QUIT PERMANENTLY: PRACTICE QUIT AND DAILY CHALLENGES TEXT MESSAGING PROGRAMS PILOT

Kisha I. Coa, PhD, MPH[1], Amy Sanders, M.A.[1], Jessica Havlak, BA, MPH Candidate[2], Tessa Heydinger, BS [3], Augustson Erik, PhD, MPH[4], Meredith Grady, MPH[4]

[1]ICF International, Rockville, MD; [2]ICF, Rockville, MD; [3]ICF International, Coronado, CA; [4]National Cancer Institute, Rockville, MD

Background: Observations from research and clinical settings indicate that the challenges of successfully sustaining cessation often leave smokers discouraged, demotivated, and ambivalent about trying again, leading to long lags between attempts. These ambivalent smokers are typically not the target of smoking cessation programs which often build the intervention around a selected quit date. Such smokers may benefit from interventions that provide motivational enhancement and skills training without the need to commit to long term cessation. The current project is a preliminary analysis of two text messaging programs designed to engage and support smokers not yet ready to make a sustained quit attempt.

Programs: *Practice Quit* (PQ) supports smokers through a time-limited (1, 3, or 5 day) quit attempt. *Daily Challenges* (DC) is designed for smokers who are not ready to quit for a full day and includes texts that suggest one cessation-related activity (e.g., resist a craving for 10 minutes) each day for 7 days. Both programs include texts which provide skills training and values clarification.

Methods: 760 users enrolled in the programs between April and June 2016. Program data were available for all users, and descriptive analysis were calculated.

Results: Users were primarily female (74.6%), daily smokers (95.7%), and a mean age of 37.3 years. Most users (71.6%) selected the DC program. Of those who selected the PQ program, the 5-day option was chosen most frequently. Dropout rates were relatively low (15.9% of users). At the end of each program attempt, users were given the option to complete another attempt, and 24.7% of users chose to complete more than one attempt. There was some indication of passive disengagement evidenced by declining response rates to program assessment questions over time. 42.7% (day 1) to 8.3% (day 7) of users responded to the daily text indicating whether they completed the daily challenge (DC), and 38.1% (day 1) to 8.7% (day 5) responded to the daily text indicating whether they had smoked (PQ).

Conclusions: The results of this pilot study have established feasibility and user interest in these programs. User data also identified areas for enhancements to improve the resources before a larger scale evaluation is launched. If successful, this type of approach may have significant value for broadening the reach and engagement of cessation interventions.

THE CLINICAL UTILITY OF DEPRESSION AND WEIGHT-RELATED SUBTYPES AMONG WEIGHT-CONCERNED WOMEN SMOKERS

Rachel H. Salk, PhD[1], Rachel P. Kolko, PhD[2], Lisa J. Germeroth, PhD[3], Rebecca Emery, MS[3], Michele D. Levine, PhD[4]

[1]University of Pittsburgh Medical Center, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]University of Pittsburgh, Pittsburgh, PA; [4]University Of Pittsburgh, Pittsburgh, PA

Weight concerns and depression symptoms are barriers to quitting smoking among women. Weight-concerned and depressed women smokers are more likely to drop out of treatment and have poorer cessation outcomes in treatment. However, extant research has not examined subtypes of women who may have different symptom profiles that are amenable to more specialized intervention. Thus, we aimed to examine whether a group-based analysis could meaningfully capture individual differences on symptom measures of depression, body esteem, and eating behaviors, and demonstrate clinical utility.

Weight-concerned women (*N* = 349; 86% white) received smoking cessation counseling and were randomized in a double-blind, placebo-controlled trial to one of two adjunctive counseling components and one of two medication conditions. At baseline, women completed measures of depression, body esteem, and eating behaviors (restraint and disinhibition). Women also completed measures to assess BMI, nicotine dependence, number of cigarettes smoked per day, age, and education. Latent profile analysis (LPA) was used to identify subtypes of weight-concerned women smokers based on dimensions of depression, body esteem, and eating behaviors. ANOVA was used to characterize baseline differences among identified subtypes.

Results supported a three-profile model: LP1 (14% of the sample; high depression and restraint, low body esteem), LP2 (35%; moderate on all measures), and LP3 (51%; low depression, high body esteem and disinhibition). Entropy for the model was .79 and average latent class probabilities ranged from 90% to 91%. Groups did not differ on age, education, or nicotine dependence. All groups differed significantly on BMI: LP1 (*M*= 30.55); LP2 = (*M* = 24.75), and LP3 (*M* = 28.21). Groups also differed on number of cigarettes smoked per day, with women in LP1 smoking significantly more cigarettes (*M* = 24.14) than the other two groups: LP2 (*M* = 19.67) and LP3 (*M* = 20.47).

Among weight-concerned women smokers, heterogeneity in the symptom presentation of depression, body esteem, and eating behaviors was captured by three distinct groups. These groups demonstrated clinical utility, as the “high-risk” group (14% of the sample) consisted of obese women who smoked over a pack of cigarettes a day. These women may need more specialized, intensive intervention. Thus, identifying groups with distinct symptom profiles can lead to more personalized medicine strategies to improve smoking cessation outcomes among women.

THE INTERACTION BETWEEN DEPRESSION AND SOCIAL ANXIETY AS A PREDICTOR OF MOTIVATION AND CONFIDENCE TO QUIT SMOKING

Hannah L. Shoemaker, B.S. , Jennifer Dahne, PhD, Bryan Heckman, PhD, Matthew Carpenter, PhD

Medical University of South Carolina, Charleston, SC

Background: Smokers with elevated depressive symptoms are at heightened risk for poor cessation outcomes, including a decreased likelihood of initiating a quit attempt and an increased likelihood of relapsing. Social anxiety (SA) is highly comorbid with depression and may convey singular or iterative risks for poor cessation outcomes. Despite this comorbidity, little is known about the interaction between depression and SA for predicting cessation-related outcomes. Both motivation to quit (or to remain quit after initiating an attempt) and confidence to quit (or remain quit) are robust predictors of sustained cessation. Thus, the present study examined the interaction between depression and SA as predictors of motivation to quit/remain quit (MTQ) and confidence to quit/remain quit (CTQ).

Methods: Participants included 543 smokers (28% female, 76% white, Age M(SD)=34.4 (8.7) recruited nationally for an online survey who either recently quit (n=242) or planned to quit in the next month (n=301). Depression was assessed via the Patient Health Questionnaire-8, SA was assessed via the Social Phobia Inventory, CTQ and MTQ were assessed via contemplation ladders (0-10) and nicotine dependence was assessed using the Heaviness of Smoking Index.

Results: Moderation analyses were performed using PROCESS bootstrapping procedures (10,000 samples). Covariates included nicotine dependence and group (current smoker, recent quitter). For MTQ, there were significant main effects of depression (b = -0.04, SE = 0.02, $p = 0.03$) and of SA (b = -0.07, SE = 0.03, $p = 0.03$), though the interaction between the two was not significant. For CTQ, there was a significant interaction between depression and SA (b = -0.02, SE = 0.01, $p < 0.001$), which was then probed at high and low levels of SA. Depression significantly predicted CTQ at both high (b = -0.25, SE = 0.03, $p < 0.001$) and low (b = -0.12, SE = 0.03, $p < 0.001$) levels of SA. The negative relationship between depression and CTQ was stronger for those with high levels of SA than those with low levels of SA.

Conclusions: Results highlight the importance of symptoms of depression and SA for predicting MTQ and CTQ. Depressed smokers and socially anxious smokers may be at heightened risk for low MTQ. In contrast, smokers who experience both elevated depressive symptoms and SA may be at comparatively higher risk for low CTQ than depressed smokers without SA. Thus, to promote sustained cessation, interventions should consider targeting both symptoms simultaneously.

UNDERSTANDING ADULT HOOKAH SMOKING THROUGH PATTERN IDENTIFICATION, 2016.

Haneen S. Abudayyeh, MPH[1], Allison M. Glasser, MPH[1], Amanda L. Johnson, MHS[1], Amy M. Cohn, PhD[1], Theodore L. Wagener, PhD[2], Jessica M. Rath, PhD, MPH, CHES[3], Andrea C. Villanti, PhD, MPH, CHES[1]

[1]Schroeder Institute at Truth Initiative, Washington, DC; [2]University of Oklahoma Health Sciences Center, Oklahoma City, OK; [3]Truth Initiative, Washington, DC

Introduction: The prevalence of hookah use has been increasing in U.S. adults; however, little is known regarding correlates and patterns of hookah use in this population. The current study examines correlates and the frequency of different patterns of hookah use in a national sample of U.S. adults.

Methods: Data were drawn from Wave 10 (November 2016) respondents aged 18–44 years from the Truth Initiative Young Adult Cohort Study (n =4,091). Respondents were asked about past hookah use; those who reported someday or everyday use were queried about number of days used in the past 30 days and if they had ever or currently used hookah regularly (i.e., at least once a week, for at least a month). Weighted bivariate analyses were used to estimate correlates and frequency of ever and past 30–day hookah use, and differences between current and non-current ever hookah users on past 30-day alcohol, marijuana, drug use, and use of other tobacco products.

Results: Of the 21% of the sample who had ever used hookah, 9% used hookah in the past 30 days. Ever hookah users were significantly more likely than never users to report alcohol, marijuana, and other drug use in the past 30 days ($p < 0.005$). Additionally, respondents who had ever used hookah were significantly more likely to report past 30-day use of any other tobacco product and e-cigarettes than those who had never used hookah ($p < 0.01$).

Compared to non-current ever hookah users, past 30-day users were also more likely to have used other tobacco products and e-cigarettes (p’s < 0.01). Few ever hookah users (8%) reported having used hookah “regularly”, while 36% of past 30-day users reported “regular” use ($p < 0.0005$). Forty percent of ever hookah users described themselves as presently using hookah “regularly”; this was also higher in past 30-day users than in ever users (68.0% vs. 6.8%, $p < 0.001$). The majority (68%) of past 30-day users reported hookah use on fewer than five of the past 30 days and 42% engaged in a single hookah session on those days.

Conclusions: Ever and past 30-day hookah use is significantly associated with concurrent tobacco, e-cigarette, and substance use. While most ever hookah users did not report frequent (> 5 days/month) hookah use, past 30-day users describe themselves as regular users more often than ever hookah users do. This suggests a difference in patterns of use and uptake between potential experimenters and regular users. Identifying ways to curb regular or weekly use may be one method to counteract the progression from experimentation to regular use.

B305 6:00 PM-7:00 PM

WHEN LESS IS MORE: SUPPORTIVE POSTPARTUM SMOKING RELAPSE PREVENTION IS MORE EFFECTIVE AND LESS COSTLY THAN AN ENHANCED VERSION

Rachel P. Kolko, PhD[1], Rebecca Emery, MS[2], Jennifer Grace, MS[3], Andrea Kass, PhD[4], Rachel H. Salk, PhD[3], Lisa J. Germeroth, PhD[2], Yu Cheng, PhD[2], Michele D. Levine, PhD[5]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]University of Pittsburgh Medical Center, Pittsburgh, PA; [4]The University of Chicago, Chicago, IL; [5]University Of Pittsburgh, Pittsburgh, PA

Postpartum smoking is linked to deleterious outcomes for women and their infants, leading to increased health care costs for individuals and society. Behavioral interventions for smoking are effective but can be costly to implement; therefore, it is beneficial to understand costs to achieve efficacy for behavioral interventions, given the implications for adoption of services. We aimed to assess the incremental cost-effectiveness of two empirically-based interventions designed to increase rates of sustained postpartum smoking abstinence among women who quit smoking during pregnancy.

Women (*N*=300) were randomized to an intervention condition prior to delivery and received treatment through 24-weeks postpartum. We compared two interventions (matched for time and attention) that were adapted for the postpartum period and addressed behavioral smoking relapse prevention. One intervention comprised an enhanced cognitive-behavioral intervention with additional specialized focus on women's postpartum concerns about mood, stress, and weight (STARTS).The other intervention involved a supportive behavioral intervention (SUPPORT). Biochemically confirmed smoking abstinence was assessed at 52-weeks postpartum. Costs to deliver the interventions from the payer, participant, and societal (payer + participant) perspectives were calculated for each intervention. The incremental cost effectiveness ratio (ICER) was derived to compare the interventions on the resources required (i.e., dollars) to obtain a unit of effectiveness (i.e., % achieving abstinence).

By 52-weeks postpartum, 21% and 27% of STARTS and SUPPORT participants, respectively, demonstrated abstinence (p=.28, number needed to treat=16.67). From the societal perspective, the mean cost per participant for STARTS was $971 (payer=$909, participant=$63) and for SUPPORT was $837 (payer=$760, participant=$77). Compared to STARTS, SUPPORT was dominant, meaning it was less costly and more efficacious (ICER=-$22.39 per % achieving abstinence).

Results show that SUPPORT yielded similar rates of smoking abstinence in postpartum women and was less costly than the more intensive STARTS intervention, suggesting SUPPORT may be well suited for dissemination. These results have clinical and policy implications for intervening in the postpartum period, as there is great importance in helping women to increase rates of sustained abstinence from smoking via interventions that reduce implementation costs while optimizing impact.

Poster Session B 6:00 PM-7:00 PM

COMPARING CHANGES TO HEDONIC HUNGER FOLLOWING A SURGICAL AND NON-SURGICAL WEIGHT LOSS INTERVENTION

Win Guan, PhD[1], Valerie H. Myers, PhD[2], Melissa N. Harris, MPH[1], Phillip Brantley, PhD[1], Robbie Beyl, PhD[1], Robert L. Newton, Jr., PhD[1]

[1]Pennington Biomedical Research Center, Baton Rouge, LA; [2]Klein Buendel, Inc., Golden, CO

Hedonic hunger is defined as a subjective state of hunger that is “prompted by exposure to food-related cues but by definition they do not occur in response to prolonged food deprivation." Previous research has shown a decrease in hedonic hunger following both bariatric surgery and non-surgical behavioral interventions. However, no research has directly compared changes to hedonic hunger for surgical and non-surgical interventions. The current study aimed to compare changes in hedonic hunger at 6 months, 1 year, and 2 years following bariatric surgery (N=148) and a non-surgical intensive medical intervention (N=180). Data utilized in this study come from an observational study (Heads Up) of obese participants undergoing either bariatric surgery (gastric banding, bypass or sleeve) or a non-surgical intensive medical intervention (IMI) composed of a liquid diet and behavior therapy to promote calorie restriction and increased physical activity). Participants completed the Power of Food (PFS) scale at baseline, 6 months, 1 year, and 2 years following intervention. A mixed effects regression model was utilized to estimate changes to hedonic hunger after adjusting for age, sex, race, and baseline BMI. Hedonic hunger decreased dramatically 6 months following both bariatric surgery and IMI. This decrease was significantly stronger for the surgical group compared to the IMI group but only for the aggregate PFS score and not for the subscale PFS scores. The change in Hedonic Hunger plateaued between 6 months and 1 year for both groups. However, hedonic hunger for participants in the IMI group slightly increased toward baseline levels 2 years following intervention while the decreased level of hedonic hunger for surgical patients was sustained. The findings in this study demonstrate 1) a greater initial decrease to hedonic hunger following bariatric surgery compared to a behavioral intervention and 2) sustained low levels of hedonic hunger for surgical patients compared to behavioral intervention participants. Further research will be analyzed to assess the implications of these findings for weight loss maintenance following surgical and behavioral interventions.

Symposium 38 8:00 AM-9:15 AM

COMMUNICATING UNCERTAIN CANCER INFORMATION IN THE ERA OF PRECISION MEDICINE

Emily B. Peterson, PhD[1], Paul K.J. Han, MD, MA, MPH[2], Kimberly Kaphingst, ScD[3], Wen-Ying Sylvia Chou, PhD, MPH[4], Jennifer Elston. Lafata, PhD[5]

[1]National Cancer Institute, Rockville, MD; [2]Maine Medical Center Research Institute, Portland, ME; [3]University of Utah and Huntsman Cancer Institute, Salt Lake City, UT; [4]Behavioral Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, Bethesda, MD; [5]Linieberger Comprehensive Cancer Center and Eshelman School of Pharmacy, The University of North Carolina at Chapel Hill, Chapel Hill, NC

Communication about cancer-related risk occurs frequently in clinical interactions across the cancer control continuum – from prevention, diagnosis, treatment, to end-of-life. These conversations inevitably contain uncertain and sometimes conflicting or confusing information. For example, consider a primary care provider recommending a mammography screening test, a genetic counselor reviewing the return of genetic testing results, and an oncologist discussing prognosis and treatment options: they must all navigate these discussions with the intent to facilitate informed decision making, despite the fact that the information they are communicating often contains caveats or may not be actionable. Evolving national/clinical guidelines and the emphasis on personalized risk factors, rapid advances in cancer treatment, and the promises behind the “Precision Medicine” movement in cancer suggest that communication about these issues will only continue to grow more complex and uncertain.

Our proposed symposium will highlight key research about this communication challenge with an overarching goal of developing a broad framework to understand communication about uncertain information in various cancer-related contexts. The panelists represent cutting-edge science in clinical communication about uncertain or complex information in three distinct but related domains, including cancer screening recommendations, genetic testing, and prognosis and goals of treatment for patients diagnosed with advanced cancer. The symposium will 1) review theories, frameworks and approaches that have been applied to communication about uncertain information; 2) identify research priorities in cancer communication in the era of Precision Medicine; 3) consider implications for health disparities. After individual presentations on diverse contexts of risk communication, ample time will be allotted for a discussion to unite the common characteristics of these areas and discuss the overarching implications of communicating complex and uncertain cancer information.

The learning objectives of this symposium are: 1) Understand the role of communicating about uncertain information on patient decision making and behavior; 2) Discuss current priorities and challenges in communicating complex information with leading experts; 3) Gain a broader understanding of issues related to communication about uncertain information that transcends a specific context or research area.

Symposium 38A

UNCERTAINTY IN THE COMMUNICATION OF GENETIC AND GENOMIC INFORMATION

Kimberly Kaphingst, ScD

Many types of uncertainty are embedded within genetic risk information, including uncertainty about penetrance (whether a gene variant will be expressed in an individual), clinical validity (strength of association between a gene variant and disease or condition) and clinical utility or implications for patient management. As exome and genome sequencing become more common in the clinical setting, more variants with uncertain clinical validity and utility and penetrance are being identified for each patient, raising the issues of what of this uncertain and complex information to return to patients and how. This presentation will first address these issues by presenting results from a case study. The case study was a survey of 1080 women diagnosed with breast cancer at age 40 or younger. The survey focused on preferences for the communication of secondary findings from whole genome sequencing, that is, findings not directly related to the breast cancer indication but that might still be of value to patients. The survey findings showed that women ranked their interest in results with more uncertain clinical implications (e.g., variants of uncertain significance) lower than their interest in sequencing results with clearer clinical implications (e.g., results with implications for prevention or medications). When asked about their preferences for timing of the delivery of results for variants of uncertain significance, about as many women never wanted to receive this information (32%) as women who wanted the information at or before the time of diagnosis with breast cancer (35%). Significant predictors of wanting to receive this type of uncertain result by the time of diagnosis included having less knowledge about the limitations of genome sequencing (OR = 0.93; 95% CI=0.86, 0.99) and being more health conscious (OR=1.35; 95% CI= 1.03, 1.77). The results from this case study will be discussed in the context of a scoping review of communication of genetic and genomic risk information across the cancer control continuum based on frameworks of uncertainty management and risk information processing. The presentation will summarize the current state of this science and discuss future directions for investigating uncertainty in the communication of genetic and genomic information.

Symposium 38B

COMMUNICATION ABOUT PROGNOSIS AND GOALS OF CARE IN ADVANCED CANCER CARE

Dr. Wen-Ying Sylvia Chou, PhD, MPH

One of the major challenges in caring for patients diagnosed with advanced or recurrent cancer concerns making decision about optimal treatment and care. One component of this challenge is that there are significant misalignments between providers and patients with regard to their understanding of prognosis (Prigerson et al. 2016, Gramling et al. 2016). This misalignment occurs in the context of well-publicized advances in cancer science which suggest the likelihood of life-prolonging treatment and which may lead patients to overestimate their chances of survival. There are numerous challenges in communicating prognosis, and the inevitable uncertainty associated with a patient's prognosis further complicated the clinical communication. Understanding and improving patient-provider communication about uncertainty when discussing prognosis and goals of care should be an urgent priority for cancer clinical practice.

This presentation describes two qualitative studies centered around the communication of prognosis in the context of advanced cancer. The first is a qualitative discourse analysis of transcripts of oncologist-patient conversations, in which dominant linguistic features in oncologists' language are identified. For instance, oncologists are frequently observed to use euphemisms, optimistic expressions, and ambiguous language in discussing the status of the disease and goals of treatment. Such expressions contribute to the limited and vague discussions of prognosis and the sense of uncertainty in patients. The second study, based on key informant interviews (N=19) members of multidisciplinary teams caring for patients enrolled in cancer clinical trials, describes the diverse range of perspectives on goals of patient care. The study findings highlight the need for communicating and managing uncertainty in caring for patients on cancer clinical trials, particularly in balancing patient's clinical goals with research goals. The presentation concludes with a summary of the current state of science and relevant theories in prognosis communication in cancer, with a focus on how to consider and manage uncertainty in caring for patients with advanced cancer.

Symposium 38C

UNSPOKEN RISK AND UNCERTAINTY: THE CASE OF CANCER SCREENING

Jennifer Elston. Lafata, PhD

Recent studies highlight the risk and uncertainties associated with common cancer screening tests, including screening mammography, prostate specific antigen (PSA), and low dose computed tomography (LDCT). Despite known risks and uncertainties, the US population remains enthusiastic about cancer screening in general, and many patients and physicians fail to understand the risk of overdiagnosis and other uncertainties related to cancer screening. Given the importance of physician recommendation to cancer screening use, particularly troubling is the void in risk and uncertainty discussion at the time of most physician recommendations for screening. As our understanding of the balance of screening risks and benefits increases, and as cancer screening capabilities are enhanced via genomics and other medical advances, cancer screening decisions are likely to become more complex and personalized.

Using data from audio-recorded primary care office visits joined with pre-visit patient survey data (N=415) and a national survey of primary care physicians (PCPs) (N=278), we highlight current challenges to supporting informed decision making in primary care. For example, while 86% of patients reported understanding testing pros and cons as important to their cancer screening decisions, only 5% of colorectal cancer screening conversations included any mention of a screening con, and only two patients explicitly asked a question about screening risks during the consultation. The presentation will describe when and how uncertainty was communicated when these risk conversations did occur. Furthermore, PCPs are more likely to report a discussion of cancer screening benefits than they are a discussion of cancer screening risks (79% vs, 64%, respectively). Likewise, PCPs are more likely to report that shared decision making is important in cancer screening contexts where there are less uncertainties (i.e., relatively more evidence that benefits of screening outweigh harms as determined by the US Preventive Services Task Force) compared to those where there is a high degree of uncertainty or when expected balance of harms and benefits is similar. Combined, these findings suggest that PCPs may view shared decision making as a tool to help convince patients to adhere to recommended screening, and not as a means to provide balanced information, including uncertain information, to patients. Ultimately, the lack of uncertainty discussions surrounding screening tests may lead to patient misunderstanding and unnecessary testing. Using these and other findings, an ecological framework for the challenges of discussing risk and uncertainty in the context of cancer screening will be presented, and the multi-levels of intervention needed for the inclusion of risk and uncertainty within cancer screening discussions highlighted.

Symposium 39 8:00 AM-9:15 AM

EXPANDING THE HORIZONS OF BEHAVIORAL MEDICINE WITH QUALITATIVE AND MIXED-METHODS RESEARCH: VOICES OF DIVERSE CANCER PATIENTS

Tess Thompson, PhD, MPH[1], Lailea Noel, PhD[2], Tess Thompson, PhD, MPH[1], Kristi Graves, PhD[3], Krystal Warmoth, PhD[4], Qian Lu, Ph.D.[4]

[1]Washington University in St. Louis, Webster Groves, MO; [2]New York University, New York, NY; [3]Georgetown University, Washinton, DC; [4]University of Houston, Houston, TX

Breast cancer is the most commonly diagnosed non-skin cancer among African American, Latina, and Asian American women. This symposium examines how qualitative and mixed-methods research can allow researchers to better understand the experiences of diverse breast cancer patients in order to inform interventions, enhance treatment, and reduce health disparities. The four presenters will describe their approaches to qualitative and mixed-methods research and incorporate cross-cutting perspectives from disciplines including medicine, public health, and social work.

The first presenter will share data from a phenomenological study of the lived experience of African American women from a socially and economically isolated urban environment who delayed initiation of breast cancer treatment for more than six months after identification of a breast abnormality. This presenter will discuss how phenomenological qualitative methodology allows for rich, in-depth data to emerge about this vulnerable group of women. The second presenter will examine how face-to-face qualitative interviews were used to delve more deeply into specific themes with a subsample of participants from a randomized, controlled trial of a video narrative intervention. In this study, married African American breast cancer survivors described how they perceived cancer to have affected their social support, their marital relationship, and their spouse’s physical and mental health. The third presenter will describe the social needs and challenges of Chinese American immigrant breast cancer survivors based on an analysis of expressive writing from three writing sessions. The final presenter will discuss mixed-methods results from a study of Latina breast cancer survivors in which qualitative approaches were used to help design an intervention that was tested in a randomized controlled trial, collect evaluation information about the intervention, and measure the study team’s engagement with the intervention.

Based on these four presentations, we will discuss the challenges and rewards of using qualitative and mixed-methods techniques in diverse populations. We will address rationales for using qualitative methods, techniques for ensuring methodological rigor, and ways of communicating qualitative findings. The goal is to deepen researchers' and clinicians' understanding of the experiences of diverse breast cancer patients in order to support patients through diagnosis, treatment, and survivorship.

Symposium 39A

EXPLORING PARTICIPATORY HEALTH DECISION MAKING AND BREAST CANCER TREATMENT INITIATION FOR MEDICALLY MARGINALIZED WOMEN

Lailea Noel, PhD

African American women have a 42% higher mortality rate from breast cancer than White women. While there are many factors contributing to this disparity, the timely initiation of treatment is growing area of interest. An under-explored area of attention for scientific studies is how to identify and engage in care women who do not follow up with treatment following a breast abnormality. Often these are among the most medically marginalized women of our society who have some of the highest rates of mortality. This study explored the lived experience of eight African American women, living in a socially and economically isolated environment in a large metropolitan area. In all cases the initiation of treatment was delayed for more than six months from the identification of a breast abnormality, with a delay in the initiation of treatment of more than a year in four of the eight examples. In accordance with phenomenological qualitative methodology, the interviews were open-ended, allowing for rich, in-depth data to emerge relatively unbiased by the assumptions and expectations of the researcher. Key findings suggest that engaging patients in health care decision making necessitates a better understanding of the processes involved in treating breast cancer, the impact that the side-effects may have on her quality of life, and access to patient support services to counter these side-effects. The findings from this study highlight that most of the communication about treatment initiation occurred at the primary care level, prior to initiating contact with oncology services. Furthermore, the context within which they experienced the phenomenon is structured by underlying conceptualizations of chronic traumatic events coupled with community resource deserts. These results indicate that future interventions focused on engaging women in care decisions and decreasing socioeconomic barriers to the initiation of the treatment for breast cancer should take place between primary care providers, oncologists, and their patients and focus on de-mystifying the process of treatment. Incorporating this information, as a type of barrier-focused community-based intervention, or improved case management services to assist cancer patients in the primary care setting, may impact cancer mortality outcomes.

Symposium 39B

“WE’RE IN THIS TOGETHER”: SPOUSAL SOCIAL SUPPORT IN AFRICAN AMERICAN BREAST CANCER PATIENTS

Dr. Tess Thompson, PhD, MPH

Social support provides health benefits both in cancer patients and in the general population. Spouses are often key sources of social support for breast cancer patients, and patients often provide their partners with support as well. Recent research has also shown small but significant effects of a cancer diagnosis on the physical and mental health of spouses of cancer patients. Less is known, however, about how cancer affects relationships in African American couples. This qualitative study examined how married African American breast cancer survivors perceived cancer to have affected their social support, their relationship with their spouse, and their spouse’s physical and mental health. We interviewed a subset of 15 married women who participated in a randomized controlled trial of a culturally tailored cancer communication intervention. We collected demographic data, and participants responded to semi-structured interview questions. Two coders coded interview transcripts independently and then reached consensus on codes in order to conduct a thematic analysis. At the time of interview, participants’ mean (SD) age was 60.2 (7.4) and mean length of marriage was 23.3 (12.4) years. All reported their spouses were African American. Eight had early-stage cancer, 11 received breast-conserving surgery, and 7 received chemotherapy. Eight participants believed their relationships stayed the same or became better after their diagnosis. Five reported marital problems, however, and 3 thought that their cancer had negatively affected their marriage. Most participants were uncertain whether their cancer diagnosis and treatment had affected their husbands’ physical and emotional health, often because husbands did not discuss their reactions to their wives’ cancer. Many participants reported their husbands provided both emotional and tangible support, and several said their husbands helped them adjust to sexual side effects of treatment and changes in body image. Many participants also reported providing support to their husbands, and many believed that clinicians could play an important role in helping couples adapt together to a cancer diagnosis and demands of treatment. Clinicians should take into account patients’ social context and provide referrals for couples with marital difficulties and for patients and partners who would benefit from psychosocial interventions.

Symposium 39C

PATIENT-REPORTED OUTCOMES AMONG LATINA BREAST CANCER SURVIVORS FOLLOWING THE NUEVA VIDA INTERVENTION

Kristi Graves, PhD

Introduction: Few research studies have evaluated evidence-based psychosocial interventions to improve patient-reported outcomes among Latina breast cancer survivors and caregivers. Using strong community-academic partnerships and mixed methods approaches, we sought to examine patient-reported outcomes among a diverse sample of Latina breast cancer survivors following the Nueva Vida Intervention.

Method: We recruited Latina breast cancer survivors and their caregivers through 4 community based-organizations across the U.S. Following feedback from qualitative interviews with survivors and caregivers, we refined the intervention. We then conducted an RCT in which survivor-caregiver dyads were randomized to either an 8-session psychosocial intervention called Nueva Vida or to usual services (e.g., support groups, patient navigation). We completed quantitative assessments at baseline, immediately post-intervention and 6-months post intervention to measure patient-reported outcomes using the Patient Reported Outcomes Measurement Information System (PROMIS). We collected intervention evaluation data using brief exit interviews from study participants and intervention process surveys from interventionists. We measured team engagement using both quantitative and qualitative approaches.

Results: We randomized 135 Latina survivors and their caregivers to the Nueva Vida Intervention (n=70) or usual care (n-65). Latinas were diverse in terms of their country of origin (>80% immigrants) and years in the US. To date, 78 survivors have completed the 6-month follow-up. Compared to survivors in usual care, intervention participants reported statistically and clinically significant lower anxiety (t(75)=2.03, p<.05); trends were noted for less fatigue (p<.10) among intervention participants. Exit interviews with participants indicated a high level of satisfaction with the intervention; interventionists provided feedback on strategies to further tailor the intervention to their specific Latino population. Team members reported consistent and strong engagement through the study period.

Conclusions: Early results from the Nueva Vida Intervention trial indicate the ability to recruit, retain and improve specific patient reported outcomes among a diverse sample of Latina breast cancer survivors. Future efforts to evaluate evidence-based interventions with Latino families facing cancer will benefit from strong community-based partnerships and efforts to ensure cultural and linguistic relevance of the intervention.

Symposium 39D

EXPLORING THE SOCIAL NEEDS AND CHALLENGES OF CHINESE AMERICAN IMMIGRANT BREAST CANCER SURVIVORS

Krystal Warmoth, PhD

Purpose: Little is known about the psychological wellbeing and social barriers among immigrant Chinese American breast cancer survivors. The aim of the present study was to explore the social needs and challenges of Chinese American immigrant breast cancer survivors.

Methods: This study used the expressive writing approach to explore the experiences among 27 Chinese American breast cancer survivors. The participants were recruited through community-based organizations in Southern California, most of whom were diagnosed at Stages I and II (33% and 48% respectively). All the participants had been living in the USA for at least 5 years (on average 19 years). Participants were asked to write three 20-minute essays related to their experience with breast cancer (in 3 weeks). Participants' writings were coded with line-by-line analysis, and categories and themes were generated.

Results: Emotion suppression, self-stigma, and perceived stigma about being a breast cancer survivor were reflected in the writings. Interpersonally, participants indicated their reluctance to disclose cancer diagnosis to family and friends and concerns about fulfilling multiple roles. Some of them also mentioned communication problems with their husbands. Related to life in the USA, participants felt unfamiliar with the health insurance and health care system, and they encountered language barriers.

Conclusions: Counseling services addressing concerns about stigma and communication among family members may benefit patients' adjustments. Tailor-made information in Chinese about diagnosis and treatment for breast cancer and health insurance in the USA, may also help patients go through the course of recovery.

Symposium 40 8:00 AM-9:15 AM

USING E-HEALTH COMMUNICATION AND TECHNOLOGY TO REDUCE HEALTH CARE DISPARITIES

Charles R. Jonassaint, PhD, MHS[1], Linda Fleisher, PhD, MPH[2], Betina Yanez, Ph.D.[3]

[1]University of Pittsburgh, Pittsburgh, PA; [2]Children's Hospital of Philadelphia, Philadelphia, PA; [3]Northwestern University Feinberg School of Medicine, Chicago, IL

Racial and ethnic minorities are at an increased risk for poor health, yet receive lesser quality healthcare than their white counterparts. Despite the availability of evidence-based interventions, there are significant disparities in the reach and impact of these treatments for underrepresented minority groups.

Over the past decade, mobile technology ownership and Internet use has drastically increased, particularly among minority groups. The pervasiveness of technology across race, ethnicity and socioeconomic strata has led to excitement surrounding the potential for e-Health to bridge the disparities gap and deliver evidence-based care to underserved, hard-to-reach populations. However, there is limited literature examining the effectiveness of e-Health interventions among minority groups. Further, the majority of available e-Health interventions have not been developed with a focus on reaching underrepresented patients and may ignore the needs and sociocultural barriers faced by racial and ethnic minorities. Tailoring e-Health intervention for racial and ethnic minorities may improve their acceptability, effectiveness and future dissemination.

In this symposium, we first present a systematic review examining the feasibility and efficacy of cancer-related e-Health interventions among racial and ethnic minorities and highlight the needs and barriers to racial and ethnic minorities’ utilization of e-Health technologies. Next, we present data from a large, pragmatic e-Health intervention trial aimed at improving mental health outcomes among a racially diverse group of primary care patients. Finally, we review the process of designing a user-centered intervention to enhance clinical trial participation among African American cancer patients.

Overall, this symposium demonstrates that e-Health interventions have the potential to improve health among underserved groups and bridge the health care disparities gap. However, there are several critical issues to consider regarding the design and implementation of eHealth to ensure these interventions are maximally effective with underrepresented groups. Future e-Health research should adopt user-centered approaches to intervention development that take into account the specific needs of the target population.

Symposium 40A

ACCEPTABILITY AND IMPACT OF COMPUTERIZED COGNITIVE BEHAVIORAL THERAPY FOR DEPRESSED AND ANXIOUS AFRICAN AMERICANS AND WHITES

Dr. Charles R. Jonassaint, PhD, MHS

Background: Access to effective treatment fordepression and anxiety in primary care is often limited, particularly for minority patients who also experience racial disparities in treatment outcomes. Recent trials demonstrate that computerized cognitive behavioral therapy (CCBT) programs may help improve access to treatment. However, it is unclear if these programs are equally acceptable to African Americans (AAs) as Whites, and whether these groups experience comparable benefits. We examined these questions among patients enrolled in our NIMH-funded trial of online collaborative care for mood and anxiety disorders.

Methods: Patients aged 18-75 with current depression, panic and/or generalized anxiety disorder were referred to our trial from 26 Pittsburgh-area primary care practices. We randomized protocol-eligible and consenting patients who reported elevated levels of mood and/or anxiety symptoms (PHQ-9 or GAD-7 ≥10) with Internet access to receive their doctors' usual care or one of two other groups (1-3-3 ratio) that included 6-months of care manager-guided access to the U.S. version of the 8-session "Beating the Blues" CCBT program. Blinded assessor determined PROMIS depression and anxiety outcomes by phone at 6-months follow-up.

Results: Between 8/1/12 and 9/30/14, we randomized 91 AA and 499 White participants to our two CCBT study arms (mean age: 43 years; SD=14; range 18-75). AA patients, compared to Whites, had higher baseline PHQ-9 scores (14.4 vs. 13.1; *p*p=0.08 and 4.7 vs. 5.5; *p*=0.03, respectively). However, AAs showed a greater 6-month decrease in depression (-4.76 vs. -1.73; p=.024) and anxiety symptoms (-5.43 vs. -1.44; p=.083) compared to whites.

Conclusion: Internet-delivered and care manager-guided CCBT is an acceptable and effective means to provide depressed and/or anxious AA patients with access to mental health care at scale and potentially reduce racial disparities in treatment outcomes.

Symposium 40B

BUILDING A BETTER E-HEALTH INTERVENTION: USING FORMATIVE RESEARCH TO GUIDE THE DEVELOPMENT OF AN E-HEALTH COMMUNICATION TOOL

Linda Fleisher, PhD, MPH

Designing salient and relevant e-Health interventions requires target audience insights throughout the development process and using formative research approaches can provide rigor and substance to those insights. Although best practice approaches and current efforts in patient engagement support patient and consumer input, a systematic approach that includes patients' perspectives on the eHealth tool in the concept phase (refining the problem), prototype development and testing and early pilot testing is often not actualized. This presentation will include an overview of formative approaches in e-Health intervention development and case study. *mychoice*, an e-Health tool to increase informed decision about clinical trials for African American cancer patients was developed using a systematic, patient engagement process to ensure that the intervention was relevant, appropriate and addressed the complex and emotional issues related to treatment trials. The formative research included 16 in-depth interviews with African American cancer patients who had and had not participated in clinical trials and a perceptual mapping survey to identify key messages with 41 African American cancer patients. The *mychoice* prototype was then shown to African American cancer patients for additional feedback and user testing. This presentation will provide practical approaches and describe in detail the methods, data collection strategies, recruitment approaches, the application of the formative research and user testing, and patient insights across the development and design of the *mychoice* communication tool.

Symposium 40C

A SYSTEMATIC REVIEW OF E-HEALTH INTERVENTIONS IN ONCOLOGY FOR DIVERSE INDIVIDUALS

Betina Yanez, Ph.D.

Background: The number of e-health interventions in oncology has been increasing over the past decade and research has demonstrated that these interventions are feasible and can yield favorable health outcomes. Although racial/ethnic minority patients are accessing the Internet and using technology devices at equivalent or higher rates of non-minority patients, it is not well documented whether e-health interventions are feasible, acceptable, and efficacious among these groups. Therefore, this systematic review sought to elucidate the use of e-health, oncology-related interventions in diverse populations. **Methods:** Using methods consistent with PRISMA guidelines, we identified 772 articles published between January 2000 and June 2016. Of these, 14 articles met inclusion criteria for this review. **Results:** Of these 14 articles, 86% included African Americans, 13% included Hispanics, and 7% included Asian Americans. Fifty-seven percent of the articles focused on cancer prevention, 29% on cancer control, and 14% on cancer survivorship. All articles evaluated a web-based computer or tablet intervention. Sixty-four percent of the 14 articles reported on the efficacy of the e-health intervention and thirty-six percent of the 14 articles only investigated usability, feasibility, acceptability, and technology use as outcomes. Four e-health interventions showed increased knowledge and cancer screening intentions, but did not increase cancer-screening behaviors relative to a control condition. All 3 of the efficacy studies focusing on cancer control and survivorship revealed a significant, favorable effect of the e-health intervention (e.g., decreased depression, quality of life) when compared to a control condition. The extent to which participants self-selected into, interacted with, and used various components of the interventions varied by race/ethnicity. **Conclusion:** Findings suggest that e-health interventions among minorities are feasible and acceptable. However, findings regarding the efficacy of e-health interventions among racial/ethnic minorities are equivocal, with interventions focusing on cancer control and survivorship demonstrating better efficacy than cancer prevention interventions. Although e-health interventions demonstrate the potential to reduce health disparities, more research is needed to delineate the mechanisms by which researchers can adapt e-health interventions to best serve the distinct needs of racial/ethnic minorities.

Symposium 41 8:00 AM-9:15 AM

MODELS OF INTEGRATING BEHAVIORAL HEALTH SERVICES IN PRIMARY CARE: GOLD STANDARD OR SUBSTANDARD?

Sherri Sheinfeld Gorin, PhD, FSBM[1], Kathryn E. Kanzler, PsyD, ABPP[2], Jürgen Unützer, MD, MPH, MA, BS[3], Rodger Kessler, ABPP[4], Deborah Cohen, PhD[5], Jeffrey Goodie, Ph.D., ABPP[6]

[1]New York Physicians Against Cancer, http://nypac.center/, New York, NY; [2]University of Texas Health San Antonio, San Antonio, TX; [3]University of Washington School of Medicine, Seattle, WA; [4]The University of Vermont, Burlington, VT; [5]Oregon Health and Science University, Portland, OR; [6]Uniformed Services University, Gaithersburg, MD

Most behavioral and mental health care occurs in the primary care setting. Psychosocial issues are involved in approximately 70% of primary care visits, with conditions such as depression among the most common complaints; these symptoms are often comorbid with other chronic diseases such as diabetes. While greater collaboration between behavioral health (including mental health and substance use) and primary care clinicians, as supported in the Affordable Care Act, could mitigate symptom-related negative outcomes for patients, collaborations are few in practice. Further, few of the existing integrated care programs are based on research evidence. The symposium will present major extant models of behavioral health in primary care, and review research and practice-based evidence for their uptake and effectiveness in diverse primary care settings. Presenter 1 will review the findings from RCTs, large-scale implementation trials, and practice evidence for the collaborative care approach. He will describe adaptations of the collaborative care approach for diverse primary care settings and populations, as well as in delivering its core components, for example, by tele-mental health. Presenter 2 will describe ***how*** to integrate behavioral health within the current fragmented health system, with the findings from a mixed methods study of 19 US based primary care practices and community mental health centers. She examines structures, processes, clinical workflows, and the interactional behaviors of primary care and behavioral health clinicians integrating care. Relying on research findings from national implementation trials and national expert panel consensus, Presenter 3 will focus on the gaps in current integration research. He will address the comparative effectiveness of different models and the degree of organizational integration. He will propose a framework for the future of research in integrated primary care settings.

Symposium 41A

MOVING FROM COLLABORATIVE TO STEPPED CARE: EVIDENCE AND TRANSLATION

Dr. Jürgen Unützer, MD, MPH, MA, BS

The evidence is mounting from RCTs and large-scale implementation studies for intervention approaches to caring for individuals with common mental disorders in primary care. The presenter will examine the evidence for collaborative care, an approach in which primary care providers are supported by a behavioral health professional and a psychiatric consultant to treat a population of patients with common mental disorders such as anxiety or depression in primary care settings. The presenter will also review adaptations of core components of the model for diverse primary care settings and populations and variations such as delivering core components of the care using tele-mental health care. Finally, the presenter will discuss the translation of research evidence to practice experience via implementation of evidence-based programs in diverse primary care settings. This presentation will explore barriers and facilitators to implementation from policy, regulatory, and cultural perspectives. Based on the current literature and clinical data, a stepped approach to integrating care will be proposed. A stepped approach to integrating care has the potential to reach and benefit a large number of individuals with common behavioral health challenges (e.g., mental health and substance abuse) in primary care.

Symposium 41B

WHY ARE WE TALKING ABOUT INTEGRATION POLICY WHEN WE DO NOT HAVE COMPELLING INTEGRATION METRICS?

Dr. Rodger Kessler, ABPP

Not much has changed in research and practice since the 2008 AHRQ report (Butler and Kane et al 2008) concluding that we know one effective model of care for treating depression and anxiety in primary care. While, in fact, there are a number of exemplar practices and organizations, we still know little about models of care. The current movement to put integrated practice into policy is premature due to lack of solid data and metrics. We cannot identify the key elements that contribute to positive patient outcomes, nor do we know the appropriate intervention dose(s) for specific patient populations and, at what cost. Further, the prevalent research paradigm does not address between-model comparative effectiveness nor does it address necessary elements or dose(s) of organizational integration. We are further hindered by a proliferation of checklists and data collection tools that have no psychometric validation and thus, no standardized comparative metrics. This presentation will discuss the findings from national and local trials and national expert panels to identify research gaps and to suggest a framework that will allow us to move past Butler and Kanes' observed limitations into the future.

Symposium 41C

FITTING THE INTEGRATION APPROACH TO THE LOCAL PRACTICE CONTEXT

Dr. Deborah Cohen, PhD

Compelling research evidence, provider and patient needs are driving the integration of health care. What is urgently needed now is empirical data on ***how*** to integrate physical, behavioral, emotional, and substance use care (hereafter referred to as behavioral health) within the current fragmented health system. We studied 19 US based primary care practices and community mental health centers that varied with respect to type, size, ownership, and location. Using mixed methods, including direct observation, interviews, surveys, assessment of expenditures, and Reach (e.g., RE-AIM), we comprehensively examined structures, processes, clinical workflows, and the interactional behaviors of primary care and behavioral health clinicians integrating care. We also evaluated the impact of practice integration efforts on expenditures to implement innovations, Reach, and patient outcomes. Our findings show that 5 key organizing constructs (integration REACH, establishing care pathways for a range of patient illness, approaches to patient transitions, location of workforce, and mental model for integration) intertwine to produce locally adapted approaches to integrating care. We observed significant decreases in adjusted mean PHQ-9 among patients. This finding was corroborated by accounts of patients’ experience of care, where they reported the benefits of receiving integrated care such as acquiring skills to cope with adverse situations. Additionally, we show that average start-up and ongoing effort expenses for integrating care are non-trivial. These results, together with a robust body of evidence from RCTs, makes a compelling case for practices to adopt integrated care and for payers to make this model feasible through finance reform.

Symposium 42 8:00 AM-9:15 AM

LEVERAGING TECHNOLOGY TO SUPPORT VULNERABLE AND DISADVANTAGED PEOPLE WITH DIABETES: A REVIEW, EXAMPLES, AND RECOMMENDATIONS

Lindsay S. Mayberry, MS, PhD[1], Courney R. Lyles, PhD[2], Monica E. Peek, MD, MPH, MSc[3], Brian Oldenburg, BSc, MPsychol, PhD[4], Chandra Y. Osborn, PhD, MPH[5]

[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California San Francisco, San Fransisco, CA; [3]University of Chicago, Chicago, IL; [4]The University of Melbourne, Melbourne, Victoria, Australia; [5]Informed Data Systems Inc., Nashville, TN

Technologies are being used to engage, educate, and support people with self-care. Hard-to-reach, low-income, less-educated, and/or racial/ethnic minorities who are often more affected by chronic health conditions, and, once diagnosed, experience more difficulty w/self-management, creating a cascade of costly health problems. Mobile self-care support can reach a wide audience, including the underserved. However, rigorous and novel methods are needed to design and evaluate mobile self-care support among vulnerable populations. A combination of limited access to certain types of devices (smartphones, smartwatches), unique barriers to self-care, and low engagement with self-care support are common among disadvantaged groups. These and other factors should be identified and addressed in the design, development, implementation and evaluation of mobile self-care support for vulnerable populations. This symposium will therefore provide:

- A case study of adapting tablet-collected patient experience data among persons with low-literacy
- An overview of a hybrid implementation-effectiveness approach to evaluating two mobile health (mHealth) interventions in community health clinics
- A review of the literature on internet and mobile interventions to improve diabetes control among disadvantaged and vulnerable people with type 2 diabetes

Each speaker will provide recommendations for improving the design and evaluation of technology-delivered tools for disadvantaged and vulnerable populations with diabetes.

Symposium 42A

BUILDING SUSTAINABILITY ALONGSIDE EVIDENCE FOR MOBILE HEALTH INTERVENTIONS IN UNDERSERVED PATIENTS

Dr. Lindsay S. Mayberry, MS, PhD

Background: Technology-based interventions are challenging among underserved patients and must reach end-users quickly to remain relevant and for evidence-based health technologies to keep pace with marketed ones. We used community engagement and iterative mixed-methods to understand and overcome implementation barriers throughout the design and evaluation of two diabetes support mHealth interventions in underserved populations.

Methods: The REACH study examines the effectiveness of two mHealth for improving self-care and glycemic control among adults with type 2 diabetes (T2D) receiving care from Federally Qualified Health Centers (FQHCs) in Nashville, Tennessee. The two interventions evaluated are REACH, a tailored, theory-based text messaging intervention, and FAMS, a family-focused intervention which incorporates phone coaching and text messages to a support person (e.g., friend or family member).We employed community-based strategies to develop a sustainable and implementable intervention: a) eliciting and incorporating input from FQHCs and patients before the evaluative trial to inform the content and form of the interventions; b) sustaining FQHC engagement throughout the trial; c) expanding to new clinics at each stage; and d) gathering information about barriers and facilitators to implementation at each stage.

Results: Through iterative mixed-methods (from intervention conception, pilot, refinement, usability/feasibility testing) we made intervention design decisions (eg, using resources patients and clinics already have; automating text messaging for minimal time, financial, or personnel costs) and trial design decisions (eg, an active control; not providing or paying for participants' cellphones/plans, allowing participants to self-tailor the intervention) to enhance clinic engagement and intervention sustainability. During the trial, we maintain community partnerships via clinic/community events and quarterly study newsletters tailored for patients and, separately, clinic staff. By expanding from two clinics (formative research and piloting) to four clinics (usability/feasibility testing) to seventeen clinics (for the trial), we created intervention elements likely to be preservable across settings. To sustain engagement and momentum generated by the initiation of the evaluative trial, we will conduct rolling focus groups with FQHC providers and administrators and participants completing the trial to discuss barriers and facilitators to sustainability should REACH and/or FAMS prove effective.

Conclusion: This presentation will discuss design decisions and provide a clear example of a hybrid effectiveness-implementation approach to mHealth among disadvantaged patients.

Symposium 42B

IN-DEPTH CASE STUDY OF ADAPTING PATIENT EXPERIENCE DATA COLLECTION FOR DIVERSE PATIENTS USING TABLETS IN CLINIC

Courney R. Lyles, PhD

Background: Healthcare policy supports the inclusion of patient experience in quality measurement and reporting. However, response rates to the gold-standard, paper-based Consumer Assessment of Healthcare Providers and Systems (CAHPS) surveys are low (<25%), and differ by racial/ethnic and language subgroups.

Methods: We sought to 1) design and implement tablet-based CAHPS administration in safety net clinical practices in the San Francisco Department of Public Health, and 2) conduct formative qualitative work to create shorter, lower literacy patient experience items (informed by CAHPS) and explore broader concepts of patient experience among vulnerable patients. We created a visually attractive, simple-to-use tablet interface with multi-lingual questionnaires. Next, we completed 25 in-depth interviews with patients to validate a new literacy-appropriate tablet questionnaire and compare it to the paper version.

Results: Over 6 months, 400 patients completed tablet-based CAHPS questionnaires in 4 SF clinics. The overall response rate and representation of Latino, Black, and younger respondents was higher for tablet vs. paper-based collection. During the interviews, paper vs. tablet CAHPS versions performed similarly, but patients strongly preferred the tablet – even those without previous experience with using mobile technology. The final tablet application improved on the CAHPS items, by 1) reducing the number of items from 31 to 17 while preserving core domains, 2) reducing the reading level of survey questions from 7th to 5th grade, and 3) adding open-ended questions.

Conclusions: Federal policy supporting patient experience data collection is moving forward. This study provides clear next steps to ensure underrepresented and vulnerable patient perspectives are engaged and represented in this process.

Symposium 42C

MHEALTH & INTERNET INTERVENTIONS FOR DISADVANTAGED PEOPLE WITH TYPE 2 DIABETES: CONSIDERATIONS & RECOMMENDATIONS FOR RESEARCH

Dr. Monica E. Peek, MD, MPH, MSc

Background: Mobile and Internet-based interventions are supporting patients' self-care efforts and, in turn, their glycemic control, but knowledge about the acceptance and benefits of technology-delivered interventions among disadvantaged patients with T2D is surprisingly limited.

Methods: We conducted a review of experimental or quasi-experimental studies evaluating the effects of technology-delivered interventions on the glycemic control (A1c) of disadvantaged adults with T2D from 2011-2015. We operationalized being disadvantaged as samples with ≥50% patients with low socioeconomic status (SES), living in rural settings, or racial/ethnic minority.

Results: Twelve studies were identified and summarized to characterize the state of knowledge with recommendations to advance the field in three key areas: the development and evaluation of technology-delivered interventions for (1) low SES and rural patients, (2) racial/ethnic minorities, and (3) patients with limited literacy and numeracy. Within-group improvements in A1c were consistently demonstrated in both mobile and Internet-based interventions, however, trials have not found between-group differences. Three studies report reductions in inpatient or emergency department use.

Conclusion: Current evidence suggests that mHealth interventions may be effective at improving diabetes outcomes within vulnerable populations. Novel study designs are needed to address questions of reach and cost. Future studies should identify best practices for developing and delivering effective content to disadvantaged patients, quantifying the reach of technology interventions to vulnerable patients, and evaluating cost-effectiveness.

Symposium 43 8:00 AM-9:15 AM

FEASIBILITY STUDIES TO INFORM PHYSICAL ACTIVITY AND WEIGHT MANAGEMENT INTERVENTIONS IN WOMEN: THREE REAL-WORLD EXAMPLES

Scherezade K. Mama, DrPH[1], Danielle Symons Downs, Ph.D.[2], Danielle Arigo, Ph.D., Licensed Psychologist[3], Shannon L. Mihalko, Ph.D.[4]

[1]The Pennsylvania State University, State College, PA; [2]The Pennsylvania State University, University Park, PA; [3]The University of Scranton, Scranton, PA; [4]Wake Forest University, Winston Salem, NC

Feasibility studies are the foundation for intervention studies and are used to explore whether an intervention should move forward to efficacy testing. However, there are not set standards to guide the design and evaluation of feasibility studies in behavioral medicine. Feasibility studies are needed but are often overlooked as the first step in physical activity and weight management intervention development, where it may be necessary to test different recruitment and research strategies, such as intervention dosage, measurement methods and tools, and user acceptability of intervention approaches. This is especially important when working with hard to reach or underserved populations whom may require more tailored or targeted recruitment and intervention approaches. This symposium presents examples of physical activity and weight management feasibility studies among three distinct samples of women. The first presentation will explore the feasibility of a wearables-supported physical activity intervention for women. The second presentation will describe the feasibility of conducting an intervention to prevent weight gain in breast cancer survivors during active treatment. The third presentation will explore the feasibility of an adaptive intervention to manage weight in overweight/obese pregnant women and will describe how feasibility outcomes were used to inform the development of the efficacy study. The symposium will conclude with a discussion of the areas of focus of feasibility studies, feasibility study designs and outcomes, and how feasibility studies are used in a two-phased approach to inform the development of intervention efficacy and effectiveness studies.

Symposium 43A

INFLUENCE OF A FEASIBILITY STUDY ON THE DESIGN OF AN INDIVIDUALLY-TAILORED, ADAPTIVE INTERVENTION TO MANAGE WEIGHT IN OVERWEIGHT/OBESE PREGNANT WOMEN

Danielle Symons Downs, Ph.D.

Half of all pregnant women in the U.S. begin their pregnancies overweight or obese (OW/OB) and 60% of these women exceed gestational weight gain (GWG) guidelines. Despite focused prevention efforts, interventions have generated limited evidence to prevent GWG outside of the Institute of Medicine (2009) guidelines, suggesting an important need for innovative weight management interventions in this population. An individually-tailored intervention that promotes healthy eating, physical activity, weight management, and self-monitoring and adapts to the unique needs of OW/OB pregnant women over the course of pregnancy may be necessary to manage GWG. However, little to no past research has used an adaptive intervention to manage weight in pregnant women. We developed a 2-phase approach to effectively and efficiently manage GWG whereby phase I (feasibility study) directly informed the development of the phase 2 randomized control trial (RCT). The goals of this presentation are to: (a) describe the conceptual design of the adaptive intervention and explain the feasibility and RCT studies; (b) discuss findings and highlight key lessons learned from implementing the feasibility study; and (c) illustrate how the feasibility study informed the RCT. The feasibility study (*N*=22) OW/OB pregnant women randomized to 1 of 7 dosages over a brief 6-week period) tested user acceptability of components (education, goal-setting, self-monitoring, healthy eating/physical activity behaviors), dosages, and intensive data collection procedures. Key aspects of the feasibility study that informed the RCT design were subject inclusion criteria/recruitment strategies, user acceptability of dosage components and intensity, use of mHealth tools for real-time feedback, data collection procedures (timing/schedule of measures), and decision rules for adapting the intervention. The RCT (*N*=30 OW/OB pregnant women) is currently underway and preliminary findings from this study will also be discussed.

Symposium 43B

TESTING THE FEASIBILITY OF FITBIT AND ONLINE PARTNERSHIPS TO PROMOTE PHYSICAL ACTIVITY AMONG WOMEN

Dr. Danielle Arigo, Ph.D., Licensed Psychologist

Regular physical activity (PA) reduces health risks, yet the majority of U.S. women fall far short of recommended PA levels. Women endorse unique barriers to PA, including lack of motivation and lack of social support. Wearable PA tracking technology, which shares users' PA data in online social networks, has the potential to address the need for scalable PA programs for women. However, two key aspects of this potential are not clear: (1) how best to use wearables to promote PA among women, and (2) whether women will use and respond to wearables as intended. This presentation will describe a series of studies designed to assess the feasibility and acceptability of a wearables-supported, online PA program for women. Novel features of this program were the use of Fitbit and an associated online social network, and the assignment of PA partners for support and accountability. Feasibility outcomes included the ability to meet recruitment targets, enrollment and retention, adherence to technology guidelines (Fitbit daily wear, number of posts to the online message board), frequency of partner communication, and perceived utility of/barriers to partner communication. Acceptability outcomes included ratings of participant satisfaction and willingness to recommend the program to other women. In Study 1, conducted entirely online, participants (n= 12, M_{Age}=46, M_{BMI}=32.60 kg/m^2) received a webinar to introduce behavioral PA promotion skills and communicated with partners via private message boards on the Fitbit social network. This study showed positive feasibility/acceptability outcomes (e.g., Fitbit daily wear=93%, retention=93%, M=2 partner contacts per week over 4 weeks) and identified key opportunities for improvement, which informed Study 2. Participants (n=20, M_{Age}=50, M_{BMI}=30.9 kg/m^2) attended a single face-to-face skills session, and communicated with their partner and with the group via Fitbit social network. Feasibility/acceptability outcomes were maintained or improved in Study 2 (e.g., daily wear=97%, retention=100%, M=2 partner exchanges per week over 6 weeks). Discussion of these studies will focus on their use in the development of an NIH R21 proposal to pilot test this PA program among women with elevated cardiovascular risk.

Symposium 43C

THE THRIVE STUDY: FEASIBILITY OF AN INTERVENTION TO PREVENT WEIGHT GAIN IN BREAST CANCER SURVIVORS DURING CHEMOTHERAPY

Shannon L. Mihalko, Ph.D.

The American Cancer Society estimated that more than 230,000 new cases of invasive breast cancer would be diagnosed among women in 2015. Weight gain, a common side effect experienced by breast cancer survivors receiving adjuvant chemotherapy, has been shown to negatively impact cancer outcomes, general health and morbidity, and positive well-being. Although weight gain can be prevented by healthy lifestyle behaviors, the task of adopting and maintaining physical activity and an energy-balanced diet is a daunting one for most adults and especially for women undergoing an intensive cancer treatment protocol. Consequently, the timing of successful weight management interventions is an ongoing debate. The primary objective of the Taking Health Realization into Valued Eating and Exercise (THRIVE) study was to demonstrate the feasibility of conducting an intervention to prevent weight gain for breast cancer survivors *during* active chemotherapy. This presentation will provide an overview of the theoretical framework and highlight findings from a preference survey that informed the design and timing of the intervention. Feasibility was determined by recruitment, accrual and adherence rates, perceived barriers, adverse events, and program satisfaction. Reasons for ineligibility and the need to reevaluate inclusion/exclusion criteria in this population will be discussed, as well as barriers to recruitment and retention. Thirty women participated in THRIVE with an average age of 51 years. The adherence rate to both testing and intervention sessions was greater than 90% with time constraint and distance the most often cited barriers to participation. There were no adverse events and participants reported an overall high program satisfaction (3.7 on 4.0 scale). This feasibility study will set the stage for a multi-center clinical trial to test the efficacy of weight gain prevention during chemotherapy that may lead to beneficial effects on recurrence of breast cancer, risk of comorbid conditions, and both stress reduction and improved quality of life in cancer survivors.

Symposium 44 8:00 AM-9:15 AM

TARGETING HEALTH BEHAVIOR CHANGE AND CLINICAL OUTCOMES WITH MINDFULNESS-BASED MOBILE INTERVENTIONS

Jessica Chandler, PhD[1], Judson A. Brewer, MD/PhD[2], Ashley E. Mason, PhD[3]

[1]Medical University of South Carolina, Charleston, SC; [2]UMass Medical School, Worcester, MA; [3]University of California San Francisco, San Francisco, CA

This symposium comprises presentations that detail, from start to finish, three mobile-delivered interventions targeting health behavior change and improved clinical outcomes using mindfulness-based intervention techniques. Each presentation reviews processes of trial conduct, spanning from participant recruitment to results. By reviewing the entire process of conducting such trials, presenters will maximize attendees' learning about how to conduct research testing the impacts of mobile-delivered interventions on health behavior change and clinical outcomes. Each presenter will speak about interventions that delivered mindfulness and meditation practices over smartphones with the goals of improving health behavior and health conditions, including pre-hypertension, cigarette smoking, or obesity. The first presentation will report on a smartphone-delivered breathing awareness meditation (BAM) that focused on reducing blood pressure among adults with pre-hypertension. The second presentation will report on a smartphone-delivered mindfulness program focused on engaging individuals who smoke cigarettes to complete ecological momentary assessments (EMA) about episodes of craving and cigarette smoking while they work toward complete smoking cessation. The third presentation will report on a smartphone-delivered mindful eating intervention focused on reducing craving-related eating and weight loss among overweight and obese individuals. All presentations will review lessons learned in conducting trials that test smartphone-delivered interventions that employ mindfulness and meditation practices in the service of improving health behavior and clinical outcomes. Presentations will also report on the effects of these interventions on metrics of health and health behavior, including change in blood pressure levels, cigarette craving and smoking, and craving-related eating and weight loss.

Symposium 44A

SMARTPHONE DELIVERED BREATHING MEDITATION FOR BLOOD PRESSURE CONTROL AMONG ADULTS WITH PREHYPERTENSION

Jessica Chandler, PhD

Background: Pre-hypertension (pre-HTN) affects ~33% of adults and is a primary risk factor for hypertension (HTN) and cardiovascular disease (CVD). Breathing awareness meditation (BAM) can reduce stress levels and blood pressure (BP) but the optimal dosage level has not been determined. Furthermore, dose adherence has often been based upon self-report. In this trial we tested the acceptability and efficacy signals of Tension Tamer (TT), an iOS and Android smartphone BAM app targeting reductions in BP. Methods: Tension Tamer (TT) uses text/audio instructions with proprietary embedded, validated reflective photo plethysmography software that captures real-time heart rate (HR) from a user's fingertip placed over video camera lens during meditation sessions. Users receive feedback graphs after each session showing their HR changes. TT time stamps all HR data, which provides an index of adherence to completing sessions. TT provides tailored reinforcement and motivational text messages along with educational information about benefits of BAM. Results: Participants were 62 adults (mean age: 35.7 years; 32 males; 33 White; 29 Black) with pre-HTN on 3 consecutive sessions (mean SBP 128.8 mmHg; 95% recruitment rate). They were randomly assigned to 5, 10 or 15 min sessions, twice daily for 6 months. Average adherence declined from month 1 through months 3 and 6 across dosage groups (ps<.001); 5 min (mth 1: 82% to mth 6: 78%), 10 min (mth1: 80% to mth 6: 70%) and 15 min (mth 1: 79% to mth 6: 53%). We observed clinically meaningful and statistically significant reductions in SBP at months 1, 3 and 6 for all 3 dosage groups (ps<.001): 5 min: -8.0, -6.4, -6.2; 10 min: -7.8, -7.6, -9.2 and 15 min: -11.1, -9.4, -9.8 mmHg. Conclusion: The TT app is acceptable and useful in objectively tracking adherence and shows promise in reducing SBP in people with pre-HTN. We will present additional quantitative and qualitative analyses of post-trial informant interviews, as well as TT refinements and dosage determination for our upcoming 12-month efficacy RCT.

Symposium 44B

MINDFULNESS TRAINING FOR SMOKING CESSATION DELIVERED VIA SMARTPHONE

Judson A. Brewer, MD/PhD

Background: Digital Health interventions for smoking cessation have become more widely used, yet challenges exist in documenting their mechanism of action and efficacy. Further, randomized controlled trials in mHealth face new opportunities and challenges: Recruitment from a broader and “real world” population is more accessible, yet participant screening and protocol adherence are more difficult to assess. Methods: We evaluated recruitment, engagement and retention in a randomized trial of a 21-day smartphone app for mindfulness training for smoking cessation: Craving to Quit. The app uses experience sampling to query smokers’ behavior and experience in real time. Queries ask participants questions such as, “how much are you craving a cigarette right now?” and participants use a sliding scale to indicate craving level. This trial compared Craving to Quit to a 21-day control app that provided goal setting, reminders, and ecological momentary assessment of cigarette craving and smoking. Participants were randomized to experimental (n=247) or control (n=263). Results: Enrollment: 5300 people accessed online screening, 5% were excluded for not having a smartphone, and 509 were randomized to treatment. We randomized twelve participants per week to treatment over 42 weeks. Demographics: Participants were mostly female (70% female), and 50% of participants used iPhone, with the other 50% using Android. The mean age was 42 years. On average, participants reported smoking 17 cigarettes/day and 6 prior quit attempts. Of participants who started treatment (treatment starters), those randomized to Craving to Quit tended to complete more treatment days (133 treatment starters) relative to those assigned to the control app (186 treatment starters), p = .051. Among treatment starters, completion rates were higher for the Craving to Quit group (47%) relative to the control group (27%), X2=14.3, p<.001. High engagement in experience sampling was achieved and did not differ between groups (p=.74). Treatment starters checked-in on average 55.3 ± 48.5 times across the study, on more than 60% of treatment days (mean=14±8 days). The average number of check-ins per day was 3.6 ± 1.7 and did not differ across groups (p=.19). At 6-month follow-up, the experimental (78%) and control (74%) groups evidenced similar retention (p=.34) and retention was greater for treatment starters (85% overall). Conclusion: Craving To Quit effectively engages individuals who are attempting to quit smoking cigarettes to check in about their cigarette cravings and smoking behavior. Craving to Quit is a promising mobile intervention for individuals attempting to quit cigarette smoking.

Symposium 44C

A MOBILE-DELIVERED MINDFUL EATING INTERVENTION TARGETING CRAVING-RELATED EATING AND WEIGHT LOSS

Dr. Ashley E. Mason, PhD

Background: Most weight loss interventions are handicapped by sampling biases due to requiring in-person meetings. Attrition rates are often high due to unrealistic expectations about abilities to adhere to diet and exercise prescriptions. In this study, we tested a 28-day self-paced smartphone-delivered intervention that targets craving-related eating using mindful eating practices. The intervention minimizes user burden by asking users to view daily lessons that are approximately 5 to 10 minutes at any time of the user's choosing, which facilitates easy incorporation into one's lifestyle. Methods: In total, 104 adult overweight or obese women (Mean age = 46.2 years, SD = 14.1 years; Mean BMI = 31.5, SD = 4.5) began the intervention. We recorded anthropometric data pre-intervention and one month after the participant completed day 28. We assessed participants' food cravings before, during, and after the intervention using ecological momentary assessment (EMA) delivered via text message (SMS). Results: Recruitment & Enrollment: Of 1,651 participants who completed an online screener, 170 completed the baseline SMS-based craving assessment, and 141 qualified by responding to at least 7 of 9 texts and endorsing at least 3 food craving experiences. Ninety-eight (94.2%) participants indicated how they learned about the study. Of these, 40.8% (n=40) learned about the study through Facebook, 25.5% (n=25) through campus email announcements, 18.4% (n=18) through a letter in the mail, 14.3% (n=14) through other means, and 1.0% (n=1) through Craigslist. Retention: Of the 104 participants who began the intervention, 6 withdrew due serious life events (e.g., death in family, overseas relocation). Seventy-six participants completed the 28-day intervention (73.1% completion rate), of which 72 attended an in-person follow-up visit one month after completing the intervention. Intervention effects: In per protocol analysis (intervention completion within 3 months) participants (N=61) lost 1.8 lbs (p = .019) and reported a statistically significant reduction in craving-related eating from pre- to post-intervention (Mean diff = -0.19, b=-.46, p<.001). In intention to treat analysis (intervention completion as of 7 months), participants (N=72) lost 1.0 lbs (p = .160) and reported a statistically significant reduction in craving-related eating (Mean diff = -0.20, b=-.42, p<.001). Conclusion: Mobile-delivered interventions that target mindful eating practices, rather than prescriptive diet and exercise recommendations, may represent a low-burden, low-cost method to reduce craving-related eating among overweight individuals.

Symposium 45 8:00 AM-9:15 AM

USING ECOLOGICAL MOMENTARY ASSESSMENT (EMA) TO ADVANCE HEALTH BEHAVIOR THEORY

Jaclyn P. Maher, Ph.D.[1], Genevieve F. Dunton, PhD, MPH[1], Chih Hsiang Yang, MEd[2], Meg Bruening, PhD, MPH, RD[3]

[1]University of Southern California, Los Angeles, CA; [2]Penn State University, State College, PA; [3]Arizona State University, Phoenix, AZ

Health behavior theories serve as a guiding framework for understanding and intervening on weight-related behaviors (e.g., physical activiy, sedentary behavior, dietary intake). However, traditional health behavior theories such as the Theory of Planned Behavior or Social Cognitive Theory face growing criticism. Traditional health behavior theories are limited in that they often (1) consider behavior as static phenomena examined at a single time point, (2) overlook contextual influences on behavior, and (3) do not incorporate concepts such as stability or instability of behavior and relevant covariates. Ecological momentary assessment (EMA) is a real-time data capture strategy that can help to address the limitations of health behavior theory by intensively sampling behavior and other relevant factors as they occur in the context of everyday life. Specifically, EMA can be used to determine (1) the extent to which explanatory factors co-occur in time and space with health behaviors (i.e. synchronicity), (2) the temporal sequence of antecedents to and consequences of health behaviors (i.e., sequentiality), and (3) patterns of fluctuation and change in explanatory factors and behavior (i.e., instability). This symposium will address how EMA is stimulating advances in health behavior theory with specific emphasis placed on the role of EMA to address sequentiality. The first presentation will explore time-varying predictors of short-term physical activity intention formation and short-term physical activity intention-behavior coupling using data collected through EMA and ambulatory monitoring. The second presentation will explore the role of mothers' momentary stress on mothers' subsequent parenting practices regarding their child's physical activity, sedentary behavior, and eating. The third presentation will explore associations between momentary positive and negative affect and physical activity and sedentary behavior in college students. Overall, these presentations will reveal both the benefits and challenges of using EMA methods to advance our understanding of the processes underlying health behavior change. The discussant will address both the specific contributions of these presentations and the broader role of using EMA in the advancement and refinement of health behavior theory.

Symposium 45A

MOMENTARY ASSESSMENT OF PHYSICAL ACTIVITY INTENTION-BEHAVIOR COUPLING IN ADULTS

Jaclyn P. Maher, Ph.D.

Background: Research attempting to elucidate physical activity (PA) intention-behavior relations has focused on differences in long-term behavior forecasting between people. However, regular PA requires a repeated performance on a daily or within-daily basis. Intensive longitudinal data (ILD) collected through methods such as Ecological Momentary Assessment (EMA) and mobile sensors can examine within-person differences in PA intentions over shortened timescales to understand how they might predict variations in one's immediate behavior. This study used ILD collected through EMA to (a) describe the extent to which short-term intention-behavior coupling occurs and (b) explore time-varying predictors of intention formation and short-term intention-behavior coupling. Methods: Adults (n =116) participated in three separate four-day waves of EMA. Each day, participants received eight EMA questionnaires assessing short-term PA intentions (i.e., "over next few hours") and current affect and context (i.e., "right now"). Participants wore accelerometers at the same time as completing EMA to assess whether they engaged in ≥10 minutes of moderate-to-vigorous physical activity (MVPA) in the 3-hour period after each EMA prompt. Results: Participants reported having short-term intentions to engage in PA in 41% of EMA prompts. However, participants engaged in ≥ 10 minutes of MVPA following only 16% of the prompts that short-term PA intentions were reported. Participants were more likely to intend to be active in the mornings (OR = 2.16, $p < 0.01$), but less likely to intend to be active in the evenings (OR = 0.32, $p < 0.01$) compared to other times during the day. Participants were also more likely to intend to be active on weekend days compared to weekdays (OR = 1.69, $p < 0.01$). Odds of intentions followed by PA were greater on occasions when individuals reported higher levels of positive affect than was typical for them (OR = 2.20, $p < 0.01$). Conclusion: Results from this study are the first of its kind to indicate the possibility of time-varying factors predicting the formation and enactment of short-term PA intentions across the day. Understanding the role that these processes play in intention formation as well as intention-behavior coupling is necessary to determine the processes that regulate PA in the context of everyday life and ultimately develop more effective, tailored interventions for individual behavior change.

Symposium 45B

MATERNAL STRESS AND WEIGHT-RELATED PARENTING PRACTICES: AN ECOLOGICAL MOMENTARY ASSESSMENT STUDY

Dr. Genevieve F. Dunton, PhD, MPH

Background: According to theories of ego depletion and self-regulation, psychological stress may compromise parenting practices related to children’s dietary intake and physical activity. However, past research in this area used retrospective measures of stress and overlooked within-person processes. This presentation will demonstrate how Ecological Momentary Assessment (EMA) can be used to examine micro-temporal sequences underlying maternal stress and subsequent weight-related parenting practices. Methods: Mothers (N = 194) (mean age = 41.0,48.5% Hispanic) of children 8-12 years old participated in 7 days of EMA with up to 7 randomly-prompted EMA surveys per day (every 2 hours) during children’s non-school time. EMA items assessed perceived stress (“right now”), exposure to stressors (i.e., work at home, family demands, spousal tension) (“over the past 2 hours”), and weight-related parenting practices (i.e., limiting of high fat/high sugar foods) (“over the past 2 hours”). Multilevel models examined prospective associations between maternal stress variables reported at any given prompt T and subsequent weight-related parenting reported at the next prompt T+1 (occurring 2 hours later), disaggregating within-subject (WS) and between-subject (BS) effects of stress and adjusting for relevant covariates (e.g., time of day, child age). Results: BS effects showed that mothers who experience greater stress from work at home (b=-0.33), family demands (b=-0.30), spousal tension (b=-0.50), and general perceived stress (b=-0.08), on average compared to other mothers, reported less limiting of high fat/high sugar foods (p’s <.05). However, WS effects showed that when mothers reported experiencing greater stress from work at home (b=0.37), family demands (b=0.32), and spousal tension (b=0.54) than their usual, they subsequently engaged in more limiting of high fat/high sugar foods in the next 2 hours (p’s<.05). Conclusion: Among mothers, overall levels of stress may deplete emotional and cognitive resources needed to successfully perform weight-related parenting. However, during times of family and home stress, mothers' vigilance toward weight-related parenting may be temporarily enhanced. The subpopulation of mothers who tend to experience the most stress may be in greatest need for interventions targeting weight-related parenting, and the effectiveness of such interventions could be maximized by enhancing parenting vigilance during situations with lower relative levels of stress. This presentation will conclude by discussing the strengths and challenges of using EMA to test and advance theories of ego depletion and self-regulation.

Symposium 45C

AFFECTIVE ANTECEDENTS OF SITTING, STANDING, AND MOVING IN DAILY LIFE

Chih Hsiang Yang, MEd

Background: Cognitive processes feature prominently in theories of physical activity and sedentary behavior. The role of affective processes, such as stress, anxiety, and pleasure, has been less well developed. Affective processes can fluctuate rapidly throughout the day and these fluctuations cannot be captured adequately cross-sectional, prospective, and panel datasets. Affective experiences during physical activities predict adherence, presumably because people become conditioned to associated activity with a reward or punishment based on this affective experience. Affective experiences may also energize or inhibit proximal activity patterns but this association has not been established. We used an experience sampling research design to test hypotheses about the role of affective processes in predicting the odds of future sedentary behavior, standing, and physical activity of different intensities. Methods: Over 14 days, 158 university students responded to eight randomly-timed prompts to complete momentary self-reports using the Personal Analytics Companion (Paco) smartphone application. A total of 14,591 experience samples were collected (M=92/participant). Results: A series of logistic multilevel models found that, after controlling for gender, the time of the day, day of the week, and duration between momentary responses, within-person deviations in prior stress levels significantly predicted increased odds of reporting sitting (odds ratio= 1.07, *p*<.05), and decreased odds of reporting standing (odds ratio= 0.86, *p*<.01) in the following responses. The odds of engaging in vigorous physical activity were also negatively predicted by prior stress levels (odds ratio= 0.81, *p*<.05) and positively predicted by prior levels of anxiety (odds ratio= 1.19, *p*<.05) and pleasure (odds ratio= 1.23, *p*<.01). At the between-person level, average levels of stress, anxiety and pleasure did not predict the odds of sitting or engaging in light/moderate/vigorous physical activity. Interaction effects were further identified between the latency of responses and levels of momentary pleasure in predicting subsequent light (*p*<.01) and moderate physical activities (*p*<.01). Conclusion: These results supported the hypothesis that within-person affective dynamics influence proximal activity patterns. Thus, affect regulation interventions may be useful for reducing sedentary behavior and promoting physical activity. Further work with both ecological momentary assessment designs and experimental trials of affective regulation interventions is needed to elaborate the role of affective processes in regulating physical activity and sedentary behavior.

Symposium 46 8:00 AM-9:15 AM

MECHANISMS OF TREATMENT CHANGE: RESULTS FROM ACCEPTANCE AND COMMITMENT THERAPY FOR CHRONIC PAIN, WEIGHT LOSS, AND BINGE EATING

Kevin E. Vowles, PhD[1], Evan M. Forman, PhD[2], Stephanie Manasse, MS[2]

[1]University of New Mexico, Albuquerque, NM; [2]Drexel University, Philadelphia, PA

Psychosocial treatments for physical illness have amassed considerable evidence of effectiveness, yet the mechanisms by which they achieve this success remains unclear. Consequently, there are few data to guide treatment development and implementation efforts focused on these active processes, or mechanisms, of change. Recent calls from several research bodies, such as the NIH, have highlighted the need to address this issue. This symposium will present the results of several studies which specifically evaluate treatment mechanisms in one model of intervention, that of Acceptance and Commitment Therapy (ACT). Data from three representative health conditions, chronic pain, obesity, and binge eating, will be presented. The presentations will share a focus on treatment processes specifically targeted by ACT, that of increases in acceptance and awareness (e.g., of pain, current weight, and urges to binge) and engagement in valued activities and will evaluate how changes in these processes relate to treatment outcomes. Dr Vowles will first discuss the results of several Latent Growth Modeling analyses using data collected as part of an interdisciplinary program of ACT for chronic pain. Results indicated two distinct patterns of change in pain acceptance and engagement in valued activities, one of substantial improvement and one of no change. Distal outcome analyses, investigating the relation of trajectory of change in treatment mechanisms (i.e., improved/unchanged) with disability and pain-related functioning at three-month follow-up indicated that membership in the improved acceptance and values trajectory was associated with significantly greater improvements in disability and functioning. Dr. Forman will next describe mediational analyses conducted on a randomized clinical trial of an acceptance-based behavioral treatment versus gold standard behavioral treatment for obesity. Bootstrapping analyses indicated that the advantage of the acceptance-based treatment in the maintenance of weight loss through 3-year follow-up was mediated by earlier changes in eating-related psychological acceptance and autonomous motivation. Finally, Ms. Manasse will present the results from a preliminary investigation of cognitive and affective mechanisms of change in an ACT for binge eating disorder. Results indicated that improvements in emotion regulation and decreases in experiential avoidance were associated with improvements in eating pathology. Exploratory analyses also indicated that improvements in working memory and inhibitory control were associated with decreases in binge eating. These data provide guidance on active treatment mechanisms within one distinctive model of treatment and the overlap across

conditions suggests these processes may be generalizable across healthcare conditions, thereby providing a potential model for future work.

Symposium 46A

ACT FOR CHRONIC PAIN: WITHIN-TREATMENT TRAJECTORIES FOR ACCEPTANCE & VALUES PREDICT IMPROVED FUNCTIONING AT FOLLOW-UP

Dr. Kevin E. Vowles, PhD

A key issue in chronic pain treatment concerns the changes necessary for improved functioning. Traditionally, reducing pain has been viewed as a prerequisite for improvement - alternatively, Acceptance and Commitment Therapy (ACT), a behavior change approach, theorizes that pain reduction is not necessary for improvement, rather responses to pain must change, such that behavior become less restricted, more flexible, and more persistent in the pursuit of adequate activity.These improvements in functioning are hypothesized to result from improvements in pain acceptance and engagement in valued activity. Support for these two treatment mechanisms have been provided via correlational findings (e.g., pre-post changes in acceptance are significantly correlated with magnitude of improvement in functioning), but modern statistical methods allow for more nuanced and informative analyses which examine how specific aspects of change relate to treatment outcome. For example, Latent Growth Modeling (LGM) allows the examination of longitudinal data to determine if multiple trajectories of change occur (e.g., a trajectory of improvement and one of no change) and if aspects of these trajectories, including intercept and slope, are statistically predictive of improvement in key treatment outcomes, such as distress and disability. This presentation will detail a LGM analyses of trajectories of pain acceptance and valued action, as well as the relation of these trajectories to outcomes at a three-month follow-up, over the course of a 4 week program of interdisciplinary ACT for chronic pain. Pain acceptance and values were assessed weekly during treatment; distress and disability were assessed at treatment onset and follow-up. Results indicated two latent trajectories for both acceptance and values, one with no change and one with an increasing quadratic slope indicating significant improvement during treatment. Further, change trajectory during treatment was significantly related with improvement at follow-up, such that greater increases (i.e., positive slope) in acceptance and values during the four weeks of treatment were statistically predictive of larger improvement at follow-up. This pattern of findings provides support for the ACT model in chronic pain and suggests that the mechanisms identified in the theoretical model have a significant statistical relation with degree of improvement following treatment.

Symposium 46B

MECHANISMS OF ACTION EXPLAINING THE SUPERIORITY OF ACCEPTANCE-BASED BEHAVIORAL OVER STANDARD BEHAVIORAL WEIGHT LOSS TREATMENT

Evan M. Forman, PhD

Acceptance-based behavioral treatment (ABT) has demonstrated superior weight loss to gold standard behavior treatment (SBT). However, the mechanisms of action that carry the effects of ABT are not well understood due to the fact that the treatment contains a suite of strategies (e.g., behavioral, tolerance of difficult internal experiences and loss of pleasure, mindful decision making and commitment to valued behavior), a paucity of data and measurement limitations. In a recent randomized controlled trial, 190 overweight or obese participants were assigned to 25 sessions of ABT or SBT over a 1-year period. At baseline, mid-treatment (6 months) and post-treatment (1 year), postulated mechanisms of action (autonomous motivation and eating-related psychological acceptance) were measured, and weights were taken at these points as well as at 1-year follow-up (2 years) Bootstrapping analyses indicated that the advantage of ABT at post-treatment and follow-up assessments was mediated by 6-month change in autonomous motivation and eating-related psychological acceptance (CIs>95%). In addition, change in eating-related psychological acceptance (but not autonomous motivation) from baseline to 6 months mediated the advantage of ABT during the maintenance period between years 1 and 2 (post-treatment to 1-year follow-up). Thus, some psychological mechanisms have effects long after they have been activated. Future investigations should work to develop and test methods of enhancing behavioral weight loss treatment on the strength of accumulating knowledge about the most (and least) potent mechanisms of action.

Symposium 46C

AN EXAMINATION OF POTENTIAL COGNITIVE AND AFFECTIVE MECHANISMS OF CHANGE IN ACCEPTANCE-BASED TREATMENT FOR BINGE EATING

Stephanie Manasse, MS

Standard treatments for binge eating disorder (BED) produce significant improvements in eating pathology, but room for improvement remains. Strategies from acceptance-based treatments (ABTs; e.g., Acceptance and Commitment Therapy and Dialectical Behavioral Therapy) show promise for enhancing the treatment of binge eating disorder (BED) specifically by providing strategies for tolerating negative affect, and slowing down decision making processes. However at this time, it is unknown whether ABT works via its hypothesized mechanisms. Examination of mechanisms is critical for eventually developing more efficacious and optimized interventions.

As such, we conducted a preliminary pilot open trial (n=19) of ABT for BED and assessed whether pre-post changes in potential process measures were associated pre-post improvements in eating pathology. Specifically, we examined whether changes in emotion regulation and experiential avoidance were associated with changes in binge eating and global eating pathology after 10 weeks of treatment. Given that the focus of several ABT strategies is to slow down in-the-moment decision-making, as an exploratory analyses, we examined several executive functioning variables (i.e., cognitive control processes that govern goal-directed behavior) as potential treatment processes. Results indicated that changes in improvements in eating pathology were associated with increases in emotion regulation (*r*=.54) and decreases in experiential avoidance (*r* =-.41). In addition, improvements in working memory (*r*=.39) and inhibitory control (*r*=.54) were associated with decreases in eating pathology.

These preliminary results from our small pilot trial show promising support for increases emotion regulation and decreases in experiential avoidance as potential mechanisms of ABT. In addition, improvements in working memory were associated with treatment gains, perhaps because slowing down in-the-moment decision making impacts the ability to keep goal-oriented information in mind. ABT may also work to decrease impulsive tendencies via improving inhibitory control. Given the small sample size and correlational nature of analyses, replication with larger samples is necessary.

Symposium 47 8:00 AM-9:15 AM

NEXT-GEN MHEALTH: INTEGRATING PHYSIOLOGICAL MEASURES WITH SMART TECHNOLOGY TO INFLUENCE HEALTH BEHAVIOR CHANGE

Yue Liao, MPH, PHD[1], Susan M. Schembre, MS PhD RD[2], David W. Wetter, PhD[3], Bonnie Spring, PhD[4], Tiffany Cvrkel, PhD[5]

[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]The UT MD Anderson Cancer Center, Houston, TX; [3]University of Utah, Salt Lake City, UT; [4]Northwestern University, Chicago, IL; [5]University of California, Los Angeles, Los Angeles, CA

Advancements in wearable sensor technology now make it possible to assess, in real-time, physiological measures that influence or are influenced by health behaviors; representing an exciting and potentially transformative development in health behavior research. The utility of integrating objective measures reflecting a person's physiological state with traditionally used self-report measures as well as ubiquitous mobile and smartphone technologies has inciting implications on both the assessment of and intervention on health behaviors. In particular, this integrative approach enables the study of the acute effects that physiological states, such as stress, have on health-related behaviors, and reciprocally, how a person's behavior could affect physiological states that have important health consequences. Importantly, this approach has the greatest potential to proactively intervene at critical moments in peoples' natural environments in an effort to support health-related decisions. Areas of research enhanced by the integration of body sensor technology and health behavior change that will be discussed during this symposium include dietary intake and smoking cessation and relapse prevention. In the first talk we will discuss the feasibility and value of using continuous glucose monitors to objectively assess dietary intake and to provide proactive dietary decision support for weight control and healthy eating. Our second speaker will discuss how body sensors can be used to facilitate the real-time assessment of stress and smoking behavior by tracking physiologic and behavioral data. Our final speaker will discuss the translation of these objective assessment techniques to the development of a real-time adaptive stress reduction intervention that is triggered by sensed physiological stress with the aim of preventing relapse to smoking. During the session the speakers will discuss the challenges of this research related to big data analytics and intervention timing. The session will highlight the need for behavioral theories that integrate physiological measures with behavior change constructs and clarify the relationship between physiological state and perceived state. In addition, the discussant - a bioethicist specializes in emerging biomedical technologies will lead the discussion around the topic of the ethical challenges around mHealth, eHealth, and Big Data.

Symposium 47A

USING MOBILE GLUCOSE MONITORING AS BIOLOGICAL FEEDBACK ON DAILY EATING BEHAVIORS

Dr. Yue Liao, MPH, PHD

Background: A number of theoretical frameworks emphasize the importance of using feedback as a strategy for health behavior change (e.g., social-cognitive theory, theory of reasoned action). Real-time physiological feedback, objectively assessed by body sensors, has the potential to influence behavior change by informing health-related decisions at critical moments. This study aims to examine the feasibility of collecting continuous glucose monitoring (CGM) data from free-living individuals as real-time physiological feedback about short-term energy status (pre-meal glucose levels) and metabolic responses to dietary intake (post-meal glucose dynamics) to influence diet-related decisions that promote dietary behavior change for weight control. **Methods:** Ten healthy participants (M age=28.9, 70% female, 30% Hispanic, 60% overweight) have completed a 7-day monitoring period. Blood glucose (BG) levels were recorded every 5 minutes using the Dexcom G4 PLATINUM CGM system. Participants also completed diet records using MyFitnessPal and indicated perceived pre-meal hunger levels in the CGM receiver using a 10-point scale. CGM data from monitoring days 3 to day 7 were analyzed. In addition, diet data will be analyzed and presented for glycemic quality using Nutrition Data Systems for Research. **Results:** On average, participants reported 33.3 (SD=12.8) eating events across the 5 analytical days. Of these eating events, 61.7% (SD=.20) were initiated when a participants' pre-meal BG level was greater than 85 mg/dl (a standard fasting BG level) and 48.8% (SD=.19) were initiated when a participants' BG level was greater than their own fasting BG level. On average, participants had 2.9 (SD=3.0) hyperglycemic events (post-meal BG rise above 140 mg/dl). The average mean amplitude of glycemic excursions (MAGE), which indicates the BG variability from peaks to nadirs, for all eating events was 35.7 mg/dl (SD=10.3). Preliminary analyses showed that overweight participants reported more frequent eating above 85 mg/dl than normal weight participants (t=-2.22, p=.058). **Discussion:** Serial CGM data provides valuable physiological feedback reflecting eating behaviors and dietary glycemic quality in free-living settings. Findings provide early evidence that pre-meal BG levels could guide decisions about when to eat. Future studies testing the use of CGM data as physiological feedback in real-time interventions that promote dietary behavior change and weight control are warranted.

Symposium 47B

ACUTE STRESSORS, DISCRIMINATION, AND SMOKING LAPSE LIKELIHOOD AMONG UNDERSERVED GROUPS

Dr. David W. Wetter, PhD

Several conceptual models posit that greater exposure to stressors is a key mechanism linking underserved status to lower rates of smoking cessation. Surprisingly, there are only a handful of studies examining the impact of acute stress on real time, real world cessation outcomes, and to the best of our knowledge, none that examine the acute effects of minority specific stressors such as discrimination. Two longitudinal cohort studies examined the influence of acute stressors on the likelihood of smoking lapse. In both studies, smokers received smoking cessation treatment (behavioral, patch) and were tracked both pre- and postcessation using Ecological Momentary Assessments (EMA). The first study included 364 predominantly low socioeconomic status smokers evenly split among African Americans, Latinos, and Whites. Participants reported the presence of a new stressor in 3%, an ongoing stressor in 10%, and both new and ongoing stressors in 31% of EMAs. The presence of any stressor (new OR=2.1, p<.001; ongoing OR=1.4, p=.003; both OR=1.8, p<.001) increased the likelihood of a lapse in the next 4 hours, even after controlling for smoking in the previous 4 hours. There was no synergistic effect of experiencing both new and ongoing stressors. The second study examined the impact of acute discrimination on lapse likelihood among 159 Spanish speaking Latino smokers. Participants reported that they were certain they had experienced discrimination in <1% of EMAs. The presence of discrimination increased the likelihood of a lapse in the next 4 hours (OR=6.1, p<.03), even after controlling for smoking in the previous 4 hours. The results from these studies suggest that acute stressors place underserved populations at greater risk for poor cessation outcomes. Ongoing research is building on these data using state of the science methodologies such as AutoSense and geographic positioning system (GPS). AutoSense tracks behavioral and physiologic data in real-time and can objectively detect when an individual smokes or encounters a stressor. GPS permits real-time spatial mapping, which can be paired with EMA and Autosense, and with relevant environmental exposures (e.g., tobacco outlets; area-level poverty).

Symposium 47C

OPTIMIZING SENSE2STOP: A JUST-IN-TIME ADAPTIVE MHEALTH STRESS INTERVENTION TO PREVENT SMOKING RELAPSE

Prof. Bonnie Spring, PhD

Technical advances in the design of wearable sensors make it feasible to passively monitor changes in physiological state, creating the potential for real time adaptive intervention. The presenter will describe the development and implementation of a stress reduction intervention triggered by sensed physiological stress and with the aim of preventing relapse to smoking among recently quit smokers. She will describe how the interdisciplinary intervention team worked through intervention development challenges that included: 1. construct validation of the physiological stress indices, 2. translation between computer science and behavioral science metrics in operationalizing the physiological trigger for intervention, 3. designing stress –management interventions that can be triggered based on momentary physiological stress indices, 4. providing processing capacity to perform big data analytics needed to infer stress accurately and make intervention decisions in real time, 5. micro-randomization approach to developing evidence based decision rules about intervention timing, and 6. managing data quality and participant burden. The Sense2Stop development process highlights the need for a more dynamic theory of stress, one that clarifies the relationship between momentary physiological and subjective stress, pinpoints substrates for stress management intervention, and posits behavior change mechanisms underlying the optimal timing of intervention triggers.

Symposium 48 8:00 AM-9:15 AM

MEASURING AND TAILORING WEIGHT MANAGEMENT TREATMENT FOR THE UNIQUE NEEDS OF VETERANS

Robin Masheb, Ph.D.[1], Lindsey Dorflinger, PhD[2], Phoutdavone Phimphasone, MA[3], Kathryn Godfrey, MS[4], Niloofar Afari, PhD[5]

[1]Yale School of Medicine/VA CT Healthcare System, North Haven, CT; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]University of North Carolina, Charlotte, New Haven, CT; [4]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, La Jolla, CA; [5]University of CA, San Diego & VA San Diego Healthcare System, La Jolla, CA

Studies show that Veterans have been disproportionately affected by overweight/obesity over the last decade, but few studies have examined eating behaviors and associated factors in this population. Given the high prevalence of binge eating among overweight/obese Veterans as well as the growing number of women Veterans, there is a pressing need to enhance assessment and better understand the unique treatment needs among Veterans seeking services related to weight and eating behaviors. The objective of this symposium is to enhance our understanding of eating behaviors, and correlates of eating disorders and obesity, among this vulnerable patient group. Data was collected from Veterans attending orientation sessions for the VA national weight management program utilizing measures of eating, weight, and psychiatric functioning, and the electronic health record. Each presenter will report on a timely and relevant aspect of eating and weight. The first presenter will discuss findings of the relatively new and controversial construct of food addiction. Pertinent to the inclusion of Binge Eating Disorder in DSM-5, the second presenter will introduce a new single-item screener for binge eating that is feasible for use in medical settings. Given the high rates of comorbid pain and overweight/obesity in the Veteran population, and the implications for the treatment of each condition, the third presenter will discuss the unique characteristics and needs of Veterans with overweight/obesity who meet criteria for clinical pain. Finally, the last presenter will examine weight reporting biases in this sample. The implications of these findings for assessment and treatment of weight management and associated eating behaviors in the Veteran population will be discussed.

Symposium 48A

FOOD ADDICTION AMONG VETERANS WITH OVERWEIGHT/OBESITY

Dr. Robin Masheb, Ph.D.

Objective: Obesity prevalence is higher among veterans compared to the general population. and thus places veterans at greater risk for morbidity, mortality, and compromised quality of life. The relationship between maladaptive eating and obesity within an addiction framework is an emerging field of study. The purpose of the present study was to investigate food addiction in a sample of veterans with overweight/obesity.

Methods: Participants were veterans with overweight/obesity who attended consecutive orientation session at VA Connecticut Healthcare System for the MOVE! program, VA's weight management program which has been implemented nationally. Veterans (n = 119, mean age 61.7 years, mean BMI 37.9, 90% male, 75% Caucasian) completed the Yale Food Addiction Survey; measures of eating behavior, including the Eating Disorder Examination-Questionnaire, Yale Emotional Overeating Questionnaire, Night Eating Questionnaire, and Questionnaire on Eating and Weight Patterns – Revised; and psychiatric screening questionnaires for depression (PHQ-2), posttraumatic stress disorder (PC-PTSD) and alcohol abuse (AUDIT-C).

Results: Twelve participants (11%) screened positive for Food Addiction (FA). Analyses of covariance (ANCOVAs) controlling for BMI were conducted to compare those who screened positive versus negative on FA. Veterans with FA had significantly higher scores on screeners for depression (F=8.18, p

Symposium 48B

A SINGLE-ITEM SCREENING MEASURE FOR BINGE EATING

Lindsey Dorflinger, PhD

Binge eating disorder (BED) is rarely screened for or detected as part of standard medical care, largely because there are currently no assessment tools that are sufficiently brief and specific enough to make routine screening feasible. However, given that BED is associated with a number of medical and psychiatric issues, including cardiovascular disease, metabolic syndrome, depression, and anxiety, and because effective and accessible treatments for BED have been established, the identification of BED in medical settings could facilitate timely referral to treatment, and potentially subsequent improvement in comorbidities. Therefore, the present study sought to examine the validity of a single-item screening measure for binge eating among veterans, who have shown to have high rates of binge eating as well as associated medical and psychiatric comorbidities. Participants were 116 veterans referred to the MOVE! program, a primary care-based weight management program implemented throughout VA nationally. Participants had a mean age of 61.66 years (SD = 8.73) and mean BMI of 37.90 (SD = 7.35). The item, the VA Binge Eating Screener (VA-BES), was derived from the widely-used VA MOVE!23 and MOVE!11 surveys, which have been used as part of clinical care within VA to assess factors that affect weight and weight-related behaviors and tailor treatment to each veterans' needs. All participants completed the Questionnaire of Eating and Weight Patterns – Revised (QEWP-R) to assess for BED, the VA-BES, and measures of disordered eating and depressive symptoms. Patient responses to the QEWP-R showed a prevalence of BED of 7.76%, and that frequency of binge eating ranged from zero to 21 episodes per week. The VA-BES was compared to the QEWP-R to determine the sensitivity, specificity, positive predictive value, and negative predictive value for each cutpoint. One cutpoint (≥2 binge eating episodes per week) maximized these values, demonstrated excellent agreement with the QEWP-R ($\chi^2 = 24.79$, $p < .001$), and had significant associations with measures of disordered eating, emotional overeating, and depressive symptoms. The VA-BES appears to be a useful and valid measure of binge eating in veterans, and is brief and targeted enough to be routinely used in primary care and other outpatient medical settings in which the identification of binge eating and referral to treatment could ultimately have beneficial effects on the medical issues at hand. The VA-BES demonstrated good concurrent validity, sensitivity, and specificity in this sample of overweight and obese veterans; future studies should also assess its utility in other samples.

Symposium 48C

VALIDITY OF SELF-REPORTED WEIGHT: MEASURING WEIGHT REPORTING BIAS IN VETERANS WITH OVERWEIGHT/OBESITY

Phoutdavone Phimphasone, M.A.

Understanding how individuals self-report height and weight is important given that measurement of objective heights and weights is not feasible or practical for many large-scale studies. Previous research has investigated reporting biases in US general populations and clinical samples, with participants generally under-reporting weight. To date, only one study investigated the accuracy of self-reported height and weight among Veterans.

This study investigated the accuracy of Veterans' self-reported weights compared to measured weights obtained from electronic medical record (EMR). Veterans (N=127) were recruited from a weight management program at VA Connecticut Healthcare System and completed a battery of self-report questionnaires at their orientation session. Veterans reported their current weight, and their weight 3, 6 and 12 months ago. The orientation session date was considered the index date. Measured weights were obtained from EMR from time points of interest (orientation, and 3, 6, and 12 months prior to orientation) with acceptable window of (+/- 30 days) from each time point. The Bland-Altman plot method was used to quantify the agreement between the self-report and EMR weights by constructing limits of agreement.

Analyses have been conducted on 88 Veterans for current and 3-month self-reported and EMR weights. Participants (n= 80 male; n = 8 female) had mean age of 62.03 (SD=8.9), average BMI of 38.03 (SD = 7.47), and 77% were Caucasian. For current weight, the average difference was -2.8lbs (0.91kgs, SD = 15.33) with Veterans under-reporting weight than EMR weight; limits of agreement -27.56 to 32.87. For 3-month weight recall, the average difference was -0.73 lbs (0.33 kg, SD = 11.76); limits of agreement -22.70 to 23.76. Linear regression analyses revealed that there were no significant proportional biases in weight recall; standard deviations were large indicating significant individual variability in recall. Final analyses will include the entire sample (N=127) and all four weight collection time periods (orientation, and 3-, 6,- and 12-months).

Preliminary analyses demonstrated that Veterans accurately recalled their current weight and their weight three months compared to EMR; they were also better reporters than the general population who significantly under-report their current weight by 6-13lbs (3-6 kg). Understanding biases in reporting of weights strengthens our confidence in studies that utilizes self-report methods for collecting weight and weight trajectory data.

Symposium 48D

MODIFIABLE RISK FACTORS AMONG WEIGHT LOSS SEEKING VETERANS WITH PAIN

Kathryn Godfrey, MS

Rates of overweight/obesity approach 75% in some Veteran samples. Chronic pain is also highly prevalent among Veterans with up to 70% of Afghanistan and Iraq Veterans endorsing pain lasting 3 months or longer. Overweight/obesity and chronic pain frequently co-occur and demonstrate a reinforcing, bidirectional relationship. Individuals with pain and obesity often attribute weight gain to difficulty with exercise due to pain. However, less is known about how pain relates to other potentially modifiable factors, such as eating behaviors and psychiatric symptoms. This study examined the characteristics of Veterans with and without pain that were initiating weight loss treatment (MOVE!) at VA Connecticut. Veterans enrolling in MOVE! (N = 126) completed measures of psychiatric, eating, sleep, and pain symptoms. The sample was mostly male (90%), White (75%), and non-Hispanic (93%) with average age of 62 years (SD = 8.6) and average body mass index (BMI) of 38 (SD = 7.4). Mean self-reported pain rating was 4.11 (SD = 2.26, range = 0-10). Moderate to severe pain, defined as a current pain rating of 4 and above, was endorsed by 57% of the sample. BMI was not significantly different between Veterans with and without pain; however, Veterans reporting pain reported higher levels of weight concern (p = 0.017), emotional overeating (p = 0.030), and night eating (p = 0.033). They also had significantly higher scores on measures of depression (p = 0.002), post-traumatic stress disorder (p = 0.005), and insomnia (p < 0.001).For Veterans seeking behavioral weight loss treatment, moderate to severe pain is associated with more severe mental health problems, disordered eating symptoms, and sleep disturbance, all of which may negatively impact weight loss outcomes. A better description of the clinical characteristics of Veterans with pain who participate in MOVE! can highlight their unique needs and improve treatments to address chronic pain in the context of weight loss treatment.

Symposium 49 8:00 AM-9:15 AM

PEER SUPPORT: GLOBAL DISSEMINATION AND LESSONS LEARNED

Edwin B. Fisher, Phd[1], Henriette Curtz Jansen, Master of Sports Science[2], Yuenxing Liu, PhD[3], Guadalupe X. Ayala, Ph.D. MPH[4], John Elder, PhD, MPH[4]

[1]Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC; [2]Municipality of Copenhagen, Farum, Hovedstaden, Denmark; [3]Shanghai Jiaotong University Affiliated Sixth People's Hospital, Shanghai, Shanghai, China (People's Republic); [4]San Diego State University, San Diego, CA

Abundant evidence supports the value of peer support interventions including involvement of community health workers, *Promotores de Salud,* coaches and others. Despite their strengths, implementation of such programs presents numerous challenges. Who will be the peer supporters? How will they be trained? Will they work with groups, individually, by phone? Who will supervise them? How will quality be assured? In what organization will they be based? Will they be part of clinical teams or community based? If dealing with complex diseases, what are the limits of their roles and the linkages with professionals? This symposium presents the lessons learned from peer support programs in Copenhagen, Shanghai, and along the California-Mexico border. In Copenhagen's *Health in Your Language,* peers carry out dialogue based meetings and varied activities to address risks for noncommunicable diseases and HIV among varied immigrant groups. *Men in Copenhagen* promotes strengthened social relations and mental health among unemployed, mostly unmarried men with limited education and who are at risk for type 2 diabetes. The Shanghai Integration Model (SIM) brings together specialty/hospital and primary care for diabetes. Drawing on training that has led to over 35 programs in China and successful models for peer support in Community Health Centers, programs in Shanghai have addressed how to place peer supporters in Community Health Centers, link them with hospital-based clinical and training resources, and deploy them to facilitate self management as well as planned care within the SIM. In southern California, an academic-community partnership led to the development and implementation of peer support programs to promote healthy eating, diabetes control, and asthma control, and to prevent and control childhood obesity in the US Hispanic/Latino community. Program structures have varied from stand-alone programs to integration into clinical care. Across all of these programs, the *continuum of peer support* – from community to clinic, mutual help to highly trained peer coaches, individual to group, general health to disease-specific objectives – emerges as both a challenge of peer support and the base of its vitality.

Symposium 49A

PEER SUPPORT IN THE COPENHAGEN MUNICIPALITY HEALTH DEPARTMENT

Mrs. Henriette Curtz Jansen, Master of Sports Science

Copenhagen Municipality has initiated three innovative peer support approaches as part of a strategy to curb inequality in health and reach populations at special risk and hardly reached by traditional health services. The respective target groups are:

1. Ethnic minority groups at risk for noncommunicable diseases (especially immigrants from Middle Eastern countries)

2. Ethnic minority groups experiencing high rates of HIV (especially from sub-Saharan Africa, Eastern Europe, Thailand and the Philippines)

3. Men at risk of type 2 diabetes (especially unemployed single men with limited education, over the age of 45).

For the two first target groups the program Health in Your Language emphasizes peer education and role modeling. Trained peer health advisors, recruited from relevant ethnic groups, facilitate dialogue-based meetings on health topics in everyday settings. Peer health advisors also facilitate activities with professional health workers, bridge building citizens and municipal staff. In 2015 more than 6000 people attended activities facilitated by peer health advisors. Based on Health in Your Language, a special team of ethnic minority health advisors from sub-Saharan Africa, Thailand and the Philippines offer tailored activities such as health advice, health quizzes, checks and on-site HIV tests.

For men at risk for diabetes, a program starting in March 2016, Men in Copenhagen addresses health in a broader perspective. Here, peers facilitate informal social activities (walks and talks, social networking, games, social cooking etc.) to the target group and when needed bridge build to health related services such as smoking cessation classes, etc. To facilitate access, there are no requirements of registration to attend activities. In contrast to Health in Your Language, the focus is not primarily on delivering health advice and knowledge, as it is assumed to create distance to the target group. Rather social relations and mental health is strengthened as a pathway to improved health. All initiatives seek to “meet participants where they are,” thus working with religious and voluntary institutions, housing areas, shelters etc. Peers are paid by the hour and continuously guided and trained.

Organizational strengths of working with peers in these programs are:
1) Continuous generation of knowledge about hardly reached groups through their interactions with peers

2) Peer workers' ability to navigate easily in settings where health professionals, even those focused on community outreach, cannot.

Organizational challenges include supporting and maintaining peer teams which can be time consuming and challenging.

Symposium 49B

PEER SUPPORT IN THE SHANGHAI INTEGRATION MODEL

Yuenxing Liu, PhD

In China, recent government reforms to establish community health centers (CHCs) as the principal providers of primary and routine health care have led to a need for innovative approaches to care of chronic conditions like diabetes. New approaches aim to redefine the model of chronic disease care in China by reversing the underutilization of CHC-based primary care, linking CHCs with hospital-based specialty care, and strengthening the capacity of CHCs through the training of care teams. Shanghai has been a national leader in the modern era of healthcare reform. The Shanghai Integration Model (SIM) brings together primary and specialty/hospital care for diabetes through shared treatment algorithms, patient education, referral plans, and information systems as well as extensive training of CHC clinicians in diabetes care. It encourages those with diabetes to receive routine care through CHCs near where they live, relying on specialty/hospital care for complex problems and complex medical treatment. Peer support can facilitate this transition, promoting excellent care as a collaboration with CHC primary care to promote daily management and quality of life, backed up by appropriate specialty/hospital care. Our previous collaborations have documented the benefits of peer support through CHCs and trained over 500 professionals, resulting in over 35 ongoing peer support programs. Applying this experience to peer support in the SIM, objectives include: 1) expand the capacity of CHCs to provide ongoing diabetes self-management support, 2) strengthen linkages between primary and specialty care, 3) improve the efficiency of healthcare utilization, and 4) improve patient outcomes and quality of life. Peer support in the SIM encourages regular care through CHCs, promotes active management of diabetes, extends the education provided to patients by professionals, works with CHC staff to provide individualized care, and reinforces referrals to specialty/hospital care as well as the return to CHCs for regular care. How to organize this is challenging. Hospital-based staff and resources assist CHCs with program development and resources for training peers. CHCs recruit and supervise peer supporters and provide their base of operations. Collaboration among CHCs and hospital staff includes common peer support protocols, materials, and monitoring procedures to provide standardization while also encouraging tailoring to individuals and communities served. This approach harmonizes the strengths of both sectors, CHCs and hospitals, in extending integration of care to integrated support for those with chronic disease.

Symposium 49C

PROMOTING HEALTH THROUGH PEER SUPPORT IN THE US HISPANIC/LATINO COMMUNITY: VARIATIONS ON A THEME

Dr. Guadalupe X. Ayala, Ph.D. MPH

Over the past 10 years, an academic-community partnership between the Institute for Behavioral and Community Health and *Clinicas del Salud del Pueblo*, Inc. has developed and evaluated a number of peer support programs to reach predominantly Mexican-origin individuals and families to prevent and control a variety of chronic diseases. Among several considerations to program development have included the extent to which the peer supporters are integrated into clinical care and whether or not they are paid for their efforts. The inception of this work began with a stand-alone model of peer support to promote healthy eating through a family-based program. Using a video based on edutainment principles, community health workers or *promotoras* from the clinic conducted home visits with families to promote the adoption of healthy eating behaviors such as family meals. This study resulted in improvements in mothers and children’s dietary intake, mothers’ parenting behaviors, and in the healthfulness of the home environment. A recent innovation involved the integration of community health workers into a clinic-based obesity care model to prevent and control childhood obesity. In this study, pediatric patients and their families were referred to a Family Wellness Program organized by the clinic’s Outreach Department to extend healthcare into the community. Community health workers led the Family Wellness Program which provided parents and children with the skills to modify their behaviors, relationships and environment to promote healthy eating, physical activity, water consumption and quality sleep. This study resulted in significant decreases in child BMI, as well as healthier eating behaviors. In addition to testing approaches that vary on level of integration, we have also considered the ongoing challenges of sustaining such models of care without adequate health care funding. As such, the team has evaluated volunteer models of peer support, including within the context of diabetes control. These efforts have resulted in improvements in glucose control as measured by glycated hemoglobin and improvements in fitness as measured by a step-test. However, sustainability remains a challenge despite the volunteer-status of the peer supporters. Peer support models can vary on a number of dimensions, including those discussed here. Researchers and practitioners need to consider the models that are most suited for the specific problems, groups, and settings programs address.

Symposium 50 8:00 AM-9:15 AM

THE IMPORTANCE OF THE FAMILY CONTEXT IN PREVENTING AND TREATING CHRONIC HEALTH CONDITIONS IN DIVERSE CHILDREN

Sarah Domoff, PhD[1], Michelle Eakin, PH.D.[2], Kristi E. Gamarel, PhD, EdM[3], Daniel Mello, N/A[4], Elizabeth Towner, PhD[5]

[1]Central Michigan University, Mt. Pleasant, MI; [2]Johns Hopkins University, Baltimore, MD; [3]Brown University School of Public Health, Providence, RI; [4]University of California, Merced, Merced, CA; [5]Wayne State University, Detroit, MI

Chronic health conditions, such as asthma, obesity, diabetes, and HIV, disproportionately affect low-income and racially/ethnically diverse children and their families. Understanding and intervening on the social and contextual determinants of health may facilitate efforts to eliminate health disparities. Addressing the cross-cutting themes of the Society of Behavioral Medicine 38th Annual Meeting (i.e., addressing health disparities and the social context and health behaviors), this symposium will present four papers that evaluate the role of family contextual factors in health conditions salient to racially/ethnically diverse children. The first paper will examine how family routines associate with asthma management in preschool-age children recruited from an inner city Head Start. The second paper will characterize how mealtime TV viewing associates with family functioning and mother engagement with child mealtime behaviors in low-income families with school-age children. The third paper tests whether HIV stigma predicts mental health symptoms in parent-child dyads in South Africa. Finally, in a sample of late adolescents from impoverished neighborhoods, the fourth paper will evaluate the role of family relationship quality on diabetes management. Particular strengths of this symposium include multidisciplinary presenters (e.g., pulmonary medicine, child clinical psychology, public health, health psychology, and family medicine) and the utilization of diverse methodologies (e.g., home observations, dyadic analyses, biological assays). The discussant will facilitate conversation among presenters and attendees on how clinicians can intervene on family and other social contextual factors to reduce health disparities in ethnic/minority children.

Symposium 50A

TV USE DURING MEALTIME IN LOW-INCOME FAMILIES: ASSOCIATIONS WITH FAMILY FUNCTIONING AND MEALTIME INTERACTIONS

Dr. Sarah Domoff, PhD

Background: Mealtimes have been proposed as a family context that could be targeted to prevent childhood obesity. However, TV viewing during mealtimes (more prevalent in low-income households) may interfere with the psychosocial benefits of shared family meals, such as parent-child engagement. The aim of this study was to examine how TV use during mealtime associates with family-level functioning and maternal engagement among low-income children and their families. These behaviors are hypothesized to be important mechanisms through which family meals may be protective against child obesity risk.

Methods: This study is part of an ongoing longitudinal study of low-income mothers and their children, originally recruited from Head Start preschools. Family mealtimes were video-recorded by mothers when children were 4-8 years old (*M* age = 5.9 years, *SD* = 0.7; 48.2% female). The majority of children (53.4%) were non-Hispanic White, with 16.7% non-Hispanic Black, 17.1% Biracial, and 12.0% Hispanic. Of the 301 participants, 251 had videorecordings (83.4%). The primary variables examined here were collected through observational coding of family mealtime recordings. After achieving reliability ($\kappa > .70$), trained research assistants coded mealtimes for family-level functioning, mother-child engagement and affect, and mealtime TV exposure (i.e., duration of audible TV during meal) and mealtime TV engagement (i.e., amount of time child/mother directed eye gaze to TV). Linear regression analyses were conducted to test whether greater mealtime TV exposure and engagement predicted poorer family-level functioning and less maternal engagement or positive affect with child.

Results: After controlling for important confounders, analyses indicated that greater TV exposure during mealtime was associated with poorer family functioning during mealtime ($B = -.13$, $p < .05$) and less maternal positive affect ($B = -.23$, $p < .05$). Mothers of children who had greater TV engagement during mealtime engaged less with their child overall ($B = -.14$, $p < .05$), and engaged less with their child’s eating during the meal ($B = -.13$, $p < .05$).

Conclusions: Utilizing observational methodology to characterize family meals, this study elucidated potential mechanisms by which mealtime TV use may confer risk for child obesity in low-income families.

Symposium 50B

MEDICATION ROUTINES ARE ASSOCIATED WITH HIGHER MEDICATION ADHERENCE AND WORSE ASTHMA CONTROL AMONG URBAN PRESCHOOL CHILDREN

Michelle Eakin, PH.D.

INTRODUCTION: Management of a child with asthma includes multiple behavioral and environmental strategies. Families of school age children who integrate these strategies into their routines report higher adherence but it is not known how these routines may impact asthma management behaviors and overall asthma control in an urban preschool population.

METHODS: Children with asthma were recruited from Baltimore City Head Start to participate in a randomized trial of asthma education. Families complete an in-home baseline assessment that included the Asthma Routines Questionnaire (ARQ), Family Asthma Management System Scale (FAMSS) and Test of Respiratory Asthma Control in Kids (TRACK).

RESULTS: 328 primary caregivers (94% African American, 63% reported earning less than $20,000/year) of a child with asthma (61% male, 3.5±0.7 years) completed the assessment. Medication routine burden was associated with higher asthma knowledge (r=0.16) symptom awareness (r=0.17), balanced integration (r=0.18) and medication adherence (r=0.19) on the FAMSS using Spearman correlations. However, there was a negative association between medication routines and asthma control (r=-0.15).

CONCLUSIONS: Preliminary results indicate that better medication routines were associated with higher self-reported adherence and asthma management skills but an inverse related to asthma control. Families with children with uncontrolled asthma are more likely to have to administer a daily medication and set up a medication routine, while families of children with mild asthma only manage it sporadically. It is important for clinicians to integrate targeted patient education about medication adherence, including the establishment of behavioral routines to reduce known asthma medication adherence health disparities.

Symposium 50C

THE DYADIC EFFECTS OF HIV STIGMA ON THE MENTAL HEALTH OF CHILDREN AND THEIR PARENTS IN SOUTH AFRICA

Dr. Kristi E. Gamarel, PhD, EdM

Background: Evidence illustrates that HIV stigma – both ‘enacted stigma’ towards people living with HIV and ‘stigma by association’ towards their families – is linked with adverse individual mental health outcomes. However, questions remain unanswered with regards to family dynamics of HIV stigma, specifically whether parental experience of HIV adversely influence child mental health outcomes and vice versa. This study examines reciprocal impacts of HIV stigma on parent and child mental health in South Africa, a country with a large generalized epidemic.

Methods: Parent-child dyads (n=2477) in KwaZulu-Natal Province, South Africa participated in a cross-sectional survey. Parents and children completed measures of enacted HIV stigma, stigma by association, depressive symptoms, and anxious symptoms. Parents reported their HIV status, child orphan status, age, gender, food insecurity, and education. Analyses using structural equation modeling were used to examine the influence of HIV stigma on depressive and anxious symptoms.

Results: Accounting for sociodemographic characteristics, both parent's and children's reports of greater HIV stigma were independently associated with higher levels of anxious and depressive symptoms (all $p < 0.001$). Parents' reports of enacted HIV stigma were independently associated with children's greater depressive symptoms (p<0.01) and anxious symptoms (p<0.01). Similarly, children's reports of HIV stigma by association were independently related to parents' greater depressive and anxious symptoms (both p<0.01).

Conclusions: Findings provide support for a cross-over effect of HIV stigma on the mental health of families affected by HIV, such that each family members' experience of stigma negatively impacts their own and their family members' mental health. Future research and family-based approaches to stigma-reduction interventions to alleviate mental health problems will be discussed to guide programs to improve the mental health of parents and children affected by HIV in South Africa.

Symposium 50D

FAMILY RELATIONS AND EXECUTIVE FUNCTION MEDIATE NEIGHBORHOOD DISORDER RISK IN ADOLESCENTS WITH TYPE 1 DIABETES

Daniel Mello, N/A

Characteristics of impoverished neighborhoods (e.g., % unemployed or receiving public benefits) are linked to poorer health (Chen & Paterson, 2006; Dulin-Keita, Casazza, Fernandez, Goran, & Gower, 2012), but the mediating processes remain unclear. Such characteristics contribute to family stress and parenting behaviors (Drew et al., 2011) that may undermine the development of adolescents' self-regulatory skills (Schroeder & Kelley, 2009), which support type 1 diabetes management (Berg et al., 2014). The current study examined whether the association of Neighborhood Disorder (ND; Dulin-Keita et al., 2012) to diabetes management during late adolescence was mediated by lower parent–child relationship

quality and its links to poorer executive functions. Late adolescents (*N* = 247; *M* Age = 17.8, *SD* = .40; 65% female; 75% non-Latino White) with type 1 diabetes completed measures of parental acceptance, executive functions (BRIEF; Guy, Isquith, & Gioia, 2004), and adherence; glycemic control was indexed by HbA1c assay kits. ND was captured by combining five U.S. Census-derived indicators (e.g., % youth living in poverty, number of vacant units). Mediation models revealed ND was linked to poorer HbA1c partially through lower parental acceptance and, in turn, poorer executive function (bias-corrected 95% confidence interval range for standardized indirect effects [ab = .006]: .001 – .021). ND was linked to poorer adherence only by full mediation through parental acceptance and executive function (bias-corrected 95% confidence interval range for standardized indirect effects [ab range = -.025 to -.015]: -.059 to -.003). Overall, family relationship quality may be a modifiable factor that underlies the risk of ND on diabetes management.

Symposium 51 8:00 AM-9:15 AM

EMERGING ISSUES IN GENOMICS IMPLEMENTATION AND TRANSLATION

Barbara B. Biesecker, PhD, MS[1], Jennifer M. Taber, PhD[2], Catharine Wang, PhD, MSc[3], Colleen M. McBride, PhD[4]

[1]National Human Genome Research institute, National Institutes of Health, Bethesda, MD; [2]Kent State University, Kent, OH; [3]Boston University School of Public Health, Boston, MA; [4]Emory University, Rollins School of Public Health, Atlanta, GA

The landscape of genomics continues to evolve rapidly and has outpaced our understanding of how to best implement and translate genomic information to improve the health of populations. Conventional models to convey genomic information have been challenged as scientific discoveries occur and the demand for genetic services increases. Moreover, the changing nature of genomic information and the online availability of personal genomics testing underscore the need for evidence of clinical and personal utility. This symposium highlights research examining the translation of genomics within this changing landscape. Presentations on evidence from three endeavors will contribute to informing future implementation: 1) models to return carrier results, 2) re-contacting individuals to convey reinterpretation of variants and 3) interpretation of raw DNA. The first speaker will present outcomes from a randomized controlled trial of 446 participants examining the effect of receiving carrier results from a genetic counselor or through an online interface. This work tests the relative value of two models for conveying carrier status from genome sequencing. The second speaker will present qualitative and quantitative data from a study designed to assess the outcomes of conveying reinterpretation of variants to 29 individuals, in comparison to a matched control group (*n*=28). The third speaker will present results from two complementary surveys conducted with (a) 321 consumers and (b) 83 genetic counselors, to examine respective experiences with online raw DNA interpretation services, and describe outcomes of genetic counseling sessions with consumer clients. Finally, the discussant will consider the implications of these findings for genomics translation, highlight related emerging issues in ongoing precision (behavioral) medicine efforts, and offer insights into future genomics translation research priorities and how the field can build upon the findings presented in this symposium.

Symposium 51A

RESULTS FROM A RANDOMIZED CONTROLLED TRIAL COMPARING TWO MODES OF DELIVERY OF CARRIER RESULTS ASCERTAINED BY GENOME SEQUENCING

Dr. Barbara B. Biesecker, PhD, MS

A growing volume of genomic testing has fueled studies to identify alternative modes of results delivery that may be as effective as genetic counseling but more efficient. We conducted a trial of 461 adult participants enrolled in a genome sequencing study to assess equivalence between return of carrier results from a genetic counselor and a tailored web-based platform. All participants were randomized to delivery mode. Those in the genetic counselor arm had significantly higher formal education, but there were no other significant differences in socio-demographics. Follow up survey data were ascertained at one month and six months after receiving results. Primary outcomes were knowledge, psychological responses including uncertainty, and communication of results to children. Participants receiving results from the genetic counselor scored higher in knowledge of heredity concepts ($p<0.05$) at one month. There were no significant differences in knowledge domains between delivery modes at six monthds. No difference was seen in perceptions of positive responses to results or uncertainty at one month and at six months. Participants receiving results from the website had significantly higher distress at one month ($p<0.05$) but not at six months. The aggregate distress ratings at both times were <0.3 on the MICRA subscale (0-5). Responses to open-ended questions about results demonstrated misunderstanding about the implications of carrier results among 20% of participants who received results from the website, suggesting that harms may have been incurred that did not occur in the genetic counselor arm. Seventy-two percent and 78% of participants communicated the carrier results to their adult children with no significant differences between arms. Additional analyses of independent variables associated with outcomes, fidelity to the intervention, participant preferences and feasibility are underway. Early results suggest little difference in primary outcomes between the study arms. Yet there is qualitative evidence of misunderstanding that may be sufficiently high to suggest that even highly educated participants may not understand their carrier results as well after receiving them from a website and that equivalence was not attained.

Symposium 51B

RESPONSES TO REINTERPRETATION OF A GENE VARIANT BY PARTICIPANTS IN A SEQUENCING STUDY

Dr. Jennifer M. Taber, PhD

As discoveries in genome science advance, people who received personalized genetic risk or carrier information may subsequently receive corrections. Little is known about the consequences of these corrections. We conducted an exploratory study examining participants' immediate and short-term responses to such a correction for one gene variant. Data were collected from participants (*n*=57, ages 50-70) in an NIH sequencing study (ClinSeq®). Some (*n*=29) originally learned they were carriers of Duarte variant galactosemia. However, the variant was later reclassified as benign and participants' sequences were reassessed. *Positive testers* (*n*=19) had a newly identified causative variant and were told they were carriers. *Negative testers* (*n*=10) were told they were not carriers. Data were also collected from 28 *controls* who had learned that they were carriers for a disease of comparable severity and had not received a correction. A survey was administered immediately after participants received corrected results. Controls received the survey after being reminded of their previous result. All participants completed a 3-month follow-up. When positive and negative testers were asked to recall the correction information, only 1 participant in each group indicated a misunderstanding or did not recall the information (for a total of 4 out 29 participants). All others demonstrated complete or partial recall accuracy. When asked how the information made them think or feel, most positive (63.2% at 3 months) and half of negative testers (50% at 3 months) indicated either positive (i.e., reassured) or neutral reactions. Positive testers reported lower intentions to share their results than negative testers (*p*=.016) and controls (*p*=.003; *F*(2)=5.46, *p*=.007). Positive (*p*=.026) and negative testers (*p*=.018) had higher intentions than controls to learn results for preventable disease in the future (*F*(2)=4.23, *p*=.020). Intentions to learn results for unpreventable disease showed a similar pattern (*F*(2)=3.39, *p*=.041). There were no differences among controls and positive and negative testers in perceived ambiguity, accuracy of the results, negative emotions (feeling upset, anxious, regret), or uncertainty about results' implications. Although it is unknown to what extent these results will generalize to actionable diseases and other samples as genome sequencing becomes more accessible, results suggest that informing people of corrections to personally relevant risk information may not have adverse effects.

Symposium 51C

DO-IT-YOURSELF (DIY) GENOMICS: CONSUMER AND GENETIC COUNSELOR RESPONSES TO ONLINE RAW DNA INTERPRETATION

Catharine Wang, PhD, MSc

Online services are currently available to assist consumers in interpreting their raw DNA, yet little is understood about the utility of these services and the downstream implications, if any, on genetic service providers. To gain insight on these issues, complementary surveys were administered online to (1) 321 consumers of raw DNA interpretive services and (2) 83 genetic counselors. Surveys were designed to examine respective experiences with raw DNA interpretation services, and corresponding issues that may have arisen from counseling these consumers. The majority of consumers use one of five companies to interpret their raw DNA; 73% used more than one. Company choice was driven by the type of results offered (51%), price (45%), online reviews (31%) and recommendations by friends/family (15%). Only 5% sought advice from a medical professional before using a service. Among the 30% who shared results with a medical provider, 80% shared with their primary care doctor, 14% with a genetic counselor, and 25% with other specialist. Overall, 81.5% of consumers reported being satisfied or very satisfied with the information they received. Among the 18.5% who were less satisfied, qualitative reasons included confusion with the information presented and feelings that the information was incomplete. Among genetic counselors, 53% reported having ever been contacted by a consumer following the use of a service to interpret raw DNA data. Among counselors who had been contacted, 72% saw at least one or more cases. Patients requested counseling for the following disease specialty areas: cancer (52%), neurology (21%), metabolism (17%), pediatrics (10%), psychiatric (10%), hematology (7%), dementia (7%), other (14%). Counselors' quantitative ratings of patients' emotional state pre- versus post-counseling included worried (67% vs 12%, p<.001), confused (43% vs 27%, ns), upset (18% vs 31%, ns), ambivalent (11% vs 15%, ns), reassured (0% vs 27%, p=.006) and relieved (0% vs 31%, p=.003). Counselors' overall impressions of the session were mostly negative (48%) or mixed (20%) versus positive (32%). Challenges during counseling included patients' unrealistic expectations about what testing would tell them and overemphasis on the validity of results reported by these services. Counselor ratings of the clarity and informativeness of the DNA reports were low. In sum, although consumer respondents reported high satisfaction with online raw DNA interpretative services, genetic counselors expressed many challenges with counseling these types of patients. The downstream implications resulting from consumer efforts to interpret their raw DNA will be discussed.

Symposium 52 8:00 AM-9:15 AM

EXPLORING INTERSECTIONALITY AND WOMEN’S HEALTH

Ariella R. Tabaac, MS[1], Veronica Njie-Carr, PhD[2], Ivy Ho, PhD[3], Jasmine Abrams, PhD, MS, BS[4]

[1]Virginia Commonwealth University, Richmond, VA; [2]University of Maryland School of Nursing, Baltimore, MD; [3]University of Massachusetts Lowell, Lowell, MA; [4]University of Maryland, Baltimore County, Baltimore, MD

Conceptualized by theorist Kimberlé Crenshaw, Intersectionality is a framework that posits that people can belong to multiple social categories (e.g., race, gender, sexual orientation) that intersect and reflect differing forms of privilege or systemic discrimination (e.g., racism, sexism, heterosexism). From a public health perspective, this entails examining how people experience different forms of societal-level discrimination, barriers to care, or health risk behaviors in relation to the intersection of personal identities. In addition, it challenges how societal-level discrimination impacts health behaviors and patient outcomes from a multidimensional approach. Given the multidimensional and multi-level approach of the Intersectionality theory, it can be adapted to provide conceptual background for behavioral health research through the use of identity-based determinants of health and the interaction of health disparities and social injustice. The primary purpose of this symposium is to present behavioral health research from an Intersectionality perspective to address the following aims: 1.) To discuss how the Intersectionality can be applied to different populations and health behaviors in women’s health research, 2.) To showcase research projects that have taken an Intersectional approach, and 3.) Discuss challenges and next steps in applying Intersectionality to women’s health research. Individual presentations will focus on unique areas of identity and its intersection with gender and will include theoretical and empirical presentations. Themes will include the intersection of gender with sexual orientation, socioeconomic status, race and ethnicity, culture, and immigration status, and will incorporate micro- and macro- levels of determinants of health.

Symposium 52A

USING INTERSECTIONALITY AS A FRAMEWORK TO EXPLORE CERVICAL CANCER SCREENING DISPARITIES AMONG SEXUAL MINORITY WOMEN

Ariella R. Tabaac, MS

Sexual minority women (SMW; i.e., lesbian, bisexual, and queer women) are at a heightened risk for cervical cancer due to low rates of cervical cancer screening and a greater incidence of smoking and other cancer risk behaviors. Research has found that primary reasons for nonscreening include lack of provider, lack of provider referral, or misconceptions about susceptibility. Provider heterosexism is one barrier to cervical cancer screening, and can influence perceptions about susceptibility to human papillomavirus (HPV), the primary cause of cervical cancer development, or lead to health care avoidance due to anticipated discrimination. Research on screening has yet to account for how identification with multiple minority groups may amplify cervical cancer risk, screening behavior, or health care access. The goal of this presentation is to address current research on cervical cancer screenings in SMW, and to discuss how an Intersectionaly framework can be applied to cervical cancer research in this population. The intersection of sexual orientation, gender identity, race, age, and disability categories will be discussed.

Symposium 52B

THE INTERSECTION OF PSYCHOSOCIAL DETERMINANTS OF HEALTH AMONG SOUTHEAST ASIAN AMERICAN WOMEN

Dr. Ivy Ho, PhD

Southeast Asian American women, specifically those who are of Vietnamese, Cambodian, Lao and Hmong descent, face significant health disparities. For example, compared to their non-Hispanic white counterparts, Southeast Asian American women are more likely to die of cervical cancer and less likely to participate in cervical cancer screening. Breast cancer is also disproportionately common among Southeast Asian American women, and screening rates are low compared to White Americans. Although these cultural groups are distinct from one another, they share various historical and social similarities such as tumultuous history of political unrest, war, and genocide. The environmental and structural challenges of living for years in refugee campsunder harsh conditions exposed survivors to emotional and physical trauma and diseases. Refugees en route to the United States underwent a harrowing voyage, fraught with danger from pirates who robbed and murdered the refugees and raped the women. Contrary to the “model minority myth” that posits Asians Americans are successful, financially secure and well educated, Southeast Asian American families face multiple disadvantages. They are of among the lowest household incomes and educational attainment. Therefore, in this presentation, the intersectionality of historical, cultural, and social (socioeconomic and polical) is reviewed focusing on how immigration history, social class, gender and race intersect to influence health status among Southeast Asian American women. The presentation will include qualitative data, gathered from research on the Cambodian American community in Lowell, Massachusetts, to illustrate the psychosocial factors discussed. These data were gathered from interviews with healthcare providers who provided their perceptions of their Cambodian American female patients with regard to participation in preventative care, adherence, and health behaviors.

Symposium 52C

USING INTERSECTIONALITY TO UNDERSTAND GENDER ROLES AND HEALTH IMPLICATIONS FOR AFRICAN AMERICAN AND VIETNAMESE AMERICAN WOMEN

Jasmine Abrams, PhD, MS, BS

Discourse in Intersectionality provides dialogue relevant to racism and sexism to address and overcome dominant cultural hegemony. Underlying Intersectionality is the recognition that identity is experienced as a single, synthesized experience of many constructs. Numerous studies have applied the perspective of Intersectionality in understanding the divergence in gender roles found between African American women and White women. However, limited research has offered insight into how gender roles may differ across ethnic minority women. Indeed, research identifying similarities or disentangling differences in ethnic minority gender role beliefs has been largely absent in the literature suggesting need for qualitative exploration to increase our understanding of the phenomena. The purpose of this study was to explore and compare gender role beliefs among African American and Vietnamese American women. Thematic analyses were conducted with data gathered from eight focus groups with 44 African American women (mean age = 44) and four focus groups 47 Vietnamese American women (mean age = 42). Women were diverse in generational, religious, and educational backgrounds. Two similar primary themes emerged: (1) women's roles as chief caretakers and (2) women's responsibilities to fulfill multiple roles. There were also similar experiences of a need to convey strength and be self-sacrificial. Two distinct differences that emerged from the focus groups were beliefs about interpersonal interactions and perceptions of societal expectations. For example, women expressed contrasting views about perceptions of how a woman should act among others when in public (e.g., mild mannered versus openly strong and resilient). This study demonstrates that the conceptualization of gender role beliefs, while at times similar, diverges among culturally different groups. Health research and programming needs to account for these and other culturally nuanced differences via cultural tailoring. Implications for research and health related programming are discussed.

Symposium 53 8:00 AM-9:15 AM

THE ROLE OF RELIGION AND SPIRITUALITY IN BEHAVIORAL INTERVENTIONS

Karen Yeary, PhD[1], Crystal L. Park, PhD[2], Aasim Padela, MD MSc[3], Ananya T. Banerjee, R.Kin PhD[4], Donna Jeffe, PhD[5]

[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]University of Connecticut, Storrs Mansfield, CT; [3]The University of Chicago, Evanston, IL; [4]University of Toronto, Toronto, ON, Canada; [5]Washington University School of Medicine, Saint Louis, MO

Faith-based interventions have been successful in changing multiple health behaviors, such as fruit and vegetable intake, cancer screening, smoking, and physical activity. However the majority of these interventions have been conducted with Protestant or other Christian religious affiliations, and studies engaging other faiths are necessary to more fully understand faith-based interventions. Further, given the prominence of religiousness and spirituality in the lives of many individuals, consideration of faith may also be relevant for non-faith-based interventions.

This symposium will present the results of two qualitative studies and one quantitative study to inform attenders of key factors to consider in designing health behavior interventions for Muslim groups and a general patient population. Aasim Padela et al. will describe the key facilitators at multiple levels of the socioecological model for successful participation in an exercise intervention for South Asian Muslim women. Ananya Banerjee et al. will report the important faith beliefs identified in their qualitative work with Muslims that were used to design a faith-based intervention to increase mammography screening in Muslims. Finally, Donna Jeffe et al. will present results showing of a randomized controlled trial designed to increase adherence to recommended treatment in newly diagnosed African American breast cancer patients, showing how religion/spirituality predicted dietary change over 2-year follow-up.

At the conclusion of the individual presentations, Karen Yeary will discuss important faith components to consider in developing interventions for diverse groups, future directions for faith-based interventions, and consideration of religion and spirituality in non-faith-based interventions.

Symposium 53A

A RELIGIOUSLY TAILORED GROUP EDUCATION INTERVENTION TO ENHANCE MAMMOGRAPHY UPTAKE AMONG MUSLIMS- DESIGN ELEMENTS AND OUTCOMES

Dr. Aasim Padela, MD MSc

Background: Faith-based health interventions adopt varied approaches to engage religious theology and faith leaders in program design. Insights into strategies and design elements that breed success will allow for greater theorization and model portability across faiths. This project fills a knowledge gap regarding religiously-tailored interventions among Muslims.

Objective: To describe the design of, and participant-level outcomes related to, a religiously-tailored peer-led group education program that addressed salient mammography-related beliefs of American Muslims.

Methods: A multi-disciplinary community advisory board worked with academicians to design an intervention project focused on cancer screening. Phase 1 involved focus groups and interviews with an ethnically-diverse group of women aged 40 and older sampled from Muslim organizations to identify salient behavioral, normative and control beliefs regarding mammography. Phase 2 involved interviews with the same target population to elicit ideas about intervention design. CAB members and staff used these data to design the curriculum and messaging for Phase 3 which involved peer-led education classes aimed to enhance mammography intention.

Results: The structural elements and messages of the classes addressed barrier beliefs in at least one of 3 ways (i) Reprioritizing- introducing another religious belief that has greater resonance with participants such that the barrier belief is marginalized, (ii) Reframing the belief within a religious worldview such that it is consistent with the health behavior desired, and (iii) Reforming- using a religious scholar to provide “correct” interpretations of religious doctrine. 50 Muslim women from diverse backgrounds completed both the program and surveys that recorded changes mammography intention and resonance with barrier and facilitator beliefs.

Discussion: This feasibility trial demonstrated that there is great potential for leveraging religion in designing health promotion messages, yet there is also risk for co-opting religious teachings in the service of biomedicine. As behavioral interventions move from being faith-placed to faith-based, dialogue over the theoretical bases and ethical justifications of religiously-tailoring health messages is needed.

Symposium 53B

FACTORS INFLUENCING THE IMPLEMENTATION AND SUSTAINABILITY OF MOSQUE-BASED EXERCISE PROGRAMS FOR SOUTH ASIAN MUSLIM WOMEN

Dr. Ananya T. Banerjee, R.Kin PhD

Research shows that South Asian (SA) Muslim women have lower rates of physical activity participation and higher rates of mortality and morbidity from diabetes compared to the general population. A six-month mosque-based exercise intervention for SA Muslim women at high-risk for diabetes was implemented in Ontario, Canada. Our evidence demonstrated the exercise intervention was feasible, acceptable and sustainable. The purpose of our follow-up qualitative study was to examine the multi-level factors influencing successful participation in the exercise intervention among SA Muslim women. Key facilitators emerged from the direct content analysis of twelve semi-structured interviews and were classified at four levels based on the Socio-Ecological Model: personal, community, built environment and social. Participants identified improved personal health, Imam leadership, accessible and gender-specific spaces and social support from peers as pertinent factors for the implementation and sustainability of exercise programs in mosques. The findings have particular relevance for physical activity promotion and public health because they suggest factors necessary to design faith-based exercise interventions for ethnic communities at risk for chronic diseases.

Symposium 53C

FAITH/SPIRITUALITY IS ASSOCIATED WITH DIET CHANGE IN NEWLY DIAGNOSED AFRICAN AMERICAN BREAST CANCER PATIENTS

Donna Jeffe, PhD

Few studies have explored associations between one’s faith/spirituality and health behavior change over the course of cancer treatment and recovery. We prospectively enrolled 227 African American breast cancer patients (stages 0-3; mean age 56 [range 33-81] years; 28% married; 52% >high school graduate) to a randomized controlled trial of a cancer-information intervention’s impact (vs. standard of care) on behavioral outcomes. At enrollment (baseline), a mean 6 days from first surgical post-op visit or start of neoadjuvant therapy, we collected demographic, psychosocial, and clinical data and administered the 15-item Systems of Belief Inventory (total scores 0-45) and the 4-item Concerns about Recurrence Scale (mean scores 1-6); higher scores reflect greater levels of faith/spirituality and concerns about recurrence. At 2-year follow-up, we asked patients if a doctor/health professional advised them to make changes in their diet “since completing breast cancer treatment to improve prognosis” and if they changed their “eating habits to improve overall health” over the past two years. Multivariable logistic regression analysis identified independent predictors of diet change (yes/no) at 2-year follow-up among baseline factors significantly associated with diet change. A greater proportion of patients who were advised to make a diet change actually changed their diet compared with the proportion of patients who were not advised to make a diet change (69/76 [90.8%] vs. 87/114 [76.3%], respectively; p=.011). Higher baseline levels of faith/spirituality (mean 41.0 vs. 37.3; p = .001) and of concerns about recurrence (mean 3.2 vs. 2.5; p = .026) were reported by patients who changed their diet at 2-year follow-up compared with those who did not. Greater faith/spirituality (odds ratio [OR] = 1.07, 95% confidence interval [CI] = 1.01-1.15), being advised to make a diet change (OR = 3.97, 95% CI = 1.50-10.47), and use of endocrine therapy (OR = 0.19, 95% CI = 0.06-0.56) were independently associated with diet change, but not study arm or concern about recurrence. Studies examining African American breast cancer patients’ faith/spirituality in association with change in other health behaviors are warranted to design targeted behavior change interventions.

Symposium 54 8:00 AM-9:15 AM

THE PRESIDENT'S CANCER PANEL ON CONNECTED HEALTH: IMPLICATIONS FOR BEHAVIORAL MEDICINE RESEARCH

David K. Ahern, PhD[1], Bradford W. Hesse, PhD[1], Paul Jacobsen, PhD[1], Ellen Beckjord, PhD, MPH[2]

[1]National Cancer Institute, Rockville, MD; [2]UPMC Health Plan, Pittsburgh, PA

The President's Cancer Panel is an external advisory committee authorized by the National Cancer Act of 1971 with a chairperson and members appointed directly by the President of the United States. The Panel's charter calls for it to review all facets of the National Cancer Program and then to issue reports directly back to the President on any "blockages or delays" hindering the rapid execution of the program writ large. From 2014 to 2015, this external advisory panel convened a series of workshops on one such blockage: the discontinuities in care that occur when patients lack personal data for self-management or when communications between patients and their care teams are jumbled or missing. The purpose of the series was to evaluate the potential of using "connected health technologies" to address these discontinuities and by so doing to improve support for proactive patient engagement, for improved communications, and for accelerated discovery in research. Connected health technology, in this context, refers to the broad array of mHealth, eHealth, patient portals, wearable devices, and wireless sensors that allow for greater support to patients away from the clinic. Although there have been significant improvements in cancer prevention, early detection, and treatment over the past several decades, cancer care delivery will face significant challenges in coming years as the U.S. population ages, the oncology workforce shrinks, the costs of cancer care continue to grow, and medical advances expand treatment options. Technology-based approaches have been proposed to address these challenges in cancer care but research is urgently needed to identify effective and scalable solutions. As Chair, David Ahern will provide an overview of the workshop series and the recommendations of the Report. Brad Hesse will highlight and review the recommendations regarding research priorities. Ellen Beckjord will discuss the relevance of the key findings and report recommendations from the perspective of SBM's Digital Health Council (DHC). Finally, as Discussant, Paul Jacobsen will review and discuss the implications of the Report for behavioral medicine research on cancer prevention and control.

Symposium 54A

THE PRESIDENT’S CANCER PANEL (PCP) REPORT ON CONNECTED HEALTH: RESEARCH PRIORITIES

Dr. Bradford W. Hesse, PhD

The President’s Cancer Panel offers recommendations to the highest levels of authority for work that is critical to accomplish across multiple levels of influence in order to accelerate progress against the disease. These recommendations frequently provide guidance to policy makers and to administrative heads of government, but they also provide guidance to the biomedical community for areas of high priority research and funding – a point of keen interest to the scientific membership of the Society of Behavioral Medicine. The specific text for recommendations will be released in the last quarter of 2016, well before the 2017 SBM annual meeting. Although the specific details of the recommendations will not be available until that time, it is safe to infer from publically available materials that research will be needed to gain a better understand of how connected health applications can serve to support patient engagement as well as individuals’ pursuit of healthy behavior. Given the topic of connected health, there will also likely be an emphasis on tool development for consumers, with a scientific focus on collecting evidence for the efficacy and effectiveness of tools in practice. Because of the implications of what happens when healthcare is not connected, there will also be a need for communication research aimed at bolstering continuity in care. Another area of likely interest from the report stems the Panel’s stated interest in fostering a learning healthcare environment – an objective shared by the Vice President’s Cancer Moonshot initiative – with data from connected devices informing a new generation of discovery and translational research. In this talk, Dr. Hesse will describe the specific recommendations for research articulated by the President’s Cancer Panel in detail, highlighting their relevance to behavioral medicine. Parallels will be drawn from the ways in which connected health research in cancer apply to more general applications across diseases.

Symposium 54B

THE PRESIDENT’S CANCER PANEL (PCP) REPORT ON CONNECTED HEALTH: PERSPECTIVES FROM SBM’S DIGITAL HEALTH COUNCIL (DHC)

Dr. Ellen Beckjord, PhD, MPH

The PCP Report on Connected Health calls for creation of a learning healthcare system for cancer that will improve prevention, detection, treatment, and survivorship. High priority research in several areas could help achieve the goal of establishing a learning health care system and increase the benefits of connected health for cancer. Better tools and interfaces could be developed if more were known about how healthcare providers work together and the factors that enhance people’s engagement with their health and healthcare. Research also is needed to ensure that the vast quantities of data being generated can be used in meaningful ways to support person-centered care. Dr. Hesse will delineate and discuss the specific research priorities of the Report and their relevance to the field of behavioral medicine.

DIFFERENCES IN PERCEIVED BARRIERS TO HCV TREATMENT INITIATION IN METHADONE USERS VS. IVDUS: APPLICATION OF PERCEPTUAL MAPPING

Sarah Bauerle. Bass, Ph.D., MPH[1], Amy Jessop, Ph.D., MPH[2], Laurie Maurer, MA, Ph.D(c)[3], Mercedes Gutierrez, MD[3], Muhamed Gashat, MD, MPH[2], Elizabeth Carmody, N/A[3]

[1]Temple University College of Public Health, Philadelphia, PA; [2]University of the Sciences, Philadelphia, PA; [3]Temple University, Philadelphia, PA

Background: IV drug users (IVDUs) and those on methadone have a 67-96% HCV seropositivity rate and without treatment may develop liver cirrhosis or hepatocellular carcinoma. However, only about 11% initiate treatment. Despite increased access to new treatments, limited research has focused on the unique perceptions of treatment initiation in these populations.

Methods: A survey of barriers and benefits to HCV treatment was administered to 100 methadone clients at four centers and 50 active IVDUs who utilize a needle exchange in Philadelphia; all were HCV+. Perceptual mapping (multidimensional scaling) and vector modeling methods were used to create 3-dimensional maps to show how barriers and facilitators to HCV treatment decision making are related, and how message/intervention strategies can be tailored for a specific audience. These commercial marketing techniques, used to influence consumers toward product purchasing, can be used to understand the unique perceptions of a decision to enhance informed medical decision making.

Results: Perceptual maps show clear conceptual differences about barriers and benefits, beliefs about healthcare, and overall knowledge of HCV between methadone users and IVDUs. MMT clients believed that treatment was “worth it”, but also were concerned about the length of time it might take to get treated and tangible barriers such as transportation and paperwork. IVDUs’ self-concept of being a drug user was seen as a significant barrier to initiating treatment, and concern with insurance and ability to pay was also important. IVDUs also believed that treatment was not needed because their HCV was “not advanced” and they had “no symptoms”. These were not significant in the MMT clients, suggesting better awareness of HCV and its progression. Neither group saw significant benefits to treatments, although the concepts of being “cured” and “being in charge” were closest, indicating a significant message strategy for an intervention. No issues of trust in healthcare providers were observed, a significant finding.

Conclusions: These methods are useful in helping understand these at-risk groups' unique perceptions regarding HCV treatment and how messages might have to differ based on drug use. To increase informed decision making, interventions must include messages that address negative perceptions of treatment and promote their benefits, rather than focusing on mistrust of medical providers. But IVDUs would need better information regarding HCV in general whereas MMT clients need strategies to overcome tangible barriers.

SHOW ME MY HEALTH PLANS: USING A DECISION AID TO IMPROVE DECISIONS IN THE FEDERAL HEALTH INSURANCE MARKETPLACE

Mary Politi, PhD[1], Marie Kuzemchak, BA[2], Abigail Barker, PhD[3], Kimberly Kaphingst, ScD[4], Jingxia Liu, PhD[1], Timothy McBride, PhD[5], Matthew Kreuter, PhD, MPH[3], Sydney Philpott, BS[1]

[1]Washington University in St Louis School of Medicine, St Louis, MO; [2]Vanderbilt University School of Medicine, Nashville, TN; [3]Brown School of Social Work, Washington University, St Louis, MO; [4]University of Utah and Huntsman Cancer Institute, Salt Lake City, UT; [5]Brown School, Washington University, St Louis, MO

Introduction: Since the Affordable Care Act was passed, over 12 million individuals have enrolled in the health insurance marketplace. Without support, many struggle to make an informed plan choice that meets their health and financial needs.

Methods: *Show Me My Health Plans (SMHP)* provides education, preference assessment, and annual out-of-pocket cost calculator with plan recommendations produced by a tailored, risk-adjusted algorithm incorporating age, gender, and health status. We evaluated whether SMHP compared to healthcare.gov improved health insurance decision quality and the match between plan choice, needs and preferences among 328 Missourians enrolling in the marketplace.

Results: Participants using SMHP had higher health insurance knowledge (LS-Mean=78 vs. 62; $p < 0.001$), decision self-efficacy (LS-Mean=83 vs. 75; $p < 0.002$), confidence in their choice (LS-Mean= 3.5 vs. 2.9; $p < 0.001$) and improved health insurance literacy (OR 2.52, $p < 0.001$) compared to participants using healthcare.gov. Those using SMHP were 10.3 times more likely to select a silver-tier plan ($p < .0001$).

Discussion: SMHP can improve health insurance decision quality and can improve odds that consumers select an insurance plan with coverage likely needed to meet their health needs. This study represents a unique context through which to apply principles of decision support to improve health care choices.

FEASIBILITY AND PATIENT PERCEPTIONS OF VIDEO DECLARATIONS REGARDING END-OF-LIFE DECISIONS BY HOSPITALIZED PATIENTS

Lisa M. Quintiliani, PhD[1], Jessica Murphy, MD[1], Pablo Buitron de la Vega, MD[1], Katherine R. Waite, BA[2], S. Emily Armstrong, BA[2], Joseph Davenport, BA[3], Lori Henault, MPH[2], Angelo Volandes, MD MPH[4], Michael Paasche-Orlow, MD MA MPH[1]

[1]Boston University, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]Boston Medical Center, Watertown, MA; [4]Massachusetts General Hospital, Boston, MA

Patients are asked to complete advanced directive forms, but may benefit from additional ways to express themselves. A videotaped declaration could be a supplemental opportunity and a source of information for family and clinicians. Our aim was to evaluate the feasibility and patient perceptions of ‘video declarations’, the term we use to describe the process of patients videotaping themselves describing their wishes. We approached hospitalized patients at an urban safety-net hospital with attending referral. After a baseline survey, we showed a brief video on an iPad describing 3 approaches to end-of-life care (i.e., life prolonging care, limited care, and comfort care). We then invited participants to video themselves with the iPad, making their own declaration about their wishes if they were very sick and asked participants about the usefulness of this process. Videos were transcribed and coded by a team, with multiple stakeholder input. There were 16 participants; mean age was 60 (SD=14) years, the majority (62%) reported being either Hispanic or Black or African American and having a high school education or lower. One participant declined. Out of 15 video declarations, the majority were able to express their wishes about CPR (n=12) and intubation (n=13). Nine video declarations had directives that were judged to be unclear. Participants also frequently discussed their family structure (n=11), religious/spiritual well-being (n=8), legacy/dignity issues (n=6), and physical symptoms (n=6). Average video length was 3:10 minutes. The majority (66%) thought this process was quite a bit or extremely helpful, and 73% would be quite a bit or extremely likely to recommend this to others. These findings show that asking hospitalized patients to make videos describing their end-of life-care goals was feasible and acceptable. While the majority of participants were able to describe their wishes around CPR and intubation, a fair amount of uncertainty remained. Further research is needed to better understand how to support patients in describing their wishes clearly. Additional work is also needed regarding embedding video declarations into the EMR and other platforms for maximum impact.

SHARED DECISION MAKING IN THE UNITED STATES: PREDICTORS AND DISPARITIES

Kiara Spooner, DrPH, MPH[1], Jason L. Salemi, PhD, MPH[2]

[1]Baylor College of Medicine, Department of Family and Community Medicine, Houston, TX;
[2]Baylor College of Medicine, Department of Family & Community Medicine, Houston, TX

Background: Effective communication between patients and providers is essential to achieving positive health outcomes and high quality of care. Shared decision making—collaborative processes involving agreed-upon approaches, goals, and expectations by both the patient and healthcare provider—is a key element of patient-centered health care. Although research supports the value of shared decision making in clinical practice, more evidence is needed to better understand the factors which may influence patient involvement in health decisions. The objective of this study is to describe the national prevalence of shared decision making in the United States (U.S.) and identify differences across patient-level sociodemographic, health and risk perception characteristics.

Methods: Nationally representative cross-sectional data from the 2012 and 2014 iterations of the Health Information National Trends Survey were analyzed. Administered biennially by the National Cancer Institute (NCI) to U.S. adults 18 years and older, HINTS monitors changes in the evolution of health communication. HINTS 4 Cycles 2 (2012) and 4 (2014) data were collected via self-administered mailed questionnaires. Descriptive statistics and multivariable regression analyses were conducted to examine associations between patient characteristics and shared decision making behavior.

Results: Among survey respondents reporting at least one non-emergency visit to a healthcare provider (N=5,631), most were Non-Hispanic (NH)-white, female, aged 35-64 years, and college educated. A majority of respondents also indicated being diagnosed with at least one chronic disease (e.g., diabetes, hypertension, cancer) and having a regular healthcare provider (73.7%). Slightly more than half (53.5%) of survey respondents reported "always" engaging in shared decision making with a healthcare provider. After adjustment for confounding factors, respondents perceiving themselves as completely confident in their self-care ability, as well as those with a regular provider (odds ratio [OR], 1.62; 95% confidence interval [CI], 1.27-2.07), were significantly more likely to indicate always participating in shared decision making; while there was a lower odds of shared decision making among Hispanics (OR, 0.73; 95% CI, 0.54-1.00), compared to NH-Whites.

Conclusion: Patients' involvement in shared decision making varies across sociodemographic and health-related factors. These findings may inform efforts aimed at improving patient-provider communication, increasing the uptake of shared decision making and achieving higher quality of care.

Paper Session 27: Understanding the Role and Impact of Physical Activity among Cancer Survivors 10:45 AM-11:00 AM

CHANGES IN MUSCLE GENE-EXPRESSION, STRENGTH AND CANCER-RELATED-FATIGUE IN PROSTATE CANCER PATIENTS

Karen Mustian, PHD, MPH, MS[1], Michelle Janelsins, PhD, MPH[1], Charles Kamen, PhD, MPH[1], Ian Kleckner, PhD[1], Matthew Asare, PhD, MBA, CHES[2], Calvin L. Cole, PhD[2], Luke J. Peppone, PhD, MPH[3], Charles E. Heckler, Ph.D., M.S. [1]

[1]University of Rochester Medical Center, Rochester, NY; [2]University of Rochester, Rochester, NY; [3]University of Rochester, Wilmot Cancer Institute, Rochester, NY

Background: Radiation therapy (RT) and androgen deprivation therapy (ADT) impair muscular, mitochondrial and immune function resulting in weakness and fatigue in prostate cancer patients. We investigated the influence of an exercise intervention (EXCAP©®) on expression of muscle genes, muscular strength, and cancer-related-fatigue.

Methods: Prostate cancer patients (N=58; mean age=67), receiving RT (47%) or ADT (53%), were randomized to 6 wks of EXCAP©® (7 days/wk) or standard care (RT or ADT with no exercise) in this phase II clinical trial. RNA was isolated from muscle biopsies for microarray analyses of 4825 mitochondrial and nuclear genes. Physical strength was assessed using multiple repetition maximum testing (chest press and leg extension). Cancer-related-fatigue was assessed via the Brief Fatigue Inventory (BFI). Assessments were pre- and post-intervention. Robust multi-array average normalization was used. Analyses included analyses of covariance (ANCOVA), correlations, and partial least squares (PLS) with cross-validation.

Results: MYH8, MYL5, ACTN3, XIRP1, MTTM, and HLA-DQB1 were significantly correlated with muscle strength and cancer-related-fatigue (all p≥2-fold down regulation in MYH8 and XIRP1 in the exercise group, no ≥2-fold changes in expression in the control group, and a ≥2-fold difference between groups on MTTM where MTTM was down-regulated ≥1.5-fold in controls with no change in exercisers (all $p \leq 0.05$). ANCOVAs revealed a trend for group differences in strength (all $p \leq 0.10$) with significant group differences in fatigue ($p \leq 0.05$): exercisers improved while controls worsened. PLS suggested down-regulation of 3 novel biomarkers, MYL5, ACTN3, and HLA-DQB1, may predict increases in cancer-related-fatigue among prostate cancer patients.

Conclusions: Results suggest that exercise influences muscle's expression of genes that regulate muscular, mitochondrial and immune function and are linked to inflammatory muscle disease in prostate cancer patients; these gene expression changes may mediate

changes in cancer-related-fatigue in prostate cancer patients due to cancer, RT or ADT, and exercise. Further research is needed to validate these novel findings, to expand our knowledge regarding the role of these biomarkers in the development of cancer-related-fatigue, and to understand the influence of exercise on these biomarkers in prostate cancer patients receiving RT and ADT. ClinicalTrials.Gov: NCT00815672 Funding: DOD PC061518, NCI CA102618B, NCI CA189961.

Paper Session 27: Understanding the Role and Impact of Physical Activity among Cancer Survivors 11:00 AM-11:15 AM

REPLACING SEDENTARY TIME WITH PHYSICAL ACTIVITY: EFFECTS ON CANCER-RELATED COGNITIVE IMPAIRMENT

Diane Ehlers, PhD[1], Jason Fanning, PhD[2], Elizabeth Awick, MS[3], Susan Aguiñaga, PhD[3], Josh Cosman, PhD[4], Joan Severson, MS[5], Arthur Kramer, PhD[6], Edward McAuley, PhD[7]

[1]University of Illinois Urbana-Champaign, Urbana, IL; [2]Wake Forest University, Winston Salem, NC; [3]University of Illinois at Urbana-Champaign, Urbana, IL; [4]Pfizer, Inc., 610 Main St, MA; [5]Digital Artefacts, Iowa City, IA; [6]Northeastern University, Boston, MA; [7]University of Illinois at Urbana Champaign, Urbana, IL

Cancer-related cognitive impairment (CRCI) is recognized as a high priority in clinical research due to its significant, often long-term impact on daily functioning and quality of life. The influence of lifestyle behaviors, such as sedentary and physical activity behaviors, on CRCI is largely unexplored. Recent research has emphasized the important health implications of reducing sedentary time in cancer survivors. The purpose of this study was to examine the cognitive effects of substituting 30 minutes of sedentary behavior with 30 minutes of light activity or moderate-to-vigorous physical activity (MVPA) in breast cancer survivors. Using an iPad-based platform, 307 breast cancer survivors aged 57.29±9.82 years completed questionnaires assessing their demographics and breast cancer history, and cognitive tests assessing their executive function and processing speed (Task-Switch, Trail Making, Swap). Participants also wore an accelerometer for seven consecutive days to assess their sedentary and activity behaviors. Isotemporal substitution was used to analyze the data. The substitution of sedentary time with MVPA was associated with better reaction time on the Task-Switch stay ($\beta=-0.19$, $p=0.007$) and switch ($\beta=-0.19$, $p=0.006$) trials, and on the Swap task ($\beta=-0.15$, $p=0.04$). A positive association was also observed between light activity and Task-Switch stay reaction time ($\beta=0.16$, $p=0.05$). The substitution of sedentary time with MVPA was marginally associated with better total time on Trails A ($\beta=-0.13$, $p=0.06$). Positive associations with total time on Trails A ($\beta=0.22$, $p=0.005$) and Trails B ($\beta=0.18$, $p=0.02$) were observed when substituting sedentary time with light activity. All effects were evident independent of age and months since last chemotherapy treatment. Substituting 30 minutes of sedentary time with 30 minutes of MVPA may help ameliorate impairments in executive function related to breast cancer treatment. Interestingly, substituting sedentary time with light activity resulted in slower times on measures of executive function and processing speed. Additional research investigating moderators and latent classes of breast cancer survivors may illuminate further information to explain these relationships between physical activity and CRCI.

EXERCISE-INDUCED STRENGTHENING OF THE INFLAMMATORY CYTOKINE NETWORK IS ASSOCIATED WITH REDUCED FATIGUE IN 348 CANCER PATIENTS

Ian Kleckner, PhD[1], Calvin Cole, PhD[1], Charles E. Heckler, Ph.D., M.S. [1], J. Philip Kuebler, MD[2], Amy Brockmeyer, MD[3], Rezwan Islam, MD[4], Michelle Janelsins, PhD, MPH[1], Shelli Kesler, PhD[5], Karen Mustian, PHD, MPH, MS[1]

[1]University of Rochester Medical Center, Rochester, NY; [2]Columbus NCORP, Columbus, OH; [3]Virginia Mason, Federal Way, WA; [4]Marshfield Clinic, Weston, WI; [5]MD Anderson, Houston, TX

Background. Chemotherapy is hypothesized to cause fatigue partly via dysregulation of the inflammatory cytokine network; namely, by weakening the normal co-regulatory couplings between concentrations of pro- and anti-inflammatory cytokines. Although preliminary research suggests that exercise treats fatigue in cancer patients by favorably influencing individual markers of inflammation, no studies have examined whether exercise influences the co-regulatory couplings between concentrations of pro- and anti-inflammatory cytokines. The purposes of this study were to assess how regulation of the inflammatory cytokine network is (1) affected by exercise and (2) related to fatigue.

Methods. We performed simple network analyses (i.e., correlations matrices) on data from 348 cancer patients enrolled in a randomized trial of chemotherapy plus 6 weeks of moderate-intensity walking and resistance exercise (N = 173) vs. chemotherapy alone (N = 175) in mixed-type, early/mid-stage cancer patients (mean age = 56, 93% female). At pre- and post-intervention, patients (1) provided blood to assess concentrations of IL-1β, IL-6, IL-8, IL-10, IFNγ, and sTNFR1 via ELISA and (2) reported fatigue using the multidimensional fatigue symptom inventory.

Results. Compared to chemotherapy alone, exercise plus chemotherapy strengthened the normal co-regulatory couplings between changes in concentrations of several pro- and anti-inflammatory cytokines; specifically, between IL-6 and all other cytokines ($p < 0.05$) and between IL-10 and all other cytokines ($p < 0.05$). Among exercise participants, decreased fatigue was associated with strengthened co-regulatory coupling between changes in concentrations of IL-6 and IL-10 ($p = 0.08$).

Conclusions. Exercise strengthened the regulation of the inflammatory cytokine network via strengthened co-regulatory couplings between concentrations of pro- and anti-inflammatory cytokines. The strength of co-regulatory coupling between IL-6 and IL-10 may mediate the beneficial effects of exercise on fatigue, considering that IL-6 and IL-10 are known to contribute to the physical conditioning effects of exercise. Our novel methods to analyze cytokine data may complement traditional analytic approaches in the investigation of immune-mediated phenomena beyond this study.

Physical Activity and Sedentary Behavior in Older and Younger Breast Cancer Survivors

Gillian R. Lloyd[1], Elizabeth A. Awick[2], Whitney A. Welch[1], Edward McAuley[2] & Siobhan M. Phillips[1]

[1]Northwestern University; [2]University of Illinois at Urbana-Champaign

Background: Approximately 72% of breast cancer survivors (BCS) are over the age of 60. The combination of treatment side-effects and comorbid conditions increases older BCS' risk for frailty, disability and premature mortality. Reducing sedentary behavior (SB) and increasing physical activity (PA) may prevent or delay these adverse outcomes, however little is known about how these behaviors may differ between older and younger BCS. The purpose of this study is to examine whether SB and PA differ between older and younger BCS, overall and in various contexts (i.e. work, leisure).

Methods: Participants (N=375) wore an accelerometer on their non-dominant hip for 7 consecutive days and self-reported their time spent in PA and SB in various contexts. We used general linear modeling analyses to examine whether differences existed between older [≥ 60; n=157; M_{age}=65.1 (SD=4.4)] and younger [age=50.5 (SD=6.8) BCS on total self-reported and accelerometer-assessed PA and SB and self-reported context-specific PA and SB when controlling for relevant covariates.

Results: Total average daily minutes self-reported and accelerometer-assessed SB were highly correlated (r=1.0; *p*p=0.003). Older BCS had higher levels of total daily average minutes of accelerometer-assessed [*M*$_{diff}$= 29.3 (SE=7.9); *p=0.001] and self-reported [M_{diff}= 29.4 (SE=7.8); p=0.001] SB. Younger BCS reported more time SB at work [M_{diff}=119.2, (SE=20.6); p=*M_{diff}=36.7

(SE=8.2); p=M_{diff}= 9.4 (SE=1.9); *p0.001] and light [M_{diff}=19.6, (SE=6.7); p=*M_{diff}=1.2, (*SE*=0.43); p=0.01].

Conclusions: Older BCS engage in more SB and less PA and report greater SB during leisure time than their younger counterparts. These findings suggest it may be important to consider age when designing PA promotion and SB reduction interventions so intervention strategies can be tailored toward relevant contexts. Future research should further explore the varying contexts of PA and SB in older BCS to further elucidate what specific activities they participate in during leisure time in order to target these behaviors through tailored interventions.

ENJOYABLE, HIGHLY ACTIVE VIDEOGAMES DECREASED PHYSICAL ACTIVITY IN CHILDREN

Kristin Schneider, Ph.D.[1], Jocelyn S. Carter, Ph.D.[2], Cynthia Putnam, PhD[2], Jacey Keeney, M.S.[3], Draycen DeCator, M.A.[2]

[1]Rosalind Franklin University of Medicine & Science, North Chicago, IL; [2]DePaul University, Chicago, IL; [3]Rosalind Franklin University of Medicine & Science, Marseilles, IL

Several reviews suggest that merely providing an active videogame (AVG) to children will not increase their physical activity. Whether an AVG increases physical activity may vary depending on the AVG played since AVGs vary on the extent to which they are enjoyable and require full-body movement. We aimed to identify AVGs preferred by children that required full body movement and explore whether providing them to children increased their physical activity. Children aged 8-14 years (n=95; 61% male; 51% overweight/obese) listed the AVGs they played the most. The most popular games were dance-related games (e.g., Just Dance©) and adventure-related games (e.g., Kinect Adventures©). Trained research assistants who played >100 different AVGs also rated the dance- and adventure-related games as high in requiring vigorous movement. A subsample of participants (n=21, 52% male, 43% overweight/obese) who owned AVGs, logged their AVG use and wore a pedometer for one week at baseline . They then received their preferred choice from one of the dance- or adventure-related AVGs; 12 weeks later, to reduce novelty effects, they again wore the pedometer and logged minutes of AVG use for one week. Mixed models that controlled for age, BMI category (lean vs overweight & obese) and month the participant wore the pedometer (time-varying covariate), revealed a significant time x AVG minutes interaction (B = -2378.87; 95th CI: -4712.23, -45.50) for pedometer steps. At baseline, average minutes of AVG use was positively associated with steps (r=0.45, p=.10), but at time 2, AVG minutes was negatively associated with steps (r=-0.59, p=.03). AVG use increased over time (B=2.26; 95th CI: 0.50, 4.02). Contrary to our hypothesis, providing children with enjoyable AVGs that require full body movement decreased physical activity. AVG use may have supplanted non-AVG physical activity. Continued caution for using AVGs in the home to increase child physical activity is warranted. Integrating all of a child’s physical activity into the AVG (e.g., receive points in the AVG for going for a walk outside) may be more successful at increasing physical activity in children.

IMPACT OF POKEMON GO ON PHYSICAL ACTIVITY: A PRE-POST ANALYSIS

Leslie Oley, MS[1], David Stuck, PhD[1], Luca Foschini, PhD[1], Jessie Juusola, PhD[1], Shefali Kumar, MPH[1], John Torous, MD[2]

[1]Evidation Health, San Mateo, CA; [2]Beth Israel Deaconess Medical Center /Harvard Medical School, Brookline, MA

Background: In July 2016, a location-based augmented reality mobile game called Pokémon GO was released and quickly saw millions of players. Anecdotal accounts suggest the game can increase physical activity, as players follow prompts to move around outdoors. We sought to quantitatively evaluate whether the game has improved activity levels and wellness by analyzing behavior before and after starting play.

Methods: To identify Pokémon GO players and non-players, we utilized a proprietary platform (Achievemint.com) where members can connect trackers and apps to receive rewards for healthy behaviors. We distributed a single question survey to members who had an activity tracker connected asking whether they were playing Pokémon GO. Affirmative responders were sent a follow-up survey with questions such as when they started playing, general experience, and perceived impact of the game on activity and mood. We analyzed both survey responses as well as activity tracker step data for 30-days pre/post each player's start date. Those who responded that they were non-players composed a control group, using step data pre/post the game's launch date.

Results: Of the 1,721 people who responded to the single question survey, 597 (35%) reported playing Pokémon GO. Of those, 340 (57%) completed the follow-up survey. Prior to starting Pokémon GO, players were less active than non-players based on activity tracker step data (8,726 vs 9,430 average daily steps, $p=0.002$). After starting, players' daily average steps increased significantly by 906 ($p < 0.001$) in the first 2 weeks; however, in weeks 3 and 4, average daily steps significantly decreased from that peak by 477 ($p=0.015$). Users who reported a body mass index (BMI) higher than 30 increased their daily average step count by 890 more than those with BMI lower than 30 ($p=0.057$).

Conclusions: Pokémon GO players had significantly increased activity levels in the short-term after starting play, and the increase in steps was two times greater in obese players. However, the increase in physical activity waned over time. This analysis highlights the potential for augmented reality mobile game concepts to be utilized for improving physical activity and wellness in certain populations.

MONSTER APPETITE: EFFECTS OF MESSAGE FRAMING ON NUTRITIONAL CHOICES IN A DIGITAL GAME ENVIRONMENT

Maria Hwang, Ed.D.

Columbia University Medical Center (CUMC), New York, NY

Americans' health has reached a dangerous epidemic of obesity and diabetes from over consumption and unhealthy food choices, one that creates disparities among race, ethnicity, region, and income. In response to this national health threat, a body of research on games for health that strive to motivate individuals to adopt healthy behaviors are growing. The most typical approach to many health games is to provide positive reinforcement for healthy behaviors. However, there exist other approaches that may have potential to further enhance health awareness and experience, for example, by rewarding players to make the conventionally unhealthy behaviors in a game environment to solidify their original belief in healthy behaviors, otherwise known as inoculation theory.

In this study, we explore two novel approaches to encourage healthy nutritional choices in real life by vicariously experiencing an unconventional, subversively-framed or inoculation-based calorie game, Monster Appetite (MA), through monster avatars. We developed MA, and an online snack shop, Snackazon, to test whether subversive or inoculation gameplay led to healthy snack shopping behavior. There were two treatment conditions: 1) subversive framing - MA's original goal to consume the highest-calorie snack items to keep their monster avatar overweight, sluggish, and inactive was maintained and the end-of-day pop-up messages were negatively-framed, and 2) inoculation-based framing: MA's goal was flipped (consume the lowest-calorie snack items to keep their monster avatar slim and active) and the pop-up messages were positively-framed. The two conditions with pre-existing information on participants’ food habits (snacking behavior) resulted in a 2 x 1 study design (N=225).

The study showed that even if participants indicated low behavioral intention to look up caloric information, on Snackazon both subversive and inoculation treatment participants showed statistically significant nutritional information seeking behavior (ISB) for the online snack items, and ISB was significantly correlated with what snack items they chose and the reasons they list for choosing those snacks. This result fit well with the Theory of Planned Behavior (TPB) as it emphasizes the progression from awareness and attention to a health issue, followed by intention to change, culminating in actual behavioral change. In addition, for the inoculation group, participants showed a statistically significant increase in healthier snack choices post-gameplay compared to pre-gameplay. However, while the subversive group did not choose healthier snacks, they provided statistically significantly healthier reasons for making their snack choices. The study shows promising results for unconventional approaches for nutrition game-based behavioral change studies as well as support for traditional theories such as TPB.

Paper Session 28: Games for Health 11:30 AM-11:45 AM

DEVELOPMENT OF A MOBILE, AVATAR-BASED APPLICATION TO MONITOR TEENS' PERSONAL BODY SHAPE GOALS

Annmarie Lyles, PhD, RN[1], ashish Amresh, PhD[2], Michael Todd, PhD[1], Rebecca E. Lee, PhD[1]

[1]Arizona State University, Phoenix, AZ; [2]Arizona State University, mesa, AZ

Background: During adolescence participation in physical activity decreases while concern about weight increases as teens get older. Using Internet-based healthy strategies with teens who need or want to make changes to their bodies may be a practical method to help them participate in physical activity to attain and maintain healthy bodies.

Objective: The purpose of this pilot test was to develop and assess acceptability and feasibility of an avatar-based, theoretically derived, mobile application entitled, Having A Positive Perception of You Application (HAPPY App).

Methods: The HAPPY App was engineered for teens to identify what they thought they looked like, what they wanted to look like, and what they actually looked like based on body measurements using three avatars.

Results: The HAPPY App was pilot tested with teens ages 15 to 18 to assess for acceptability and feasibility. A total of 42 students created and viewed their avatars. A majority of the students were female (67%), age 16 (38.1%), white (74%), non-Hispanic (86%), and in Grade 10 (47.5%). The students had positive reactions to the avatar application. Almost half thought it was good to be able to see their actual selves. Most of the students were comfortable creating and viewing the avatars (95.2%) and would use the application in the future to see how their bodies change over time (95.2%).

Conclusion: Avatar-based mobile applications, such as the HAPPY App, provide immediate feedback and allow users to engage with images that are personalized to represent their perceptions and actual body images. This pilot study adds to the increasing but limited research of using games to improve health outcomes among teens. There is a need to further adapt the HAPPY App and implore feedback from a larger number of teens including those from diverse backgrounds.

SOCIAL NETWORK INFLUENCES IN A HOME-BASED CHILDHOOD OBESITY PREVENTION PROGRAM

Kayla de la Haye, Ph.D.[1], Sarah-Jeanne Salvy, Ph.D.[2]

[1]University of Southern California, Los Angeles, CA; [2]University of Alabama at Birmingham, Birmingham, AL

Social Network Influences in a Home-Based Childhood Obesity Prevention Program

Social networks have been found to exert considerable influence on obesogenic behaviors and resulting obesity in observational studies, yet are rarely the focus of obesity prevention or treatment efforts. Social network characteristics likely to be important to the adoption and maintenance of a healthy weight and energy balance behaviors include: *social isolation*, because social connections provide support and resources needed to engage in healthy behaviors; and *weight and behavior norms,* because social connections are a source of influence via several mechanisms (e.g., normative influence, mimicry).

This study builds upon a childhood obesity prevention program called COPE (Childhood Obesity Prevention at homE), which is a new, add-on module for existing Home Visitation Programs (HVPs). HVPs provide in-home services to low-income mothers and their infants across the U.S.; a population with health and obesity disparities. Specifically, this 6-month pilot study assessed if mothers' social network characteristics were related to the focal outcomes of the COPE intervention (mother diet, physical activity, weight status; infant diet, weight trajectory), and tested if social network characteristics moderated the intervention effects. Fifty mothers and infants (70% Hispanic/Latino) were recruited through our community HVP partner and randomized to receive (1) the HVP core curriculum only or (2) the HVP core curriculum + COPE module, for six months. Assessments, conducted at baseline and post-intervention included: (1) mothers' social network characteristics, (2) mother/infant food intake and physical activity, and (3) mothers' postpartum weight retention and children's growth velocity.

Several features of mothers' social networks, including the proportion of females in their network, network density, and the proportion of network members who provided social support, were significantly associated with the intervention outcomes ($p < .05$), and moderated change in mother and infant outcomes. These findings suggest that family-based obesity interventions should consider the social networks in which families are embedded, and develop appropriate strategies to foster social connections that provide support and healthy social influence, to bolster healthy behavior and weight outcomes.

SELF-RATED HEALTH AMONG CHILDREN: WHAT DOES IT MEASURE?

Noel Kulik, PhD CHES[1], Mary Cornwell, MPH, CHES[2]

[1]Wayne State University, Detroit, MI; [2]Macomb County Health Department, Fair Haven, MI

Adults' self-rated health (SRH) has been a consistent independent predictor of morbidity and mortality, and has been associated with obesity and level of physical activity (PA) among both adolescents and adults. Little is known about SRH and children. The purpose of this study is to examine SRH by race/ethnicity, sex, and income (school free/reduced lunch status), and to determine its relationship to children's self-reported quality of life (PedsQL: physical, emotional, social, school and overall health), fruit and vegetable (F&V) consumption and PA. Participants were 3rd through 5th grade students (N= 427; 48.5% female) from lower-, middle or higher-income elementary schools in the Midwestern USA. Children ranged in age from 8 to 13 years (Mean: 9.7 ± 1.0) and were mostly African American (n=156; 37.3%), Caucasian (n=181; 43.3%) or multiracial/other (n=81; 19.5%). Demographic, PedsQL, F&V, PA and SRH data were collected via questionnaire during one classroom visit. Children self-reported their health as excellent (n=114; 26.7%) very good (n=171; 40.0%), good (n=111; 26.0%), fair (n=27; 6.3%) or poor (n=4; 0.9%), with a mean of 3.85 ± .92. SRH did not differ by school, sex, age, grade or race/ethnicity. There was a significant, small positive correlation between F&V and SRH (Fr: $r = 0.16$, $p = .001$; Veg: $r = .20$, $p < .001$) and PA and SRH ($r = 0.11$, $p = .022$) such that children who ate more F&V and engaged in more PA reported higher SRH. When looking at PedsQL variables, SRH was significantly positively correlated with physical ($r = 0.28$, $p < .001$), emotional ($r = 0.25$, $p < .001$), social ($r = 0.19$, $p < .001$), school ($r = 0.14$, $p = .004$), and overall ($r = 0.27$, $p < .001$) health. A multiple regression was run to predict SRH from F&V, PA and overall PedsQL health. The model statistically significantly predicted SRH, $F(4,415) = 11.824$, $p < .001$, adj. $R^2 = .094$. Only overall health and vegetable consumption significantly added to the prediction, $p < .05$. Findings from this study suggest that SRH can discriminate between self-reported quality of life in children as young as 8 years of age, and may be a valid and quick 1-iterm measure of overall health in children, especially related to diet behaviors. Future research on SRH in children is needed to understand how children qualitatively view health, and how SRH is related to objectively assessed health by a physician.

MORE THAN JUST FOOD: A META-ANALYSIS OF FAMILY MEALTIME PRACTICES ASSOCIATED WITH CHILDREN’S NUTRITIONAL HEALTH

Mattea Dallacker, PhD Student[1], Jutta Mata, Professor[2], Ralph Hertwig, Professor[1]

[1]Max Planck Institute for Human Development, Berlin, Berlin, Germany; [2]University of Mannheim, Mannheim, Baden-Wurttemberg, Germany

Family meals can be seen as the cradle of eating behavior: by the age of 10, a child has eaten about 10,000 meals, most of them in a family setting. A higher frequency of family meals is known to be associated with better diet quality and lower body mass index (BMI) in children. But what aspects of family meals are healthy for children? This meta-analysis systematically summarizes studies on social, environmental, and behavioral attributes of family meals that have the potential to positively influence children’s nutritional health. Six frequently investigated family mealtime practices (43 studies, 57 effect sizes, 42,929 participants) were identified. Positive associations between the following practices and children’s nutritional health were consistently found in separate meta-analyses: TV off during meals (r = .08), food quality (r = .11), parental modeling (r = .11), positive atmosphere (r = .12), and longer meal duration (r = .20). Children’s involvement in meal preparation was associated with better diet quality (r = .08), but also with higher BMI (r = −.06). Mechanisms potentially underlying these effects are proposed, building on Herman et al.’s model of how the presence of others shapes eating behaviors (Herman, Roth, & Polivy, 2003). The generalizability of the identified mealtime practices is discussed, as are potential policy implications.

WEEKEND SLEEP DELAY IS ASSOCIATED WITH SEVERITY OF OBESITY AND INCREASED SCREEN TIME IN ADOLESCENTS WITH OBESITY

Jacqueline Hayes, MA[1], Myra Altman, MA[1], Katherine N. Balantekin, PhD, RD[2], Denise Wilfley, Ph.D.[1], C. Barr Taylor, Ph.D.[3], Joanne Williams, Ph.D.[4]

Weekend Sleep Delay is Associated with Severity of Obesity and Increased Screen Time in Adolescents with Obesity

Jacqueline F. Hayes[1], Myra Altman[1], Katherine N. Balantekin[1], Denise E. Wilfley[1],

C. Barr Taylor[2], & Joanne Williams[3]

[1] Department of Psychiatry, Washington University in St. Louis

[2] Center for m^{2}Health, Palo Alto University and Stanford Medical Center

[3] School of Health and Social Development, Deakin University

Sleep duration is often linked to childhood obesity; however sleep patterns, specifically weekend sleep delay (e.g. later bedtimes on weekends than weekdays), have also been associated with behavioral and metabolic changes that promote obesity, independent of sleep duration. Given that adolescents commonly have later bedtimes on weekends than weekdays, this sleep pattern may play a role in adolescent obesity and obesogenic behaviors. This study assesses weekend sleep delay and its relation to relative weight as well as physical activity and weekend screen time (i.e., TV, computer, video games) in adolescents with overweight/obesity participating in an online behavioral weight loss study. At baseline, adolescents (n=189, mean age = 14.66±1.60, mean zBMI = 2.05±0.41) were weighed and measured, reported typical sleep and wake times on weekdays and weekends, and responded to questionnaires assessing typical physical activity habits and number of weekend hours engaged in screen time. Results showed that, on average, adolescents reported going to bed

1.38±1.07 hours later on weekends than weekdays. In a hierarchical regression model controlling for age, gender, and sleep duration on weekends and weekdays, greater weekend sleep delay was associated with greater severity of overweight ($\beta = .16$, $p < 0.05$). In similar follow-up models predicting behavioral outcomes, weekend sleep delay was not associated with any differences in physical activity; however, it was significantly related to greater weekend screen time ($\beta = .23$, $p < 0.01$). Thus, above and beyond sleep duration, weekend sleep delay is positively related to severity of overweight/obesity and time spent on the computer/playing video games in treatment-seeking adolescents with obesity. Reducing sleep delay on the weekends and promoting a consistent sleep schedule throughout the week may be a worthwhile treatment target to optimize behavioral and weight outcomes in adolescent obesity treatment.

AEROBIC TRAINING IMPROVES AFFECTIVE AND COGNITIVE RESPONSES TO DAILY STRESSORS IN FAMILY CAREGIVERS

Adam M. Caplin, B.A & Sci[1], Jordan Weiss, BSc[2], Samantha J. Schilf, BA[3], Kirsten Johansen, MD[3], Ben A. Hives, BKIN[1], Elissa S. Epel, PHD[3], Eli Puterman, PhD[1]

[1]University of British Columbia, Vancouver, BC, Canada; [2]University of Pennsylvania, Philadelphia, PA; [3]University of California, San Francisco, San Francisco, CA

Introduction: Individuals differ in their cognitive and emotional responses to stressful events, with maladaptive responses predicting the development of physical and mental health conditions. Observational studies show that physically inactive individuals have worse mood and are more anxious in response to laboratory or daily stressors than those who are active. Here, we report a randomized controlled trial of the effects of aerobic training on measures of psychological reactivity to daily stressors in previously inactive caregivers.

Methods: Sixty-three informal family caregivers of patients with Alzheimer's disease or other dementia were randomized to either a 6-month exercise program (N=30) or a waitlist control (N=33) if they reported < 150 minutes/week [the Center for Disease Control and Prevention recommended minimum] of moderate-to-vigorous physical activity and high levels of psychological stress (≥0.5 SD above the national mean on Cohen's Perceived Stress Scale). Participants completed ecological momentary assessments 6 times/day for 7 days pre and post intervention. At each assessment, they reported whether a stressor occurred since their last assessment, and if so, answered questions on stress appraisals (perceived stress, perceived control), coping (rumination, positive reappraisal) and negative affective (NA) responses (mean of anger, anxiety, sadness, and shame). Intent-to-treat mixed model analyses were completed with random intercepts, fixed slopes, and restricted maximum likelihood estimation.

Results: Change over time (Δ) between exercise and control group caregivers was significantly different for perceived stress ($p = .015$) and NA ($p = .004$), and marginally significant for perceived control ($p = .089$). Although caregivers in the control group did not change in appraisals or NA, caregivers in the exercise group significantly increased in control [$\beta_0 = 39.95$, SE = 3.01, CI = 33.95, 45.96; $\beta_\Delta = 6.65$, SE = 3.22, CI =0.32, 12.98] and decreased in perceived stress [$\beta_0 = 75.10$, SE = 2.09, CI = 70.92, 79.29; $\beta_\Delta = -5.56$, SE = 1.89, CI = -9.27, -1.85] and NA [$\beta_0 = 43.44$, SE = 2.43, CI = 38.58, 48.31; $\beta_\Delta = -5.93$, SE = 1.96, CI = -9.78, -2.08] when a stressful event occurred.

Summary: The benefits of exercise are widespread and alter the ways individuals respond to stressful life events. We demonstrated novel findings showing that physical activity strengthens adaptive appraisals and reduces negative affect in response to stressors experienced by a previously inactive group of caregivers.

OUTCOME EXPECTANCY MEDIATES THE RELATIONSHIP BETWEEN AFFECTIVE AND PHYSICAL FEELING STATES AND NEXT-DAY PHYSICAL ACTIVITY

Yue Liao, MPH, PHD[1], Jaejoon Song, MS[2], Michael Robertson, MPH[3], Karen Basen-Engquist, PhD, MPH[2]

[1]University of Texas MD Anderson Cancer Center, Houston, TX; [2]The University of Texas MD Anderson Cancer Center, Houston, TX; [3]MD Anderson Cancer Center, Houston, TX

Background: A growing number of studies have shown affective and physical feeling states as predictors of daily physical activity (PA) in free-living settings, yet little is known about the mechanism underlying such effects. This study aims to test social cognitive states as mediators of the relationship between affective and physical feeling response to PA and PA levels next day using ecological momentary assessment (EMA). **Methods:** The EMA protocol was administered via a handheld computer (PDA) for 7 consecutive days at baseline, and 5 consecutive days at 7 different time points across a 6-month period (42 EMA days total) among 99 endometrial cancer survivors participating in the Steps to Health Study. In the morning of each EMA day, the PDA prompted participants to record their self-efficacy (SE) for exercising that day (1 item), as well as expected positive (EPO; 6 items) and negative outcomes (ENO; 3 items) of exercising that day. Participants were also asked to record all exercise sessions using the PDA, and to complete the Exercise-induced Feeling Inventory (EFI; 12 items) and Somatic Sensations (SS; 10 items) both pre- and post-exercise. Difference scores were calculated to indicate feeling responses to exercise. Each feeling response was linked with the SE/EPO/ENO and the overall physical activity level (PAL; derived from a composite measure of accelerometer and EMA self-report data) the following day. Multilevel mediation models (1-1-1) were used to examine the within-person (WP) and between-person (BP) effects using EFI/SS as the predictor, SE/EPO/ENO as the mediator, and PAL as the outcome. **Results:** ENO mediated the effect of affective response to exercise (EFI) on next day PAL at the BP level (beta=0.176, SE=0.086, p=0.040), suggesting more positive affective response led to higher PAL through a decrease in ENO (beta=-0.036, SE=0.009, pConclusion: Affective and physical feeling responses to exercise predict daily PA level partly through their effects on individuals' negative outcome expectancy. Future interventions could consider targeting this mechanism for PA promotion.

THE ACUTE BIDIRECTIONAL RELATIONSHIPS OF CHILDREN'S AFFECTIVE STATES AND PHYSICAL ACTIVITY: THE ROLE OF CHRONIC STRESS

Cheng K. Fred Wen, MPH[1], Yue Liao, MPH, PHD[2], Jimi Huh, PhD[1], britni R. belcher, PhD, MPH[1], Eldin Dzubur, MS[1], Adam Leventhal, PHD[3], Genevieve F. Dunton, PhD, MPH[1]

[1]University of Southern California, Los Angeles, CA; [2]University of Texas MD Anderson Cancer Center, Houston, TX; [3]USC, Pasadena, CA

Introduction: There is a growing literature suggesting that affective states are acutely and bi-directionally related to physical and sedentary behavior. Yet, these relationships and potential moderators of these relationships are rarely examined in children.

Methods: A sample of 180 children (mean age=9.6 years old, 51.7% girl, 53.9% Hispanic) and their mothers completed an ecological momentary assessment (EMA) study that examined parenting factors and obesity risk. Across 1 week, children wore accelerometers on waist to measure moderate-to-vigorous physical activity (MVPA) and sedentary behavior (SB), and received 3-7 EMA prompts/day by smartphones asking about their current positive and negative affective states. Perceived chronic stress, age, sex, and ethnicity were measured at baseline for children and mothers. Multilevel regression models tested the within-(WS) and between- person (BS) associations of: (1) time spent in MVPA or SB within the 60 mins before each EMA prompt predict affective states at that prompt and (2) affective states at each EMA prompt predict time spent in MVPA or SB in the 60 mins after that prompt. Interaction terms were created by multiplying the both the WS- and BS- versions of the main predictor of each model with children's and mothers' chronic stress scores. Models controlled for child sex, age, race, body mass index (BMI) percentile, and affective states and activity levels at the prior EMA prompt.

Results: When engaged in more SB than usual in the 60 mins before an EMA prompt, children reported lower positive affect at that prompt (WS; b=-0.01, SE=0.01, $p < 0.1$). In contrast, engaging in more MVPA than usual before a prompt was associated with higher positive affect at that prompt (WS; b=0.02, SE=0.01, $p < 0.1$). Mother's baseline chronic stress moderated this association (WS; b =-0.02, SE=0.01, $p < 0.05$), such that the positive affective response to MVPA was weaker for children of mothers with higher levels of chronic stress.

Conclusions: Promoting MVPA and decreasing SB may help acutely improve children's affective states. These acute effects may be impacted by mother's stress, underscoring the potential importance of modulating mother's stress and the need to further understand the mechanism underlying children's affective response to MVPA.

AEROBIC EXERCISE TRAINING IMPROVES AFFECT IN NORMAL HEALTHY YOUNG ADULTS

Richard Sloan, PhD[1], Paula McKinley, PhD[2], Peter Shapiro, MD[1], Eli Puterman, PhD[3], Matthew Bartels, MD[2], Keith Diaz, PhD[1], Kathleen McIntyre, LCSW[1], Martina Pavlicova, PhD[1], Jennifer Scodes, MS[4], Pamela Flood, MD[5]

[1]Columbia University Medical Center, New York, NY; [2]Montefiore Medical Center, Bronx, NY; [3]University of British Columbia, Vancouver, BC, Canada; [4]New York State Psychiatric Institute, New York, NY; [5]Stanford University, Palo Alto, CA

Objective: Aerobic conditioning is associated with beneficial effects on affect but most data come from observational studies. Here we report the effect of a randomized controlled trial of aerobic training program on measures of affect.

Method: Normal healthy sedentary young (age 20-45 y) adults were randomized to a 12-week aerobic training program or a waitlist control condition and measures of depressive affect (Beck Depression Inventory, BDI), hostility (Cook Medley scale, CKM), and anxiety (Spielberger Trait index) were collected at study entry (T1) and at 12 weeks (T2). Longitudinal linear mixed effect models with generalized estimating equations were fit separately for each outcome. Final models were adjusted for age, sex, BMI, body fat percentage, and the alternative Mediterranean diet index.

Results: 119 participants were randomized to the exercise (n=60, 32 women) or wait list (n=59, 31 women) conditions. Mean age was 31.3 (± 5.9) years. Mean study entry VO_2max was 30.4 ± 6.9 and 31.0 ± 6.4 ml/K/min in the exercise group and control groups respectively. After training, VO_2max increased to 34.7 ± 8.4 in the exercise group but did not change (30.1 ± 6.2) in the control group. Within the exercise group, BDI scores significantly decreased by 29% from T1 to T2 (ES = 0.71, p = .0470); within the waitlist group, the BDI scores increased by 9%, though not significantly (ES = 1.09, p = .4871), while adjusting for covariates. Within the exercise group, CKM scores significantly decreased by 1.50 points from T1 to T2 (ES = -1.50, p

= .0091); within the waitlist group, CKM scores increased by 0.25 points, though not significantly (ES = 0.25, p = .5838), in the adjusted model. Exercise training had no effect on trait anxiety.

Conclusions: In this randomized controlled trial of a 12-week aerobic training program administered to healthy, young, sedentary adults, aerobic capacity increased significantly as predicted in the training but not the control group. Training also led to significant reductions in depressive affect and hostility but not anxiety. These findings are noteworthy especially in light of the fact that participants had normal levels of affect at study entry.

Paper Session 31: Engagement with Genetic Testing and Information 10:45 AM-11:00 AM

LONG-TERM OUTCOMES OF TELEPHONE VS. IN-PERSON GENETIC SERVICES DELIVERY

Mary K. Interrante, MA[1], Beth N. Peshkin, MS, CGC[1], Heiddis Valdimarsdottir, PhD[2], Marc D. Schwartz, PhD[3]

[1]Georgetown University, Washington, DC; [2]Reykjavik University, Reykjavik, N/A, Iceland; [3]Georgetown University/Lombardi Cancer Center, Washington, DC

Genetic counseling and testing for *BRCA1*/2 mutations has become integral to the clinical care of women at risk of hereditary breast and ovarian cancer (HBOC). As the demand for cancer genetic counseling and testing has risen, alternatives to traditional face-to-face genetic counseling and testing are needed to ensure widespread access. We conducted a multi-site, randomized noninferiority trial comparing telephone delivery to standard in-person delivery of genetic counseling and testing for HBOC. Over the short-term, we found that telephone delivery was less expensive and yielded comparable (i.e., noninferior) genetic counseling (knowledge, decision conflict, satisfaction) and psychosocial (distress, quality of life) outcomes. In this report, we examined 12-month outcomes from this trial, to determine if telephone delivery remains noninferior to in-person delivery over the long-term.

Eligible women were age 21-85 who did not have newly diagnosed or metastatic cancer, were at high-risk for HBOC and were self- or physician-referred for genetic counseling at one of our study sites. Overall, 669 women were randomized to receive usual care (UC) or telephone counseling (TC). Of those, 514 completed the 12-month follow-up assessment. There were no differences in attrition across the two study groups (χ^2= 0.88, p = 0.767).

At 12-months post-randomization, TC was statistically noninferior to UC on all outcomes. Cancer distress (d = -0.50, upper bound of 97.5% CI, 1.99) did not cross the 4-point noninferiority limit, genetic testing distress (d = -0.54, upper bound of 97.5% CI, 1.08) did not cross the 3-point noninferiority limit, physical function (d = 0.77, lower bound of 97.5% CI, -0.74) and mental function (d= -0.17, lower bound of 97.5% CI, -1.73) did not cross their 2.5 point noninferiority limits and satisfaction with genetic testing decision (d = 0.15, lower bound of 97.5% CI, -0.31) did not cross its 1-point noninferiority limit. In follow-up analyses adjusting for genetic test result and potential confounders, the results were unchanged.

These results, confirming the long-term noninferiority of TC compared to UC, provide further evidence that remotely delivering genetic services is a safe and effective approach to increasing access and reducing the costs of genetic testing.

Paper Session 31: Engagement with Genetic Testing and Information 11:00 AM-11:15 AM

ENGAGEMENT WITH GENETIC INFORMATION AND UPTAKE OF GENETIC TESTING: THE ROLE OF TRUST AND PERSONAL CANCER HISTORY

Megan Roberts, PhD[1], Jennifer M. Taber, PhD[2], William Klein, PhD[3]

[1]NCI, Rockville, MD; [2]Kent State University, Kent, OH; [3]NCI/NIH, Rockville, MD

Background: Targeted screening and treatment using genetic technologies is increasingly common. For individuals with a family and/or personal history of cancer, genetic testing might identify those at especially high risk. This is particularly important when there are corresponding guidelines for the management of high risk individuals (e.g., those with *BRCA1/2* mutation, Lynch Syndrome). However, use of genetic testing remains low among those eligible. This may be partially due to lack of communication about genetic testing and low trust in genetic testing information sources. No studies have explicitly examined the association between receiving genetic information from trusted sources and cancer-related genetic test uptake within a national sample of US adults. Our objectives were to better understand (1) the extent to which individuals trust the sources from which they receive information about health-related genetic tests, (2) whether level of trust for sources of genetic information might be related to health-related genetic testing uptake, and (3) whether factors such as cancer history or numeracy play a role in the latter association.

Methods: We used cross-sectional data from the Health Information National Trends Survey (HINTS 4, Cycle 3). Our study sample included individuals who responded “yes” to the following survey item: “Genetic tests that analyze your DNA, diet, and lifestyle for potential health risks are currently being marketed by companies directly to consumers. Have you heard or read about these genetic tests?” (n=1117). All analyses accounted for the complex survey design to achieve population-based estimates.

Results: Although respondents trusted information from health professionals the most, they were less likely to report hearing about genetic testing from them compared to the television ($p < 0.01$). Regardless of source, higher levels of trust in the information source from which participants heard about genetic tests were associated with increased odds of genetic testing uptake. This was particularly true among individuals with a personal history of cancer. Numeracy did not moderate the association between trust and uptake of testing.

Conclusion: Overall, these results suggest that trust is important among individuals with a personal cancer history. Because providers were among the most trusted sources of health

information, they may be important sources for genetic testing information, particularly for individuals with a personal cancer history.

Research on the communication of genetic test results in families have focused on predominately non-Hispanic White mutation positive families. Little is known about this process for racially and ethnically diverse individuals who undergo genetic testing. As part of a prospective clinical trial of patient experience with a 25-gene test, participants were sent a questionnaire three months after results disclosure, including questions about sharing test results. This is an interim analysis of the first 562 56.2% (n=562/1000) respondents. Responses were analyzed by results groups (Negative “Neg”, n=297; Variant of Uncertain Significance “VUS”, n=207; Positive “Pos”, n=59).

Self-reported race/ethnicity is 44.8% non-Hispanic White, 37.9% Hispanic, 10.1% Asian, and 2.8% Black. The majority (97.2%, n=546) had shared their test results. The Pos group was over six times more likely to encourage family members to undergo genetic testing than the Neg (OR=6.6, $p < 0.0001$, 95% CI [3.2, 14.7]) and VUS groups (OR=6.1, $p < 0.0001$, 95% CI [2.9,

13.8]). When compared to the Neg and VUS groups the Pos group was 12.4 and 13.8 times more likely, respectively, to report family members having undergone genetic testing (OR=12.4, *p* p < 0.00001, 95%CI [5.7,35.3]). All Pos respondents (n=59) shared their test results. When asked if they had encouraged family to undergo genetic testing, Asian respondents less frequently reported having done so than non-Hispanic Whites ($p < 0.05$). Additionally, Asian participants in the Pos group responded in the negative more frequently when asked if their family members underwent genetic testing ($p < 0.05$).

Three months post genetic testing, communication of results was very high among all result groups. However, individuals in the Pos group were more likely to encourage testing in their family members and their family members were more likely to undergo genetic testing, suggesting that participants correctly understood the implication of their results and were able to convey that information to their relatives. Differences by race/ethnicity merit further exploration. Longitudinal data will continue to be collected on these and the subsequently accrued participants, allowing for expanded analyses.

Paper Session 31: Engagement with Genetic Testing and Information 11:30 AM-11:45 AM

BRCA-POSITIVE PREVIVORS’ INFORMATION NEEDS REGARDING HEREDITARY BREAST AND OVARIAN CANCER RISK

Marleah Dean, PhD[1], Courtney L. Scherr, PhD[2], Meredith L. Clements, BA, MA[1]

[1]University of South Florida, Tampa, FL; [2]Northwestern University, Chicago, IL

Introduction: *BRCA1* and *BRCA2* carriers are at significantly increased risk to develop breast and ovarian cancer. Because of this genetic risk, *BRCA*-positive, unaffected patients—referred to as previvors—experience uncertainty regarding decision-making. Information is a key mechanism for managing such uncertainty. While previous research has explored cancer patients’ and survivors’ information needs, the information needs of previvors are likely to be distinct. Framed by the Messaging Model for Health Communication Campaigns (MMHCC)—which incorporates components of social marketing to provide a rigorous approach for the development of communication campaigns—we assessed previvors’ information needs and behaviors in order to inform the development of an educational intervention to manage uncertainty and promote uptake of appropriate prevention activities.

Methods: 25 qualitative, in-depth interviews were conducted with *BRCA*-positive, female, English-speaking previvors. Interviews were audio-recorded, transcribed verbatim by a professional transcription service, and checked for accuracy by study team members. The constant comparison method of grounded theory was utilized to code the interview data. Inter-coder reliability was established using Krippendorf’s alpha. Coders were reliable at α =.92.

Results: Qualitative analysis of previvors’ experiences revealed information needs were related to the stage in their health journey. Specifically, a four-stage model was identified: 1) pre-testing information needs, 2) post-testing information needs, 3) pre-management information needs, and 4) post-management information needs. Two recurring dimensions of desired knowledge also emerged within the stages—medical knowledge and personal/social.

Conclusion: Results suggest previvors’ information needs are distinct from cancer patients and survivors’ needs and change overtime as they navigate their health journey. Future research should confirm these results with a more diverse population, and if confirmed, develop educational materials to assist patients in managing uncertainty and reducing decisional conflict.

Paper Session 32: Helping Mom Know Best: Maternal Health Research 10:45 AM-11:00 AM

IMPROVING MOTHERS' DIETARY INTAKE – AN ANALYSIS OF INDIVIDUAL AND FAMILY MEDIATORS IN A FAMILY-BASED INTERVENTION

Lucy Horton, MPH, MS[1], Donald J. Slymen, PhD[2], Elva M. Arredondo, PhD[2], Humberto Parada, Jr., PhD, MPH[3], Guadalupe X. Ayala, PhD, MPH[2]

[1]San Diego State University Research Foundation, San Diego, CA; [2]San Diego State University, San Diego, CA; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Purpose. The US Hispanic/Latino population is estimated to almost double between 2014 and 2050, representing 25% of the US population. Alongside this rapid growth, disparities in health outcomes between racial/ethnic groups persist, and continue to lead to more illnesses and premature death for communities such as US Hispanics/Latinos. Implementing effective, culturally appropriate interventions to improve the dietary intake of Hispanics/Latinos is, therefore, a priority to reduce health disparities in this rapidly growing population.

Methods. This study describes dietary changes among Hispanic/Latino mothers, and mediators of those changes over a 10-month period from an RCT conducted in a rural region along the US-Mexico border in California, US. A convenience sample of 361 families (children between 7-13 years old and their mothers, and in a 25% subsample, fathers) was recruited from community locations and using flyers and mass media. Intervention families (n=180) completed an 11-session community health worker-delivered home-based intervention designed to improve dietary outcomes. Remaining families (n=181) were part of a delayed-treatment control condition.

Results. The mean age of mothers was 39 years (SD=7.86). Most were born in Mexico (82%), and were either overweight (36%) or obese (50%). Daily servings of fruits was higher among mothers in the intervention condition (mean=1.86, SE=0.14) compared to those in the control condition (mean=1.47, SE=0.14) at 10-months post-baseline ($p \leq 0.05$). Mothers in the intervention condition reported consuming a lower percent energy from fat (mean=30.0%, SE=0.26% versus 31.0%, SE=0.27%; $p \leq 0.01$) and a higher diet quality (mean=2.93, SE=0.07) compared with mothers in the control condition (mean=2.67, SE=0.07; $p \leq 0.01$). These changes were mediated by improvements in behavioral strategies to increase fiber and lower fat intake and family support for vegetable purchasing, as well as decreased unhealthy eating behaviors and perceived family barriers to healthy eating.

Discussion. Both individual (behavioral strategies to increase fiber and lower fat intake, reducing unhealthy behaviors) and family (family support for vegetable purchasing, perceived family barriers to healthy eating) mediated changes in mothers' dietary intake. Future

interventions should consider approaches that target mediators of change, in addition to focusing on the dietary behavior itself.

BEHAVIORAL & PSYCHOSOCIAL SCREENING & DECISION AIDS FOR MOTHERS OF YOUNG CHILDREN: DESIGN & LESSONS LEARNED

Lorraine Walker, MPH, EdD[1], Heather Becker, Ph.D.[2], Bo Xie, Ph.D.[3], Bobbie S. Sterling, RN, MSN, PhD[4], Sherry Hendrickson, PhD, APRN, CNS-BC[2]

[1]University of Texas at Austin, Austin, TX; [2]The University of Texas at Austin, Austin, TX; [3]School of Nursing, Austin, TX; [4]University of Texas at Austin, Georgetown,, TX

Behavioral and psychosocial health (B&PH) is important to health after pregnancy, but is often overlooked during healthcare visits. Screening tools are a strategy to increase attention to B&PH (including diet, physical activity, tobacco and alcohol use, mood, and body image). Moreover, inclusion of decision aids eliciting women's preferences may promote a more patient-centered screening process. Aim 1 of this study was to identify an acceptable format and method of receiving results after B&PH screening. Aim 2 was to identify key values/preferences for inclusion in decision aids related to B&PH change-decisions. Individual interviews were done with 26 women of diverse income and race/ethnicity (7 White, 16 Latina, 2 Black, 1 Asian). Women were recruited by mailed flyers or flyers posted in a clinic serving children of low-income families. Women's mean age was 28 (range 18 to 40), with 1-5 children and the youngest ≤ 3 years. During interviews, women first completed a B&PH screening questionnaire, and then responded to open- and closed-ended questions about design of materials to convey screening results. The interview also included their ratings of 11 values/preferences (from behavioral theories and maternal health research) for use in a decision aid. Analysis involved computing percentages and the chi-square, where appropriate. Findings included: women preferred a feedback form entitled "Mom's Health" (54%) over using terms such as "dashboard" or "report card." They preferred screening results shown in a graphic format (56%) with 3-level, positively worded labels (42%) rather than other wording. Hispanic versus non-Hispanic ethnicity was unrelated to format preferences. Phone/computer was preferred for receiving results over receiving results from a care provider. The 4 top ranked values/preferences for inclusion in a decision aid were: most important to being a mother, most needing improvement, most motivated to change, and most family support for a change. 24 of 26 women rated the screening and decision aid as "very useful" in helping mothers to make changes to improve health. Our findings provide direction for communicating screening results and design of decision aids for B&PH changes to improve health of mothers of young children.

A MULTIFACETED COMMUNITY PROGRAM TO SUPPORT BREASTFEEDING IN KANSAS

Lisette Jacobson, PhD, MPA, MA[1], Brenda Bandy, BS, IBCLC[2], Martha Hagen, MS, RD, LD, IBCLC[3]

[1]University of Kansas School of Medicine-Wichita, Wichita, KS; [2]Kansas Breastfeeding Coalition, Inc., Manhattan, KS; [3]Kansas Department of Health and Environment, Topeka, KS

Background: The “Communities Supporting Breastfeeding” (CSB) program is a multifaceted community approach to improve breastfeeding support in Kansas. This session covers all aspects of the program including goals, program evaluation, and shared communities’ experiences.

Methods: The CSB designation as defined by the Kansas Breastfeeding Coalition (KBC) requires meeting specific criteria within six sectors of the community: local breastfeeding leadership, peer support, maternity care practices, societal support, employer support, and childcare provider support. The KBC provides an assessment, hospital staff education, coalition building assistance, continuity of breastfeeding care, and education to home visitors. The CSB program is now in its third year. During year one and two, a survey to assess progress toward the designation was administered to all mothers who benefited from breastfeeding services.

Results: Since July 2014, eleven communities representing diverse populations have achieved the CSB designation. During program years one and two, five and six communities respectively achieved the CSB designation within the allotted 10-month time period. About 20 mothers in each of the respective communities participated in the survey (N=211). The majority of women believed local breastfeeding leadership, peer support, and hospital support provided adequate breastfeeding support in their community. Women were less familiar with programs that promote breastfeeding among employers and childcare providers. Further, year one communities appear to benefit from improved exclusive breastfeeding rates that may be associated with the CSB designation.

Conclusion: The CSB program informs other Kansas communities in their effort to build a culture of breastfeeding support and is now in its third year with five new communities. The program is currently listed as an “emerging practice” on the Innovation Station website of the Association of Maternal & Child Health Programs.

Paper Session 32: Helping Mom Know Best: Maternal Health Research 11:30 AM-11:45 AM

CHANGES IN FRUITS AND VEGETABLES AVAILABILITY AND CONSUMPTION AMONG LOW-INCOME PREGNANT WOMEN: HEALTHY EATING ACTIVE LIVING

Ru-Jye Chuang, DrPH[1], Shreela Sharma, PhD RD LD[2], Gregory Bounds, MPH[2]

[1]UTHealth School of Public Health, Houston, TX; [2]University of Texas School of Public Health, Houston, TX

Availability of fruits and vegetables (FV) increases consumption among adults, and is known as a protective factor to obesity. Healthy Eating Active Living (HEAL) is a multi-component, community-based, Community Health Worker (CHW)-led six-week program designed to promote healthy eating, physical activity, and intention to breastfeed among Medicaid-eligible pregnant women in Houston, TX. Pregnant women are recruited through clinics and participate in weekly 90-minute facilitated and experiential, group-education sessions. The purpose of this pilot study is to evaluate the feasibility of HEAL in increasing home nutrition environment and daily FV consumption, and if the impact vary by participants' perceived food security (PFS).

This was a one-group pre-post evaluation design. Availability to FV (23 items), daily consumption (24 items), and PFS (6 items) were measured using self-administered surveys. Ninety-two Medicaid-eligible pregnant women completed both surveys at baseline and post-intervention from October 2014 - September 2015. More than half (52.2%) of the women reported low food security at baseline. McNemar's test was conducted to evaluate the change of home availability of FV between the high/low-PFS groups, and Wilcoxon signed-rank test for FV consumption.

Results showed that participation in HEAL significantly increased home availability of 11 FV ($p < 0.05$) and increased women's daily consumption of FV ($p < 0.05$). When stratified by perceived food security, low-PFS women had increased availability of 9 FV and daily consumption of FV pre-to-post-intervention ($p < 0.05$). For their high-PFS counterparts, HEAL helped increase availability of 5 FV items and daily consumption of vegetables ($p < 0.05$) but not fruit.

This pilot study demonstrates the initial feasibility of using multi-component, community-based, CHW-led intervention approach to increase home availability and daily consumption of FV among low-income pregnant women, especially in women with low perceived food security.

STRATEGIES FOR ENGAGING, RECRUITING AND RETAINING DIVERSE WOMEN IN MEDICAL RESEARCH

Aisha T. Langford, PhD, MPH[1], Jennifer Wenzel, PhD, RN, CCM, FAAN[2], Ruth J. Geller, MHS[3], Marjorie R. Jenkins, M.D., M.Ed., F.A.C.P.[3]

[1]New York University School of Medicine, New York, NY; [2]Johns Hopkins School of Nursing, Baltimore, MD; [3]U.S. Food and Drug Administration, Silver Spring, MD

The importance of increasing the representation of women and minorities in medical research has gained recognition. Barriers to the participation of these groups in research have been documented and discussed. Progress will be achieved by moving from understanding barriers to implementing and evaluating solutions. In January 2016, the US FDA Office of Women's Health launched the Diverse Women in Clinical Trials Initiative. The chair of the proposed panel led a group of national expert collaborators in the development of professional education webinars hosted through the Association of Clinical Research Professionals. The chair is a national leader in sex and gender-specific women's health research and educational programming innovations. The panelists are academic faculty with extensive research and leadership experience in relevant fields including decision science, health communication, health disparities, and the participation of underrepresented groups in clinical trials. Panelists will describe strategies implemented in their work to increase the participation of diverse women in medical research, discussing the evidence base, results, and feasibility of each approach. Aspects of diversity to be discussed include race/ethnicity, age, co-morbidities, rural location, and socioeconomic status. A Q&A session will provide opportunity for attendees to interact with panelists. After attending this session, attendees will be able to describe and apply appropriate strategies to increase the feasibility of research participation for diverse women; describe effective applications of digital health to the engagement, recruitment, and retention of diverse women in research; and develop culturally competent communication about research participation tailored to diverse women. The panel will equip attendees with cutting-edge strategies to engage diverse women in behavioral and medical research, in order to achieve effective, acceptable, and culturally competent interventions. This panel represents a collaboration between the US FDA Office of Women's Health and innovative academic leaders within the clinical trials space.

Panel Discussion 16 12:15 PM-1:15 PM

THE INTEGRATED PRACTICE UNIT (IPU) AS TRANSLATION ACCELERATOR: REAL-WORLD IMPLEMENTATION IN DIABETES, PAIN, AND PRIMARY CARE

James E. Aikens, PhD[1], William D. Tynan, Jr., PhD, ABPP[2], Ellen Poleshuck, PhD[3], Andrea Cherrington, MD MPH[4], Amy Huebschmann, MD, MS[5], Lara Dhingra, PhD[6], Kathryn E. Kanzler, PsyD, ABPP[7]

[1]University of Michigan, Ann Arbor, MI; [2]American Psychological Association, Washington, DC; [3]University of Rochester Medical Center, Rochester, NY; [4]University of Alabama at Birmingham, Division of Preventive Medicine, birmingham, AL; [5]University if Colorado School of Medicine, Aurora, CO; [6]MJHS Institute for Innovation in Palliative Care, New York, NY; [7]University of Texas Health San Antonio, San Antonio, TX

With the advent of population-based health, successful translation and implementation of behavioral medicine interventions will require a clear economic understanding of healthcare delivery. Although most chronic conditions require a coordinated treatment team, healthcare is often fragmented, redundant, and inefficient. The fee-for-service payment model is a significant obstacle to improving healthcare delivery because it only reimburses for the quantity of service, not its quality, outcome, or efficiency.

This panel will provide in-depth examination of the “Integrated Practice Unit” (IPU; Porter and Lee, 2013) model for improving illness management, outcomes, quality, and costs for virtually any chronic condition. In this model, treatment units are organized around specific patient problems rather than clinical specialties.

Although many existing multidisciplinary clinical teams are structured this way, few are true IPUs. A fully-developed IPU also focuses on systematically improving care quality, coordinating patients’ transitions across inpatient and outpatient settings, and monitoring key clinical outcomes and treatment costs. Importantly, its clinical objectives are to address quality and outcomes rather than RVU generation, and its business objectives are to target improved outcomes, efficiency, and growth. Effective IPUs then expand to new geographic locations and use their data to establish their bundled care rates for defined populations.

Following an overview of the general IPU model, panel members will present real-world exemplars of how IPUs are being implemented to address diabetes, chronic pain, and primary care. The panel will also discuss how researchers can use IPUs’ existing data to increase the utility of clinical trials, advance the most effective treatment models, approach population care from an economically-informed perspective, and advocate for improved healthcare policies in a language understood by administrators and insurers.

BEHAVIORAL MEDICINE SCIENTISTS IN INDUSTRY: OPPORTUNITIES, CHALLENGES AND LESSONS LEARNED

Cynthia M. Castro Sweet, PhD[1], Heather Cole-Lewis, PhD, MPH[2], Leanne Mauriello, Ph.D.[3], Danielle Blanch-Hartigan, PhD, MPH[4]

[1]Omada Health, Inc., San Francisco, CA; [2]Johnson and Johnson Health and Wellness Solutions, New York, NY; [3]Spectrum Health System, Grand Rapids, MI; [4]Bentley University, Stoneham, MA

The explosion of mHealth and eHealth technologies has opened new career pathways for behavioral medicine scientists, and created innovative opportunities to apply expertise in behavior theory and scientific methods to diverse, health-related organizations outside of academic settings. Many health-related organizations (from small start-ups to large multi-national organizations) benefit from behavioral medicine specialists to inform the creation, application and evaluation of new health behavior-based tools and services for varied audiences. This panel of SBM members will present their experiences in bringing behavioral medicine expertise to life in careers outside of academia, and will highlight the unique opportunities and obstacles across different organizations and settings. The panelists will discuss the roles and responsibilities of their positions, the impact of their work on their organizations, and challenges experienced as academically-trained scientists in non-academic settings. The first speaker will discuss her role as the lead outcomes researcher for a digital behavioral medicine company focused on chronic disease prevention. The second speaker will discuss her career integrating evidence-based science on human behavior change with technology across various sectors—consumer healthcare, medical devices, and pharmaceutical--in a large healthcare corporation. The third speaker will discuss her role in bringing innovative lifestyle management programs to patients within a large, not-for-profit health care system. The final speaker will discuss her perspective as an early-career researcher consulting with a start-up company. Through sharing their experiences, the panelists aim to expose students and early-career scientists to the varied career paths after behavioral medicine training, and further collaborative discussion between behavioral medicine scientists across industry and academia.

This presentation is supported by the Industry Collaboration subcommittee of the SBM Digital Health Council.

Panel Discussion 18 12:15 PM-1:15 PM

INTEGRATING PATIENT REPORTED DATA INTO BEHAVIORAL PRAGMATIC TRIALS: CHALLENGES AND SOLUTIONS

Wendy J. Weber, ND, PhD, MPH[1], Susan M. Czajkowski, Ph.D.[2], Lynn DeBar, PhD, MPH[3], Doug Zatzick, MD[4]

[1]National Center for Complementary and Integrative Medicine/ National Institutes of Health, Bethesda, MD; [2]National Cancer Institute, Rockville, MD; [3]Kaiser Permanente, Center for Health Research, Portland Oregon, Portland, OR; [4]University of Washington, Harborview, Level 1 Trauma Center, Seattle, WA

In the last few years there has been a growing interest by the public and the scientific community in pragmatic clinical trials that test research hypotheses, which will directly inform the health care system. This interest has been driven by a number of factors including the high cost of traditional efficacy studies and the exclusion of many individuals from efficacy trials resulting in results that do not generalize to many patients. The proposed discussion session will include presentations that will provide an overview of pragmatic trials for behavioral interventions; how patient reported outcomes can be incorporated into pragmatic trials; examples from two large scale pragmatic trials that are incorporating patient reported outcomes; and provide resources for planning and conducting pragmatic trials. Dr. Weber will highlight an overview of pragmatic trials for behavioral interventions. Dr. Czajkowski will present on how pragmatic trials can capture patient reported outcomes (PROs), and give examples of some common PRO measures used in these trials. Dr. Debar will present the challenges of including patient reported outcomes of pain measures in a large pragmatic trial evaluating integration of multidisciplinary services within the primary care environment versus usual care. Dr. Zatzick will present about the challenges of collecting patient reported information to determine participant eligibility for a large pragmatic trial to evaluate a coordinated care delivery program for patients treated for acute trauma to prevent PTSD and other related conditions. Dr. Weber will provide a summary of resources developed by the NIH Health Care System Research Collaboratory for investigators who are planning and conducting pragmatic trials (www.nihcollaboratory.org). The session will close with a panel discussion with all presenters to answer questions from the audience.

This session will provide attendees with a strong overview of how to overcome challenges to incorporating patient-reported outcomes into pragmatic trials. Attendees will also be informed of resources and tools available to help them better understand the complexity of planning and conducting pragmatic trials.

Panel Discussion 19 12:15 PM-1:15 PM

USING CONSUMER PRODUCTS IN BEHAVIORAL RESEARCH: LESSONS LEARNED FROM THE FRONTLINES

Ernesto Ramirez, PhD, MS[1], Sarah Kunkle, MPH[2], Job Godino, Ph.D.[3], Sheri J. Hartman, PhD[4], Chad D. Rethorst, Ph.D.[5], Lisa Gualtieri, PhD, ScM[6], Valentin Prieto-Centurion, MD[7]

[1]Fitabase, San Diego, CA; [2]Fitbit, San Francisco, CA; [3]UC San Diego, La Jolla, CA; [4]Department of Family Medicine and Public Health, UC San Diego, La Jolla, CA, USA, La Jolla, CA; [5]UT Southwestern Medical Center, Dallas, TX; [6]Tufts University School of Medicine, Boston, MA; [7]University of Illinois at Chicago, Chicago, IL

Over the last five years, Fitbit and other consumer health devices and applications have rapidly become key tools for measurement and intervention studies. Consumer products provide novel and user-friendly methods for behavioral data collection including, but not limited to, physical activity, heart rate, sleep, dietary behaviors, and weight. Additionally, most, if not all, consumer products are designed to collect data over longer periods of time than what is commonly gathered by typical “research grade” devices (e.g., accelerometers) and subjective measurement methods (e.g., questionnaires). In this panel, we will discuss the opportunities available to behavioral researchers when consumer devices are included as part of a measurement and/or intervention study. This panel represents key stakeholders in the current consumer device and research ecosystem. Each panelist will present their work and participate in a moderated discussion. The panelists have been involved with supporting and/or conducting research using consumer products, including: 1) a representative from Fitbit, the leading consumer physical activity and sleep tracking device brand; 2) an industry-academic partner with Fitabase, specializing in data management of behavioral data produced by consumer tools; 3) researchers who have deployed various consumer products as part of validation, measurement, and intervention studies across diverse participant populations. These researchers have designed and conducted innovating technology-enabled studies with children and adolescents, cancer survivors, patients with COPD, mental health patients, and historically underserved populations. Audience members will learn about the current best practices for using consumer products, including current validation outcomes, and how to best design studies for longitudinal data collection, interactivity, and maximal participant engagement.

Panel Discussion 20 12:15 PM-1:15 PM

ACCELERATING INNOVATION WITH THE SPEEDING RESEARCH INTERVENTIONS (SPRINT) PROGRAM

Cynthia A. Vinson, PhD, MPA[1], Heather Greenlee, ND, PhD, MPH[2], Lisa S. Miller, PhD[3], Nora L. Nock, PhD, PE[4], Edmund Pendleton, MS[5], Amanda Marin-Chollom, MA[6]

[1]Division of Cancer Control and Population Sciences, National Cancer Institute, Bethesda, MD; [2]Mailman School of Public Health, Columbia University, New York, NY; [3]University of California, Davis, Davis, CA; [4]Case Western Reserve University, Cleveland, OH; [5]University of Maryland, College Park, MD; [6]Columbia University Medical Center Mailman School of Public Health & The Graduate Center, City University of New York, New York, NY

During the summer of 2016, the National Cancer Institute (NCI) kicked off the SPeeding Research INTerventions (SPRINT) Program which is designed to foster, grow and nurture an innovation ecosystem for behavioral interventionists. The program is run by instructors with extensive startup and teaching experience and provides real world, hands-on training on how to successfully incorporate innovations in cancer control into successful products. The ultimate goal is to create scalable research-tested behavioral interventions that are ready to be put into real world practice and which will reach a large audience of users.

Ten teams consisting of a Principal Investigator, Mentor and Entrepreneurial Lead participated in the 8-week pilot of SPRINT. The teams participated in both a 3-day opening and a 1-day closing in-person training session at NCI and weekly webinars. Teams also interviewed at least 30 potential customers, competitors and stakeholders. Teams integrated the information acquired during the interview with quantitative data to refine their respective intervention/product and develop a viable business model for their NCI-funded behavioral interventions.

The first team will share how the SPRINT training influenced plans for dissemination and implementation (D&I) of a Spanish language nutrition and physical activity program for breast cancer survivors. At the beginning of the SPRINT training, the team had the goal of scaling their intervention to reach a wider audience of Latina breast cancer survivors. After completing 50 interviews they pivoted to creating a website and/or phone app focused only on nutrition, which can be used by a larger and more diverse group of cancer survivors. Going forward, in order to facilitate delivering the product to the consumer at a faster pace, the team intends to think of scalability when beginning to design and test new interventions.

The second team will discuss how SPRINT helped the team in pursuing D&I of their intervention which involves an 'assisted' exercise technology. They will discuss the challenges faced in scaling-up their 'assisted' cycling prototype and modifications made based on lessons learned from SPRINT training and 'customer' interviews.

The third team will present on SPRINTs impact on D&I of a research-tested food label training program. The team started the program with a vague idea of selling an app to consumers to improve their food label reading skills. They ended SPRINT with a strategy for adoption, implementation and sustainability of a web-based nutrition literacy tool to help employers promote healthy food choices and reduce costs associated with diet-related chronic conditions.

An overview of the course design and content as well as evaluation results will be presented along with a discussion of future opportunities for SPRINT training by NCI representatives.

Panel Discussion 21 12:15 PM-1:15 PM

GETTING STARTED WITH QUALITATIVE METHODS IN CANCER RESEARCH: TIPS FOR DESIGN, DATA COLLECTION AND ANALYSIS

Shirley M. Bluethmann, PhD, MPH, Michelle A. Mollica, PhD, MPH, RN, OCN, Katharine Rendle, PhD, MSW, MPH, Erin Kent, PhD

National Cancer Institute, Rockville, MD

There is increasing emphasis on use of qualitative and mixed-methods approaches in the field of cancer prevention and control research. Qualitative methods can be used to systematically capture contextual data in ways that are difficult to do with quantitative approaches alone. These methods can be used to provide rich insights on a particular topic, or they can serve as the foundation for additional quantitative research and intervention development. Planning and managing qualitative research, however, can be challenging for those new to the field. This panel will present a broad overview of how to conceptualize, conduct, and analyze qualitative research projects, with a focus on interview methods in cancer prevention and control research. This session is geared toward early-stage investigators and those that are new to qualitative research.

Panel Discussion 22 12:15 PM-1:15 PM

APPLYING FOR GRADUATE FUNDING FROM THE NATIONAL SCIENCE FOUNDATION AND THE NATIONAL INSTITUTE OF HEALTH

Margarita Sala, BS[1], Amy Heard, BA[2], Stephanie Manasse, MS[3], Austin S. Baldwin, PhD[4]

[1]Southern Methodist University, Dalas, TX; [2]Loyola University Chicago, Chicago, IL; [3]Drexel University, Philadelphia, PA; [4]Southern Methodist University, Dallas, TX

For graduate students and trainees, applying for grants from the National Science Foundation (NSF) or the National Institute of Health (NIH) is an important experience in their professional development. Receiving one of these grants guarantees funding during graduate school, opens opportunities for professional development, allows for the freedom to conduct independent research, and positions the trainee well to be competitive for future funding. However, these grants are highly competitive and guidance is limited, and thus the application process may seem overwhelming and daunting. In this panel, three graduate students who have been awarded pre-doctoral funding from the NIH or NSF will discuss their perspectives on preparing applications for the NSF Graduate Research Fellowship Program (GRFP) and the NIH Pre-doctoral Fellowship (NRSA F31), emphasizing their thoughts regarding what constitutes a successful application. In addition, an experienced reviewer will discuss his experience reviewing NIH Pre-doctoral Fellowship grants, emphasizing the review criteria set by NIH and his insights into what constitutes a good application. Attendees will have the opportunity to ask questions to the panelists.

CORRESPONDING AUTHOR: Margarita Sala, BS, Southern Methodist University, Dalas, TX, 75204; msala@smu.edu

Panel Discussion 23 12:15 PM-1:15 PM

RESULTS AND LESSONS FROM COMPASS: NATIONAL IMPLEMENTATION OF EVIDENCE-BASED COLLABORATIVE CARE MODEL

Claire Neely, MD, MD[1], Karen J. Coleman, MS, PhD[2]

[1]Institute for Clinical Systems Improvement, Bloomington, MN; [2]Kaiser Permanente Southern California, Pasadena, CA

Introduction: Collaborative care for the treatment of mental and physical health conditions in primary care settings has been shown to be effective in controlled trials. We present outcomes from a national dissemination and implementation project for depression and comorbid diabetes and/or cardiovascular disease, funded by the Center for Medicare & Medicaid Innovation. Barriers and facilitators that influence successful implementation and sustainability of this model across diverse populations, organizations and geographies will be discussed.

Background: The comorbidity of depression with diabetes and cardiovascular disease increases health care costs. Recently, randomized trials have shown that collaborative care models for depression can be expanded to comorbid conditions such as diabetes. Until now, wide-scale dissemination and implementation of this collaborative approach had not been tested.

Methods: 3,609 patients in 18 primary care systems and 172 clinics were enrolled in the Care for Mental, Physical and Substance Use Syndromes (COMPASS) program as part of a project to implement a proven chronic care model for patients with depression and diabetes and/or cardiovascular disease. COMPASS involved a minimum of monthly contact with care managers and weekly case review by a team of consulting physicians and psychiatrists. Eligible adult patients met these criteria: Patient Health Questionnaire (PHQ9) score 10 or higher and another poorly controlled medical condition; diabetes mellitus (HgbA1c > 8%) and/or cardiovascular disease (blood pressure > 140/90 mmHg).

Results: Of 3,609 patients with uncontrolled disease at enrollment, 40% achieved depression remission or response, 23% glucose control, and 58% blood pressure control during a mean follow-up period of 11 months. Depression improvement was directly related to the frequency of care management contact. Patients and clinicians were satisfied with COMPASS care. There were large variations in outcomes across medical groups. Challenges in implementation included changing scope and practice of physicians, psychiatrists, and existing care managers and care management systems.

Conclusions: Results from COMPASS provide support for institutionalizing proven collaborative care models in high volume primary care settings. Widespread implementation and improved patient outcomes were feasible through a collaborative effort among diverse health care systems; however, both implementation and outcomes varied greatly.

Panel Discussion 24 12:15 PM-1:15 PM

MIND-BODY RESEARCH: A PANEL DISCUSSION OF SCIENTIFIC AND FUNDING TRENDS, PRIORITIES AND STRATEGIES

Crystal L. Park, PhD[1], Lanay M. Mudd, PhD[2], Frederick (Rick) Hecht, MD[3], Beth C. Bock, PhD[4]

[1]University of Connecticut, Storrs Mansfield, CT; [2]National Center for Complementary and Integrative Health, Bethesda, MD; [3]University of California, San Francisco, San Francisco, CA; [4]Brown Medical School, Providence, RI

This panel session will provide a stimulating discussion of the current landscape and future prospects of mind-body science and is designed to promote extensive interaction between panelists and audience. The session will begin with a brief overview of current NCCIH funding priorities and opportunities by Lanay Mudd, program director at NCCIH. Two grantees with substantial NCCIH support, Rick Hecht and Beth Bock, will provide their perspectives on cutting-edge developments in mind-body research and their own strategies for maintaining adequate resources to pursue research. Panelists will discuss the importance of thinking systematically about sustained funding for ongoing lines of research and consider what makes funding proposals stand out—and what can sink them. The moderator, Crystal Park, will take questions from the audience and will also be ready with prepared questions to foster dialog.

CORRESPONDING AUTHOR: Crystal L. Park, PhD, University of Connecticut, Storrs Mansfield, CT, 06269; crystal.park@uconn.edu

Panel Discussion 25 12:15 PM-1:15 PM

COMPLEX BEHAVIORAL MEDICINE PATIENTS: ADVANCING THE NEED FOR BEHAVIORAL MEDICINE SERVICES VIA CASE STUDIES

Kelly Gilrain, PhD[1], Cori E. McMahon, PsyD[2], David A. Moore, PsyD[3], Gonzalez A. Efrain, Psy.D., MSClinPharm, ABPP[4], Kaplan M. Lynne, Ph.D.[5], Petrongolo Jennifer, MSW, MA[6]

[1]Cooper University Hospital, Haddonfield, NJ; [2]Cooper University Hospital/ MD Anderson Cancer Center at Cooper, Camden, NJ; [3]La Salle University, Philadelphia, PA; [4]University of Miami School of Medicine, Miami, FL; [5]Children's Hospital of Philadelphia, Philadelphia, PA; [6]La Salle University, Lancaster, PA

Behavioral Medicine IP Consultation Teams are becoming more prevalent across hospital systems to address the psychological needs of medical patients in a manner that differs greatly from Social Work and Psychiatry services. The reasons for consulting an IP Behavioral Medicine Team are varied from adjustment concerns of mood and anxiety related to medical issues, trauma symptoms after injuries, new medical diagnoses that are causing emotional distress and varying types of losses related to medical concerns, as well as advisement on cognitive issues for our patients struggling with dementia versus delirium versus depression. While many of these cases are straightforward, Behavioral Medicine teams are more regularly being asked to provide insight into the more complex patient, particularly when there is no medical rationale to explain a patient’s pain, nausea, inability to use a limb, refusal to eat or engage with care or understand altered mental status. Many consultations now cross over to more complex challenges in assessment, management, and recommendations. These cases are typically associated with factitious, somatization and conversion disorders, which may also be complicated further by personality issues. Additionally, the capacity evaluations requested are oftentimes multifaceted due to cognitive issues, patient versus familial desires, as well as ethical concerns.

This Panel Discussion will showcase a variety of complex patient consultations received by Behavioral Medicine Teams across the country as well as those patients who would benefit from having Behavioral Medicine input. These new and complex consults are expanding the horizons of typical Behavioral Medicine requests from adjustment, anxiety or depression to a more intricate consult which must take into account biopsychosocial factors, the interconnectedness of physical and emotional wellbeing and how psychological functioning impacts medical presentations and subsequent medical care. The panel will provide insight on how to assess, conceptualize, and work with patients and their medical teams to ensure understanding of the medical patients’ psychological needs within the context of a complex and often vague symptom presentation. Clinicians from Cooper University Hospital (Camden, NJ), University of Miami, Department of Psychiatry and Behavioral Sciences (Miami, FL); WellSpan Behavioral Health (York, PA), and CHOP (Philadelphia, PA) will discuss these complex cases.

CORRESPONDING AUTHOR: Kelly Gilrain, PhD, Cooper University Hospital, Haddonfield, NJ, 08033; gilrain-kelly@cooperheatlh.edu

Panel Discussion 26 12:15 PM-1:15 PM

GROUP VISITS AND GROUP PSYCHOTHERAPY IN INTEGRATED PRIMARY CARE: PROMOTING CHILDREN’S MENTAL AND PHYSICAL HEALTH.

Amber J. Landers, PhD[1], Shireen F. Cama, MD[1], Amelia Swanson, PhD[2], Bianca S. Shagrin, MD[3]

[1]Cambridge Health Alliance/Harvard Medical School, Cambridge, MA; [2]University of Massachusetts Medical School/UMass Memorial Medical Center, Worcester, MA; [3]Cambridge Health Alliance, Cambridge, MA

Group interventions are a useful intervention to promote change via accessible exercise, social and education opportunities for families at their primary care clinic. This panel will discuss two group modalities in primary care (a psychotherapy group and a group visit) that were developed for promoting health behaviors among children and families These interventions will be considered from a multidisplinary team-based model and cultural-ecological theory that considers interplay of the social environment on children and families. Panel members will discuss the following groups from these frameworks, including lessons learned and implications for training.

Parent group – Led by psychologist, psychiatry resident, and psychology fellow in primary care clinic. Offered supportive therapy, mindfulness and education, as well as a training opportunity. Will discuss challenges and opportunities at the intersection of adult and child work in clinical practice and training, logistics and future goals.

Wellness group –led by pediatrician and conducted with multidisciplinary team (psychology, social work, nursing, nutrition). Offered health intervention and exercise activity (zumba!) as well as training opportunity. Will discuss logistics, outcomes of team-based approach, and future goals.

CORRESPONDING AUTHOR: Amber J. Landers, PhD, Cambridge Health Alliance/Harvard Medical School, Cambridge, MA, 02138; drlandersaj@gmail.com

Symposium 55 1:30 PM-2:45 PM

BEHAVIORAL INTERVENTIONS FOR OBESITY: A DEBATE ON THE STATE OF THE EVIDENCE

Dawn K. Wilson, Ph.D., FSBM[1], Peter Kaufmann, PhD[2], Robert M. Kaplan, PhD[3], Karina Davidson, PhD, MASc[4]

[1]University of South Carolina, Columbia, SC; [2]NHLBI, Bethesda, MD; [3]Stanford University, Palo Alto, CA; [4]Columbia University Medical Center, New York, NY

This debate will focus on several themes common to the proposed presentations that include: 1) The importance of measuring patient centered health outcomes in contrast to surrogate markers, 2) Interpretation of null RCTs in light of study power, patient population, and study designs, and 3) Evidence requirements for public policy. A brief overview of these themes and the overall importance of the session from a national perspective will be provided by the chair.

Symposium 55A

A NULL RESULT IS NOT A TRIAL FAILURE: AN IN-DEPTH EXAMINATION OF THE IMPACT OF TRIAL DESIGN ON CLINICAL OUTCOMES.

Dr. Peter Kaufmann, PhD

Many large NIH trials produce null results. Dr. Kaufmann was the co-author of an important paper in Clinical Trials that described changes in the primary outcome of the Look AHEAD trial necessitated by low event rates (http://www.ncbi.nlm.nih.gov/pubmed/22334468). The presentation will describe how clinical trial design influences outcome, with implications for clinical application and future clinical trials.

Symposium 55B

EFFECT SIZES AND PRIMARY OUTCOMES IN LARGE NIH-BUDGET, CARDIOVASCULAR-RELATED BEHAVIORAL RANDOMIZED CONTROLLED TRIALS

Robert M. Kaplan, PhD

Dr. Kaplan will summarize the results of all large-budget behavioral trials funded by NHLBI and by NIDDK. In the context of current results, the presentation will suggest new directions for behavioral clinical trials. Dr. Kaplan published a review article on this topic in Feb. 2016, Annals of Behavioral Medicine, http://www.ncbi.nlm.nih.gov/pubmed/26507906.

Symposium 56 1:30 PM-2:45 PM

DIGITAL HEALTH TOOLS TO SUPPORT POPULATION HEALTH IN AN INTEGRATED DELIVERY AND FINANCING SYSTEM

Ellen Beckjord, PhD, MPH, Darren Olson, MBA, Ryan E. Cummings, MS, Amber Blackwood, MPH, CHES

UPMC Health Plan, Pittsburgh, PA

Evidence-based digital health interventions have the potential to extend the reach and enhance the impact of behavioral medicine. As part of an integrated delivery and financing system responsible for three million covered lives across commercial and governmental products, the UPMC Health Plan has been working to leverage digital tools to optimally manage the health and wellbeing of its members. This work includes the design, implementation, and evaluation of digital solutions focused on a variety of target behaviors in the service of multiple health-related goals. In this symposium, we will feature three digital tools developed and used by the UPMC Health Plan for population health management. The first presentation will focus on a member-facing mobile application; its features; and its importance as a “gateway” for members into a longitudinal and positive relationship with their health insurer (Olson). Next, we will discuss the translation of an internally-developed, evidence-based stress management program into a mobile solution, with an emphasis on the practices used to develop and evaluate a minimum viable product (Cummings). The third presentation will detail analytical approaches to optimizing member use and completion of a web-based, cognitive behavioral intervention for mild to moderate depression and anxiety (Blackwood). Our Discussant (Beckjord) will review what we have learned about best practices as well as challenges across these three solutions, including the importance of iterative development; the capture and use of consumer-generated data; defining member engagement in actionable ways; and using member input to provide digital solutions that meet and are consistent with consumers’ needs, preferences, and values.

Symposium 56A

USING A MEMBER APP TO ALIGN CONSUMER EXPECTATIONS IN THE MARKETPLACE WITH THEIR HEALTH PLANS

Darren Olson, MBA

Consumer expectations are at an all-time high when it comes to top-of-the-line service and user experience, and differentiating oneself from the competition is a challenge for many. Health insurance is not excused. As Moore's law accelerates the affordability and availability of technology, consumers expect their health plans to keep pace. In 2012, the UPMC Health Plan developed and released a mobile application for members and over the past year has conducted six studies with 143 participants to iteratively improve the solution and align it with member expectations. User testing focused on consumers' attitudes about and behaviors with the app as well as roadblocks or barriers to utilization. We used the findings to prioritize the roadmap of feature development in our sprint cycle. We will describe multiple features of the app; their utility for serving health plan members; and iterative improvements made to features including enabled fingerprint ID login; a streamlined registration process; use of push notifications; and the integration of other digital health tools into the mobile app environment. Results show that moving to fingerprint ID login reduced login errors by 30%; that redesigning key elements of the information architecture in response to user feedback decreased time spent on the login screen by 50%; increased monthly app downloads by 5%; increased app utilization by 25%; and increased monthly unique return visitors by 10%; and that streamlining the registration process decreased the time required to create a new account by two to three minutes. We will discuss these features and associated results in the context of supporting preventive health behavior; health behavior change; and optimizing consumer experiences as part of an integrated delivery and financing system serving three million members across commercial and governmental insurance products.

Symposium 56B

THE BREATHE STRESS MANAGEMENT APP: LONGITUDINAL EVALUATIVE RESEARCH TO VALIDATE A LIFESTYLE DIGITIZATION CONCEPT

Ryan E. Cummings, MS

Stress is a common experience among health care consumers, and often the most frequently endorsed lifestyle risk factor reported on health risk assessments. The UPMC Health Plan has had an evidence-based stress management intervention available to members for over a decade; however, digitizing this intervention and offering it as a mobile solution is necessary to achieve adequate reach and to optimize impact. In 2015, in collaboration with a digital entertainment and gaming company, we designed and user-tested a prototype of a mobile stress management solution called Breathe. This minimum viable product (MVP) used ecological momentary assessment (EMA) to measure levels of stress throughout the day and provided guided instruction on deep breathing for stress reduction. Using qualitative methods, we conducted a 14-day longitudinal study to assess the effectiveness of the app to reduce and manage stress over time. We guided the study with 30 individuals (15 iPhone users and 15 Android users). We recruited participants through a remote usability platform, UserTesting. We conducted an initial evaluative exercise wherein users access the application and are asked to rank their overall health and stress levels and their expectations of the app. We then guided them through the setup process. asking them to 'speak aloud' about their experiences. Data collection included recording participants' on-screen device interactions, voice, and inter-study response to survey questions. At one week, we conducted a "check-in" with our users to validate their on-going participation. The test concluded with asking participants to explain their experience through both written and verbal prompts. Results showed that most users expected the app to be contextually aware, with notifications functioning as suggestions for techniques. Regarding app features, users viewed tagging reports of stress with triggers as cumbersome and confusing. However, they found the check-in interaction (EMA) to be very easy and intuitive. Participants found milestone badges very motivating and perceived the color palette as calming, and some users felt less stress just from viewing the app. Finally, participants stated that the setup process was lengthy, and warned it might deter people from completing the setup process. These results allowed us to provide recommendations to improve the overall experience and align continued development with prioritization of feature sets as we continue to translate evidence-based behavior change interventions into mobile solutions for health plan members.

Symposium 56C

BEATING THE BLUES: USING CONSUMER USAGE DATA TO DRIVE ENGAGEMENT AND INCENTIVE STRATEGIES

Amber Blackwood, MPH, CHES

Many patients with anxiety or depression seek mental health treatment in a primary care setting where medication is often prescribed. The UPMC Health Plan is enhancing their members' experiences by offering digital tools as an alternative or supplement to traditional treatment. Beating the Blues is a web-based, cognitive behavioral intervention for mild to moderate depression and anxiety that is made up of 31 interactive modules. While the program design is evidence-based and theory-driven, completion of all 31 modules remains low (n=1334; completion=8.8%). Consumer usage data from digital health tools can be utilized to drive incentive strategies that encourage participation and increase program completion. We analyzed usage data to determine whether the time elapsed between completing modules was associated with continued participation in the program. We identified two high risk points where attrition was greater than 18%, and the number of days between modules was significantly ($p<0.05$) different between those who completed the next consecutive module and those who did not. 19% of individuals who completed module 2 did not go on to complete module 3, and 18% of individuals who completed module 11 did not go on to complete module 12. Among those who completed module 3 (n=935), the average time between completing modules 1 and 2 was significantly ($p<0.05$) shorter (0.93 days; SD=4.53) than among those who did not complete module 3 (n=212; 2.59 days (SD=9.55)). Among those who completed module 12 (n=414), the average time between completing modules 10 and 11 was significantly ($p<0.05$) longer (1.38 days; SD=3.61) than among those who did not complete module 12 (n=13; 0.19 days (SD=0.87)). These data suggest that an opportunity exists for engagement to be optimized through strategically incentivizing the pace at which individuals progress through web-based mental health treatment. When managing digital health intervention tools that involve a high level of patient effort and are of high value to the payer/provider, analytical approaches should be used to guide the design of strategic incentive structures to optimize engagement and achieve positive health outcomes.

Symposium 57 1:30 PM-2:45 PM

ADVANCING BEHAVIORAL MEDICINE IN OBESITY RESEARCH ACROSS THE LIFESPAN

Danielle E. Jake-Schoffman, PhD[1], E. Amy Janke, PhD[2], Claudio R. Nigg, PhD, FSBM[3], Andrea T. Kozak, PhD[4], Bernard F. Fuemmeler, PhD, MPH[5], Jennifer Huberty, PhD [6]

[1]University of Massachusetts Medical School, Worcest, MA; [2]University of the Sciences, Philadelphia, PA; [3]University of Hawaii, Honolulu, HI; [4]Oakland University, Rochester, MI; [5]Massey Cancer Center, Virginia Commonwealth University, Richmond, VA; [6]Arizona State University School of Nutrition and Health Promotion, Phoenix, AZ

The future of behavioral medicine lies in our ability to transform our science into action. Our field sits at the intersection between communication science, consumer education, industry, medicine, public health, and technology. The Society of Behavioral Medicine (SBM) has the unique ability to bring together experts from diverse fields to facilitate a collaborative environment through which synergy can be created across behavioral medicine disciplines. Over the past year, members of SBM’s Special Interest Groups (SIGs) have prepared manuscripts highlighting the future directions of behavioral medicine research in their respective fields of interest, to contribute to a landmark special issue for the *Journal of Behavioral Medicine*, a call for action to promote research advancing the science to inform policy and practice. Among the common themes that emerged across the special issue manuscripts was the critical issue of advancing obesity prevention and treatment across the lifespan. This symposium will highlight the future of behavioral medicine research in obesity prevention and treatment as outlined by 4 SBM SIGs: Obesity and Eating Disorders, Child and Family Health, Women’s Health, and Multiple Health Behavior Change. The Obesity and Eating Disorders SIG presentation will focus on advances in technology-based solutions for weight management, particularly for younger and older adults and the accompanying research gaps in this emerging field. The Child and Family SIG presentation will focus on the prevention of childhood obesity through lifecourse and systems perspectives, highlighting critical milestones for intervention and the multilevel nature of effective preventive medicine approaches. The Women’s Health SIG presentation will focus on the need for effective interventions to help women with weight and stress management during the critical inter-conception period. Finally, the Multiple Health Behavior Change SIG presentation will focus on areas of future research to maximize health behavior change for the prevention and treatment of multiple chronic diseases concurrently, including obesity, cardiovascular disease, and type 2 diabetes. Together, the symposium will present a range of perspectives on the future of obesity research that will stimulate an engaging dialogue among the presenters and the audience to further advance the conversation about the advancement of obesity research.

Symposium 57A

FUTURE DIRECTIONS OF MULTIPLE BEHAVIOR CHANGE RESEARCH

Dr. Claudio R. Nigg, PhD, FSBM

Non-communicable diseases (i.e., chronic diseases including cardiovascular disease, cancer, chronic respiratory disease, diabetes and obesity) result in 36 million deaths each year. Individuals' habitual participation in a single health-risk behaviors can seriously contribute to morbidity and mortality (e.g., tobacco use, daily fast food intake, etc.); however, more concerning is the typical co-occurrence or clustering of multiple health-risk behaviors. This burden can be minimized through successful cessation of health-risk behaviors and adoption of healthy behaviors; namely healthy lifestyle adoption or multiple health behavior change (MHBC). MHBC is an emerging field and, in order to advance MHBC research, future research recommendations are provided. A valid measure of MHBC (i.e., lifestyle) is warranted to provide the needed basis for MHBC investigations and evaluations. MHBC is thought to occur through shared co-variation of underlying motivating mechanisms, but how these relationships influence behavior remains unclear. A better understanding of the relationship between behaviors and the related motivating mechanisms (and potential cross-relationship of influences) is needed. Future research should also aim to improve lifestyles through understanding how to change multiple health behaviors. Finally, MHBC research should target the development of sustainable interventions which result in lasting effects (e.g., capacity, systems, policy and environmental changes), with dissemination considered during development. Focusing MHBC research in these areas will increase our understanding and maximize the impact on the health of populations.

Symposium 57B

CURRENT RCT EVIDENCE AND FUTURE DIRECTIONS FOR TECHNOLOGY-BASED WEIGHT MANAGEMENT AMONG ADULTS

Andrea T. Kozak, PhD

Obesity is a prevalent health care issue associated with disability, premature mortality, and high costs. Traditional, face-to-face behavioral weight management interventions lead to clinically-significant weight losses in overweight and obese adults; however, individuals might not be able to participate in these programs due to limited access as well as the cost and time constraints associated with participation. Technological advances such as widespread access to the Internet, increased use of smartphones, and newer behavioral self-monitoring tools have resulted in the development of a variety of eHealth weight management programs. This presentation will provide a review of the current literature, potential solutions to methodological limitations (e.g., high attrition, minimal participant racial/ethnic diversity, heterogeneity of technology delivery modes), and future directions for the field, including important dissemination and policy implications. Younger and older generations' comfort with technological intervention modalities as well as the expectations of digital natives versus novices will be highlighted.

Symposium 57C

CHILDHOOD OBESITY IN THE ERA OF PREVENTION: NEW OPPORTUNITIES AND CHALLENGES

Bernard F. Fuemmeler, PhD, MPH

Since passage of the Patient Protection and Affordable Care Act (ACA) in 2010, there is revitalized interest in prevention and population health management. This increased focus on prevention requires new ways of thinking about child and family health in research, practice, and policy contexts. Given childhood obesity increases risk for chronic health conditions into adulthood, it will become necessary for prevention models to address childhood obesity research from a broader perspective that embrace both a life course perspective and systems or multilevel thinking.

There are a number of "touch-points" that offer opportunities for implementing prevention strategies throughout the life course and across social systems that could be leveraged to affect changes in population obesity prevalence. For instance, the first 1,000 days from conception to 24 months after birth represents a critical window to address risk factors associated with childhood obesity, including maternal weight, tobacco use, and lack of breastfeeding. In addition, as a child matures from early childhood to adolescence there is a potential to shape weight-related trajectories by intervening on social-contextual factors, such as the family, school and community contexts.

Child and family health researchers will need to advance models and methods that incorporate a life course and systems perspective. Effective prevention efforts will require a better understanding of how early life factors shape future health trajectories and how broader family, school and community systems can be strategically leveraged to influence these trajectories in such a way as to maximize child health and minimize later adult chronic health conditions. This presentation will provide a brief overview of research on risk factors for childhood obesity in the first 1,000 days through early childhood with a focus on findings addressing a life course and systems perspective.

Symposium 57D

EXPLORING THE NEED FOR INTERVENTIONS TO MANAGE WEIGHT AND STRESS DURING INTER-CONCEPTION

Dr. Jennifer Huberty, PhD

More than half of women in the U.S. enter pregnancy overweight or obese. More than 2/3 of these women exceed Institute of Medicine recommendations for healthy weight gain during pregnancy leading to adverse maternal, infant, and child health outcomes. Managing weight is a critical component of health during pregnancy. Strategies that encourage weight management, with emphasis on those that include ways to manage stress during the inter-conception period (i.e., time immediately following childbirth to subsequent pregnancy) are needed to promote optimal maternal and infant health outcomes.

The purpose of this presentation is to 1) summarize the current state of knowledge, 2) critically evaluate the research focused on weight and stress management during the inter-conception period, and 3) provide future recommendations for research in this area.

Symposium 58 1:30 PM-2:45 PM

TRANSLATING LIFESTYLE INTERVENTIONS FOR REDUCING CARDIOMETABOLIC RISK IN VULNERABLE AND DISADVANTAGED POPULATIONS.

Delwyn Catley, Ph.D.[1], Thandi Rose. Puoane, Dr PH.[2], Brian Oldenburg, BSc, MPsychol, PhD[3], Christie Befort, PhD[4], Ken Resnicow, Ph.D.[5]

[1]Children's Mercy Hospital & University of Missouri-Kansas City, Kansas City, MO; [2]University of the Western Cape, Bellville, Western Cape, South Africa; [3]The University of Melbourne, Melbourne, Victoria, Australia; [4]University of Kansas Medical Center, Kansas City, KS; [5]University of Michigan, Ann Arbor, MI

While rigorous RCT's often demonstrate the efficacy of behavioral medicine interventions, their translation into practice and public health impact remains limited. There are increasing efforts to bridge this gap as well as an interest in understanding methods for successfully translating effective interventions into real-world settings. One important example is a lifestyle intervention approach to modify behavioral risk factors for cardiovascular disease and Type 2 diabetes. Although large trials in the US and Finland have provided strong evidence for the efficacy of lifestyle interventions, the challenge is to translate these interventions in such a way as to have high public health impact across a wide variety of real-world contexts. In this symposium we will describe trials being undertaken in three countries to translate effective lifestyle interventions to real-world practice. One presenter will describe the ongoing process of adapting a proven intervention for delivery by Community Health Workers in a poor urban township in South Africa in preparation for a large randomized effectiveness trial. Another presenter will describe the process they used for adapting and scaling up a peer-led, group based intervention in rural India for a large effectiveness trial. The third presenter will describe an on ongoing comparative effectiveness trial of alternative methods of delivering a lifestyle intervention in rural primary care practices in the U.S. Each presenter will describe the rationale for adapting the intervention for the targeted setting, the conceptual or theoretical approach to adaptation, the methods and processes of adaptation, the approach to measurement of the adaptation process, and the results. The discussant will integrate these presentations by highlighting commonalities in the approach to adaptation as well as key differences and lessons learned.

Symposium 58A

ADAPTING THE U.S. NATIONAL DIABETES PREVENTION PROGRAM FOR THE DEVELOPING WORLD

Dr. Thandi Rose. Puoane, Dr PH.

Increasing rates of cardiovascular disease and diabetes in developing countries are presenting significant challenges for the health care systems of countries with scarce resources. The National Diabetes Prevention Program (DPP) is a proven lifestyle intervention for reducing cardiometabolic risk that could be a powerful prevention tool, however the lack of health professionals to deliver the program, the high literacy and numeracy levels required of participants, and cultural differences in lifestyle (e.g., food preferences) need to be addressed. Informed by the RE-AIM framework and using a Community Engaged approach we are translating the DPP for delivery to overweight/obese community members in two impoverished urban townships in South Africa. The adapted program will be evaluated in a large cluster-randomized trial. Three major adaptations are: 1) to deliver the program using video and Community Health Workers (CHWs), 2) to capitalize on the widespread cell phone use to add interactive text-messaging support, and 3) to enhance CHW's communication skills through simplified Motivational Interviewing training. These adaptations together with lower literacy requirements, and cultural and language adaptations are expected to enhance program adoption, reach, and effectiveness. Community engagement is consistent with the implementation principle and is achieved through the recruitment of study team members drawn from the community and the formation of Community Advisory Boards that guide the project throughout. Support and engagement from the community is enhanced by years of preliminary work in the community. The research team drafts session scripts and expert consultants and Community Advisory Board members provide feedback to ensure the intervention will be adoptable and maintained. Implementation evaluation measures will include quantitative and qualitative measures of implementation feasibility and fidelity, perceived strengths and weaknesses of the program from the perspective of participants, CHW's and the NGO. Results of pilot sessions conducted by CHW's indicated 100% completion of fidelity requirements with rating of 4 out of 5 on overall quality). Session attendance and completion of homework was acceptable and 100% gave the highest satisfaction rating possible. Upon completion of the adaptation process the cluster randomize efficacy trial will begin and, if successful, dissemination will begin.

Symposium 58B

EVIDENCE-BASED DIABETES PREVENTION IN INDIA: THE KERALA DIABETES PREVENTION PROGRAM

Professor Brian Oldenburg, BSc, MPsychol, PhD

A number of real world diabetes prevention programs have been well implemented and evaluated in high income countries; however, efforts to adapt to low and middle-income countries have been lacking. A strong, community-based model is required in India because the majority of people still live in rural areas and accessibility to health services is quite limited. The Kerala Diabetes Prevention Program (K-DPP) has been adapted to rural Kerala, India from Finland’s GOAL Lifestyle Implementation Trial. This has occurred in four steps over the last 5 years: 1) Needs assessment and participatory design; 2) Program translation and modelling; 3) Piloting of program delivery model; 4) Program refinement, active implementation and controlled evaluation. We used Intervention Mapping to identify program objectives, key determinants of target behaviors, learning and change objectives, behavior change techniques and practical strategies for implementation. The peer-led intervention program was also guided by learnings from US Global Peers for Progress program. Needs assessment identified environmental and personal determinants of unhealthy lifestyle changes. Barriers included limited state-wide policies and programs for diabetes prevention, poor accessibility to and availability of health services and low self-efficacy regarding lifestyle change. Program piloting also identified the need to improve knowledge and awareness of diabetes prevention, increase male participation and simplify intervention delivery. The resulting program, K-DPP, includes four components: 1) a peer-led program conducted in community-based groups; 2) a training and support program for lay peer leaders; 3) resource materials; 4) specific strategies for community engagement. A cluster RCT has been undertaken in 60 rural communities in Kerala and 24-month findings show a reduction in key cardiometabolic risk factors in intervention communities as well as a 36% reduction in diabetes incidence in the impaired glucose tolerance subgroup, compared to control communities. Scalability is now being evaluated in a further 15,000 communities in India.

Symposium 58C

IMPLEMENTING BEHAVIORAL OBESITY TREATMENT IN RURAL PRIMARY CARE: THE RE-POWER COMPARATIVE EFFECTIVENESS TRIAL

Christie Befort, PhD

Rural residents have higher obesity rates and less access to evidence-based lifestyle interventions. Primary care has the potential to fill a major gap in the provision of weight management services for rural communities. The objective of this cluster-randomized pragmatic trial is to evaluate the comparative effectiveness of three obesity treatment models in rural primary care. The three models are operationalized as Fee-for-Service (FFS; one-on-one office visits delivered by local clinic staff), Patient-Centered Medical Home (PCMH; group visits delivered by local clinic staff), and Disease Management (DM: group phone visits delivered by centralized interventionists). 36 practices from the Midwestern U.S. were randomized to deliver one of the three interventions to 40 patients (n=1440) age 20 to 75 with a BMI 30-45 kg/m^2. The trial design was guided by patient and provider input since its inception. The Patient Advisory Board includes 10 men and women living in rural communities across 4 states. Provider stakeholders are rural PCPs with a vested interest in improving the treatment of obesity in their practices. To enhance engagement, a day-long kick off meeting was held where approximately 35 patient and provider stakeholders and investigators shared personal and practice-level experiences, discussed intervention design across the three arms, and brainstormed potential barriers and solutions to both patient and practice-level engagement. Resulting adaptations have included reducing the level of training for group counselors in the PCMH arm to represent what a practice might typically cover for a chronic disease care coordinator, and providing an intervention toolkit (previously unplanned but deemed necessary) for sites randomized to the FFS approach. To reach the targeted 36 sites, a total of 75 practices were approached. Participating practices includes 10 Rural Health Clinics (9 hospital-owned, 1 physician-owned), 11 Federally Qualified Health Centers (8 healthcare system-owned, 3 non-profit), 2 VA clinics, and an additional 6 hospital-owned practices and 7 physician-owned practices. Only 14 practices have co-located behavioral health specialists. An ongoing mixed methods process evaluation is examining characteristics influencing practice-level implementation and adoption. In sum, practice-based trials in geographically dispersed regions require working with heterogeneous practices with limited access to behavioral health and where local adaptations are necessary.

Symposium 59 1:30 PM-2:45 PM

USING EHEALTH AND MHEALTH METHODS TO PROMOTE HEALTHY BEHAVIORS AMONG WOMEN

Lisa Cadmus-Bertram, Ph.D.[1], Emily L. Mailey, Ph.D.[2], Danielle Symons Downs, Ph.D.[3], Danielle Arigo, Ph.D., Licensed Psychologist[4], Katarzyna Wac, PhD[5]

[1]University of Wisconsin - Madison, Madison, WI; [2]Kansas State University, Manhattan, KS; [3]The Pennsylvania State University, University Park, PA; [4]The University of Scranton, Scranton, PA; [5]Stanford University, Stanford, CA

Electronic and mobile health tools have great potential to improve the effectiveness of health promotion programs for women, as they can increase the reach of behavioral interventions and respond to users' needs in real time. Electronic health (eHealth) tools such as web-based intervention programs allow women to access audiovisual content at their convenience, which can address problems such as difficulty scheduling appointments (e.g., around childcare needs). Similarly, mobile health (mHealth) tools such as wearable activity sensors and smartphone applications are carried with the user, and can passively collect health data to address women's individual health behaviors (e.g., reminders to increase physical activity or log food intake). Yet currently, these tools are not optimally engaging nor well matched to women's changing health needs across the lifespan; as a result, commercially available tools alone rarely foster sustained behavior change. The goal of this symposium is to describe the design and preliminary outcomes of three technology-supported interventions tailored to women's health behavior change needs. Each speaker will address the theoretical basis for integrating and tailoring eHealth and mHealth tools for women; these tools were used to augment traditional behavioral intervention to actively engage the specific populations of interest. First, Dr. Mailey will describe a web-based health promotion program for military spouses, which incorporated tailored podcasts and group dynamics features. Second, Dr. Downs will discuss an individually-tailored intervention to prevent excessive gestational weight gain among overweigtht/obese pregnant women, which incorporated Jawbone activity sensors and Aria wireless scales. Third, Dr. Arigo will present on the feasibility and preliminary effectiveness of a physical activity promotion program for obese post-menopausal women, which incorporated the self-monitoring and online social networking features of Fitbit. The discussant, Dr. Katarzyna Wac, will synthesize lessons learned from these studies and discuss necessary next steps for improving the use of eHealth/mHealth tools for health promotion among women.

Symposium 59A

WEB-BASED HEALTH PROMOTION FOR MILITARY SPOUSES: INCREASING ENGAGEMENT AND EFFECTIVENESS

Dr. Emily L. Mailey, Ph.D.

Military spouses report numerous barriers to health behaviors and could benefit from interventions that empower them to prioritize their own health and wellness. Web-based interventions would allow content to be highly accessible for this population, but are often plagued by low engagement and retention. The purpose of this study was to compare the effects of a comprehensive, theory-based web-delivered intervention (INT) and a standard educational web-delivered intervention (CONT) on physical activity, stress, depression, and anxiety among military spouses. CONT (n=46) provided links to health-related resources on the military's Operation Live Well website and a weekly discussion board. INT (n=73) was based on Self-Determination Theory and utilized original podcasts to deliver weekly content related to stress management, physical activity, and nutrition. In addition, all INT participants were placed on teams with 4-5 other spouses and engaged in weekly team challenges to facilitate social support. Both interventions lasted for 10 weeks. INT participants logged onto the website more often [median=12] than CONT participants [median=3.5]. Mixed design 2 (group) X 2 (time) repeated measures ANOVAs revealed significant main effects for stress [F(1,76)=35.0, pF(1,79)=30.2, pF(1,78)=39.0, pF(1,81)=6.61, p=.01] and moderate activity [F(1,81)=5.77, p=.02], but not vigorous activity [F(1,81)=2.27, p=.14], on the International Physical Activity Questionnaire. There were no significant between-group differences. These results suggest web-delivered interventions can improve physical activity and mental health among military spouses; however, additional work is needed to optimize effectiveness and engagement. In addition to discussing the primary results, this presentation will describe the formative research that informed the development of the theory-based intervention, and will highlight qualitative and quantitative follow-up data from participants that offer valuable insight about how to make web-based interventions maximally engaging and beneficial.

Symposium 59B

MHEALTH SELF-MONITORING OF PHYSICAL ACTIVITY AND WEIGHT WITHIN A PRENATAL INTERVENTION TO MANAGE GESTATIONAL WEIGHT GAIN

Danielle Symons Downs, Ph.D.

Physical inactivity is prevalent in pregnant women and it can increase the risk of excessive gestational weight gain (GWG), which is associated with pregnancy and delivery complications. Innovative strategies to promote perinatal physical activity and reduce excessive GWG are strongly needed. Novel mHealth tools such as wrist-worn activity monitors, Wi-Fi weight scales, and smartphone applications can assist with self-monitoring to promote increased physical activity and weight management. However, little to no past research has utilized these tools to promote prenatal activity and manage GWG. We have developed an individually-tailored behavioral intervention that adapts intervention dosages to the unique needs of overweight and obese pregnant women and uses mHealth methods to promote physical activity and manage GWG. The goals of this presentation are to: (a) describe the intervention and mHealth methods for using the Jawbone activity monitor and Aria Wi-Fi weight scale for self-monitoring of physical activity and weight and (b) discuss preliminary findings and highlight key lessons learned from the initial trial on the use of the mHealth devices within the prenatal intervention. Overweight/obese pregnant women (N=22) were randomized to one of seven intervention dosages over a brief 6-week intervention period. Daily activity steps/minutes and weight were analyzed with SPSS and MATLAB; visualizations were used to provide real-time feedback to participants. The use of mHealth data to develop participant-specific energy balance models and reporting energy intake underreporting will be described. Average participant compliance rates were 95% (Jawbone) and 84% (Aria). Key lessons learned to be discussed will include designing the mHealth device self-monitoring procedures to provide real-time feedback to participants, overcoming technology issues, and user acceptability of the devices.

Symposium 59C

FEASIBILITY OF A FITBIT-SUPPORTED BEHAVIORAL INTERVENTION TO INCREASE PHYSICAL ACTIVITY AMONG OBESE POST-MENOPAUSAL WOMEN

Dr. Danielle Arigo, Ph.D., Licensed Psychologist

Exercise is strongly recommended for obese post-menopausal women in order to mitigate cardiovascular risk, but less than 15% currently meet exercise guidelines. These women cite lack of both time and social support for exercise as primary barriers, indicating two critical targets of intervention. To address these targets, this study tested the feasibility of a technology-supported, social intervention to promote exercise among obese post-menopausal women. Participants (n=11, M_{AGE}=59, M_{BMI}=32.0 kg/m^2) increased either

traditional endurance exercise (EE, e.g., brisk walking; *n*=5) or short-duration interval exercise (SDIE, guided by DVDs; *n*=6). EE participants progressed to 250 exercise minutes per week, whereas SDIE participants progressed to 75 minutes per week, over 16 weeks. All participants attended one group treatment session per month. They tracked their exercise using the Fitbit system, and communicated with their treatment group between sessions using the Fitbit social network. This network included a group message board and a ranking of participants' exercise minutes (highest to lowest). Using a short recruitment window, enrollment approached the intended 12 participants (11/12, 92%), and retention over 16 weeks was 10/11 (91%); 8/11 participants (73%) attended all four group sessions. Among completers, daily device wear was 92% across groups. The average participant also responded to 11/16 weekly Fitbit social network threads (70%) and viewed the exercise rankings twice per week. Regarding exercise adherence, 3/5 EE participants met prescribed exercise minutes at both mid- and end-of-treatment, whereas 5/5 SDIE participants (who completed) met prescribed exercise at both time points. Findings demonstrate that introducing the novel components of this intervention (i.e., Fitbit self-monitoring and social networking, SDIE) to behavioral treatment is feasible and acceptable to obese post-menopausal women, and that adherence to SDIE might be greater than to EE. Consequently, this intervention may effectively address both lack of time and lack of social support for exercise as perceived barriers to engagement in the target population, and warrants investigation on a larger scale.

Symposium 60 1:30 PM-2:45 PM

USING DIGITAL SOCIAL TOOLS FOR SMOKING CESSATION: INTERVENTION ENGAGEMENT AND EFFICACY

Judith J. Prochaska, PhD[1], Lorien Abroms, ScD, MA[2], Danielle Ramo, PhD[3], Cornelia Pechmann, MS, MBA, PhD[4]

[1]Stanford University, Stanford, CA; [2]George Washington University, Washington, DC; [3]University of California, San Francisco, San Francisco, CA; [4]University of California Irvine, Irvine, CA

Tobacco use is the leading preventable cause of death in the US. Novel interventions are needed for prevention and intervention to reduce smoking among high risk groups. With wide reach and integration into the lives of users, digital tools (e.g., text messaging, social media) hold promise to help smokers quit. Yet scientific evidence for the utility of some digital tools is limited and inconclusive. This symposium will present the results of three randomized trials testing the efficacy of digital interventions for smoking cessation. Presentations will focus on strategies used to adapt interventions to a digital format, characterize engagement, and report efficacy in helping smokers quit. The first presentation is a text-messaging intervention for pregnant smokers (*Quit4baby*). Results provide support for the intervention's efficacy after 3 months of enrollment. The second presentation is a Facebook-based intervention for young adults tailored to readiness to quit smoking (*The Tobacco Status Project*) reporting 6-month outcomes. Results demonstrate efficacy with respect to biochemically-verified smoking abstinence at 3 months, reduction in smoking at 6 months, and the utility of using Facebook to engage the young adult population and tailoring to readiness to quit. The final talk is a trial testing the efficacy of a Twitter intervention for relapse prevention. Results demonstrate efficacy at 6 months among adult smokers, and highlight moderators of engagement and quit smoking status. The discussant will highlight lessons learned in carrying out trials with digital tools, unique strategies for measuring engagement in a digital environment, and the impact digital social tools can have on delivering engaging evidence-based smoking cessation interventions. The symposium will include dedicated time for a question-and-answer session with the panel of presenters.

Symposium 60A

A RANDOMIZED TRIAL OF A TEXT-MESSAGING PROGRAM TO PROMOTE SMOKING CESSATION IN PREGNANT SMOKERS

Dr. Lorien Abroms, ScD, MA

While automated text messaging programs have been found to be successful for adult smoking cessation, their efficacy for pregnant smokers is unknown. The Quit4baby study explores whether an interactive and intensive text messaging program can promote smoking cessation in pregnant smokers. Women were recruited from Text4baby, an existing text messaging program aimed at pregnant women. From July 2015 to February 1016, over 35,000 Text4baby subscribers were sent a recruitment text message. Interested and eligible women were enrolled (n= 497) and randomized to receive Text4Baby + Quit4Baby (intervention) or Text4Baby (control). Participants were surveyed at 1-month, 3-month and 6-months post-enrollment, and saliva samples were collected at 3-months for biochemical verification of smoking status. Using an Intention-to-Treat analysis, where missing are assumed to be smoking, 28.80% of the intervention group and 15.79% of control group reported not smoking in the past 7 days at 1-month (p<.01) and 35.20% of the intervention group and 22.67% of the control group reported not smoking in the past 7 days at 3-month (p<.01). Biochemical verification of smoking status at 3-months indicated no significant differences among groups, though quit rates favored the intervention group. Results will also be presented for the 6-month follow-up. Current results provide mixed support for the efficacy of the Quit4baby program. Future study is warranted.

Symposium 60B

THE TOBACCO STATUS PROJECT: OUTCOMES FROM A RANDOMIZED TRIAL OF A FACEBOOK SMOKING CESSATION INTERVENTION FOR YOUNG ADULTS

Dr. Danielle Ramo, PhD

Introduction: Social media represents a promising strategy to deliver evidence-based smoking cessation treatment to young adults. Our group has developed the *Tobacco Status Project (TSP)* smoking cessation intervention for young adults, tailored to readiness to quit smoking. Previously we demonstrated feasibility and promising 12-month quit rates. Here we present outcomes from a randomized trial comparing the TSP to an online control condition. *Methods:* Young adult cigarette smokers (N=500; age 18-25) were recruited online and randomized to either the 3-month TSP intervention or a referral to the National Cancer Institute Smokefree.gov website, including Internet, Smartphone, and social media features. TSP included assignment to a private Facebook group tailored to Transtheoretical Model readiness to quit smoking (precontemplation, contemplation, preparation), daily Facebook contacts, weekly live counseling sessions, and for those ready to quit, six Cognitive Behavioral Therapy counseling sessions. *Results:* The sample was 73% White, 55% female, 87% daily smokers; 48% smoked 10 or fewer cigarettes per day, and averaged 2.8 years smoking; 30% were in precontemplation; 49% contemplation, and 21% preparation for quitting smoking. Posttreatment abstinence was modeled via logistic GEE. At treatment end (3 months), the follow-up rate was 70% (67% treatment, 74% control; χ2=.124, *p*=.14). In a modified intent-to-treat analysis, biochemically-verified 7-day point prevalence abstinence was significantly higher for TSP than control (8.3% vs 3.3%; odds ratio [OR]=2.52; 95% confidence interval [CI]=1.56, 4.04; *p.0001).* A greater proportion of TSP participants reduced the number of cigarettes they smoked in the past week by at least half from baseline to 3 months (52.7% vs. 38.8%; OR=1.82; 95% CI=1.33, 2.49; p=.0002). There were no differences in likelihood of having made a quit attempt during treatment or readiness to quit smoking in the next month across groups. 6-month follow-up rate was 68% (64% treatment, 73% control; χ2=.124, P=.14). Only reduction in smoking was still significantly different at 6 months (58.2% vs. 51.7%; OR=1.37; 95% CI=1.04, 1.83; p=.026). TSP participants who commented at least once (75%) averaged 42 comments, baseline stage of change and monetary incentive predicted comment volume, and comment volume marginally predicted abstinence at 3 months. Conclusion: A novel Facebook intervention was engaging and associated with smoking abstinence at 3 months and smoking reduction at 6 months. Social media intervention could be disseminated widely, and be helpful even for those not ready to quit smoking.

Symposium 60C

PREDICTORS AND OUTCOMES OF DYADIC TIES IN ONLINE SMOKING CESSATION GROUPS

Cornelia Pechmann, MS, MBA, PhD

Tweet2Quit is a smoking-cessation intervention that involves creating 20-person groups of smokers on Twitter who agree to quit together and support each other’s cessation for 90 days, aided by daily automated discussion-topics tweets and individualized texts on engagement. An initial randomized controlled trial found 40% sustained abstinence for Tweet2Quit vs. 20% for control. Also strong dyadic ties related to engagement and

engagement to abstinence (p’s < .01). This study examined what facilitated dyadic ties and we studied 8 online groups. A dyad was identified when a group member sent a tweet to a specific individual, and 630 dyads were identified. Dyadic tie strength was measured as the number of tweets exchanged between two members who tweeted. Engagement of the dyad with the group was measured as the total count of tweets sent by dyad members to themselves or others. Dyadic goal attainment assessed whether one or both dyad members attained abstinence. Based on past research, people perceive that self-disclosing dissimilarities may result in rejection, yet there are potential benefits to self-disclosure in terms of rapport building. We tested a mediational model that predicted that dyadic dissimilarity would relate negatively to dyadic self-disclosure, but dyadic self-disclosure would relate positively to dyadic tie strength, engagement of the dyad with the group, and dyadic goal attainment (abstinence). The results supported the mediation model for gender β= -.02, employment status β= -.02, and marital status β= -.01 (*p*’s < .05), but not age β= -.0003 which was rarely self-disclosed. When one member of a dyad self-disclosed a demographic dissimilarity, this discouraged the other dyad member from self-disclosing that same demographic, but self-disclosing dyads benefitted greatly in terms of tie strength, engagement and abstinence. Our findings indicate that making online groups demographically homogeneous may encourage self-disclosure but this may run counter to diversity goals. Alternatively one can create dyads (buddy pairs) that are demographically similar and encourage self-disclosure. In our larger randomized controlled trial of Tweet2Quit, we will test both women-only and coed groups, assign people to demographically similar dyads, and encourage self-disclosure.

Symposium 61 1:30 PM-2:45 PM

EXPANDING THE HORIZONS OF BEHAVIOR CHANGE RESEARCH WITH AN EXPERIMENTAL MEDICINE APPROACH: THE NIH SOBC RESEARCH NETWORK

Jennifer A. Sumner, PhD[1], Christine M. Hunter, PhD[2], Donald Edmondson, PhD, MPH[3], Jun Ma, MD, PhD[4], Susan M. Czajkowski, Ph.D.[5]

[1]Columbia University Medical Center, Center for Behavioral Cardiovascular Health, New York, NY; [2]Division of Diabetes, Endocrinology, and Metabolic Diseases, Bethesda, MD; [3]Columbia University Medical Center, New York, NY; [4]University of Illinois at Chicago, Chicago, IL; [5]National Cancer Institute, Rockville, MD

Unhealthy behaviors—including smoking, overeating, medication nonadherence, and sedentary lifestyles—contribute to negative health outcomes and disease. Unfortunately, it is extremely difficult to initiate and maintain lasting healthy behavior changes. A major challenge facing the field in addressing these often intransigent behaviors is insularity of scientific domains that together might inform more effective prevention and intervention efforts. In response to these challenges, the NIH Common Fund's Science of Behavior Change (SOBC) program was formed to bring together researchers across disciplines to develop a more unified science of behavior change. The program represents a fundamental shift in the approach to behavior change research and aims to improve our understanding of mechanisms of behavior change by supporting cross-cutting research that integrates basic and translational science. In 2015, the SOBC Research Network was formed and brought together several interdisciplinary research teams to employ a mechanisms-focused, experimental medicine approach to behavior change research. These researchers are developing assays to measure putative intervention targets related to common mechanisms of behavior change, including self-regulation, stress reactivity and resilience, and interpersonal and social processes. The teams will then engage these targets through experimentation and/or intervention and examine subsequent behavior change. In this symposium, we will introduce the SOBC Research Network and provide examples of a mechanisms-focused, experimental medicine approach to behavior change research. First, an NIH representative from the SOBC program will describe the rationale and goals of the SOBC Research Network. Next, researchers supported by the SOBC program will present their approach to examining mechanisms of change common to multiple health behaviors and demonstrate how the experimental medicine paradigm and collaborative SOBC approach have been fundamental to their work. The symposium will conclude by having an NIH representative review the implications of the SOBC research approach for future basic and

translational research and discuss how basic science findings can be applied to develop and test innovative prevention and treatment strategies.

Symposium 61A

THE NIH SCIENCE OF BEHAVIOR CHANGE (SOBC) COMMON FUND PROGRAM: RATIONALE AND GOALS

Dr. Christine M. Hunter, PhD

The Science of Behavior Change (SOBC) Common Fund Program at the National Institutes of Health is supporting a mechanisms-focused, experimental medicine approach to behavior change research. An experimental medicine approach involves identifying putative intervention targets, developing assays (measures) to permit verification of target engagement, engaging the target through experimentation or intervention, and testing the degree to which target engagement produces the desired behavior change. Putative intervention targets are synonymous with "mechanisms of action" and with processes that are hypothesized to be malleable and to play a causal role in producing behavior change. By integrating work across basic science disciplines and between basic and clinical scientists, this effort will lead to an improved understanding of the underlying principles of behavior change as they apply to the initiation and maintenance of change, and to the personalization of intervention strategies. The current stage of the program supports the SOBC Research Network, which focuses on three classes of intervention targets that are highly relevant to understanding the mechanisms of behavior change: self-regulation, stress reactivity and stress resilience, and interpersonal and social processes. This introductory presentation will explain the rationale and steps involved in the experimental medicine approach as implemented in the SOBC Program and discuss how it is being used to examine mechanisms of change common to multiple health behaviors. The overarching goal of the SOBC Program is to transform the approach to behavioral mechanisms research, develop tools that can support the implementation of this approach in future research, and enhance the development of future behavioral interventions.

Symposium 61B

SYSTEMATIC REVIEW OF MECHANISMS OF ACTION IN NIH-FUNDED TRIALS TO IMPROVE MEDICATION ADHERENCE

Dr. Donald Edmondson, PhD, MPH

Background: Many patients do not take their medication as prescribed and although many interventions have been tested to increase adherence, few effective approaches exist. The NIH Science of Behavior Change (SOBC) program approach offers an experimental medicine method to optimize behavioral interventions by targeting underlying mechanisms of behavior change. We conducted a systematic review and meta-analysis to determine the proportion of NIH-funded adherence trials that measured a mechanism of action, and determined the strength of association between those mechanisms and nonadherence.

Methods: Multiple electronic databases were searched using all relevant subject headings and free-text terms to represent medication adherence and behavior change. We applied a search filter to limit results to studies funded by NIH only. Reference lists and cited reference searching were also conducted. Unpublished studies were sought through trial registries and grey literature sources, and by contacting authors of included studies. Eligibility criteria were the following: population, all adult human participants taking medication for any condition; intervention, any that aims to change the behavior of participants' adherence to medication; study design, randomized and quasi-randomized studies funded by NIH. Screening, data extraction, and quality assessment were conducted by two independent reviewers, with disagreements resolved through discussion. In our overall analysis, we will examine whether interventions are more effective when mechanisms were measured, and we will also analyze the associations of different mechanisms/mechanism classes with adherence. This systematic review and meta-analysis will be complete by February 2017.

Conclusion: We will discuss the proportion of NIH-funded intervention trials that tested mechanisms of behavior change hypothesized as influential in medication adherence. We will assess the relative strengths of association between mechanisms and adherence outcomes. This research will illustrate the current state of the science of behavior change, and highlight opportunities for behavior change research going forward.

Symposium 61C

MECHANISTIC SELF-REGULATION TARGETS IN INTEGRATED BEHAVIOR THERAPY FOR OBESE AND DEPRESSED ADULTS: RAINBOW-ENGAGE STUDY

Dr. Jun Ma, MD, PhD

Obesity and depression are top contributors to the global burden of disease and disability; when comorbid, the burden is exacerbated. Understanding the processes and mechanisms contributing to risk will facilitate the development of targeted and personalized approaches to behavior change. Self-regulation is a core construct in empirically supported behavioral interventions for these disorders and a candidate target mechanism for behavior change. Human neuroscience has identified large-scale brain circuits for key self-regulation targets: emotion regulation, cognitive control, and self-reflection. Using a target-driven, experimental medicine approach, the ENGAGE study leverages an ongoing randomized controlled trial (RAINBOW) of integrated behavior therapy for comorbid obesity and depression in primary care to measure self-regulation targets among trial participants. The study aims are to identify and refine the measures (assays), validate target engagement and malleability, and test target-driven optimization of behavior therapy for comorbid obesity and depression. The chosen assays of emotion, cognitive and self-reflective regulation involve multiple domains (neural, physiological, behavioral, and psychological) and settings (brain imaging lab, virtual reality environments, and smartphone-based passive sensing). The assays are included at baseline, 2, 6, 12 and 24 months. We will examine the relationships between assays within and between domains and settings, and how assays of self-regulation targets predict health behaviors and outcomes through 24 months. ENGAGE will provide a toolkit of validated assays of self-regulation targets important for health behavior change. Findings on how self-regulation mechanisms predict behavior and outcomes will advance the development of targeted and personalized intervention strategies for treating obesity and depression, with implications for other common lifestyle-related comorbidities.

Symposium 62 1:30 PM-2:45 PM

THE IMPACT OF ADVERSE CHILDHOOD EXPERIENCES [ACES] ON CHILD AND YOUNG ADULT HEALTH FUNCTIONING

Pamela Behrman, PhD[1], Kimberly A. Randell, MD, MSc[2], Sheela Raja, PhD[3], Nisha Beharie, DrPH[4], Emily F. Rothman, ScD[5]

[1]College of Mt St Vincent, New Britain, CT; [2]Children's Mercy Kansas City, Kansas city, MO; [3]University of Illinois at Chicago, Chicago, IL; [4]NYU Rory Meyers College of Nursing, New York, NY; [5]Boston University School of Public Health, Boston, MA

In 1998, a team of researchers led by Drs. Vincent Felitti, of Kaiser Permanente, and Robert Anda, of the Centers for Disease Control, found that certain potentially traumatic exposures in childhood were significantly associated with serious adult health outcomes. These traumatic exposures, called “Adverse Childhood Experiences,” or “ACEs,” include adversities such as childhood physical abuse, childhood sexual abuse, parental interpersonal violence, parental substance abuse, parental separation or divorce, economic hardship, and parental incarceration. In addition to adult psychosocial effects (e.g. depression and homelessness), ACEs were strongly related to adult chronic diseases such as cancer, heart disease, and COPD. High reported ACEs were also associated with 20-year reductions in life expectancy. The authors noted “dose-response patterns,” with higher reported ACEs more strongly related to serious adult health outcomes. Since the publication of the original ACE studies, there have been more than 60 investigations published by the original authors and several hundred peer-reviewed studies using ACEs as a primary variable.

The researchers in this symposium add to this auspicious body of literature. Using data collected at two Midwest academic hospitals, Dr. Kimberly Randell presents her study outcomes on the relations between parents’ reported ACEs and their school-aged (ages 6-12) children's adversities. Using data collected at a university-administered dental clinic, Dr. Sheela Raja illustrates the influences of ACEs and previous negative dental care experiences on children’s (ages 4 and over) behavior during routine dental care appointments. Finally, using longitudinal data from a nationally-representative sample of adolescents, Dr. Nisha Beharie showcases her findings on the impacts of childhood trauma and homelessness on adult drug abuse. Our discussant, Dr. Emily Rothman, concludes this symposium by analyzing these study outcomes in the context of existing literature. She also recommends future directions for child-focused ACEs research and prevention efforts.

Symposium 62A

ASSOCIATIONS BETWEEN PARENT ADVERSE CHILDHOOD EXPERIENCE SCORE AND CHILDREN'S ADVERSITY IN PEDIATRIC HEALTHCARE SETTINGS

Dr. Kimberly A. Randell, MD, MSc

Purpose: Limited data suggest parent adverse childhood experiences (ACEs) are associated with increased risk of child adversity. We aimed to determine associations between parent ACE score and child adversity in pediatric healthcare settings.

Methods: This was a secondary analysis from a study examining parent ACEs and child weight. Parents of children age 6-12 years attending general pediatric or pediatric weight management clinics at two Midwest academic hospitals completed a survey assessing parent and child conventional and expanded ACEs. ACE scores were calculated by summing individual ACEs.

Results: 339 parents participated. 58 (17%) parents had a conventional ACE score of $\geq$ 4, 26 (8%) an expanded ACE score $\geq$ 4, and 89 (26%) a total ACE score $\geq$ 4. Univariate analysis showed parent conventional, expanded and total ACE score $\geq$ 4 was associated with increased risk for child exposure to household criminal activity, household mental illness, household substance abuse, family violence, neighborhood violence, homelessness, racism, bullying, poverty, and child conventional and total ACE score $\geq$ 4. Logistic regression found parent total ACE score $\geq$ 4 is associated with increased risk for child conventional and total ACE score $\geq$ 4.

Conclusions: Findings support the call for pediatric healthcare delivery within a two-generation model. Parental ACE score $\geq$ 4 was common and associated with increased child risk for multiple adverse experiences as well as a child ACE score $\geq$ 4, suggesting parent ACE history may identify children at increased risk for adverse experiences and the attendant negative health outcomes. Consideration should be given for parental ACE assessment and provision of targeted resources for families in which parent ACE score is $\geq$ 4.

Symposium 62B

THE ROLE OF ADVERSE CHILDHOOD EVENTS IN PEDIATRIC DENTAL CARE: IMPLICATIONS FOR TRAUMA INFORMED DENTAL CARE

Sheela Raja, PhD

Purpose: Adverse childhood experiences such as exposure to violence, serious illness, and sudden death can impact children’s health and their ability to cope with stressful situations.

We examined the relationship between a history of childhood trauma and a child's behavior during non-invasive, routine dental treatment.

Methods: Parents of healthy children ages four years and over attending their initial dental appointment at a university pediatric dental clinic were asked to complete the Traumatic Events Screening Inventory- Parent Report Revised. Following the dental appointment, a pediatric dental resident completed the Frankl Scale, a clinician-based rating of a child's behavior in the dental chair.

Results: One hundred-seventy parent-child pairs participated. Fifty-three percent of parents indicated their child had experienced at least one traumatic event. Forty-four percent of parents indicated their child had a prior negative experience at the dentist. Analysis showed no significant relationship between traumatic events history and poor dental behavior, but a significant relationship between a previous negative dental experience and poor dental behavior.

Conclusion: Children with a history of traumatic events did not exhibit uncooperative behavior more often than those who did not experience it. However, future studies should examine the relationship between trauma history and behavior during dentally invasive procedures (e.g., fillings, extractions). Additionally, our results suggest that in addition to serious medical procedures, surveys of childhood trauma should also include dentally stressful experiences, including the potential consequences of immobilization and protective restraints in dental treatment.

Symposium 62C

THE SYNDEMIC EFFECT OF CHILD ABUSE AND HOMELESSNESS ON SUBSTANCE USE

Dr. Nisha Beharie, DrPH

Previous research has indicated elevated substance use as well as experiences of childhood trauma (e.g. physical and sexual abuse) among homeless populations relative to their housed counterparts. However, no research to date has investigated the syndemic effect of homelessness and history of abuse on substance use. As such, this study investigates the independent and combined effects of homeless and child abuse on drug use.

Logistic regression was employed using data from Wave I (adolescence), III (emerging adulthood), and IV (adulthood) of the National Longitudinal Study of Adolescent to Adult Health (Add Health) (N = 12,288). The independent variable was a four-level categorical variable: no experience of homelessness or child abuse, experience of only child abuse, experience of only homelessness, and experience of both child abuse and homelessness. All outcome variables of substance use were dichotomous (yes/no) and included binge drinking, marijuana, cocaine, methamphetamine, prescription pain medication, and injection drug use.

Homelessness was found to have stronger strengths of association than experiences of child abuse alone when predicting substance use. However, the strengths of association were greatest among those who had experienced both homelessness and child abuse. For example, those who had experienced only childhood abuse or only homelessness were at an approximately two-fold increased odds of ever using cocaine by emerging adulthood (OR=1.76, 95% CI:1.41, 2.20; and 2.23, 95% CI:1.45, 3.44 respectively). However, those who had experienced both childhood abuse and homelessness were at an almost six-fold increased odds of using methamphetamines by emerging adulthood (OR=6.56, 95% CI:3.85, 11.18).

Findings from this study highlight the crucial need to address past trauma as well as housing instability in order to reduce substance use among those who have experienced homelessness.

Symposium 63 1:30 PM-2:45 PM

INNOVATION IN INDOOR TANNING MEDIA, MESSAGING, AND INTERVENTION SCIENCE

Darren Mays, PhD, MPH[1], Molly E. Waring, PhD[2], Derek Reed, PhD[3], W. Douglas Evans, PhD[4], Sherry Pagoto, PhD[2]

[1]Georgetown University Medical Center, Lombardi Comprehensive Cancer Center, Washington, DC; [2]University of Massachusetts Medical School, Worcester, MA; [3]University of Kansas, Lawrence, KS; [4]George Washington University Milken Institute School of Public Health, Washington, DC

Skin cancer is the most common malignancy in the US, and indoor tanning in adolescence and young adulthood significantly increases skin cancer risks, accounting for an estimated 10% of all cases. Research indicates patterns of indoor tanning behavior are complex, ranging from pre-event and seasonal tanning to potential tanning addiction. Like other cancer risk behaviors, indoor tanning is influenced by a suite of risk factors, including exposure to pro-tanning messaging in the media. Innovative strategies to investigate the indoor tanning media environment, how young people may respond to pro-tanning messaging, and how messaging can in turn be designed and delivered to prevent and reduce indoor tanning is needed to address the growing burden of skin cancer. This symposium will feature three presentations reporting on highly innovative approaches to indoor tanning media, messaging, and intervention science. The first study describes a content analysis of indoor tanning tweets, demonstrating the vast majority are generated by indoor tanners characterizing their motives and consequences of tanning, and indicating presence of few public health messages in this media space. The second study uses a novel cue-reactivity paradigm within a simulated indoor tanning salon to characterize indoor tanning cravings and motivations among young women. The study findings point to policy approaches to limit indoor tanning marketing as have been implemented in other behavioral cancer prevention domains (e.g., tobacco control). The final study pilot tested the feasibility, acceptability, and preliminary effects of a theory-driven, mobile phone text messaging intervention among young adult women who indoor tan. With further testing, this novel intervention approach has the potential for scalability and high public health impact. Our discussant will provide a critical synthesis of these innovative studies and lead a discussion of the implications for future research on indoor tanning behavior and approaches to prevention.

Symposium 63A

WHO IS TWEETING ABOUT INDOOR TANNING AND WHAT ARE THEY SAYING?

Dr. Molly E. Waring, PhD

Conversations about healthy and unhealthy behaviors have been observed on Twitter and may provide insight into attitudes and motivations for these behaviors. We content analyzed tweets that included the terms “tanning bed” or “tanning salon” to describe the content of conversations about indoor tanning on Twitter and to determine what proportion of tweets were posted by tanners. We extracted 4,691 tweets using the terms “tanning bed” or “tanning salon” over a 7-day period (17-23 March 2016). We randomly selected 1,000 tweets stratified by search term and timing of tweet (weekday or weekend). After replacing ads (n=200), we conducted a content analysis of tweet content. The research team developed a codebook and two coders coded all tweets. Twenty percent of tweets were double-coded (κ=0.74, 81% agreement) and consensus on discrepantly-coded tweets was reached through discussion. Among tweets expressing a desire to tan, we analyzed the proportion of tweets in which the tanner mentioned mood or appearance as reasons they tan (κ=0.89, 98% agreement for mood, κ=0.92, 99% agreement for appearance). Tweets (n=1,000) were posted by 978 unique accounts. The majority of tweets (71%) were by tanners (n=699 individuals). Themes included: tanner expressing desire or eagerness to tan (41%), tanner complaining about a negative experience at the tanning salon (12%), tanner reporting a burn (11%), tweets mocking tanners or the act of tanning (11%), tanner reporting sleeping in a tanning bed (6%), tanning salon employee chatter (4%), anti-tanning message (4%), and tweets arguing against tanning legislation (1%). Eleven percent of tweets were about other topics or unrelated to tanning. Among the 405 tweets in which a tanner expressed the desire to tan, 10% mentioned mood and 9% mentioned appearance as the reason they tan. Findings revealed a rate of 670 tweets per day about indoor tanning using two search terms. The majority of tweets were from tanners, with some reporting risky habits including burning or sleeping in the tanning bed. Very few tweets were public health messages. Twitter may provide an opportunity to study and intervene upon indoor tanners.

Symposium 63B

CUE-REACTIVITY IN INDOOR TANNING DISORDER: STATE-BASED INFLUENCES ON CRAVINGS AND MOTIVATION TO TAN

Dr. Derek Reed, PhD

Excessive indoor tanning is a behavioral excess mimicking behavioral addiction characteristics associated with other addiction-related disorders such as drug use and gambling. Dense literature in the addiction sciences suggests that cue-reactivity is a behavioral marker of conditioned cravings and motivation for substances of abuse. Unlike other commodities of abuse, there are very few regulations on the prevalence of tanning-related advertisements and cues in public settings. Our study examined the extent to which indoor tanners exhibited cue-reactivity in a study translated from those using cigarette and alcohol cue-reactivity preparations. Findings suggests that tanning-related cues and paraphernalia significantly increased markers of craving and motivation to tan in college-aged indoor tanners. These tanning cue-reactivity findings provide novel insights into the role of tanning-related messages and visual cues in tanning disorders; such findings also contribute to a growing empirical body of support for tanning as a behavioral addiction. Notably, these cue-reactivity findings suggest that tanning disorder may be a function of both trait and state influences. Finally, the impact of cues on cravings and motivation for tanning also provide novel implications for regulating the extent of tanning-related cues in advertisements, messages, and media targeting youth.

Symposium 63C

INNOVATION IN INDOOR TANNING MEDIA, MESSAGING, AND INTERVENTION SCIENCE

Dr. W. Douglas Evans, PhD

Background: Although skin cancer is largely preventable, it affects nearly 1 of 5 U.S. adults. There is a need for research on how to optimally design persuasive, public health indoor tanning (IT) prevention messages.

Objectives: To examine whether framed messages on indoor tanning behavioral intentions delivered through text messaging (SMS) will produce: 1) positive responses to the messages, including message receptivity and emotional response; 2) indoor tanning efficacy beliefs, including response efficacy and self-efficacy; and 3) indoor tanning risk beliefs.

Methods: We conducted a pilot study of IT prevention messages delivered via mobile phone text messaging in a sample of 21 young adult women who indoor tan. Participants completed baseline measures, were randomized to receive gain-, loss-, or balanced-framed text messages and completed post-exposure outcome measures on IT cognitions and behaviors.

Participants received daily mobile phone indoor tanning prevention text messages for 1 week, and completed the same post-exposure measures as baseline.

Results: Over the 1-week period there were trends or significant changes after receipt of the text messages including decreased IT behavioral intentions (*p* = 0.105) and increased perceived susceptibility (*p* p p = .027). OLS stepwise linear regression models showed an effect of text message exposure on self-efficacy to quit indoor tanning (*t* = -2.475, *p* < .023). OLS linear regression including all measured scales showed a marginal effect of texts on self-efficacy (*t* = 1.905, *p* < .077). Participants endorsed highly favorable views towards the text messaging protocol.

Conclusions: This study supports this use of mobile text messaging as an IT prevention strategy. Given the nature of skin cancer risk perceptions, the addition of multimedia messaging service (MMS) is another area of potential innovation for IT prevention messages.

Symposium 64 1:30 PM-2:45 PM

THE TRANSFORMATION FROM 'I EXERCISE' TO 'I AM AN EXERCISER': HOW SELF-IDENTITY INFLUENCES EXERCISE BEHAVIOR & MAINTENANCE

Angela D. Bryan, PhD[1], Ryan E. Rhodes, PhD[2], Arielle S. Gillman, MA[1], Courtney J. Stevens, MA[3], Bess H. Marcus, Ph.D.[4]

[1]University of Colorado Boulder, Boulder, CO; [2]University of Victoria, Victoria, BC, Canada; [3]Alpert Medical School of Brown University, Providence, RI; [4]University of California, San Diego, La Jolla, CA

The transformation from “I exercise” to “I am an exerciser”: How self-identity influences regular exercise behavior and maintenance

An estimated 80 percent of US adults do not meet government recommendations for physical activity, and interventions to increase exercise, primarily based on social cognitive models, continue to have only modest success, especially when it comes to behavior maintenance over the long-term. To find insight into potential solutions to this problem, our symposium turns to a long history of social psychological research on identity and behavior, and applies these findings to exercise interventions to understand and enhance long-term maintenance of physical activity behavior. We present novel mixed-methods research addressing this question. Rhodes presents meta-analytic findings demonstrating a reliable relationship between exercise identity and regular exercise behavior, and identifies correlates of identity formation that link to theoretical frameworks that can guide intervention content. Gillman examines the link between past behavior and identity formation in the exercise context, and finds that regular exercise as a result of study participation can lead to spontaneous exercise identity formation in previously sedentary women, leading to maintenance of exercise behavior several months after study conclusion. Stevens examines psychological mechanisms through which an acceptance-based clinical intervention to increase exercise behavior may enhance exercise identity, and suggests that treatment-related effects on values congruent behavior and remembered affect during and after exercise may support increases in exercise identity, leading to greater maintenance at follow-up. Taken together, these investigations highlight important connections between self-identity and the exercise experience that may influence the maintenance of exercise behavior over time. Discussion will focus on factors that may help guide incorporation of “exerciser” into the self-identity of insufficiently-exercising individuals, and thus can be used in interventions to boost long-term behavioral sustainability.

LO1: To highlight a growing body of research demonstrating that exercise identity and regular exercise behavior are reliably linked.

LO1: To translate meta-analytical findings on identity and exercise into novel interventions to increase exercise behavior and maintenance

Symposium 64A

FORMING AN EXERCISE IDENTITY: A REVIEW OF CORRELATES AND POTENTIAL THEORETICAL FRAMEWORKS

Professor Ryan E. Rhodes, PhD

Forming an Exercise Identity: A Review of Correlates and Potential Theoretical Frameworks

Exercise identity represents a reflexive, self-regulating behavioral maintenance system that has shown a reliable, medium-sized correlation with regular physical activity (PA). Despite this evidence, the process of how an exercise identity forms has received limited research attention in the PA domain. Furthermore, the integration of exercise identity into contemporary theories of PA has been under-developed. The purpose of this symposium presentation is to provide a thematic review and analyses of the correlates of exercise identity, as well as the contemporary theories that address identity formation in the PA domain in order to facilitate future intervention research. Eligible studies were from English, peer-reviewed published articles that examined identity (and/or schema) in the context of PA. Searches were completed in June 2015 in five databases. Sixty-two independent data-sets, primarily of modest quality, were identified. Results showed that identity was associated with commitment, perceived capability, affective judgments, identified/integrated regulation and social comparison but not associated with perceived benefits of PA or introjected/extrinsic regulation. Theoretical models for understanding identity formation in the PA domain included adapted self-efficacy and self-determination theories, the PA self-definition model, multi-process action control, and variants of social identity, group cohesion and self-perception theories. Overall, contemporary research on the correlates of exercise identity support specific variables that span commitment, capability, affect, and social comparison and these link to several applicable theoretical frameworks in order to explore identity formation. Interventions employing experimental manipulations of these proposed antecedents are now needed for a better understanding of exercise identity formation.

Symposium 64B

EXERCISE IDENTITY AND BEHAVIOR MAINTENANCE AFTER A SUPERVISED EXERCISE INTERVENTION

Arielle S. Gillman, MA

Given recent meta-analytic work demonstrating that exercise identity is reliably associated with long-term maintenance of physical activity behavior, the next logical question to explore is how to encourage inactive individuals to incorporate an exercise identity into their self-concept. A long history of social psychological research has demonstrated that individuals are likely to explain their past behavior as being the result of stable, internal characteristics. As such, we examined whether simply committing to regular participation in exercise as part of a short-term study could lead women to associate with an "exerciser" social category label, leading to maintenance of exercise behavior after the study. Our participants were 240 previously sedentary women participating in a larger study that examined changes in biological markers of breast cancer risk after 16 weeks of supervised exercise at differing levels of intensity and duration. Participants were not given explicit guidance regarding exercise maintenance after the intervention. Before and after the exercise program, participants completed the Exercise Identity Scale (Anderson & Cychosz, 1994), a measure examining the degree to which one identifies with exercise as an integral part of his or her self-concept. 6 months post-intervention, participants self-reported their exercise behavior, as well as psychosocial predictors including attitudes, norms, self-efficacy, and intentions to exercise. We found that across our sample, exercise identity increased from baseline to post-intervention (*t*=8.18, pr=.32), norms (*r*=.29), intentions, (*r*=.18), and minutes of exercise (*r*=.18). These findings suggest useful implications for behavior change. It appears that individuals can relatively spontaneously incorporate healthy behavior engagement into their self-concept, even without explicit encouragement to do so. Continuous participation in exercise behavior might thus create lasting effects on identity that can translate to behavior maintenance over the long-term.

Symposium 64C

ASSOCIATIONS AMONG IDENTIFIED REGULATION, VALUES CONCORDANCE, AND EXERCISE BEHAVIOR OVER TIME: AN ACCEPTANCE-BASED APPROACH

Courtney J. Stevens, MA

Regular exercise participation is associated with reduced risk for all-cuase mortality and has also been shown to confer both prophylactic and therapeutic benefits for mental and emotional health. Unfortunately, half of American adults are insufficiently active and another quarter engage in no exercise at all. Prior work has shown that discomfort/displeasure experienced during exercise is associated with less esercise engagement, but how to best address these factors is not well understood. Rather than attempt to change or control the experience of exercise, acceptance-based interventions seek to facilitate values identification and promote behavior engagement consistent with those values (even in the presence of experiential discomfort). Identified regulation is a construct posited by self-determination theory to underlie motivation for behaviors that individuals personally identify with or value. The aims of the present investigation were to (1) evaluate the influence of an acceptance-based exercise intervention on exercise identified regulation and associated exercise behavior change over time; and (2) explore the associations between identified regulation, values concordance, and exercise behavior adoption and maintenance. The study was divided into two phases: Phase 1 (adoption, baseline visit – post intervention), and Phase 2 (maintenance, 3 and 6 months follow up). Data were collected at these 4 time points from a sample of N = 119 insufficiently active women randomly assigned to 1 of 3 conditions: (1) an acceptance-based health coaching intervention, (2) an information-based health coaching intervention, or (3) a no-health coaching control intervention. Results showed that identified regulation increased through Phase 1 among the acceptance-based intervention participants, but decreased over time among education and control participants, $t(107) = 2.13$, $p = .03$. Further, across conditions, identified regulation at post-intervention was associated with more exercise minutes completed at 3- and 6-months follow up, $r = .19 - .29$, respectively. Daily journal data for participants in the acceptance-based condition indicated that acting in accordance with values was positively associated with more minutes of exercise completed during both the exercise adoption, $r = .66$, and maintenance phases, $r = .27 - .45$. These results point to meaningful associations between identified regulation, values concordance, and exercise behavior adoption and maintenance.

Symposium 65 1:30 PM-2:45 PM

MILITARY AND VETERAN HEALTH BEHAVIOR RESEARCH AND PRACTICE

Jeffrey Haibach, PhD, MPH[1], Daniel Cassidy, PhD[2], Margaret Dundon, PhD[3], Jennifer S. Funderburk, PhD[4], Gerald W. Talcott, PhD, ABPP[5]

[1]U.S. Department of Veterans Affairs, Washington, DC; [2]U.S. Air Force, San Antonio, TX; [3]VHA, Buffalo, NY; [4]VA Center for Integrated Healthcare, Syracuse, NY; [5]University of Tenessee, Lackland AFB, TX

There are2.1 million current military Servicemembers and 21 million living Veterans in the United States. Although they were healthier upon entering military service compared to the general U.S. population, in the longer term Veterans tend to be of equivalent or worse health than civilians. One primary explanation for the Veterans' health disparity is poorer health behaviors during or after military service, especially areas of physical activity, nutrition, tobacco, and alcohol. In response, the Department of Defense and Department of Veterans Affairs continue to develop, evaluate, and improve health promotion programs and healthcare services for military and Veteran health behavior in an integrated approach. In this symposium, the chair will first present the context and overview of Military and Veteran health behavior research and practice, followed by presenters on specific interventions and programs in key areas. Presenter 1 will discuss tobacco research and prevention through DoD's initial military entrance training. Presenter 2 will discuss a quality improvement implementation of VA's new primary care group health promotion program, *Gateway to Healthy Living*. Presenter 3 will discuss the latest status on VA's primary care behavioral health program including DoD collaboration. Symposium presenters and participants will then discuss health behavior research and practice in both general and specific areas in forward movement for the health of Servicemembers, Veterans, and their Families.

Symposium 65A

INTERVENING DURING THE TRANSITION INTO MILITARY SERVICE ON TOBACCO AND HEAVY ALCOHOL USE

Daniel Cassidy, PhD

Every year, nearly 40,000 men and women enlist in the United States Air Force (USAF). Prior to arrival at Basic Military Training, Lackland Air Force Base, TX, these individuals will have met or exceeded the military's rigorous medical screening standards. While each of these Airmen enters the USAF with fundamentally good health, many also arrive with or subsequently develop health risk behaviors that have long-term costs of increased healthcare expenditure, reduced operational readiness, and lower quality of life. The Department of Defense spends an estimated $2.5 billion each year managing the ramifications of tobacco use and alcohol misuse. In the critical transition from civilian to military life, the Military Health System strives to apply the best available behavioral science for the short and long term health and wellbeing of servicemembers. Early efforts to reduce tobacco use leaned heavily upon an 8 week or greater tobacco ban during initial entry training, and the initial ban remains in place. Despite the majority of trainees espousing "complete confidence" in their ability to remain tobacco-free after initial training, only 17-28% of those who used tobacco prior to enlistment remain abstinent for at least 1 year, and new users are added. The resulting total percentage of tobacco users remains higher at 1-year follow-up and, in general, higher in the military than the civilian population. The story is much the same with regard to heavy alcohol use, which is also prohibited during initial entry training: The ban on consumption is of enduring benefit for some while others initiate or resume heavy use after the restrictions are lifted, suggesting a persisting challenge and opportunity to intervene during this period. Brief individual and group-based interventions delivered during and after initial entry training have demonstrated utility in the reduction of both health risk behaviors. For example, the Alcohol Misuse Prevention Program (AMPP) was associated with a 36% reduction in alcohol-related incidents in one evaluation (e.g., driving under the influence; underage drinking) and can be delivered to a large audience in less than 45 minutes. The AMPP data outcomes, along with similar projects targeting tobacco use, cast light on characteristics common to successful population-level prevention efforts. These interventions are generally delivered in a Socratic style, and preliminary evidence suggests that effects are stronger when the verbal behavior of the interventionist or program is aligned with the tenets of motivational interviewing. Programs under investigation also leverage behavioral economic principles (e.g., choice architecture; temporal discounting) to preserve freedom of choice while at the same time promote healthier behavior that persists across the military and beyond.

Symposium 65B

VA'S GATEWAY TO HEALTHY LIVING

Dr. Margaret Dundon, PhD

The Veteran population has high rates of unhealthy eating, physical inactivity and tobacco use, similar to the general population. These 3 health behaviors are linked to many diseases and half of global mortality. The challenges of supporting health behavior change include helping people feel motivated, confident and willing to engage in evidence-based interventions. The Gateway to Healthy Living Program was designed by the VHA National Center for Health Promotion and Disease Prevention (NCP) to serve as an entry point for Veterans who might benefit from self-care and healthy living programming. Gateway is designed to evoke and increase motivation and confidence for health behavior change, and link Veterans with effective interventions, programs (e.g., weight management, increasing physical activity, tobacco cessation, limiting alcohol, and managing stress) and self-management tools. Gateway offers participants help with goal setting, problem-solving and change strategies as well as access to existing VHA clinical programs. Following the 90 minute group session, there are two subsequent clinician/participant contacts to ensure access to their program of choice, problem-solve, and affirm success. Gateway was piloted in 2015 in six sites across the VA. All of the 83 participants reported being “very satisfied” or "somewhat satisfied” with their Gateway session. The majority of patients reported that Gateway helped them set a goal to improve health. Sixty three percent of the 78 who completed the second follow-up call reported linking to a program or resource.Staff were also surveyed (n = 50), with 86% reporting that Gateway was “very helpful” in connecting Veterans to programs and resources. Fifty-six percent indicated that Gateway was helpful for supporting health behavior change, 74% reported Gateway helped improve efficiency of referrals to behavior change resources, and 68% reported that it saved them time. Based on the pilot success, Gateway training and program support are now being offered to all facilities in the VHA.

Symposium 65C

CURRENT STATUS AND RESEARCH FOR VA PRIMARY CARE AND BEHAVIORAL HEALTH INTEGRATION

Dr. Jennifer S. Funderburk, PhD

One of the largest evidence-based transformations that the VA has implemented to help address the high rates of mental and behavioral health symptoms within Veterans is the integration of behavioral health services into primary care. To accomplish this, the VA has integrated behavioral health providers into each primary care setting to provide focused assessment, intervention, and consultation, and offers evidence-based care coordination via care management models. This has resulted in over 1600 staff being hired to provide these services in 89% of the 365 VA primary care sites across the nation. These integrated service delivery models afford opportunities for trained mental health providers to provide both secondary and tertiary prevention interventions targeting a variety of mental health (e.g., anxiety, depression) and behavioral health (e.g., diabetes management, insomnia) concerns. Due to the increasing implementation of integrated delivery models outside of the VA, this presentation will provide an overview of the current status of integration and evaluation efforts within the VA to stimulate ideas for research and practice across both VA and non-VA settings. This overview will help identify opportunities for behavioral medicine researchers to expand their current work into the primary care setting. Although research has found integration to improve patient access to services, many additional gaps remain. Therefore, this presentation will also summarize gaps in our knowledge regarding integrated primary care, including the effects of brief interventions on clinical outcomes, the best methods to address multimorbidities, the most efficient ways to coordinate complementary services, keys to improving communication and collaboration among the team, the need for brief measures to assess patient functioning, and barriers and facilitators to implementation of integrated primary care service delivery models. Discussion will focus on opportunities for future research at a system- to patient-level on integration.

Symposium 66 1:30 PM-2:45 PM

MECHANISMS WITHIN ROMANTIC RELATIONSHIPS THAT IMPACT HEALTH BEHAVIORS AND OUTCOMES: IDENTIFYING INTERVENTION TARGETS

Krista Ranby, PhD[1], Jennalee Wooldridge, MA[1], Michelle vanDellen, PhD[2], Megan Lewis, PhD[3], Sydneyjane Varner, M.A.[1]

[1]University of Colorado Denver, Denver, CO; [2]University of Georgia, Athens, GA; [3]RTI International, Research Triangle Park, NC

An individual's social environment impacts their health behaviors, yet, the processes by which this influence occurs is not well understood (LaGuardia & Patrick, 2014). Correlational research indicates a positive association between social support and health behaviors yet interventions focused on enhancing social support to change behaviors have fallen short. For this reason, additional targets relevant to interpersonal relationships that may be useful for health behavior interventions will be the focus of our symposium. With data from 280 engaged couples in Denver, CO, we found couples who had been living together for over 2 years were more similar on physical activity and BMI as compared to couples living together for less than 2 years. This study highlights how individuals may change some health behaviors, particularly daily habits, to match one's partner. Second, we will present an experimental study in which 100 dual-smoker couples received either a couple-focused or individual-focused message promoting smoking cessation. Message type and the relationship context (i.e. conflict) interacted to impact motivations to quit smoking. We will discuss how the effectiveness of dyadic interventions may be improved by considering qualities of the couple's relationship. Third, we examined relationship functioning and illness uncertainty at four time points during the year following a prostate cancer diagnosis. Couples (N=165) were recruited from Duke University Medical Center. Unsupportive behaviors increased and support provision decreased following diagnosis; baseline illness uncertainty negatively related to later measures of relationship functioning. Ways to intervene with couples to improve their adjustment will be discussed. Finally, in a national sample of couples participating in a physical activity (PA) intervention for Type II diabetes patients, we examined whether collaborative implementation intentions (e.g., joint planning) improved accelerometer assessed PA and whether this effect is mediated by partner investment in the PA goal and effectiveness of social support and social control attempts. This symposium will encourage researchers to consider the complex nature of the interpersonal environment for health behavior engagement and change. Further, we will discuss the importance of considering both partners' perceptions, unique aspects of life transitions, and appropriate methodological approaches for addressing these research questions.

Symposium 66A

HOW COHABITATION AFFECTS HEALTH BEHAVIOR CONCORDANCE AMONG ENGAGED COUPLES

Dr. Krista Ranby, PhD

Long time married couples experience similar health behaviors and health outcomes (Meyler, Stimpson, & Peek, 2007). Potential causes of this concordance includes partnering with similar others, shared resources and environments, and direct influences between partners. The current study adds to our understanding about how couples come to be similar by examining health behaviors within young adult, engaged couples. Couples who were over 18 and considered themselves engaged were recruited from the Denver, Colorado metro area. Both partners within 280 couples answered questions about their health behaviors, health goals, and relationship. Participants were an average of 27.2 years old (SD=4.0) and had been in a relationship with their current partner for an average of 46.5 months (SD=26.4); 90% of couples were heterosexual relationships. When considering cohabitation, 18% did not live together, 20% had lived together for less than a year, 22% had lived together for 13-24 months, and 41% had lived together for more than 2 years. Correlations of self-reported health behaviors and outcomes from both partners were examined. Stronger correlations emerged on BMI and days of exercise for couples who had lived together longer. This same pattern was not found for smoking and alcohol use which were correlated among all couples or sleep quality which was not correlated within couples. Longer relationship length did not relate to stronger correlations to the same extent as did longer cohabitation time suggesting daily habits may become more similar as people live together. Although couples were more similar after living together, couples who had been living together longer were not significantly more or less healthy than other couples. More work is needed to identify predictors of which partner is likely to change within the relationship. It seems that in some couples, one partner is improving their behaviors and in others, one partner is developing poorer habits. Given that behavioral changes are naturally occurring during this life transition, prevention interventions that consider relevant goals, motivations, and relationship dynamics may be better able to shift behavioral habits in a positive direction so that habits established within this interpersonal context might be maintained over time.

Symposium 66B

COLLABORATIVE IMPLEMENTATION INTENTIONS AMONG COUPLES FACING TYPE 2 DIABETES: MECHANISMS OF BEHAVIOR CHANGE

Jennalee Wooldridge, MA

Many people with type 2 diabetes (T2D) do not engage in recommended self-management behaviors (SMB), particularly physical activity (PA). Relationship partners are highly interdependent and any significant lifestyle change made by one partner likely impacts the other. Considering the interpersonal context of behavior change and necessity of maintaining health behavior over time, couple-level processes are one promising area to incorporate into behavior change interventions. The current study tests a PA intervention with couples in which at least one partner had been diagnosed with T2D. The experimental manipulation involved having couples make collaborative implementation intentions (CIIs), or specific plans for how the diagnosed partner would overcome barriers to PA and follow specific plans to engage in PA. We theorized this manipulation would be successful by changing several important mediators. First, we believed CIIs would increase partner investment, or the degree to which one’s partner has a shared responsibility and takes action to support the goal of the patient engaging in PA. Second, we believed CIIs would increase patient’s self-efficacy if their partner is supporting the goal and possibly modeling the behavior themselves. Third, we believed CIIs would increase health-related social support and positive control behaviors provided by partners. Increases in all of these putative mediators are hypothesized to be positively related to PA. PA (Actigraph accelerometers) and self-management behaviors were assessed at baseline and 6 weeks post manipulation. Mediators were assessed from both partners at baseline, 3 weeks, and 6 weeks. The relationship of the experimental manipulation to the proposed mediators as well as the relationship of the mediators to PA and other SMB will be discussed. This talk will focus on theoretical mechanisms, within relationship partners, for behavior initiation, particularly within management of a chronic illness.

Symposium 66C

THE INTERPLAY BETWEEN MESSAGE FRAME AND CONFLICT DURING SUPPORT ATTEMPTS IN DUAL-SMOKER COUPLES

Dr. Michelle vanDellen, PhD

Nearly 2/3 of smokers are partnered with other smokers. These dual-smoker couples are less likely than other smokers to try to quit. Very little is known about how relationship dynamics—including social support—relate to smoking cessation in dual-smoker couples. In the present talk, we will discuss the interplay between dyadic interventions and the relationship context among 100 dual-smoker couples. Specifically, we examined the impact of a 2 (gain/loss) by 2 (couple/individual) message framing manipulation on motivation to quit smoking. After completing baseline measures (including conflict during social support such as nagging, criticism, and distrust), partners independently read scenarios discussing either the benefits of quitting (gain-frame) or costs of not quitting (loss-frame) as it affected the individual or the couple. After reviewing the scenarios and reporting their desire to quit smoking, the couple members came together to discuss views on smoking. After the discussion they again reported desire to quit. Post-discussion desire to quit varied by whether the outcomes of framing focused on the individual or the couple and by baseline level of conflict $p < .05$. Individuals who reported less conflict were more motivated to quit when the messages were couple- rather than individual-focused. In contrast, individuals who reported more conflict were more motivated to quit when the messages were individual- rather than couple-focused. Thus, when individuals felt the relationship context was characterized by low conflict, focusing on couple outcomes increased motivation to quit. These results suggest that relationship dynamics may moderate the effectiveness of certain kinds of messages. Tailoring messages to couples based on their relationship functioning (e.g., conflict) could increase effectiveness. Future research examining how the relationship context changes motivations to quit smoking may improve effectiveness of interventions for dual-smoker couples.

Symposium 66D

ILLNESS UNCERTAINTY AND RELATIONSHIP FUNCTIONING AMONG COUPLES FACING PROSTATE CANCER: A DYADIC, LONGITUDINAL EXAMINATION

Sydneyjane Varner, M.A.

Couples, both patients and partners, high in relationship functioning (RF) experience improved biopsychosocial outcomes in the illness recovery process for prostate cancer (PC). Illness uncertainty (IU), a major stressor for couples facing a PC diagnosis, may negatively affect several domains of RF, thus impacting important health outcomes. Little is known, however, about how the stress of IU impacts specific domains of RF between partners over time during the year following diagnosis. Couples (N=165) in which one partner was diagnosed with early stage PC were recruited from a urology clinic. Couples were assessed for a year following diagnosis and prostatectomy. Participants completed measures of illness uncertainty (IU), received partner support (PS), unsupportive behaviors (USB), and sexual functioning (SF) at diagnosis, 1-month, 6-months, and 12-months. In the year following diagnosis, USB increased significantly in both partners, while PS decreased significantly in both partners. USB and PS are significantly correlated across time points within couples indicating that there is variability in couples' adjustment during the illness recovery process. Further, significant correlations between baseline IU and relationship measures at various points throughout the year suggest the stress of illness may be having a deleterious effect on couples' relationship functioning. These findings reveal trends in distinct measures of relationship functioning during the year following PC diagnosis that have important implications for future intervention development.. Rather than focusing on increasing general relationship quality, targeting specific interaction patterns within couples, such as the ones in this study, may improve relationship functioning in couples coping with illness recovery.

Symposium 67 1:30 PM-2:45 PM

ADVANCES IN UNDERSTANDING HEALTH EFFECTS OF STIGMA AND DISCRIMINATION IN FAMILY CONTEXTS

Lisa Rosenthal, PhD[1], David M. Frost, PhD[2], Nicole M. Overstreet, PhD[3], Hector F. Myers, PhD[4]

[1]Pace University, New York, NY; [2]University of Surrey, Guildford, England, United Kingdom; [3]Clark University, Worcester, MA; [4]Vanderbilt University, Nashville, TN

Much research demonstrates that stigma and discrimination have adverse consequences for mental and physical health.The majority of this work has focused on the individual level, finding links between one's experiences of stigma or discrimination and one's own mental and physical health outcomes. However, recent research and theory suggest stigma and discrimination is not only experienced at the individual level, but rather should be understood within the context of social networks, such as within family contexts. This symposium includes three presentations of empirical studies that make advances in our understanding of health effects of stigma and discrimination in family contexts across a range of populations, types of stigma, and mental and physical health outcomes. The first presenter will report results finding that among same-sex couples, both individual- and couple-level expectations of rejection due to their socially stigmatized relationship were associated with greater depressive symptoms and more problematic drinking behavior. The second presenter will report results finding that among women exposed to intimate partner violence, stigmatizing reactions to disclosure of that violence were associated with greater depressive symptoms through the mechanism of greater avoidance coping. The third presenter will report results finding that everyday discrimination reported by pregnant women of color prospectively predicted poorer social-emotional development outcomes in their infants at one year old. The discussant will address the presentations' contributions to understanding inter-generational and couple/family-level effects of stigma and discrimination on health, and implications for future research and intervention. Overall, this symposium helps move the field forward in developing a deeper understanding of dynamic health effects of stigma and discrimination within family contexts, which can improve intervention efforts aimed at reducing health disparities faced by stigmatized groups in the U.S.

Symposium 67A

DISCRIMINATION IN PREGNANCY PREDICTS POORER INFANT DEVELOPMENT AT ONE YEAR

Dr. Lisa Rosenthal, PhD

Black women and some subgroups of Latina women in the U.S. experience disproportionately high rates of adverse birth outcomes, such as preterm birth and low birth weight. Black and Latino infants also have poorer behavioral, social, cognitive, and health outcomes than White infants in the first year of life, and these disparities grow larger over time. Increasing evidence suggests women's experiences of discrimination predict increased risk of adverse birth outcomes, supporting that there are inter-generational consequences of discrimination. However, almost no research has explored inter-generational effects of discrimination beyond birth outcomes. In a sample of 334 predominantly Black and Latina teens and young women receiving prenatal care in New York City, we longitudinally tested the hypothesis that women's experiences of discrimination reported during pregnancy would prospectively predict poorer infant development outcomes at one year old.

Participants reported their experiences with discrimination during second and third trimesters, and an aggregate score for pregnancy was calculated. Participants also completed items from the Infant Toddler Social Emotional Development Scale (ITSEA) assessing inhibition/separation problems, attention skills, negative emotions, and positive emotions at one year postpartum. Regression analyses controlling for a range of sociodemographic risk factors found that women's experiences with discrimination reported during pregnancy prospectively predicted greater inhibition/separation problems (B=0.87, SE=0.30, p=.026) and greater negative emotions (B=0.99, SE=0.35, p=.030), but not attention skills or positive emotion in their infants at one year old.

Findings support that there are inter-generational consequences of women's experiences of discrimination for their infants' development and well-being. Inter-generational effects of discrimination may help to explain persistent disparities in a range of developmental, physical health, and mental health outcomes across the life.

Symposium 67B

THE EFFECT OF COUPLE-LEVEL MINORITY STRESS ON THE HEALTH OF SAME-SEX COUPLES

Dr. David M. Frost, PhD

Minority stress theory (Meyer, 2003) posits that sexual minority individuals are at risk for poor health due to the stress they experience stemming from social stigma. Being in a same-sex couple has been theorized to result in exposure to unique forms of stigma, which are thought to represent a risk to sexual minorities' health, above and beyond the risk associated with the stigma they experience as individuals (LeBlanc, Frost, & Wight, 2015). This presentation reports the results of the first empirical test of this theory of "Couple-Level Minority Stress." A purposive sample of 216 partners in 108 sample-sex couples living in the US completed a web-based questionnaire containing measures of individual minority stress in the form of expectations of rejection, a newly developed measure of couple-level minority stress, relationship satisfaction, depression (i.e., CESD) and alcohol use (i.e., AUDIT). The purposive nature of the sampling design ensured that participants were nearly evenly distributed by couple gender, relationship duration, and region of the country. Due to the dyadic nature of the data, the Actor-Partner Interdependence Model (APIM) was used to analyze the data. Analyses demonstrated that heightened expectations of rejection at both the individual- and couple-level were associated with poorer health in the form of increased depressive symptoms and more problematic drinking behavior. Couple-level expectations of rejection explained poor health above and beyond expectations of rejection at the individual level (actor effects) for both depression and drinking behavior, as well as at the dyadic level (partner effects) for drinking behavior. Additionally, evidence for the proliferation of couple-level minority stress was found in the form of a significant indirect effect of couple-level expectations of rejection on depression that operated via decreased levels of relationship satisfaction. Implications for research on sexual minority health disparities and clinical interventions aimed at improving the health of sexual minority individuals and same-sex couples will be discussed.

Symposium 67C

STIGMATIZING REACTIONS TO INTIMATE PARTNER VIOLENCE DISCLOSURE AS PREDICTORS OF AVOIDANCE COPING AND DEPRESSIVE SYMPTOMS

Dr. Nicole M. Overstreet, PhD

Women exposed to intimate partner violence (IPV) are at higher risk for elevated depressive symptoms and major depressive disorder than women not exposed to IPV. Recent research suggests that negative social reactions to IPV disclosure may be associated with women's depressive symptoms. Despite increased attention to the relation between negative social reactions to intimate partner violence (IPV) disclosure and poorer mental health outcomes for victims, research has yet to examine whether certain types of negative social reactions are associated with poorer mental health outcomes more so than others. Further, research is scarce on potential mediators of this relationship. To fill these gaps, the current study examines whether stigmatizing reactions to IPV disclosure, such as victim-blaming responses and minimizing experiences of IPV, are a specific type of negative social reaction that exerts greater influence on women's depressive symptoms than general negative reactions, such as being angry at the perpetrators of IPV. We also examine avoidance coping as a key mediator of this relationship. A cross-sectional correlational study was conducted to examine these relationships. Participants were 212 women from an urban northeast community who indicated being physically victimized by their male partner in the past six months. Findings from a multiple regression analysis showed that stigmatizing reactions, not general negative reactions, predicted women's depressive symptoms. In addition, a multiple mediation analysis revealed that avoidance coping strategies, but not approach coping strategies, significantly accounted for the relationship between stigmatizing social reactions and women's depressive symptoms. Implications of the study findings for improving support from informal and formal sources and IPV-exposed women's psychological well-being will be discussed.

Symposium 68 1:30 PM-2:45 PM

PROMOTING PSYCHOLOGICAL WELL-BEING IN CANCER PATIENTS AND SURVIVORS: META-ANALYSES OF RANDOMIZED CLINICAL TRIALS

John M. Salsman, PhD[1], Judith T. Moskowitz, PhD, MPH[2], Crystal L. Park, PhD[3], Thomas V. Merluzzi, PhD[4]

[1]Wake Forest School of Medicine, Winston Salem, NC; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]University of Connecticut, Storrs Mansfield, CT; [4]University of Notre Dame, Notre Dame, IN

Positive affect, meaning and purpose, and self-efficacy represent dominant concepts in human flourishing and are core components of psychological well-being. In cancer patients and survivors, these concepts are significantly associated with better health outcomes above and beyond the influence of distress and dysfunction. Several systematic reviews and meta-analyses highlight the importance of psychosocial interventions to reduce negative effects of depression, pain, and fatigue in patients with cancer, but we lack similar meta-analyses of interventions that promote and sustain well-being. As more people survive cancer, understanding and facilitating positive adjustment and growth is an important complement to understanding and mitigating impairment, disability and psychosocial morbidity. In this symposium, we will provide a summary and meta-analysis of psychosocial intervention effects on positive psychological outcomes and identify those interventions that have been optimally beneficial for people with cancer. Our aims are threefold: (1) obtain current, comprehensive, and robust estimates of the effectiveness of psychosocial interventions on positive affect, meaning and purpose, self-efficacy among cancer patients and survivors, (2) determine whether the effects of psychosocial interventions on positive affect, meaning and purpose, and self-efficacy differ by the intervention focus and modality, and (3) examine patient sociodemographic (age, gender) and clinical characteristics (cancer type, stage, and phase) as moderators of the strength of the relationship between psychosocial interventions and positive affect, meaning and purpose, and self-efficacy. Our first presentation is on the effects of interventions on positive emotions, optimism, and vigor. Our second presentation examines the effects of interventions on meaning, life purpose, and posttraumatic growth. Our final presentation analyses the effects of interventions on general self-efficacy as well as domain or task-specific self-efficacy. We will close by underscoring important similarities and differences among the three presentations and delineating the utility of psychosocial interventions to promote positive psychological outcomes among cancer patients and survivors. In so doing, we will clarify the role of psychosocial interventions in promoting better health and well-being among patients with cancer.

Symposium 68A

DON'T WORRY, BE HAPPY? META-ANALYSIS OF RANDOMIZED INTERVENTIONS ON POSITIVE AFFECT IN CANCER PATIENTS AND SURVIVORS

Judith T. Moskowitz, PhD, MPH

Introduction: Positive affects such as happiness, excitement, and contentment have unique beneficial effects in the context of health-related stress including improved health behaviors, better quality of life, and increased longevity. In the past decade, empirical evidence has emerged suggesting that positive affect may be an important target for behavioral interventions given its unique beneficial relationship with health outcomes. However, no systematic reviews exist to quantify the effects of behavioral interventions and better understand what works, for whom, and under what conditions within the context of cancer. This meta-analysis investigated the extent to which psychosocial interventions in people with cancer have effects on positive affect outcomes. **Methods:** Drawing from seven electronic databases, 1138 abstracts were identified, evaluated, and coded by reviewer pairs, yielding thirty-one randomized behavioral clinical trials. Effect sizes were calculated for positive affect outcomes such as positive emotion, optimism, and vigor. Synthesis was conducted using correlated random effects models with robust variance estimation to account for dependence among multiple effect sizes within each study. Potential moderators included sample age, gender, cancer type, cancer phase, intervention focus, and delivery format. **Results:** The weighted average effect across thirty-one studies of positive affect outcomes was $g = 0.134$, 95% CI [-0.043, 0.312]. There was substantial heterogeneity of effects across studies, with an estimated between-study variance of 0.193 (I^2: 83%). None of the moderators were statistically significant (all $P > 0.574$). Results did not exhibit outcome-reporting biases ($P = 0.412$ from a robust Egger regression test). **Discussion:** Although several behavioral interventions included positive affect as an outcome, few targeted positive affect as the primary outcome and results were typically small in magnitude. Surprisingly, intervention efficacy did not vary as a function of clinical, demographic, or intervention characteristics. Tailored interventions to promote positive affect with careful attention to measurement of positive affect may potentially yield greater effects, but more studies are needed to draw firmer conclusions.

Symposium 68B

DO PSYCHOSOCIAL INTERVENTIONS WITH CANCER PATIENTS AND SURVIVORS INCREASE MEANING AND PURPOSE? A META-ANALYTIC APPROACH

Dr. Crystal L. Park, PhD

A sense of meaning and purpose are important for individuals dealing with cancer. Meaning can buffer stress effects by allowing individuals to view their cancer experiences as one part of a larger, richer whole or to reframe it in more positive ways (post-traumatic growth). Yet, cancer can threaten individuals' sense of meaning by undermining their views of the world as benevolent and controllable, their identities as healthy and intact, and their futures as optimistic and long. Identifying whether interventions can promote a sense of meaning, purpose and growth is important for improving the well-being of cancer patients and survivors. This meta-analytic study examined the efficacy of interventions that promote meaning and purpose and potential moderators (age, gender, cancer type, cancer stage, cancer phase, intervention modality, and delivery format) of this effect. 2080 abstracts from 7 electronic databases were evaluated by reviewer pairs. Inclusion criteria included randomized controlled trials of a psychosocial intervention with cancer patients and/or survivors that included an outcome measure of meaning, purpose, or growth. A total of 38 randomized trials met these criteria. Meta-analyses used correlated random effects models with robust variance estimation to account for dependence among multiple effect size estimates within each study. The overall average effect across studies that included over 3000 people was $g = 0.313$, 95% CI [0.165, 0.461], $P < .001$. Effects were heterogeneous with an estimated between-study variance of 0.138 (I^2 71%). No moderating effects were identified. There was a strong indication of publication bias ($P = .0196$ from a robust Egger regression test). Using Egger regression to adjust for potential small-sample bias reduced the overall average effect to $g = -0.059$, 95% CI [-0.323, 0.205], $P = .642$, I^2 68%. These results suggest that, although many interventions for improving meaning and purpose have reported salutary effects, the overall pattern of findings may be a function of outcome reporting biases rather than evidence that the interventions are effective in bolstering meaning and purpose in the context of cancer.

Symposium 68C

A META-ANALYTIC REVIEW OF INTERVENTIONS TO ENHANCE SELF-EFFICACY BEHAVIORS IN CANCER PATIENTS AND SURVIVORS

Dr. Thomas V. Merluzzi, PhD

Background: Peoples' beliefs and expectations about their ability to exercise control or mastery over their behaviors represent an underlying and central mechanism of human agency and personal efficacy. Self-efficacy (SE) theory posits that greater confidence in the ability to execute courses of action enhances the probability that desired goals will be attained. Thus, cancer patients with higher SE for processes like coping, symptom management, and adherence to medical regimens are more likely to persist in strategies to achieve desired psychosocial (e.g., better adjustment and quality of life) and medical outcomes (e.g., less and/or less intense symptoms and side effects) compared with those with lower SE. This meta-analytic study determined 1) whether interventions to increase SE are effective and 2) if moderators like intervention focus are important. **Method:** Synthesis was conducted using correlated random effects models with robust variance estimation to account for dependence among multiple effect size estimates within each study. Outcome reporting bias was examined using funnel plots and a robust variant of Egger's regression. Moderators examined included age, gender, cancer type, intervention focus, and delivery format. **Results:** Across 45 randomized control trials examining the effects of psycho-social interventions, the weighted average effect on SE outcomes was g=0.338, 95% CI[0.233, 0.443],P<.001. There was substantial heterogeneity of effects across studies, with an estimated between-study variance of 0.092 (I-squared:72%). Intervention focus explained significant variation in the effect size estimates (F(2,11.2)=7.73,P=0.008). The average effect for individual-based interventions was g=0.218 (95% CI[0.121, 0.315], k=28 studies), for dyad-based interventions g=0.458 (95% CI[0.089, 0.829], k=9 studies), and for group-based interventions g=0.702 (95% CI [0.409, 0.995], k=7 studies). Effects for group-based interventions were statistically distinguishable from effects for individual-based interventions (P=.015) after multiple-comparisons correction). Results were not sensitive to outcome-reporting or small-sample biases (P=.547, robust Egger regression test). **Discussion**: Results suggest that SE does improve in the context of an intervention. Moreover, group interventions enhance self-efficacy more effectively than individually administered interventions. Consistent with SE theory, the group format may enhance SE through social modeling, persuasion in a group context, and support. Thus, in general, this preliminary evidence supports a preference for group-based rather than individual-based interventions to enhance SE.

Symposium 69 1:30 PM-2:45 PM

MEASURING PERCEIVED RISK: THE PROFOUND IMPLICATIONS OF SEEMINGLY TRIVIAL CHOICES ABOUT ITEM WORDING AND FORMATTING

Annette Kaufman, PhD, MPH[1], Erika A. Waters, PhD, MPH[2], Daniel L. Hall, Ph.D.[3], Marc T. Kiviniemi, BA, PhD[4], Rebecca A. Ferrer, PhD[5]

[1]Tobacco Control Research Branch, Behavioral Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, National Institutes of Health, Rockville, MD; [2]Washington University in St. Louis, St. Louis, MO; [3]Harvard Medical School/MGH/BIDMC, Wellesley, MA; [4]University at Buffalo, Buffalo, NY; [5]National Cancer Institute, Rockville, MD

Most health behavior theories assert that higher perceptions of personal risk are associated with higher engagement in healthy behaviors and lower engagement in unhealthy behaviors. Yet, many empirical studies have reported conflicting results in which the link between perceived risk and behavior was positive, negative, or absent. This has led some researchers to conclude that perceived risk is not an important predictor of behavior change and that health communication and behavior interventions should focus on addressing other key concepts (e.g., perceived benefits) or levels of influence (e.g., policy change).

However, conclusions such as these have not adequately addressed whether conflicting findings might be due to methodological considerations such as the specificity or generality of item wording and the characteristics of response options. If the inconsistent association between risk perception and behavior is attributed to limitations of risk perception as an important construct in health behavior change, rather than to methodological characteristics that limit the predictive validity of risk perception measures, health communication and behavior interventions that do not address risk perceptions may be unnecessarily self-limiting. Furthermore, such methodological variation may cloud our understanding of the meaning and magnitude of population perceived risk, obscure the “true” relationship between perceived risk and behavior, and consequently inhibit the advancement of health behavior theory and the development of effective health behavior change interventions.

This symposium will provide insight into the effects of common decisions about the wording and formatting of perceived risk items. It accomplishes this by (1) providing a systematic review of how risk perceptions are measured in the literature using tobacco use as a case study; (2) demonstrating that the correlations between perceived risk and other health beliefs, behavioral intentions, and behavior differ dramatically based on whether the risk perception items are or are not contingent on plans to engage in risk-mitigating behavior; (3) describing how perceptions of risk among current and former smokers who undergo lung cancer screening vary in magnitude depending on the specificity of the risk perception item and whether the items assess absolute or comparative risk perceptions; and (4) providing evidence against the common practices of (a) not including a “don’t know” response option for risk perception items, and (b) treating “don’t know” responses as missing data. The discussant, a program director at the National Cancer Institute, will identify future research needs and will describe the theoretical, methodological, and practical implications of the research.

Symposium 69A

RISK PERCEPTION MEASUREMENT IN TOBACCO CONTROL RESEARCH: A SYSTEMATIC REVIEW

Dr. Annette Kaufman, PhD, MPH

Despite the importance of perceived risk and the extraordinary breadth and volume of tobacco control research assessing risk perceptions, no studies have been conducted to review how this construct is measured across tobacco studies. The present review describes the characteristics of risk perception measures used in tobacco control research and evaluates whether studies incorporate best practices for risk perception measures put forward by risk perception researchers. Three databases (PubMed, PsycINFO, and Web of Science) were searched in March 2015, for published English language peer-reviewed articles measuring tobacco risk perceptions (N=2,557). Three coders independently coded abstracts for initial inclusion. A total of 441 articles met initial inclusion criteria and 100 were randomly selected for full-text review. Three coders independently coded critical aspects of each article, multi-item measure, and item: 54 articles, 33 measures, and 239 items were coded. We found large gaps in the use of best practices for measuring risk perceptions. Only 14 articles had a multi-item measure focused exclusively on risk perception and 11 articles had only one risk perception item. Many items asked about general health outcomes (43%), did not specify the person for whom risk was being judged (44%; e.g., self, average person), or did not specify the conditions for which the risk was being judged (27%; e.g., the product used, intensity of use). Few items assessed constructs known to provide additional information about how people deal with risk, including: perceived severity (11%), affective responses to risk (9%), perceived controllability (8%), or the extent to which risks are seen as unknown to experts (3%). Findings suggest that tobacco research inconsistently incorporated risk perception measurement suggested best practices, despite their established importance. Further promulgating best practice guidelines for assessing risk perception could be useful to tobacco research. A set of risk perception consensus measures may benefit the field.

Symposium 69B

CONDITIONING PERCEIVED RISK ITEMS ON FUTURE BEHAVIOR: IMPLICATIONS FOR ADVANCING THEORY AND DEVELOPING INTERVENTIONS

Erika A. Waters, PhD, MPH

Background: Risk perception survey items that are conditioned on behavior (e.g., How likely is that you will get colon cancer IF YOU DO NOT GET REGULAR EXERCISE) may be interpreted differently than unconditioned items.

Objective: Examine whether conditioning risk perception items on exercise behavior alters the association between perceived risk and health beliefs, intentions, and behavior.

Methods: Secondary analysis of data from a risk communication study (N = 812). Participants were members of GfK Knowledge Networks, an Internet survey panel. Each participant answered an unconditioned and conditioned version of 4 types of colon cancer risk perception items: cognitive absolute perceived likelihood, affective absolute perceived likelihood, cognitive comparative perceived likelihood, and affective comparative perceived likelihood.

Results: Conditioned items elicited fewer “don’t know” responses than unconditioned items for the cognitive items (McNemar test ps < .005) but not the affective items (McNemar ps > .48). Mean risk perceptions were higher for all conditioned than non-conditioned items (paired t-test ps < .001). All conditioned items were positively correlated with intentions to exercise (ps < .0001), but none of the unconditioned items were (ps > .10). Conditioned items were positively correlated with current exercise behavior (ps < .05), but unconditioned items were either unrelated to (ps > .18) or inversely correlated (ps < .02) with current exercise behavior. Conditioned items had weaker correlations with worry and stronger correlations with anticipated regret than unconditioned items (Steiger z-test ps < .001). Perceived severity was independent from conditioned items (ps > .22) but positively correlated with unconditioned items (ps < .005). Both conditioned cognitive items and the affective

comparative likelihood item accounted for variance in intentions not accounted for by response efficacy (ps < .05), which suggests that conditioned risk perception items are not simply another way to assess response efficacy.

Conclusion: The decision about whether or not to condition perceived risk items on behavior has critical implications for participant comprehension of survey items, potential missing data, operationalization of health behavior theory constructs, and drawing correct inferences about the relationship between perceived risk, other health behavior constructs, and behavior. Not attending to such considerations may impede intervention development and evaluation.

Symposium 69C

RISK PERCEPTIONS AMONG LUNG SCREENING PATIENTS: ONE SIZE DOES NOT FIT ALL

Daniel L. Hall, Ph.D.

Background: Multiple U.S. health agencies have recommended ongoing lung screening for current and former heavy smokers, which Medicare has recently began covering. Risk perceptions are known to influence patient uptake of screening guidelines. To date, little is known about risk perceptions about lung cancer (LC) or smoking-related diseases (SRD), and whether these perceptions vary by smoking status and/or reference point (i.e., absolute vs. comparative risk).

Method: This observational, cross-sectional study examined current smokers (n=88) and former smokers (n=81) who were undergoing lung screening at a large academic medical hospital. Ten self-report items assessed risk perceptions regarding LC and SRD, framed in either absolute or comparative terms. Items were scored (1=Low to 5=High), summed, and averaged to facilitate comparisons (i.e., LC vs. SRD; absolute vs. comparative). Independent and paired-samples t-tests were conducted to assess (dis)concordance in responses for the total sample as well as by smoking status.

Results: Overall, lung screening patients perceived moderate levels of health risk (M=3.57, SD=.68), although there was variability by smoking status and reference point. Specifically, patients endorsed higher health risk when questions were presented in terms of absolute health risk versus comparative health risk (p < .001). This pattern was true for both current and former smokers (ps < .001). When asked about risk for LC and SRD separately, current smokers perceived lower risk for LC than for SRD's ($p < .001$), while former smokers assessed their risk for both disease groups equally ($p = .29$).

Discussion: While lung screening patients endorsed moderately elevated health risk overall, ratings varied by reference point, smoking status, and disease in question. The significant variability by each of these factors among current and former smokers underscores the heterogeneity of risk perceptions in the context of lung screening, as well as the complexity involved in communicating lung screening recommendations and results.

Symposium 69D

DO PEOPLE KNOW WHAT THEY SAY THEY DON'T? PRESENCE AND POSITIONING OF DON'T KNOW RESPONSE OPTIONS SHIFT PERCEIVED RISK ESTIMATES

Dr. Marc T. Kiviniemi, BA, PhD

BACKGROUND: People sometimes report not knowing their risk for health problems. Some argue that don't know responses (DKR) reflect satisficing and are essentially error variance. One should therefore discourage DKR by not providing a response option and/or treat DKRs as missing data. Others hold that DKRs are meaningful, reflecting differences in health knowledge and other factors, and should be assessed by including a DKR option. We conducted two online survey studies of US adults to examine evidence for these competing assertions.

METHODS AND RESULTS: In Study 1, absolute and comparative risk for both colon cancer and diabetes was assessed. A DKR option was presented as either the first or last response option. Participants ($N=280$) were more likely to use the DKR option when it was presented first (e.g., for colon cancer absolute risk, DKRs were 10.4% percentage points higher when presented first). For colon cancer, for which more people say they don't know their risk than for diabetes, the means for both types of risk were both significantly higher when DKR was last; both $ts>2.34$, both $ps<.05$. This pattern was also found for diabetes, although differences were not statistically significant. In Study 2, participants ($N=960$) reported absolute and comparative perceived risk for four health problems. Participants received items that either did or did not have a DKR option (placed last). In all risk domains, the DKR option was used when presented, with rates ranging from 3.5% (absolute risk, car crash) to 12.7% (comparative risk, colon cancer). For absolute risk, risk estimates were systematically higher in the DKR provided condition for all four risk domains, Fs<3.78, all ps<.05. For comparative risk, means did not differ by condition.

CONCLUSIONS: These findings cast serious doubt on the idea that one should simply reduce DKRs by not providing an option or treat DKRs as missing data. The differing patterns for diabetes versus cancer (Study 1) and for absolute versus comparative risk (Study 2) also call into doubt the idea that DKRs simply reflect satisficing, as this would predict the same response patterns across domains. The presentation will further explore implications for understanding of lay estimation of health risks and guidance on how to address DKRs in questionnaire development and data analysis.

IMPACT OF INDIVIDUAL AND AREA LEVEL RACE/ETHNICITY ON ILLNESS INTRUSIVENESS AMONG CANCER SURVIVORS

Corinne Leach, MS PhD MPH[1], Rhyan Vereen, MPH[2], Arthi Rao, PhD[2], Katie Ross, BSPH[3], Liora Sahar, PhD, GISP[2]

[1]American Cancer Society's Behavior Research Center, Atlanta, GA; [2]American Cancer Society, Atlanta, GA; [3]Rollins School of Public Health, Emory University, Decatur, GA

Illness intrusiveness describes how much a specified disease, such as cancer, disrupts various aspects of someone’s life, including physical wellbeing, work, finances, relationships, and recreational activities. The socioecological model posits that individual health status is simultaneously produced by individual biology and the surrounding physical, social, and cultural environment. Despite evidence of the need to consider these hierarchical influences on cancer outcomes, little is known about the impact of area level factors on cancer-related outcomes, including illness intrusiveness.

Data from 993 breast, colorectal and prostate cancer survivors within the first year of completing active treatment were analyzed. Individual level data for the Illness Intrusiveness Ratings Scale were linked to census tract level data to characterize neighborhood conditions. As components of area indices, area-level race and education were investigated along with corresponding individual factors to study their interactive effect on illness intrusiveness.

232 (23.4%) participants reported relatively high illness intrusiveness (score >28). Education was not a significant predictor of illness intrusion. A model including interaction between area and individual-level race among other individual confounders exhibited significantly improved model fit ($p < 0.05$). The model showed that racial minorities living in areas with a higher percentage of racial minorities had higher odds of having greater illness intrusiveness when compared to Whites living in areas with a low percentage of racial minorities (aOR: 1.65, CI: 1.01, 2.68).

The results of this study suggest a differential effect of area level race composition, often characterized by fewer resources, by individual level race. While this study assesses area-level factors independently, these measures are also components of combined measures such as area deprivation indices. Further research will evaluate our research question using an Area Deprivation Index that is currently being developed. Findings may support the collective resources model which posits that the effect of area deprivation is greater in certain

sociodemographic groups who may find it difficult to seek potentially beneficial resources outside of their living area.

REACHING A HARD TO REACH PATIENT POPULATION: USING A MOBILE TECHNOLOGY-BASED TOOL TO PROVIDE INFORMATION AND SUPPORT

Catherine Benedict, PhD[1], Dave Fuehrer, N/A[2], Brad Love, PhD[3], David Victorson, PhD[4]

[1]Hofstra Northwell School of Medicine, Manhassat, NY; [2]Stupid Cancer, New York, NY; [3]University of Texas at Austin, Austin, TX; [4]Robert H. Lurie Comprehensive Cancer Center, Northwestern University, Chicago, IL

Background: Adolescent and young adult (AYA; 15-39 years old) cancer survivors report an unmet need for emotional and informational support. Instapeer is a mobile app that provides AYAs access to instant, anonymous peer support and cancer information. Users complete a profile and are matched with peers based on self-selected criteria or can participate in unstructured group chats. This study evaluated AYAs' use of the app and preferences for peer-to-peer connection and app-based support.

Methods: In the first 12 months of public launch, 2,343 AYAs representing 44 countries downloaded the app and completed a profile (demographic/medical information, treatment side effects, and psychosocial concerns). A product and user analysis was conducted to evaluate app functioning and user satisfaction including quantitative app metrics and in-depth qualitative user interviews (N=6).

Results: Users were primarily female (74%), single (41%), childless (65%), and post-treatment (54%). Most common diagnoses were lymphoma (21%) and breast (18%). 23 unique treatment side effects and 24 psychosocial concerns were endorsed; 46% of users reported ≥6 side effects and 65% reported ≥6 psychosocial concerns. Users averaged 1,121 interactions per week for a total of 3,595 hours of time spent in the app over 12 months. Group chat rooms represented the majority of total message exchanges; however, users participating in one-to-one messaging appeared to make stronger connections with more frequent message exchanges.Qualitative user feedback centered around 3 primary themes: desire to connect with others of the same age and diagnosis; interest in connecting with peers based on non-medical information (e.g., interests/hobbies, location); and hesitation to connect (i.e., send a request).

Conclusions: Findings provide initial evidence for AYAs' interest and enthusiasm for using an mobile phone app to connect with peers and access support. Features that allow AYAs to connect with peers based on non-medical similarities and for one-to-one communication may be critical. Strategies to facilitate initial connections may also be needed to encourage

connections. App-based support tools may offer a promising approach to reach this underserved patient population. Strategies to promote peer connections and meaningful exchange of support should be explored based on AYAs' preferences and needs. Future research should evaluate whether access to support via this technology leads to improvements in psychosocial outcomes such as perceived support and social isolation.

MATERIAL FINANCIAL HARDSHIP AND LIMITING CARE DUE TO COST IN A MULTI-RACIAL COHORT OF CANCER SURVIVORS

Theresa A. Hastert, Ph.D., M.P.P.[1], Matthew Banegas, Ph.D., M.P.H., M.S.[2], Lauren M. Hamel, PhD[3], Ann G. Schwartz, Ph.D., M.P.H.[4], Tara Baird, M.A. [1], Jennifer L. Beebe-Dimmer, Ph.D., M.P.H.[1]

[1]Wayne State University School of Medicine/Karmanos Cancer Institute, Detroit, MI; [2]Kaiser Permanente, Portland, OR; [3]Wayne State University/Karmanos Cancer Institute, Detroit, MI; [4]Karmanos Cancer Institute/Wayne State University, Detroit, MI

Background: Nearly one-third of cancer survivors in the United States experience financial hardship due to cancer. We examined whether experiencing material financial hardship was associated with limiting care due to cost among cancer survivors in Metropolitan Detroit.

Methods: Data from the Detroit Research on Cancer Survivorship (ROCS) cohort include responses from 682 (275 white, 407 black) adults (ages 27-79) diagnosed with a first primary breast, colorectal, lung, or prostate cancer since January 1, 2013 and diagnosed or treated at the Karmanos Cancer Center. Material financial hardship included experiencing a decrease in income, borrowing from friends or family, remaining in debt, or accessing existing assets (refinancing/selling a home, selling investments, withdrawing money from savings or retirement) due to cancer. Limiting care included skipping doses of medication to save money or refusing treatment or needing to see a doctor but not going due to cost. Logistic regression tested the association between material financial hardship and limiting care, adjusting for age, sex, race, marital status, income, education, health insurance, employment, cancer site, and treatments received. Effect modification by race was assessed.

Results: Overall, 49% of participants experienced material financial hardship, and 19% reported limiting care due to cost. In adjusted analyses, survivors who experienced material financial hardship were more than six times as likely to limit care (OR: 6.6, 95% CI: 3.7, 11.5). This association was strongest for participants who borrowed money from friends or family (OR: 8.8, 95% CI: 6.6, 16.8) and remained in debt (OR: 5.6, 95% CI: 3.4, 9.1); however, accessing existing assets (OR: 2.9, 95% CI: 1.6, 5.2) and experiencing a decrease in income (OR: 2.8, 95% CI: 1.7, 4.5) were also strongly associated with limiting care due to cost. Marginal effect modification was detected by race, suggesting that the association between any material financial hardship and limiting care may be stronger among black (OR: 10.0, 95% CI: 4.8, 21.0) than white survivors (OR: 3.5, 95% CI: 1.3, 9.6; $P_{interaction}$=0.10).

Conclusion: Cancer survivors who experienced material financial hardship were much more likely to report limiting care due to cost than those who did not. Left unaddressed, the impact of material financial hardship may exacerbate health disparities and lead to worse outcomes across U.S. cancer survivor populations.

CHANGE IN SOCIAL SUPPORT IN AFRICAN AMERICAN BREAST CANCER PATIENTS AFFECTS DEPRESSED MOOD AND GENERAL HEALTH

Tess Thompson, PhD, MPH[1], Maria Pérez, MA[2], Matthew Kreuter, PhD[3], Julie Margenthaler, MD[2], Graham Colditz, MD, DrPH[2], Donna Jeffe, PhD[4]

[1]Washington University in St. Louis, Webster Groves, MO; [2]Washington University School of Medicine, St. Louis, MO; [3]Washington University in St. Louis, St. Louis, MO; [4]Washington University School of Medicine, Saint Louis, MO

Higher perceived social support is associated with better psychological and quality of life outcomes in breast cancer patients. Less is known about how changes in social support affect these outcomes in patients. We interviewed 227 African American women with non-metastatic breast cancer (72% early stage; 58% annual income < $25,000; 27% married/partnered; mean age 56, range 33-81 years) in a randomized controlled trial of a culturally tailored intervention using breast cancer survivor stories. Demographic and psychosocial interview data were collected at baseline, 1 month later, and then 6 months, 1 year, and 2 years after definitive surgical treatment. Mean Center for Epidemiologic Studies-Depression Scale (CES-D) score was 11.9 (*SD* = 11.4) at baseline and 11.1 (*SD* = 12.1) at 2 years; mean RAND 36-item general health subscale score was 59.1 (*SD* = 22.4) at baseline and 54.7 (*SD* = 22.9) at 2 years. An unconditional growth curve model estimated the intercept (estimated starting point) and slope (change over time) of perceived social support (19-item Medical Outcomes Study Social Support Survey) from baseline through 1-year follow-up after definitive surgical treatment. Two separate growth curve models then used this intercept and slope of social support over the first year after surgery to predict depressed mood and perceived general health 2 years after surgery. Models that controlled for the baseline measure of the outcome of interest showed good fit (CFI/TLI > .99, RMSEA ≤ .01, SRMR = .04). Patients who had lower estimated starting points of social support or experienced declines in social support in the first year after definitive surgical treatment reported higher depressed mood and lower perceived general health at 2-year follow-up. These results held after controlling for demographic and cancer-related variables. Thus, declines in social support in the first year after a breast cancer diagnosis had negative consequences a year later for African American women in terms of mental and general health. Screening for availability of social support at diagnosis and monitoring support levels during and after treatment could help patients with low or declining social support receive support services and psychological intervention as needed.

PSYCHOLOGICAL DETERMINANTS OF EHEALTH ACTIVITY AMONG AFRICAN AMERICAN AND WHITE CANCER SURVIVORS: A NEW APPLICATION OF THEORY

Nicole Senft, PhD[1], Judith Abrams, PhD[2], Jennifer L. Beebe-Dimmer, Ph.D., M.P.H.[3], Charity A. Barnes, B.S.[4], Anne Katz, PhD[5], Ke Zhang, PhD[4], Tara Eaton, PhD[6], Deborah H. Charbonneau, PhD[4], Elisabeth Heath, MD[7], Hayley S. Thompson, Ph.D.[8]

[1]Karmanos Cancer Institute/Wayne State University, Ann Arbor, MI; [2]Wayne State university/Karmanos Cancer Institute, Detroit, MI; [3]Wayne State University School of Medicine/Karmanos Cancer Institute, Detroit, MI; [4]Wayne State University, Detroit, MI; [5]Wayne State University/Karmanos Cancer Institute, Detroit, MI; [6]Levine Cancer Institute, Charlotte, NC; [7]Karmanos Cancer Institute, Detroit, MI; [8]Karmanos Cancer Institute - Wayne State University, Detroit, MI

eHealth is a promising resource for cancer survivors coping with their physical, psychosocial, and economic needs, and it may play an especially important role in reducing racial disparities in cancer survivorship. The current research is a preliminary examination of associations between beliefs about eHealth and reported eHealth activity. This is part of an ongoing study using a mixed-method design to assess eHealth activity among African American and white cancer survivors in the metropolitan Detroit area. The study assesses 17 eHealth activities spanning 5 categories—information seeking, connecting with informal support, connecting with healthcare providers, managing health, and medical transactions. We drew from the Unified Theory of Acceptance and Use of Technology, which suggests the adoption of new technology can be predicted by beliefs about its ease of use, usefulness, and social acceptability. We adapted the model to relate to use of technology for health-related reasons and extended it to include belief in the security of online health services. In a sample of African American (n=53) and white (n=34) survivors, we tested whether attitudes about ease (3-items, α=.80), usefulness (3-items, α=.94), social acceptability (4-items, α=.77), or security (3-items, α=.85) of eHealth were associated with eHealth activity, controlling for social-structural determinants (i.e. age, education, access to internet). The sample was comprised of primarily older adults (mean age=59, SD=10.37) and survivors of breast cancer (n =67). There was significantly less eHealth use among African American (M=4.37, SD=3.13) than white survivors (M=7.97, SD=3.19; $t(83)$=5.14, p < .001). The belief that eHealth was useful was positively associated with eHealth activity among both African American (r=.36, p=.02) and white survivors (r=.36, p=.05). Belief that eHealth was socially acceptable was associated with increased activity for African American (r=.28, p=.05), but not white survivors (r=.16, p=.41).

Beliefs in the ease and security of eHealth were not associated with use for members of either group (*r*s < .10, *p*s>.10). These results suggest interventions aimed at adjusting attitudes about eHealth may be effective in encouraging the adoption and use of this promising resource. Furthermore, the particular attitudes associated with eHealth activity differ across racial groups, suggesting targeted interventions may be most effective in encouraging eHealth use among cancer survivors.

Paper Session 34: Novel Tools to Support Digital Health 3:00 PM-3:18 PM

DEVELOPING AUDIENCE PERSONAS THROUGH WEB ANALYTICS TO INFORM HEALTH PROMOTION AND OUTREACH

Brian Keefe, MA[1], Paula Novacki, B.A - Journalism & Mass Communications[2], Kisha I. Coa, PhD, MPH[1], Augustson Erik, PhD, MPH[3]

[1]ICF International, Rockville, MD; [2]ICF, Washington, DC; [3]National Cancer Institute, Rockville, MD

Introduction: One of the greatest health communication challenges is understanding target audiences and developing content that meets their needs. In an environment where acquiring detailed marketing data is often cost-prohibitive and secondary data is often too broad, gaining detailed insights about the target audience can be difficult. The goal of this study was to systematically develop audience personas using website usage, demographic, and engagement data from Google Analytics to describe users of Smokefree.gov. Smokefree.gov is the National Cancer Institute’s digitally based smoking cessation program with a presence on a number of different platforms (e.g., web, social, text, app). Persona development is a foundational activity for digital health programs. When appropriately established, personas represent key audience segments which can be used to inform promotional decisions, optimization or content for specific browsers or devices, tailoring content, and overall outreach activities.

Methods: The current project utilized custom development work within Google Analytics to identify a number of user characteristics, including age, gender, geographic location, content needs, device preference, and browser preference, in order to build specific Smokefree personas. Data was collected from January 1, 2016-August 1, 2016, encompassing over 1.1 million visitors to Smokefree.gov.

Results: We identified 4 unique types of Smokefree.gov personas: 1) General website users, 2) Users entering the site through social media, 3) Users who downloaded the Smokefree mobile applications, and 4) Users entering the site through the SmokefreeTXT program. These persona groups differed in a number of ways, mainly their engagement levels with the website and the devices used to access the content. For example, Group 1 General website users were younger (age 18-24 (29%)), found the site through an organic search using terms such as “how to quit smoking,” and visited an average of 1.23 pages, with the “nicotine withdrawal” page being the most popular. In contrast, Group 4 visitors from SmokefreeTXT were slightly older (25-34), entered the site using an iPhone, landed on the QuitGuide mobile app page, and visited an average of 2.14 pages.

Conclusion: Personas such as these will enable us to create smoking cessation content that meets the specific needs of various users, is relevant to their lived experiences, and provides the means to better target outreach activities moving forward. Specifically, Smokefree can highlight specific resources and content on different channels based on findings from the personas, re-target promotional efforts to users who more align with the personas, and create new content based on the characteristics of various user types.

Paper Session 34: Novel Tools to Support Digital Health 3:19 PM-3:36 PM

DEVELOPMENT OF THE MOBILE PHONE AFFINITY SCALE: ASSESSING PERSON'S RELATIONSHIP TO THEIR MOBILE PHONE

Beth C. Bock, PhD[1], Ryan Lantini, MA[2], Herpreet Thind, PhD, MPH, MBBS[3], Kristen Walaska, BS[1], Rochelle K. Rosen, PhD[4], Joseph L. Fava, PhD[5], Lori A. J. Scott-Sheldon, PhD[6]

[1]Brown Medical School, Providence, RI; [2]The Miriam Hospital, Providence, RI; [3]University of Massachusetts Lowell, Lowell, MA; [4]Brown University School of Public Health, Providence, RI; [5]Centers for Behavioral and Preventive Medicine, The Miriam Hospital, Providence, RI, 02903, Providence, RI; [6]The Miriam Hospital and Brown University, Providence, RI

Background: Existing instruments that assess an individual's relationship with mobile phones tend to focus on negative constructs such as "addiction" or "dependence" and appear to assume that high mobile phone and technology use reflects pathology. Since mobile phones can be beneficial for health behavior change, disease management, work productivity and social connections, there is a need for an instrument that provides a more balanced assessment of the various aspects of individuals' relationship to their mobile phones.

Objective: The purpose of this research is to develop, revise, and validate the Mobile Phone Affinity Scale (MPAS), a multi-scale instrument designed to assess key factors associated with mobile phone use.

Methods: Participants (N = 1058; mean age = 32.5, SD=10.3; 50% female) were recruited in a national sample using Amazon Mechanical Turk (MTurk) to complete a survey that assessed participants' attitudes and use patterns regarding their mobile phone, as well as assessments of anxiety (State-Trait Anxiety Inventory), depressive symptoms (Centers for Epidemiological Studies Depression Scale), impulsivity (Barratt Impulsiveness Scale) and resilience (Brief Resilience Scale).

Results: Confirmatory factor analysis was used to develop a six-factor model. The final model fit well (RMSEA = .059, CFI = .941, TLI = .931, SRMR = .042), and consisted of 24 items (4 items each) measuring six factors: Connectedness, Productivity, Empowerment, Anxious attachment, Addiction, and Continuous use. The subscales demonstrated strong internal consistency (coefficient alpha range = 0.76 to 0.88, M = 0.83), and high item factor loadings (range = 0.57 to 0.87, M = 0.75). Validity analyses further demonstrated support for the individual subscales. For example, Attachment and Addiction subscales were significantly and

positively correlated with symptoms of depression and anxiety, and correlated negatively with resilience, while Productivity was positively correlated with resilience.

Conclusions: The Mobile Phone Affinity Scale (MPAS) is a reliable, valid assessment of both positive and negative characteristics associated with the individual's relationship to their mobile phone. Mobile phone affinity may have an important impact on the efficacy and effectiveness of mobile health interventions. However, research is needed to assess its predictive ability in health behavior change interventions delivered through mobile phones.

Paper Session 34: Novel Tools to Support Digital Health 3:37 PM-3:54 PM

E-EMBRACERS, WARY WEARERS, AND DATA DODGERS: PROFILES OF DIABETES DEVICE USERS

Molly Tanenbaum, PhD[1], Esti Iturralde, Ph.D.[2], Regan C. Barley, BS[2], Sarah Hanes, BA[1], Hillary Kroll, N/A[3], Korey K. Hood, Ph.D.[2]

[1]Stanford University, Palo Alto, CA; [2]Stanford University School of Medicine, Palo Alto, CA; [3]Stanford University, East Brunswick, NJ

Background: Diabetes devices (insulin pumps, continuous glucose monitors-CGM) are associated with improved health outcomes and quality of life in adults with type 1 diabetes (T1D). Rates of device uptake, particularly CGM, are low. This study aimed to understand profiles of adults with T1D in relation to device use and attitudes to ultimately inform tailored interventions to address barriers and increase device uptake among each group.

Methods: Participants were 1503 T1D Exchange participants (M±SD age 35.3±14.8 yrs; dx duration 20.4±12.5 yrs) who completed surveys on barriers to uptake, diabetes distress, and technology attitudes. Clinical data available from the T1D Exchange included device use and health outcomes (glycemic control). K-means cluster analyses were used to group the sample by barriers to device use and technology attitudes. ANOVAs and chi-square tests assessed differences among groups by demographic and psychosocial variables (e.g. hypoglycemia worry, diabetes distress).

Results: Cluster analyses yielded four distinct profiles. The *e-Embracer*s (n=712) endorse few barriers to device use and have the highest rates of device use, lowest levels of distress, and lowest A1c (M±SD=7.3±1.1). *Data Dodgers* (n=170) have the lowest CGM use. The barrier that most differentiated them was not wanting more diabetes data. *Off-the-Grid-ers* (n=444) have the most negative technology attitudes and endorse average levels of barriers to device use. *Wary Wearers* (n=177) have the lowest overall device use, are the youngest, and have shortest T1D duration. They do not want attention or daily hassle of devices, are most distressed and worried about hypoglycemia, and have highest average A1c (M±SD=8±1.6). Cost, a commonly endorsed barrier to using devices, did not distinguish among groups.

Conclusion: *Off-the-Grid-ers* may benefit from addressing attitudes toward diabetes technology; *Data Dodgers* may benefit from increasing comfort with handling diabetes-related information. *Wary Wearers* may benefit from comprehensive psychosocial intervention targeting diabetes distress and hypoglycemia worries along with issues related to

wearing devices and having other people notice them. These profiles will help clinicians to identify adults with T1D needing each intervention to ultimately increase device uptake.

Paper Session 34: Novel Tools to Support Digital Health 3:55 PM-4:12 PM

HABIT APP: FEASIBILITY OF A WEIGHT LOSS PROBLEM SOLVING APP

Sherry Pagoto, PhD[1], Jessica Oleski, MA[1], Molly E. Waring, PhD[1], Emmanuel Agu, PhD[2], Bengisu Tulu, PhD[3]

[1]University of Massachusetts Medical School, Worcester, MA; [2]Worcester Polytechnic Inst, Worcester, MA; [3]Worcester Polytechnic Institute, Worcester, MA

A behavioral strategy employed in virtually every visit of weight loss counseling but not yet included in weight loss mobile apps is problem solving. Problem solving is a process used to identify barriers to a goal and generate solutions to be iteratively attempted until barriers are overcome. We developed an app that employs Nezu's problem solving algorithm to produce expert-derived solutions to diet and exercise problems. Each problem solving session on the app produces a list of solutions or "habits." The user selects a habit and then schedules reminders to execute the habit during the week. We performed a pilot study to evaluate the feasibility of the Habit app.

Adults who were overweight or obese were enrolled in an 8-week intervention that included the Habit app and support via a private Facebook group. Participants were instructed to use Habit app weekly to identify 1-2 habits to work on. In the Facebook group, a counselor emphasized the importance of trying new habits to overcome weight loss challenges, asked them to share weekly habit goals and accomplishments, and encouraged dietary self-monitoring. Problem solving skills were measured with the Social Problem Solving Inventory-R at baseline and follow-up.

Participants (N=27) were on average 37.2 (sd=11.6) years old, baseline BMI of 31.1 (sd=4.6), 67% female, and 85% non-Hispanic white. Three participants dropped out (88% retention). Of the 41 diet and exercise challenges identified by participants, only 3 were not addressed in the app. Participants reported using the Habit app on an average of 7.1 weeks (sd=1.7). Higher baseline positive problem solving scores were associated with greater use of the app ($r= .414$, $p=0.04$), but no changes were observed in positive problem solving over 8 weeks ($p=0.27$) Participants lost on average 0.20% (sd=0.03%) per week ($p=0.004$), comparable to 0.28% in the Diabetes Prevention Program Lifestyle Intervention.

The Habit app addressed the majority of participants' weight loss challenges, was used on most weeks, but did not improve problem solving skills. In an ongoing pilot, Habit app is being delivered with brief problem solving training to better impact problem solving skills. Data from the ongoing pilot will also be presented.

Paper Session 34: Novel Tools to Support Digital Health 4:13 PM-4:30 PM

EMBRACING ITERATION GUIDED BY MIXED METHOD EVALUATION DURING MHEALTH CLINICAL TRIALS

Angela Fidler Pfammatter, PhD[1], Gwendolyn Ledford, BA[1], Susan Hood, PhD [2], Sean Arca, B.S.[3], Shirlene Wang, BA[4], Bonnie Spring, PhD[2]

[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Northwestern University, Chicago, IL; [3]Northwestern Medicine, Chicago, IL; [4]Northwestern University Feinberg School of Medicine, Wilmette, IL

mHealth strategies are increasingly used in clinical intervention research, yet much remains unknown regarding optimization of engagement in interventions delivered by mobile phones. Although formative work is often involved in intervention design, many interventions and smartphone applications are not modified based on feedback after launch of a traditional RCT. As previous research has supported, mHealth app use declines 40-50% over time. To reasonably expect long term engagement, researchers must identify ways to initiate and sustain engagement of the app user. Concepts from design research may be used to evaluate engagement, receive feedback, and make modifications that positively affect engagement and thus, outcomes. The NUYou Study enrolled 150 freshmen students, in its first year, for a 2-year cardiovascular health promotion study. The purpose of this work was to systematically evaluate recruitment and engagement strategies to iterate key trial components, like the NUYou smartphone application, push notification recommendation system, and social media groups. Potential participants not enrolled in the trial (n=365) were surveyed about the effectiveness of advertisement and initial engagement initiatives. Enrolled participant (n=150) app use was continuously monitored via app log data 6 months after recruitment opened, and users were interviewed during the trial. While 98% of potential participants recognized and recalled aspects of the study, only 7% of the total target population enrolled in the trial. Significant barriers included lack of time and being too busy. App monitoring indicated that although 14% of the sample used the app consistently, great variability existed in the amount and length of continued use of the application, pointing to issues with sustained engagement. Surveys found that although 55% indicated agreement that the app was relevant to their health goals, 21% indicated agreement that the app helped achieve goal attainment. Qualitative interviews revealed that students generally liked reminding features, that the app was easy to use, and that further personalization could help them reach health goals. Results were applied to inform further iteration of features to optimize engagement in the intervention and the smartphone application. Specifically, small daily incentives, additional tracking of stress, happiness, and cognitive performance, and dynamic data visualization were

added to the trial for continuing and new participants in year 2. Opportunities to maximize learning and optimization during mHealth clinical trials are essential to behavior science and as such, potential methods and impact are discussed.

Paper Session 35: Stress, Pain and Fatigue in Cancer Survivors 3:00 PM-3:18 PM

MINDFULNESS-BASED STRESS REDUCTION FOR FATIGUED CANCER SURVIVORS: EFFECTS ON MINDFULNESS, ACCEPTANCE, AND SELF-COMPASSION

Kelly Chinh, B.A.[1], Catherine E. Mosher, Ph.D.[1], Linda F. Brown, PhD[2], Kathleen Beck-Coon, MD[3], Kurt Kroenke, M.D.[4], Shelley A. Johns, PsyD, ABPP[4]

[1]Indiana University-Purdue University Indianapolis, Indianapolis, IN; [2]Indiana University School of Medicine, Bloomington, IN; [3]Indiana University School of Nursing, Indianapolis, IN; [4]Indiana University School of Medicine, Indianapolis, IN

Mindfulness-based stress reduction (MBSR) has resulted in reduced physical and psychological symptoms in cancer populations, but little is known about theory-based psychological processes through which mindfulness-based interventions may decrease symptoms. In the present trial of MBSR for fatigued cancer survivors, mindfulness, acceptance, and self-compassion were psychological processes theorized to play a role in symptom outcomes. This trial randomized 35 cancer survivors with clinical levels of cancer-related fatigue (CRF) to either a 7-week MBSR intervention for CRF or a waitlist control condition. We hypothesized that the MBSR group would show increases in one aspect of mindfulness (i.e., non-reactivity), acceptance, and self-compassion relative to controls.

The majority of participants were White (80%), female (94%), and college educated (71%) with an average age of 57 years (*SD* = 9.3). Participants were primarily diagnosed with early-stage breast cancer (80%), and all had completed cancer treatment at least 9 months prior to enrollment. All 35 participants completed assessments of mindfulness, acceptance, and self-compassion at baseline, immediately post-intervention, and 1-month follow-up.

Three linear mixed models were conducted to examine main effects of time, study group, and the time x group interaction on mindfulness, acceptance, and self-compassion. A significant effect of study group in favor of MBSR was found for non-reactivity ($F(1,33)=9.46$, $p=.004$) and acceptance ($F(1,33)=5.75$, $p=.022$). A significant time x group interaction ($F(2,66)=5.80$, $p=.005$) was found for self-compassion, such that the MBSR group showed a steady increase in self-compassion, whereas the control group's scores remained relatively stable.

Findings suggest that MBSR for fatigued cancer survivors leads to increased levels of mindfulness, acceptance, and self-compassion. Further research is needed to examine whether these psychological processes mediate the effects of MBSR on symptom outcomes during cancer survivorship.

CITATION AND MERITORIOUS AWARD WINNER

CANCER-SPECIFIC STRESS AND ABSOLUTE LYMPHOCYTE COUNT TRAJECTORIES IN PATIENTS WITH CHRONIC LYMPHOCYTIC LEUKEMIA

David M. Weiss, M.A.[1], Barbara L. Andersen, PhD[1], Amy J. Johnson, PhD[1], John C. Byrd, MD[2], Kami J. Maddocks, MD[1]

[1]The Ohio State University, Columbus, OH; [2]Ohio State University, Columbus, OH

Chronic stress has been commonly observed in cancer patients and is associated with immune system down regulation. The effect of stress on immunity in hematologic cancers such as chronic lymphocytic leukemia (CLL) has not been studied despite the role of immune system dysfunction in CLL's pathogenesis. In a phase II clinical trial, 154 patients with relapsed/refractory CLL received ibrutinib and provided blood samples and completed a self-report measure of psychological stress specific to cancer over an 18-month treatment period (nine assessments). Targeted treatments like ibrutinib have been effective in reducing disease progression in CLL despite the occurrence of lymphocytosis, which is an increase in absolute lymphocyte counts (ALC) and has previously been regarded as a marker of active disease. Controlling for demographic, health status, number of prior treatments, and CLL genetic risk (del17p) factors, random changepoint models were estimated to evaluate the impact of stress on ALC trajectories. Stress was associated with pretreatment ALCs (β_0 = 0.13; 95% CI = 0.02, 0.25) but did not impact the timing of lymphocytosis (δ_{x1}= 0.03, CI = -0.15, 0.22), or the ALC trajectory before (β_{x1} = -0.11, CI = -0.23, 0.01) and after (o_{x1}=0.10, -0.01, 0.22) lymphocytosis. Stress affects pre-treatment ALC such that a 10% increase in stress results in a 1.3% increase in ALC. However, stress has little impact on ALC trajectories after beginning drug therapy. Additional analysis showed that lymphocytosis occurs later in the treatment trajectory for individuals classified as drug non-responders compared to responders at 18-months (δ_{x2} = -0.89; CI= -1.48, -0.30). However, there are a variety of ways a patient can exhibit lymphocytosis (e.g. lymphocytosis before ibrutinib administration or treatment-induced lymphocytosis) and it is unclear whether the mechanism of lymphocytosis or specific ALC trajectories can predict treatment response. Overall, results suggest that while stress increases pre-treatment ALC, patients exhibit similar ALC trajectories after treatment initiation. Future trials may assess whether clinical, demographic, or other psychological risk factors can predict ALC trajectories or treatment responses. The current study provides a novel way to provide knowledge of how psychological stress impacts disease trajectories in patients undergoing a new cancer therapy.

Paper Session 35: Stress, Pain and Fatigue in Cancer Survivors 3:37 PM-3:54 PM

OMEGA-3 VERSUS OMEGA-6 SUPPLEMENTATION FOR CANCER-RELATED FATIGUE: EXAMINING INFLAMMATORY AND ANTI-OXIDANT PATHWAYS

Luke J. Peppone, PhD, MPH[1], Karen Mustian, PHD, MPH, MS[2], Charles Kamen, PhD, MPH[2], Matthew Asare, PhD, MBA, CHES[3], Calvin L. Cole, PhD[3], Sarah Kerns, PhD MPH[2], Michelle Janelsins, PhD, MPH[2]

[1]University of Rochester, Wilmot Cancer Institute, Rochester, NY; [2]University of Rochester Medical Center, Rochester, NY; [3]University of Rochester, Rochester, NY

Background: Cancer-related fatigue (CRF), one of the most troublesome side effects of cancer and its treatment, is associated with increased levels of inflammation. We conducted a nationwide, multi-site, phase II RCT through the URCC NCORP Research Base to examine the effect of omega-3 supplementation (ω-3) from fish oil versus omega-6 supplementation (ω-6) from soybean oil for improving CRF. ω-3 was chosen for its anti-inflammatory properties while ω-6 was chosen as a control condition.

Methods: Breast cancer survivors between 4-36 months post-adjuvant therapy with a CRF level of 4 or greater (on a 0-10 scale) were stratified by baseline CRF (4-6: moderate and 7-10: high) and randomized into 3 arms: 1) High-dose ω-3 (ω-3; 6 g/day), 2) Low-dose ω-3/Low-dose ω-6 (ω-3/ω-6; ω-3: 3 g/day and ω-6: 3 g/day) and 3) High-dose ω-6 (ω-6; 6 g/day) for 6 weeks. CRF was assessed pre- and post-intervention via the Symptom Inventory (SI). Serum protein and RNA levels of inflammatory (PGE2, sTNFRI, sTNFRII, and CRP) and anti-oxidant (SOD2) markers were also measured at pre- and post-intervention. ANCOVAs assessed associations between changes in CRF and biomarker levels.

Results: 108 female breast cancer survivors were accrued (93% Caucasian, mean age = 59.8). Mean baseline CRF levels did not differ between groups and serum levels of fatty acids confirmed high compliance in all study arms with minimal contamination. After controlling for baseline CRF, ω-6 supplementation significantly improved CRF in a dose-response manner (SI Change score: ω-3 = -2.5 vs. ω-3/ω-6 = -2.1 vs. ω-6 = -0.9; Cohen's δ=0.72; p=0.02). ω-3 supplementation failed to significantly reduce markers of inflammation, potentially due to low baseline levels of inflammation. RNA levels of SOD2 significantly increased in the ω-6 group (Cohen's δ=0.48; p=0.02), while there was a trending increase in SOD2 protein levels for the ω-6 group compared to the ω-3 group (Cohen's δ=0.22; p=0.17). RNA levels of PGE2 declined significantly (Cohen's δ=−0.78; p‹0.01) for the ω-6 group, but there was no change in PGE2 protein levels (p=0.21).

Conclusions: ω-6 supplementation from soybean oil significantly reduced CRF compared to ω-3 supplementation in breast cancer survivors. These findings are contrary to our hypothesis and provide new information on the mechanisms underlying CRF. ω-6 supplementation resulted in a subtle anti-inflammatory effect, with a more pronounced anti-oxidant effect, providing a potential mechanism of action. Future studies are needed to confirm these findings. Funding: NCI UG1CA189961 & R03CA175599. Nordic Naturals, Inc. supplied all study agents.

Paper Session 35: Stress, Pain and Fatigue in Cancer Survivors 3:55 PM-4:12 PM

THE ROLE OF ILLNESS PERCEPTIONS IN CANCER-RELATED FATIGUE OUTCOMES IN OVARIAN CANCER PATIENTS

Crystal Hare, BA, BSc[1], Lindsey Torbit, MA[1], Cassandra Crangle, MA[1], Sarah Ferguson, MD[2], Tae Hart, PhD[1]

[1]Ryerson University, Toronto, ON, Canada; [2]Princess Margaret Cancer Centre, Toronto, ON, Canada

Background: Cancer-related fatigue (CRF) is one of the most common and debilitating symptoms reported by cancer patients (Jensen et al., 2011). Factors implicated in the severity of CRF include cancer treatment, age, and pain (e.g., Anderson & Hacker, 2008). Research suggests that ovarian cancer (OC) patients may be at greater risk for the development of CRF, compared to other cancer populations (Payne, 2002), yet little research has examined the factors contributing to CRF in OC. One factor that may contribute to fatigue variability is the impact of patient illness perceptions (IPs; Leventhal et al., 1980) related to the diagnosis of cancer and treatment. Using Leventhal's Common Sense Model (CSM), this study examined the role of IPs (i.e., illness identity, timeline—chronicity and cyclicality, consequences, personal and treatment controllability, and coherence) on fatigue severity in patients with OC.

Method: Women with OC (N=265) were recruited from the Princess Margaret Hospital in Toronto. Participants completed the following self-report questionnaires: Illness Perception Questionnaire-Revised (Moss-Morris et al., 2002); Brief Pain Inventory (Cleeland & Ryan, 1994); and Functional Assessment of Chronic Illness Therapy Fatigue Scale (Cella et al., 2005). Controlling for three factors commonly associated with CRF: age, cancer treatment, and pain severity, a two-step hierarchical regression examined the impact of IPs on fatigue severity.

Results: Step one of the hierarchical regression was significant, $F(4,184) = 21.12$, $p < .001$; only pain severity ($\beta = -.43$, $p < .001$) was significantly associated with more fatigue severity. The overall model in step two was significant, $F(10,178) = 12.65$, $p < .001$. Out of the six IPs included in the model, greater endorsement that cancer is cyclical in nature ($\beta = -.13$, $p < .05$), and endorsement of significant consequences associated with OC ($\beta = -.22$, $p < .001$) were associated with greater fatigue severity, predicting an additional 10.1% of the variance in fatigue, $F(6,178) = 5.12$, $p < .001$. The total model accounted for 38.2% of the variance in fatigue severity.

Discussion: This is the first examination of the full array of Leventhal's illness perceptions in association with CRF. Believing that one's cancer has serious negative consequences on one's life and that it is likely to recur appears to be associated with intensified fatigue. These data provide partial support for the CSM in understanding CRF.

Paper Session 35: Stress, Pain and Fatigue in Cancer Survivors 4:13 PM-4:30 PM

A RANDOMIZED PILOT TRIAL OF AN MHEALTH PAIN COPING SKILLS TRAINING INTERVENTION FOR HEMATOPOIETIC STEM CELL TRANSPLANT PATIENTS

Caroline Dorfman, Ph.D.[1], Sarah Kelleher, Ph.D.[1], Rebecca Shelby, Ph.D.[1], Hannah Fisher, B.S.[2], Francis Keefe, Ph.D.[1], Krista Rowe, RN, MSN, AOCNS[3], Tamara Somers, Ph.D.[1]

[1]Duke University Medical Center, Durham, NC; [2]University of Miami, Miami, FL; [3]Duke University Health System, Durham, NC

Pain is common and persistent among patients following Hematopoietic Stem Cell Transplant (HSCT) and associated with decreased quality of life. Current behavioral cancer pain interventions have limited reach among HSCT patients who, after weeks of intense medical care, are discharged home often far from the hospital. To address the unique needs of these patients, we developed a home-based mobile pain coping skills training (mPCST) protocol. A small RCT was conducted to test the feasibility and acceptability of the protocol and examine intervention-related changes in pain, pain self-efficacy, pain disability, fatigue, and physical disability. Participants were randomized to mPCST (n=18) or usual care (n=18). mPCST bridged hospitalization (1 session) and home (5 video-conferencing sessions) using CBT skills (e.g., relaxation, cognitive-restructuring, activity pacing/planning); a website with personalized messages was used. Participants completed assessments at pre- and post-treatment. mPCST participants completed M=4.9/6 sessions. Skill use increased over time, and participants found sessions to be helpful, easy to understand, highly acceptable, and rated the intervention to be good or excellent overall. mPCST participants evidenced significant improvements in pain self-efficacy and the two-minute walk test; the usual care arm did not. Both groups experienced significant improvements in pain disability and fatigue; however, the magnitude of the effect sizes were greater for the mPCST arm. Participants in both arms evidenced significant improvements on a self-report measure of physical disability. There were no significant changes in pain. The results demonstrate that an mPCST protocol tailored to meet the needs of HSCT patients is feasible and acceptable. Many HSCT patients have pain that varies over time; patients who improve their pain coping skills may be better able to manage pain and decrease pain-related disability and interference. Psychosocial interventions that increase pain self-efficacy and decrease pain disability may lead to improved outcomes for HSCT patients. Longitudinal studies are necessary to examine the long-term implications of the observed improvements in pain self-efficacy on patient outcomes.

Paper Session 36: Translation of Interventions in Disease Prevention and Management 3:00 PM-3:18 PM

TRANSLATING RESEARCH INTO PRACTICE FOR HEALTH: A COMMUNITY-BASED, LIFESTYLE INTERVENTION FOR ADULTS WITH TYPE 2 DIABETES

Emily A. Finch, MA, David Liss, PhD, Ronald T. Ackermann, MD, MPH

Northwestern University, Chicago, IL

Background: At least 1 out of 3 people will develop type 2 diabetes in their lifetime and risk of death is 50% higher for adults with diabetes than for adults without diabetes. The LookAHEAD study of over 5,000 overweight patients with type 2 diabetes showed that participants in the intervention program lost more weight and had improvements in urinary incontinence, sleep apnea, depression, quality of life, physical functioning, and mobility. However, the Look AHEAD intervention is not currently available on a population scale, because the approach is prohibitively costly and difficult to translate into real-world settings.

Methods: Working with primary-care providers between January 2013 and July 2014, we enrolled 331 adults with BMI ≥24 kg/m^2 and prior diagnosis of type 2 diabetes from two ethnically diverse Chicago area neighborhoods into the study. Participants were randomized to: (1) brief lifestyle counseling with nearby community resource information; or (2) brief lifestyle counseling plus encouragement to participate in a group-based adaptation of the LookAHEAD program offered in both English and Spanish languages, free-of-charge by the YMCA. The primary outcome was mean difference in body weight at 12 months. Secondary outcomes included changes in HbA1c, cholesterol, and blood pressures. Interim intent-to-treat (ITT) analyses accounted for clustering of longitudinal patient-level data and imputed missing follow-up data.

Results: At baseline, participants had a mean (SD) age of 57.4 ± 11.4 years, BMI 35.6± 7.6 kg/m2, HbA1c 7.22 ± 1.25%. Approximately half (50.2%) were women, 30.5% were African American, 34.4% were non-Hispanic White, and 27.5% were Hispanic. Approximately one third (38.9%) reported annual household incomes of < $25,000. Overall, 75 participants (45.7%) participated in at least 1 intervention session. In ITT analysis, the average effect of randomization to GLI encouragement was -1.58 pounds per six months (95% CI, -2.83 to -0.34; P=0.01). Over the 12-month follow-up period, this effect equates to an additional 3.16 pounds of weight loss. Mean weight losses of non-Hispanic white, African American, and Hispanic participants were not statistically significantly different.

Conclusions: Delivery of a group adaptation of the LookAHEAD program by YMCA’s suggests a

scalable lower cost mechanism to help a diverse, predominantly low-income adults with type 2 diabetes lose a modest amount of weight. Health care reform models and reimbursement policies should include access to community-based intensive healthy lifestyle interventions to translate interventions into practice.

CAN A PEDOMETER-BASED WALKING PROGRAM LOWER HEALTH CARE COSTS AMONG ADULTS WITH TYPE 2 DIABETES?

Mona AuYoung, PhD, MS, MPH[1], Melissa Plegue, M.A.[2], Elizabeth Jackson, MD MPH[2], Ananda Sen, PhD[2], Kara Zivin, PhD[3], Caroline Richardson, MD[2]

[1]VA CCMR, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]VA Ann Arbor Healthcare System, Ann Arbor, MI

Physical inactivity is associated with higher health care utilization and costs among adults with diabetes. Pedometer-based walking interventions have been shown to be effective in increasing physical activity for diabetics, but the effect on health care utilization and costs is unclear. This study examines how an incentivized pedometer-based walking intervention impacts both physical activity and health care costs for adults with diabetes.

In 2009, Blue Cross Blue Care Network enrollees with a body mass index (BMI) of 30 kg/m^2 or greater were given a choice to join an internet-mediated pedometer-based walking program (Walkingspree). Participation was financially incentivized because individuals could potentially save an estimated 20% of out-of-pocket expenses by uploading their step count data at least once every 30 days to the program website and averaging at least 5000 daily steps every three months. The pedometer assessed both total daily steps and aerobic steps, measured as continuous steps for at least 10 minutes. A multiple linear regression analysis determined the impact of average daily steps and aerobic steps on the change in health care costs after one year, controlling for diabetes status, age, gender, body mass index, length of program participation and other comorbidities.

Of the 7,594 WalkingSpree participants, 15 percent had diabetes. On average, every 100 daily steps were associated with a $9.07 decrease in health care costs (p=0.049). Among participants with a mean of 5000 daily steps, predictive margins show the average person without diabetes experienced cost savings of -$441.93 (p=0.004). In comparison, those with diabetes averaged increased costs ($872.67, p < 0.001), particularly for those with diabetes with complications ($2491.88, p < 0.001). However, these costs decreased for every 100 daily steps.

Greater daily steps are associated with decreased total health care costs for all three groups, but there was a nonlinear differential effect by diabetes status. Further investigation is needed to better understand the relationship between step counts and health care costs for diabetics, especially those with more serious complications. Although people with diabetes may incur greater health care costs, daily steps may help to slow these increased costs over time.

Paper Session 36: Translation of Interventions in Disease Prevention and Management 3:37 PM-3:54 PM

EFFECTIVENESS OF AN OBESITY TREATMENT APP WITH PROVIDER COUNSELING FOR MEDICALLY VULNERABLE PATIENTS IN PRIMARY CARE PRACTICE:

Gary G. Bennett, PhD[1], Dori M. Steinberg, PhD, RD[1], Sandy Askew, MPH[1], Erica Levine, MPH[2]

[1]Duke University, Durham, NC; [2]Duke Global Health Institute, Durham, NC

INTRODUCTION: Obesity treatment is less successful for those in medically vulnerable populations. These disparities extend to treatments delivered in the primary care setting, where there is little evidence that we can produce clinically meaningful weight loss among populations who have the greatest obesity risk.

OBJECTIVE: We examined whether obesity treatment app, combined with counseling from a primary care provider and a dietitian, could outperform weight losses produced by usual care among medically vulnerable primary care patients.

METHODS: Track is a 12-month randomized controlled trial of a digital health weight loss intervention in a community health center system. Participants were 351 adults (aged 21-65) with obesity and a diagnosis of hypertension, diabetes, and/or hyperlipidemia. We randomized participants to usual primary care or the 12-month Track intervention which comprised: algorithm-generated tailored behavior change goals, weekly self-monitoring via mobile technologies, daily self-weighing using a network-connected scale, skills training materials, and 18 counseling phone calls with a dietitian. Primary care providers delivered counseling to intervention participants using electronic-health record-based recommendations generated by the Track app. The primary outcome was weight change over 12 months.

RESULTS: Participations (n=337) were largely female (69%) and non-Hispanic Black (52%), with a mean age of 50.6 years and a mean body mass index of 35.9 kg/m^2. Most (90%) had less than a college degree, 32% were unemployed, and half (52%) were living under or near the poverty line. The Track intervention produced larger weight losses than usual care at 6- (net effect: -4.4 kg, 95% CI [-5.5, -3.3], P < .0001) and 12-months post-randomization (net effect: -3.8 kg, 95% CI [-5.1, -2.5], p < .0001). Intervention participants (n=170) completed a median 93.2% (IQR: 54% to 100%) of weekly self-monitoring via mobile device and a median 89% (IQR: 50% to 100%) of counseling calls. Intervention participants were more likely to lose 5% or more of their baseline weight at 6- (43% vs. 6%, p < .0001) and 12-months (40% vs. 17%, p < .0001) post-randomization.

DISCUSSION: We can effectively treat obesity among medically vulnerable patients in community health centers using a scalable, low cost, digital treatment that both informs and optimizes provider counseling.

PROVIDER COUNSELING IS ASSOCIATED WITH INCREASED WEIGHT LOSS IN A PRIMARY CARE-BASED DIGITAL HEALTH WEIGHT LOSS INTERVENTION

Megan McVay, PhD[1], Dori M. Steinberg, PhD, RD[2], Sandy Askew, MPH[2], Gary G. Bennett, PhD[2]

[1]Duke University School of Medicine, Durham, NC; [2]Duke University, Durham, NC

Background: Digital health weight loss interventions offer substantial promise for addressing obesity in primary care. Primary care providers may play an important auxiliary role in these treatments by counseling patients to stay engaged in treatment. **Methods**: This is a secondary analysis of Track: a randomized clinical trial testing a 12-month digital health behavioral weight loss intervention delivered at community health centers compared to usual care. At 6 and 12 months, participants reported whether their providers counseled them about weight generally (general weight counseling) or specifically about intervention participation (intervention counseling) at their most recent clinic visit, as well as their perceptions of providers' empathy. Weight was also collected at these times points. We used adjusted linear regression models to compare differences in weight outcomes based on provider counseling among intervention participants (no counseling vs. general weight counseling only vs. intervention counseling) and separately among usual care participants (no counseling vs. general weight counseling). **Results:** Study participants were 69% female, 52% Black, and had a mean age of 51 years and BMI of 36 kg/m^2. Intervention participants (6 month, n=119; 12 month, n=115) and usual care participants (6 and 12 months, n=124) reported similar likelihood of receiving any counseling from providers at 6 months (75.6% vs. 69.8%, p=.31) and 12 months (72.2% vs. 66.9%, p=.38). Provider counseling reported at 6 months was not associated with weight change at 6 or 12 months among intervention participants, p>.05. However, provider counseling reported at 12 months was associated with weight change among intervention participants; those receiving intervention counseling lost more weight

than those receiving general weight counseling only (adjusted M_{diff} = 4.1 kg, 95% CI [0.2, 7.9], *p*=.04) and no counseling (adjusted M_{diff} = 4.4 kg, 95% CI [0.04, 8.9], *p*=.047). Among intervention participants only, perceptions of provider empathy reported at 12 months was associated with 12 month weight loss, *b*=-0.13 kg, t(110)=2.0, *p*=.049. Among usual care participants, weight loss counseling was not associated with weight loss at any time point. **Conclusions**: Our findings suggest that whereas general weight counseling by primary care providers is unlikely to influence weight, counseling patients to engage in a specific, evidence-based digital health treatment can contribute to weight loss. Providers conveying empathy towards patients may also impact weight.

Paper Session 36: Translation of Interventions in Disease Prevention and Management 4:13 PM-4:30 PM

IMPLEMENTING A PRIMARY CARE ELECTRONIC HEALTH RECORD-BASED MODEL FOR BEST PRACTICES IN PAIN MANAGEMENT FOR LOW-INCOME PATIENTS

Lara Dhingra, PhD[1], Robert Schiller, MD[2], Jack Chen, MBS[1], Sarah Nosal, MD[3], Raymond Teets, MD[2], Nandini Shroff, MPH[4], Saskia Shuman, MHS[2], Regina Ginzburg, PharmD[2], Russell Portenoy, MD[1]

[1]MJHS Institute for Innovation in Palliative Care, New York, NY; [2]Institute for Family Health, New York, NY; [3]Institute for Family Health, Bronx, NY; [4]The Institute for Family Health, New York, NY

Health Information Technology (HIT) can address gaps and variation in provider knowledge and skills, but studies have noted challenges to the adoption of new technology into daily patient care. While HIT solutions to improve pain management in primary care may be valuable, obstacles to adoption must be overcome to realize any benefits. As part of a randomized trial, we implemented a new electronic health record (EHR)–based decision support tool (the “Pain Management Support System for Primary Care” [PMSS-PC]) in 6 practices of a large Federally Qualified Health Center, which serve a low-income population in New York City and upstate New York. We evaluated uptake of the PMSS-PC by primary care providers (PCPs) in the practices as part of an examination of its implementation. The PMSS-PC was programmed into Epic’s® platform and used a “best practice alert” format similar to extant decision support for health screening and management of chronic diseases, like diabetes. It included informational screens, checklists, documentation requirements, and validated practice support tools. Specific elements included screening tools for depression, anxiety, and substance use; a pain assessment tool; opioid risk assessment, and treatment guidelines. Treatment guidelines were developed for primary care and included first-line non-pharmacological approaches, referral for psychological, integrative, and other care, as well as pharmacotherapy. EHR data extracted between 3/2014-4/2016 showed that 46 PCPs used the pain assessment tool a total of 1,595 times for 237 patients. Further, 63 PCPs accessed the treatment guidelines a total of 1,061 times for 433 patients. While few referrals and treatments were provided using the PMSS-PC (a total of 109 times for 97 patients), overall referrals increased in the practices between the first 3 months, and last 3 months of implementation by 110.3% (1,561 to 3,283; physical therapy, 33.5%, 37.8%; psychological and behavioral care, 29.5%, 29.2%; orthopedic care, 27.0%, 21.9%; pain management, 6.7%, 8.0%; acupuncture and chiropractic care, 3.3%, 3.1%, respectively). Similarly, the number of patients who received prescriptions increased by 156.8% (1,376 to 3,533) during this same

time: 7.9%, 6.9% opioids; 92.1%, 93.1% non-opioids. Only 39.8% of PCPs reported high-moderate satisfaction with the PMSS-PC. These results suggest that provider use of the PMSS-PC in this trial was limited, but changes in pain practice were more substantial. We will report final analyses on uptake and potential modifiers of PCP use of the program over time, including patient (e.g., depression), provider (e.g., satisfaction), and practice-related (e.g., location) characteristics. Future results may show the importance of using HIT to promote best practices for pain management and its positive effect on patient-reported outcomes.

Paper Session 37: Older Adult's Physical Activity: Determinants and Interventions 3:00 PM-3:18 PM

DEVELOPING A SUSTAINABLE PEER-LED PHYSICAL ACTIVITY PROGRAM FOR SENIOR

Michelle Takemoto, PhD Candidate[1], Khalisa Bolling, MPH [1], Brittany Lewars, MPH[2], Katie Crist, MPH[3], Eileen Johnson, BA[4], Porchia Rich, MD, MPH, MSW[1], Kelsie M. Full, MPH, PhDc[5], Jacqueline Kerr, PhD, MSc[6]

[1]University of California, San Diego, San Diego, CA; [2]University of San Diego, California, El Cajon, CA; [3]UC San Diego, La Jolla, CA; [4]University of California, San Diego, La Jolla, CA; [5]University of California - San Diego, La Jolla, CA; [6]Department of Family Medicine and Public Health, UC San Diego, La Jolla, CA, USA, La Jolla, CA

Less than 3% of older adults meet physical activity (PA) guidelines. Our previous project, Multilevel Intervention for Physical Activity in Retirement Communities (MIPARC), increased participants' step counts and prevented the inherent decline associated with aging. Additionally, participants successfully completed advocacy projects to improve walkability in and around the retirement communities (e.g., safer crosswalks, cleaner pedestrian bridges).

However, once the study ended, transitioning leadership from UCSD staff to individuals within the community was challenging. Based on these results, the Peer Empowerment Program for PA (PEP4PA) is designed to promote & assess delivery and sustainment of a peer-led multi-level PA program in senior centers. PEP4PA transitions intervention delivery from UCSD research staff to peer health coaches (PHCs) and center staff from within senior centers. PHCs and a center staff member complete a 16-hour training course and certification to lead the program and build a sustainment plan.

We employ mixed-methods to evaluate program implementation. Intervention fidelity is assessed through an online tablet that PHCs use to track intervention delivery including attendance, participant step counts, and progress towards goals. To promote success, the intervention dose was simplified to ensure PHCs have capacity to deliver the components. PHCs meet with participants in person for counseling, use color coding to identify goal setting, and are encouraged to work with participants who are most in need. As a pragmatic trial, PEP4PA has rolling recruitment which helps with motivation during the two year project by continuing to have new participants enroll. Results from the implementation measures are used to improve the project under the Plan, Do, Study, Act framework.

Training PHCs within the senior centers to lead and deliver the program has empowered individuals to seek out additional advocacy opportunities. Two PHCs have joined local committees and all sites secured funding from local businesses to cover some program expenses. Building capacity within the community and discussing long-term sustainability in the beginning ensures the program will continue after the research study ends.

FORMATIVE RESEARCH OUTCOMES FOR THE SMART TELEVISION EXERCISE PROGRAM FOR INDEPENDENT LIVING FACILITIES STUDY (STEP FOR LIFE)

Valerie H. Myers, PhD[1], Courtney Fultineer, MPH[2], Sophia M. Strickfaden, BA[1], Antonio Galvan, MS[3]

[1]Klein Buendel, Inc., Golden, CO; [2]Colorado Foundation for Public Health and the Environment, Denver, CO; [3]Life Care Service, Plainfield, IL

Despite its significance in maintaining functional independence, physical activity (PA) is lowest among Older Adults (OA). Streaming technology offers innovative potential in delivering personalized wellness programs to OAs. *STEP for LIFE* is an NIH-funded study evaluating the feasibility of a PA program for senior adults residing in Independent Living Facilities (ILF) using interactive web-enabled television that can be individually tailored. Study goals are to 1) examine both individual- and organizational-level factors to inform translation of PA for OAs into a scalable delivery medium, and 2) inform future translation of other evidence-based health promotion programs with OAs and other senior living settings. To guide prototype development, a national sample of ILF residents (n=136; mean age 82.4 +/- 6.9 years; 91% White; 67.9% female) and ILF administrators (n=51; mean age 41 +/- 13.1 years; 80% White; 72% female) were surveyed. Administrators were asked to assess the type, quality, quantity, and attendance of PA programs available for their residents and the organizational decision-making process and level of interest in technology approaches for delivery of PA programs. Results revealed that 88% strongly agreed that providing organized PA programs was important, that a variety of approaches were used to promote organizational programs (word of mouth, newsletters, family members, etc.), and on average, half of the facilities had regular resident participation. Less than 16% of administrators disagreed that a SmartTV exercise program would be helpful or of interest. Over 70% of administrators indicated that the ability to tailor the exercise would be highly appealing. ILF residents were surveyed on their exercise and social activities, and use and comfort with different technologies. Results revealed that 90% rated their health as good or very good, 51.3% participated in a PA program at their facility 2-3 times a week, and 37.3% reported 5-8 hours a day of sitting. Over 83% reported comfort using the Internet and 59.7% reported comfort with using a tablet device. Nearly 63% reported that with some help or training they would be agreeable to trying a SmartTV exercise program. To further inform prototype development, focus groups and semi-structured

interviews were also conducted. Real-world usability testing is currently underway. Survey and formative research results as well as the quantitative outcomes from the completed study will be presented.

Paper Session 37: Older Adult's Physical Activity: Determinants and Interventions 3:37 PM-3:54 PM

TESTING PSYCHOSOCIAL MEDIATORS OF INTERVENTION STRATEGIES TO PROMOTE PHYSICAL ACTIVITY IN OLDER ADULTS

Siobhan K. McMahon, PhD, Beth Lewis, PhD, J Michael Oakes, PhD, Weihua Guan, PhD, Jean Wyman, PhD, Alexander J. Rothman, PhD

University of Minnesota, Minneapolis, MN

Purpose: Evidence is inconclusive about which behavioral change strategies effectively promote physical activity (PA) among older adults. Thus, we conducted an experiment testing the relative effects of two theoretically driven sets of behavioral change strategies—interpersonal and intrapersonal—delivered in combination with an evidence-based PA protocol, on average daily step count. The purpose of this study is to explore whether psychosocial constructs targeted by these behavioral change strategies can help explain why specific sets of strategies were and were not effective.

Methods: Data for this study are from a 2x2 factorial experiment in which older adults (n=102) were randomized to one of 4 conditions: (1) Otago (an evidence-based PA protocol); (2) Otago+interpersonal behavioral change strategies; (3) Otago+intrapersonal behavioral change strategies; or (4) Otago+interpersonal and intrapersonal behavioral change strategies. All participants received a PA monitor (Fitbit One^{TM}) and intervention content during 8 weekly small group (4-6 people) meetings, 90 minutes each. Data was collected at 3 time points: baseline, post-intervention, and 6 months follow-up. PA was measured as average daily step count via Fitibit monitors. Using the PROCESS macro, ordinary least squares regression models were assessed in which sets of interpersonal and intrapersonal behavioral change strategies were considered as independent variables; changes in the psychosocial constructs *social support, readiness, self-efficacy, self-regulation and goal attainment*, post-intervention--controlling for baseline--were considered mediators; and PA, post-intervention and 6 months follow-up--controlling for baseline--were considered outcomes.

Results: Participants who received interpersonal behavioral change strategies, compared to those who did not, had significantly greater increases in their average daily step count post-intervention ($p < .001$) and six months post-intervention ($p < .001$). They also reported greater increases in *readiness, self-regulation*, and *goal attainment* at both time points (p's $< .05$), but only *self-regulation* mediated the intervention-PA reltionship. Receipt of intrapersonal behavioral change strategies did not lead to an increase in PA, but was associated with higher ratings of *social support* from family by participants at both time points (p's $< .01$).

Conclusion: By exploring the psychosocial constructs targeted by specific sets of interpersonal and intrapersonal behavioral change strategies, this study contributes to current knowledge related to the development of PA interventions for older adults and suggests it may be important to target *self-regulation* through interpersonal behavioral strategies rather than intrapersonal strategies.

REDUCTIONS IN LONELINESS THROUGH EXERCISE TRAINING IN OLDER ADULTS: PSYCHOSOCIAL AND NEURAL DETERMINANTS

Diane Ehlers, PhD[1], Ana M. Daugherty, Ph.D.[2], Agnieszka Burzynska, PhD[3], Jason Fanning, PhD[4], Elizabeth Awick, MS[5], Laura Chaddock-Heyman, PhD[5], Arthur Kramer, PhD[6], Edward McAuley, PhD[7]

[1]University of Illinois Urbana-Champaign, Urbana, IL; [2]Beckman Institute for Advanced Science and Technology, University of Illinois at Urbana-Champaign, Urbana, IL; [3]Colorado State University, Fort Collins, CO; [4]Wake Forest University, Winston Salem, NC; [5]University of Illinois at Urbana-Champaign, Urbana, IL; [6]Northeastern University, Boston, MA; [7]University of Illinois at Urbana Champaign, Urbana, IL

Despite the prevalence of and negative health consequences associated with perceived loneliness in older adults, few studies have examined interactions among behavioral, psychosocial, and neural mechanisms. Research suggests that physical activity and improvements in perceived social support and stress are related to reductions in loneliness. Yet, the influence of brain structure on these changes is unknown. The present study examined whether change in regional brain volume (i.e., amygdala volume) mediated the effects of changes in social support and stress on change in perceived loneliness after an exercise intervention. We also examined the extent to which baseline amygdala volume moderated the relationship between changes in social support, stress, and loneliness. Participants were 247 older adults (65.4±4.6 years-old) enrolled in a 6-month randomized controlled trial comprised of three exercise conditions: Dance (n=69), Strength/Stretching/Stability (n=70), and Walk (n=108). All groups met for one hour, three times weekly. Participants completed questionnaires assessing perceived social support, stress, and loneliness at baseline and post-intervention. Amygdala volume before and after the intervention was measured with automatic segmentation of each participant’s T1-weighted structural MRI. Data were analyzed in a latent modeling framework, with regression coefficients presented as unstandardized estimates. Perceived social support increased ($p=0.003$), while stress ($p < 0.001$) and loneliness ($p=0.001$) decreased over the intervention. Increased social support predicted improved loneliness directly (-0.63, $p < 0.01$) and indirectly through decreased stress (-0.10, $p = 0.02$). Amygdala volume did not change over the

intervention (p=0.40) and was unrelated to change in psychosocial variables (all $p \geq 0.44$). However, individuals with larger baseline amygdalae experienced greater reductions in stress, and in turn greater decreases in loneliness (0.35, p = 0.02). No group differences in these pathways were observed. The social support environment of exercise sessions, as opposed to exercise mode, may represent an important feature of exercise programs aimed at improving older adults' perceived loneliness. As amygdala volume has been linked to anxiety, depression and impaired cognitive control processes, moderation findings suggest further investigation in this area is warranted.

Title: **GrOup based physical Activity for oLder adults (GOAL) randomized controlled trial: 3- and 6-month adherence outcomes.**

Abstract: The GrOup-based physical Activity for oLder adults (GOAL) trial was a three-arm RCT (ClinicalTrials.gov # NCT02023632) that was designed to test the efficacy of two different group-based exercise programs for older adults (informed by the tenets of self-categorization theory; SCT) in relation to a standard group-based exercise program. 630 older adults (M age = 71.44, SD = 5.36; 71.1% female) were randomized to similar-age same gender (SASG), similar-aged mixed gender (SAMG), or ‘standard’ mixed-aged mixed gender (MAMG) exercise group conditions. In addition to considering group composition, the SCT-informed conditions included older-adult instructors, and operationalized key principles and strategies from SCT designed to foster a sense of social connectedness among exercise group participants. In this paper we report the results of the trial’s primary outcome, namely adherence behavior (assessed through objective measures of class attendance) over 3 and 6 months. Based on intent-to-treat (ITT) analytic principles, analyses of covariance (controlling for pre-intervention physical activity behavior) revealed that older adults randomized to the SAMG (3 months d = .48, p = .001; 6 months d = .44, p= .004) and SASG (3 months d = .34, p= .008; d = .35, p = .01) conditions adhered to a greater extent than those in the MAMG comparison condition. At both time points these effects were invariant by gender, and the differences between the SAMG and SASG conditions were non-significant. In conclusion, the results of this RCT provide support for the efficacy of group-based physical activity programs informed by the tenets of SCT. Furthermore, the results suggest that community group-based exercise programs should attempt to engage in age-targeting but not necessarily gender-targeting among older adults.

EXAMINING DIFFERENT REACTIONS TO NARRATIVES FROM COLON CANCER SURVIVORS VS. HEALTHY SCREENERS

Amy McQueen, PhD[1], Julianne A. Sefko, M.P.H.[2], Charlene A. Caburnay, PhD, MPH[3], Matthew Kreuter, PhD[3]

[1]Washington University, School of Medicine, St. Louis, MO; [2]Washington University School of Medicine, Saint Louis, MO; [3]Washington University in St. Louis, St. Louis, MO

The use of patient narratives or testimonials in interventions and on the Internet is becoming ubiquitous, and has outpaced empirical research regarding how and for whom narratives are effective. Most research has compared narratives with didactic messages rather than compare across narratives. To inform future interventions that incorporate narratives, we tested the effects of different role models (”survivors” vs. “screeners”) for increasing colorectal cancer screening (CRCS) intentions and behaviors. We randomized adults age 50-75 not adherent to CRCS guidelines with no history of cancer to one of three groups: 1) CRCS information only, 2) CRCS info plus a narrative from a CRC survivor, or 3) CRCS info plus a narrative from a healthy CRC screener. Role model photos were tailored to the participant’s sex, age group and race/ethnicity. Participants (n=487) completed surveys online before and after the intervention and at 1 & 6 month follow up. We used structural equation modeling (AMOS 16) to test our conceptual model of the direct and indirect effects of narratives on CRCS intention and behavior via post-exposure mediators including engagement, emotions, message acceptance, and psychosocial determinants of CRCS, controlling for significant covariates. Results showed good model fit. Narratives were more engaging (β=.27,$p < .001$) and emotionally evocative (β=.10,$p < .01$), but less believable (β= -.09,$p < .01$) than information only. Engagement was related to greater perceived benefits and social norms for CRCS ($p < .001$); greater affect was related to perceived risk, worry and intention ($p < .01$). Survivor (vs. screener) stories aroused more negative emotions (β=.33,$p < .001$) which was related to greater perceived risk, worry, barriers, and info avoidance ($p < .001$). Survivors were perceived as less similar to participants (β= -.13,$p < .05$), which was positively related to message acceptance and social norms ($p < .001$). Survivor stories produced less self-relevant engagement (β= -.22,$p < .001$), which was related to greater perceived risk, benefits, norms, self-efficacy, and intention; less counterarguing and perceived barriers. Only intention post-intervention predicted CRCS by 6 months follow up. Cancer survivor narratives evoke more negative emotion and reduced self-related engagement and identification which may

indirectly undermine message effects on CRCS. Understanding the mechanisms of how different role models influence health behaviors is important for selecting or creating effective narratives.

REACTIONS TO COLORECTAL CANCER RISK ESTIMATES AMONG A NATIONALLY REPRESENTATIVE SAMPLE OF ADULTS WHO HAVE NEVER BEEN SCREENED

Constance M. Johnson, PhD[1], Sathya Amarasekara, MS[2], Wei Pan, PhD[1], John A. Updegraff, PhD[3], Isaac Lipkus, PhD[4]

[1]Duke University, Durham, NC; [2]Duke University Health System, Durham, NC; [3]Kent State University, Kent, OH; [4]Duke University School of nursing, Durham, NC

Screening for colorectal cancer (CRC), the 3rd leading cause of cancer death among men and women in the United States, saves lives. Yet, among adults ages 50 to 75, about 30% have never been screened. Internet-based strategies that deliver tailored CRC risk estimates can promote screening, especially among those at higher risk. To be effective, recipients of feedback should be able to extract their risk level delivered online, find the risk estimate accurate and useful, and it should influence their perceived CRC risk. We examined these reactions to online tailored CRC risk estimates among adults who have never been screened for CRC. Potential participants were recruited from GfK's Knowledge Networks online panel, a panel representative of the U.S. population. Eligible participants were between the ages of 50 to 75 who self-reported never having been screened. Using the Harvard Disease Risk Index algorithm, participants received tailored 10-year risk of getting CRC compared to others their age and sex ranging from very much below average to very much above average – seven levels of risk total. Participants were asked to recall their estimate and rate on a 7-point Likert scale its accuracy and usefulness, as well as their perceived comparative 10-year risk from very much below average to very much above average. Among the 619 participants who qualified, mean age was 58 (SD=6.4), 46% were male, and 75% were Non-Hispanic, White; 39% of the sample had a high school education or less. The mean level of the tailored comparative risk estimate was average. Overall, 29% of the sample could not reflect back their estimated risk. Greater inaccuracy was higher among the less educated. Perceived comparative risk was slightly below average (M=3.2; SD=1.3) and correlated with the risk estimate (r=.40, $p < .0001$). The risk estimate was viewed as somewhat accurate (M=4.0, SD= 1.3) and somewhat useful (M=4.7, SD=4.7). These reactions varied by risk estimate. With increasing risk, estimates were viewed as less accurate (r=-.14, $p < .05$) and less useful (r=-.28, $p < .001$). Findings suggest that many individuals, especially the less educated, have trouble extracting their online risk estimate and view it as less acceptable (e.g., accurate, useful) with higher degree of risk, pointing to defensive processing. Strategies to curb these potential barriers to online risk communication strategies to promote CRC screening targeting adults who have never been screened appear warranted.

Paper Session 38: Understanding Risk Perception 3:37 PM-3:54 PM

DIFFERENT TYPES OF RISK: RISK UNCERTAINTY VARIES BY RISK FRAMING.

Caitlin Biddle, MA, MS[1], Jennifer Hay, PhD[2], Erika A. Waters, PhD, MPH[3], Marc T. Kiviniemi, BA, PhD[1], Heather Orom, PhD[1]

[1]University at Buffalo, Buffalo, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Washington University in St. Louis, St. Louis, MO

Purpose: There is debate over the conceptualization and measurement of risk perception. A variety of measurement approaches have been employed, including assessing perceived risk as an absolute or comparative judgment and attempting to capture the corrections people make in their risk judgments based on their past or expected behavior (conditional risk). In order to assure that our measurement strategies are valid, it is important to understand whether people are able to make meaningful judgments in response to researchers' risk perception questions. The purpose of this study was to compare participants' level of uncertainty about their risk judgments based on measurement approach.

Methods: Participants were 280 MTURK workers (median education = some college; 80% White; mean age = 34(SD = 9)) who completed an on-line survey. We assessed conditional and non-conditional absolute and comparative heart disease risk using a Likert-type scale with a "don't know" option. Those who chose a "valid" response (don't know responders were excluded) were asked to rate their certainty about their judgment. Paired t-tests were used to compare mean certainty of participants' risk as a function of 1) being conditioned on healthy behavior change and 2) framed as absolute vs. comparative risk.

Results: More people reported being uncertain or very uncertain about their absolute risk and non-conditioned risk: 66.36% of participants were uncertain about absolute risk, 44.35% about comparative risk, 31.45% about conditional absolute risk, and 29.30% about their conditional comparative risk. For both absolute and comparative heart disease risk, participants were more uncertain about their non-conditional risk (mean difference= -.5, t = -8.8, p < .001; mean difference= -.3, t = -6.1, p < .001) than conditional risk. For both conditional and non-conditional risk, participants were more uncertain about their absolute risk than comparative risk (mean difference= -.09, t = -2.0, p=.02; mean difference= -.27, t = -6.4, p < .001).

Discussion: Even after eliminating individuals who say that they don't know their risk, participants were uncertain about their judgments. The way participants are asked to appraise their risk contributes to this uncertainty; participants are more uncertain about non-

conditional than conditional judgments and about absolute than comparative judgments. While our previous research demonstrates that lack of knowledge contributes to uncertainty about risk, this association does not explain why levels of uncertainty vary by question format. Non-conditional and absolute risk items are more ambiguous and may be more difficult to answer for participants because there a lack of information or no frame of reference, which may lead to more uncertainty.

BARRIERS AND PROMOTERS OF COMMUNICATION ABOUT FAMILY CANCER HISTORY AMONG AFRICAN-AMERICANS IN BALTIMORE

Melinda Krakow, Phd MPH[1], Gypsyamber D'Souza, PhD[2], Rebkha Atnafou, MPH[2], Anne Rositch, PhD, MSPH[2]

[1]National Cancer Institute, Washington, DC; [2]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Objective. Although cancer is the second leading cause of deaths for Americans, African-Americans remain more likely to die from cancer than any other racial or ethnic group in the U.S. Family cancer history (FCH) plays a key role in shaping individual prevention and early detection behaviors to decrease cancer risk. However, many individuals may lack knowledge of FCH, and be unaware of increased risk for cancers based on family patterns. For some African-American communities, a lack of communication about FCH is pronounced and barriers to this communication have not been well studied. To optimize the use and impact of FCH, it is crucial to better understand how patients gather and share FCH with family members, and discuss information with healthcare providers.

Methods. We conducted four community focus groups (40 participants) and seven key informant interviews (9 participants) to investigate knowledge and experiences of FCH and barriers/promoters of FCH in the East Baltimore African American community.

Results. Thematic analysis of transcripts identified 11 distinct themes across 4 topic areas: Definitions of FCH, past FCH communication, and barriers/promoters of FCH. FCH was most often defined by narratives of cancer experienced by individual family members, rather than records or patterns of disease over time. The majority of participants had gathered or shared little or no FCH information with family members. Three psychosocial domains (fear/denial, pride/dignity, and fatalistic attitudes about cancer) were commonly reported barriers to sharing family cancer history. Additionally, distrust/skepticism about medical care was a barrier to sharing FCH with healthcare providers. Diagnosis/death of a loved one and need for caregiving/social support promoted FCH communication and encouraged cancer prevention behaviors such as screening.

Conclusion. Although most participants had experienced cancer in their families, reported communication about FCH was low and psychosocial barriers were common. Understanding these communication domains in minority populations is crucial to addressing disparities in

cancer prevention, particularly where effective screening and care recommendations exist for those with positive family histories. Community-based interventions are needed to improve understanding of FCH, address common barriers, and provide communication tools to promote family cancer history communication among African American families in Baltimore.

PERCEIVED THREAT AND PRESSURE RELATED TO SPORT ACHIEVEMENT EXPLAIN WHY SOME SPORT PARENTS DON'T TALK ABOUT CONCUSSIONS

Emily Kroshus, ScD MPH

University of Washington, Seattle, WA

Early identification and removal from play of athletes who have sustained a concussion is an important aspect of reducing concussion-related harm. This process is often dependent on athlete self-report of injury. Prior research finds that some athletes experience pressure from their parents to continue playing with concussion symptoms (Kroshus et al., 2015). However, it is not clear whether this perceived pressure is the result of direct communication or whether it is inferred from factors such as parent investment in their sporting career. As one step towards addressing this gap in the literature, the present study examines parent-described direct communication to encourage concussion reporting, testing three hypotheses. First, that greater perceived susceptibility to and seriousness of concussion would be associated with greater parent-child communication about the importance of seeking care for a suspected concussion. Second, that parents who put more pressure on their child related to sport achievement would be less likely to encourage care seeking. Third, that there would be a significant interaction between parent attitudes about the child’s sport participation and perceived seriousness and susceptibility in predicting concussion care seeking communication, with the relationship between perceived severity, susceptibility and communication being weaker among parents who put more sport achievement pressure on their child. Participants were 246 parents of competitive youth club soccer players (ages 8-18 years) in a league located in a large urban center in the northwest region of the United States who completed an anonymous online survey. Across the full sample, just over two thirds of parents (68.38%) indicated that they communicated with their child about the importance of reporting suspected concussions. Consistent with the Health Belief Model (Rosenstock, 1974) and as presently hypothesized, parents who believed that their child was more likely to sustain a concussion were more likely to encourage their child to report symptoms of a suspected concussion. However, parents who believed that the consequences of this concussion would be more harmful were significantly less likely than other parents to encourage concussion reporting. Further, there was an interaction between parent pressure and concussion severity in that when parents reported greater pressure for sport achievement on their child, the association between perceiving concussions to be more harmful and encouraging concussion symptom reporting was significantly less strong. Results will be discussed in the context of fear appeals, and the implications that these findings have for the development of health

education targeted at parents of youth sport participants to encourage concussion safety-supportive communication.

Paper Session 39: African American Women's Health 3:00 PM-3:18 PM

A QUALITATIVE EXAMINATION OF THE INFLUENCE OF CULTURE ON ENGAGEMENT IN PHYSICAL ACTIVITY AMONG BLACK WOMEN

Allyson Diggins, M.A. , Nicole Whitehead, PhD

University of Florida, Gainesville, FL

Despite the noted benefits of physical activity, engagement among minorities and women, particularly Black women, remains low. In response to the lower rates of physical activity among Black women, there has been an increase in intervention studies promoting physical activity. However, intervention studies for both inactive and underactive Black women have produced modest success in short-term engagement and almost no success in long-term maintenance. Understanding cultural context may be instrumental to developing effective and sustainable solutions to address health disparities associated with inactivity. Therefore, the purpose of the current investigation was to gain a better understanding of how culture influences Black women's experiences with physical activity. Specifically, the associations between cultural values, beliefs and attitudes and participation in physical activity were examined. Data were collected using individual semi-structured interviews with participants (N=12). The interview guide was designed to address common factors related to physical activity adoption while also discovering additional factors. Women ranged in age from 19-52 (M = 29.38). Mean income for the sample was $33,100 (SD = 25.34). Participant BMIs ranged from 18.60 to 47.30, with 42% being classified as overweight or obese. Audiotapes of the interviews were transcribed verbatim and thematic analysis was used to generate key themes. Emergent themes were then summarized, interpreted and categorized using the PEN-3 Model. Women identified the need for psychoeducation related to health versus aesthetic benefits of physical activity, significance of communal support, the role of spirituality, acceptance of larger body sizes as a barrier to a physically active lifestyle, lack of exposure to physical activity as a familial/cultural norm, and the tendency to prioritize others over themselves. Analysis of interviews conducted with this sample of women suggests an interplay among the PEN-3 domains and physical activity behavior, with implications for the design of culturally sensitive interventions. Results support the importance of incorporating culture into the development and dissemination of an intervention. Thus, physical activity interventions should aim to incorporate these perspectives without focusing exclusively on cultural barriers. Instead, culture should be used to understand and then empower Black women to increase their levels of physical activity while still remaining true to their culture.

Paper Session 39: African American Women's Health 3:19 PM-3:36 PM

PATIENT OPINIONS ON THE DESIGN OF A RACIALLY TAILORED EXERCISE INTERVENTION FOR BLACK INDIVIDUALS WITH MULTIPLE SCLEROSIS

Dominique Kinnett-Hopkins, B.S. [1], Robert W. Motl, PhD[2]

[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]University of Alabama at Birmingham, Birmingham, AL

Black individuals with multiple sclerosis (MS) experience a more aggressive disease course and worse comorbidity and prognosis with disease modifying drug therapies than white individuals with MS. This requires further consideration of approaches for managing MS in this population, and one approach may be exercise training. There is substantial evidence of the benefits of exercise training for managing the disease, yet the samples have been mostly white. We further note that black individuals with MS engage in less physical activity and exercise than white counterparts. This necessitates the need for developing a racially targeted exercise training program for black individuals with MS. Such an intervention should include patients during the designing phase, as the range of input is invaluable when creating the best-suited exercise program for this population. To that end, we conducted a survey among black individuals with MS about the development of a targeted-exercise training program. Participants answered a series of items administered through Qualtircs (Prove, UT) regarding demographics and opinions of an ideal exercise program, the importance of racial considerations, and current physical activity levels. 40 black individuals with MS (age of 52.24 ± 8.95, BMI of 30.39 ± 9.28 kg/m^2, & 92.5% female) completed the survey. The mean physical activity score was 44.54 ± 22.19. Regarding the exercise program, participants wanted to exercise 5.0 ± 1.6 days per week at a moderate intensity (50% of participants). 62.5% of participants desired an exercise program that was longer than 6 months, with 57.5% of participants wanting the aid of a behavioral coach for supporting exercise behavior change. The desired program consisted of mainly resistance/weight training exercises (52.5%) and easy walking (35%). The expectations from exercising were primarily to increase muscle strength (65%), to improve overall body functioning (60%), increase ability to perform daily activities (57.5%) and to help manage stress (57.5%). The anticipated barriers to exercise were largely fatigue (40%) and not having enough time (32.5%). There was variation in the importance of racial considerations in the design of the program. The data from this study should be considered when creating an exercise training intervention for black individuals with MS.

SIX MONTH PHYSICAL ACTIVITY AND PSYCHOSOCIAL OUTCOMES FROM THE HIPP STUDY FOR AFRICAN AMERICAN WOMEN IN DEEP SOUTH

Dori Pekmezi, PhD[1], Matthew C. Ainsworth, MPH[1], Rodney P. Joseph, PhD[2], Karen Meneses, PhD, RN, FAAN[1], Bess H. Marcus, Ph.D.[3], Wendy Demark-Wahnefried, PhD RD[4], Renee Desmond, xx[5], Victoria A. Williams, MPH, MED, CHES [6], Elizabeth A. Kvale, MD, MSPH[1]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]Arizona State University, Phoenix, AZ; [3]University of California, San Diego, La Jolla, CA; [4]UAB, Birmingham, AL; [5]xx, xx, AL; [6]University of Alabama at Birmingham, Atlanta, GA

Purpose: To establish the feasibility and acceptability of a Home-based, Individually-tailored Physical activity Print (HIPP) intervention for African American women in the Deep South.

Methods: A pilot randomized controlled trial was conducted to test the HIPP intervention (N=43) vs. wellness contact control arm (N=41). Physical activity (7-Day Physical Activity Recall interviews, accelerometers) and related psychosocial variables were assessed at baseline and 6 months.

Results: The sample was recruited in Birmingham, AL and included 84 overweight or obese African American women between the ages of 50-69. Retention was high at 6 months (90%). Group differences in physical activity and related psychosocial variables at 6 months were examined with a generalized linear model controlling for baseline values. On average, HIPP intervention participants reported larger increases (M=+73.9 minutes/week, SD=90.9) in moderate intensity physical activity from baseline to 6 months than the control group (+41.5, SD=64.4), p> .05. The intervention group reported significantly greater improvements in physical activity goal-setting and enjoyment from baseline to 6 months compared to the control group. There were no other significant group differences [weight, BMI, % body fat (BIA), 6MWT, physical activity planning, behavioral processes of change, stage of change]; however, trends in the data for cognitive processes of change, self-efficacy, outcome expectations, and family support for physical activity indicated small improvements for the HIPP arm (P> .05) and declines for the control arm. Significant increases in waist circumference and decreases in decisional balance and friend support for physical activity from baseline to six months were observed in the control arm and not the intervention arm. Of the 36 intervention participants surveyed at follow-up, most reported being satisfied with the HIPP program and finding it helpful (N=33, 91.67%). Almost all (N=35, 97.22%) would recommend it to a friend.

Discussion: The HIPP intervention has great potential as a low cost, high reach method for reducing physical activity-related health disparities. The approach was well received by our sample. The lack of improvement in some domains may indicate that additional resources and supports will be required to help this target population reach national guidelines for MVPA (> 150 minutes/week of moderate intensity physical activity).

Paper Session 39: African American Women's Health 3:55 PM-4:12 PM

OPTIMIZING SOCIAL COGNITIVE THEORY IN THE DESGIN OF PHYSICAL ACTIVITY PROGRAMS FOR AFRICAN AMERICAN WOMEN: A QUALITATIVE STUDY

Rodney P. Joseph, PhD[1], Barbara E. Ainsworth, PhD, MPH[1], Steven P. Hooker, Ph.D.[1], Colleen Keller, PhD[2]

[1]Arizona State University, Phoenix, AZ; [2]Arizona State University, phx, AZ

Introduction. The Social Cognitive Theory (SCT) is one of the most widely used theories in physical activity (PA) promotion research. Through focus group methods, this study examined the cultural relevance of five SCT constructs in the design and acceptability of a PA intervention for sedentary and obese African American (AA) women.

Methods. Twenty-five AA women (*M* age = 38.5 years, *M* BMI = 39.4 $kg{\cdot}m^2$) were enrolled in a series of 3 focus groups held over a 6 week period. Focus group guides were designed to gain information on how five SCT constructs can be culturally tailored in the design of a PA program for AA women: self-efficacy, self-regulation, behavioral capability, outcome expectations, and social support. Focus groups were audio recorded and transcribed verbatim. Content analysis was used to capture and extend knowledge and understanding of cultural and contextual resources for participation in a theory-based PA intervention for AA women.

Results. Participants provided in-depth data on how the five SCT constructs examined were relevant and can be leveraged in the design of a PA program for AA women. Pertaining to the construct of behavioral capability, AA women were generally unaware of the amount, intensity, and types of PA needed for health benefits. Participants discussed a variety of outcome expectations associated with regular PA engagement, including increased energy, improved functional status, weight loss, and positive role modelling behaviors. Results for the constructs of self-efficacy and self-regulation indicated that women perceived their own intrapersonal processes as their primary barrier to PA and that PA programs should: a) leverage an AA women’s previous positive experiences with PA (i.e., during childhood and early adulthood), and b) illustrate how PA is relevant to their familial, societal, and caretaking roles. For the construct of social support, participants endorsed the need of a strong social support component with a variety of sources acceptable to include in a PA program (i.e., family members, other study participants, friends).

Conclusions. Findings highlight the utility of the SCT as a theoretical basis for PA programs for

AA women. PA programs should clearly outline the dose and intensity of PA necessary to achieve health benefits. Programs should also leverage AA women’s previous positive experiences with PA and illustrate how PA is relevant to their familial, societal, and caretaking roles.

Paper Session 39: African American Women's Health 4:13 PM-4:30 PM

EXAMINING PEER SUPPORT AND SURVIVORSHIP OUTCOMES FOR AFRICAN AMERICAN WOMEN WITH BREAST CANCER

Shannon E. Nicks, PhD, MPH[1], Ricardo Wray, PhD, MS[2], Sherrill Jackson, MHSA, RN, CPNP[3], Olivia Peavler, MPH[4], Stephanie McClure, PhD, MPH[2], Theresa Schwartz, MD[2]

[1]Ohio University, Athens, OH; [2]Saint Louis University, St. Louis, MO; [3]The Breakfast Club, Inc., Florrisant, MO; [4]Mayo Clinic, Rochester, MN

More than three million female breast cancer (BrCa) survivors live in the United States, and the number continues to grow. Health status and quality of life amongst survivors is variable, and African American (AA) BrCa survivors suffer disproportionately from BrCa morbidity and mortality. Emerging evidence suggests peer support is an effective strategy to promote positive survivorship outcomes for AA women with BrCa. The aim of this study was to explore the role of structured peer support in the BrCa experiences of AA survivors. The research team worked collaboratively with The Breakfast Club, Inc. (BCI), a community-based BrCa support and advocacy organization with twenty years of experience providing peer support to survivors, to compare similarities and differences in the survivorship experiences of AA women with BrCa according to receipt of structured peer support. Data were collected, analyzed and triangulated from three sources to generate findings. These sources included: participant observations of BCI members attending monthly support group meetings, key informant interviews with BCI leadership and semi-structured interviews with two groups of AA BrCa survivors, such that one group of survivors received structured peer support (in addition to social support from other sources) and a comparable group of survivors received standard care (only social support from other sources). Triangulated results indicate that peer relationships function to assure social connectedness and provide consistent, quality social support in addition to or in the absence of support from other sources. This consistent peer support helps survivors cope with the continued stress of BrCa and may result in better psychosocial health and quality of life. These findings expand our current understanding of peer support and may enable public health and clinical practitioners to promote improved quality of life during survivorship by better recognizing and intervening with those for whom additional support services are needed.

Paper Session 40: Skin Cancer Prevention: Policies, Intentions and Measurement 3:00 PM-3:18 PM

SUNSCREEN APPLICATION KNOWLEDGE AND REPORTING IN SURVEY FORMAT

Anne Julian, M.A., Sheryl Thorburn, PhD, MPH

Oregon State University, Corvallis, OR

Background: Sunscreen use is the most commonly reported method of UV protection in the U.S. Despite increasing public awareness of the risks of UV exposure, skin cancer incidence has increased over the past decades. The effectiveness of sunscreen against the harms of UV depends on proper application, and consumers frequently do not apply adequate sunscreen to achieve the advertised SPF. The purpose of this study was to examine reported sunscreen application, knowledge of proper sunscreen use, and quantity of sunscreen used.

Method: Undergraduate students (N = 335) from a university in Oregon completed an online survey about their UV exposure beliefs and behaviors. Sunscreen use was measured with the original and modified versions of NHIS sunscreen use frequency item. Sunscreen quantity used was measured with two items; response options offered 1) a choice of written descriptions of sunscreen quantity (i.e., 1/2 tsp.) and 2) an array of photographic depictions of quantities of sunscreen in a hand, with a coin included for scale. Univariate and bivariate analyses were performed first on the full sample and then stratified by gender.

Results: Whereas 34% of respondents reported using sunscreen consistently (i.e., “almost always” or “always”) on warm sunny days, only 9% reported consistent sunscreen use on most days. The majority of participants (89%) either did not know (48%) or reported incorrectly (41%) the amount of sunscreen needed to achieve the advertised SPF. Sunscreen use among participants who responded that they did not know the amount of sunscreen needed did not significantly differ from use among participants who believed they knew the appropriate amount (p = .22). Reported quantity of sunscreen applied was inconsistent between the two formats of sunscreen quantity measurement (Weighted kappa = .20).

Discussion: Inconsistent and inadequate application of sunscreen is a challenge for skin cancer prevention. Perceived lack of knowledge, however, was not associated with use of smaller or larger amounts of sunscreen used. Inconsistent responses between written and photographic items measuring sunscreen use highlight the need for more accurate measures of sunscreen application. Future research is needed to clarify how sunscreen users decide when and how much sunscreen to apply and to validate items measuring sunscreen use.

PROJECT SOL: TESTING A SUN-SAFETY PROGRAM FOR HISPANIC OUTDOOR DAY LABORERS

Elliot Coups, PhD[1], Carolina Lozada, MPH[2], Michele Ochsner, Ph.D.[3], Louis Kimmel, BA[4], Germania Hernandez, N/A[4], Reynalda Cruz, N/A[4], Ashley Day, Ph.D. [2], Daniel Giovenco, MPH[5]

[1]Rutgers, The State University of New Jersey, New Brunswick, NJ; [2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; [3]Rutgers University, New Brunswick, NJ; [4]New Labor, New Brunswick, NJ; [5]Rutgers School of Public Health, Piscataway, NJ

Introduction: Individuals who work outside often encounter high temperatures, humidity, and excess exposure to the sun's ultraviolet (UV) rays. These factors increase the risk for heat illness (heat exhaustion/stroke), sunburns, skin damage, and skin cancer. Hispanic individuals in the United States are over-represented in many outdoor occupations, including landscaping and construction. Few interventions have been tested to promote sun-safe behaviors among Hispanic outdoor workers. In Project SOL (Sun-safety for Outdoor Laborers), we evaluated the impact of a sun-safety program for Hispanic outdoor day laborers (who typically seek work in informal, open-air urban settings such as street corners).

Methods: 119 Hispanic men (39% Mexican, 28% Ecuadorian, 13% Honduran; *M* age 39 years) were recruited from outdoor locations where day laborers commonly congregate in New Brunswick, NJ. We trained peer trainers, who delivered a Spanish language, culturally targeted, 2-hour sun-safety program to groups of 7–22 individuals. Guided by a participant workbook (developed using preliminary focus group and survey research), trainers led participants through small group activities focused on the risks and precautions associated with high heat, humidity, and UV exposure. Participants completed a survey immediately prior to and after the program that included questions on sunburns and heat illness symptoms last summer, sun-safety knowledge (8 *true-false* items), frequency of engaging in sun-safe behaviors (8 items, 5-point *never* to *always* scale: taking regular breaks, drinking water, working in the shade, and wearing a long-sleeved shirt, long pants, a wide-brimmed hat, sunglasses, and sunscreen) while working outdoors last summer and intended frequency next summer, and an evaluation of the program's content and format (9 items, 5-point *strongly disagree* to *strongly agree* scale).

Results: Most participants reported having a sunburn (66%) and/or heat illness symptoms (66%) last summer.Sun-safety knowledge increased significantly from before to after the program (*Ms* = 4.4, 6.5 items correct, $t = 13.3$, $p < .001$). The frequency of engaging in sun safe-behaviors as a whole last summer was low (*M* = 3.0) and the intended frequency was significantly higher after the program (*M* = 4.2, *t* = 14.5, *p* < .001). Statistically significant increases were also seen separately for each of the 8 behaviors (*t*s ≥ 3.4, *p*s ≤.001). Participants evaluated the program very favorably (*M* = 4.7 out of 5).

Conclusions: We demonstrated the feasibility of delivering a peer-led sun-safety program to Hispanic outdoor day laborers. The program was well-received by participants and there were increases in knowledge and sun-safe behavioral intentions after the program. Future research is warranted to test the impact of the program on behavioral outcomes and to explore potential dissemination approaches.

THE IMPACT OF INDOOR TANNING LEGISLATION ON INDOOR TANNING PREVALENCE IN ALABAMA

Aaron Blashill, Ph.D. [1], Sherry Pagoto, PhD[2]

[1]San Diego State University, San Diego, CA; [2]University of Massachusetts Medical School, Worcester, MA

A growing list of U.S. states have enacted restrictions on minor's use of indoor tanning; however, few studies have examined the impact of these restrictions.

In 2014, Alabama passed HB 254, which enacted a series of restrictions on indoor tanning among minors. Analyzing changes in the prevalence of indoor tanning between 2013 and 2015 may provide some evidence for the impact of HB 254. Moreover, data from Florida were included as a control, as the only restriction in place in Florida during 2013-2015 is a ban in indoor tanning for minors under 14.

Data were extracted from the 2015 Alabama and Florida YRBS. These surveys are conducted every two years and assess health risk behaviors among 9-12 grade public and private school students. The Alabama and Florida surveys are of representative samples of the entire population of high school students in their respective states. Indoor tanning was assessed with the item: "During the past 12 months, how many times did you use an indoor tanning device, such as a sunlamp, sunbed, or tanning booth? (Do not count getting a spray-on tan)." As in previous studies, this item was dichotomized as "0 times" vs. "1 or more times." The total employed sample was *N* = 14,389 (population *N* = 1,864,241). Mean age of participants was 16.10 (*SD* = 1.20). Given differences in the prevalence of indoor tanning by age and sex, all analyses were stratified by sex and age. Four levels of age were created: 14, 15, 16-17, and 18 year olds. This approach allows a test of the various indoor tanning regulations enacted within Alabama. Logistic regression models were used, with the independent variables of year (2013 vs. 2015), state (Alabama vs. Florida), and the year by state interaction term. The dichotomous indoor tanning variable was set as the criterion variable. Complex Samples in SPSS 24 was used to account for weighting, clustering, and stratification, allowing for population based estimates.

Female High School Students

Within each age group, only significant main effects of state emerged, with Alabama girls reporting higher indoor tanning compared to Florida girls. No significant main effects of time or state by time interactions were significant for any age group.

Male High School Students

Within each age group, only significant main effects of state emerged, with Alabama boys reporting higher indoor tanning compared to Florida boys. No significant main effects of time or state by time interactions were significant for any age group.

The current study found no significant changes in indoor tanning among teens since the enactment of Alabama's tanning restrictions. More oversight and monitoring is needed to assure that indoor tanning facilities are compliant with emerging laws. As the FDA considers a national ban on minor's use of indoor tanning, enforcement interventions will be necessary to realize its impact.

Paper Session 40: Skin Cancer Prevention: Policies, Intentions and Measurement 3:55 PM-4:12 PM

RESULTS OF A CROSS-NATIONAL RANDOMIZED TRIAL ON THE EFFECT OF BUILT SHADE ON USE OF RECREATION AREAS IN PUBLIC PARKS

David Buller, PhD[1], Suzanne J. Dobbinson, BSc, MSc, PhD[2], Dallas R. English, PhD[2], Melanie Wakefield, Professor[3], Mary K. Buller, M.A.[1]

[1]Klein Buendel, Inc., Golden, CO; [2]Cancer Council Victoria, Melbourne, Victoria, Australia; [3]Cancer Council Victoria, Melbourne, Victoria, N/A, Australia

Shade use is recommended to prevent skin cancer. A randomized controlled trial tested the hypothesis that individuals were more likely to use recreation areas in public parks in which shade was introduced (i.e., ultraviolet protection factor [UPF]-rated shade cloth structures) than unshaded control areas. Shade was built in public parks in Denver, Colorado (US) and Melbourne, Victoria (Australia) to test also if built shade would increase use of the recreation areas more in Australia with its 25-year-long skin cancer prevention campaign than in the United States. Public parks (n=144) containing two unshaded passive recreation areas (PRA) suitable for building shade (study and comparison PRAs) were selected in three annual waves. Following pretest, parks were randomized in a 1:3 ratio to built shade or unshaded control. Primary outcome was observation of whether the study PRA was in use during four 30-minute observations at pretest and posttest on weekends between 11 am and 3 pm in summer months. Adjusting for clustering of observations within parks, analyses showed that shaded PRAs (probability of PRA in use: pre=0.09, post=0.31) were more likely to be in use at posttest than unshaded control PRAs (pre=0.13, post=0.15), odds ratio (OR)=3.87, 95% CI=1.70, 8.82 (adjusted for wave, pretest, weather [temperature, cloud cover, and wind], type of recreation, comparison PRA use, user age and race [proportion white]). City moderated the impact of shade on PRA use, OR=2.90, 95% CI=1.07, 7.84. Shade increased the probability of PRAs in Denver being in use (control: pre=0.17, post=0.18; shaded: pre=0.14, post=0.47) but the increase was not statistically significant in Melbourne (control: pre=0.10, post=0.13; shaded: pre=0.05, post=0.17). Purpose-built shade may improve sun protection (i.e., shade use) in public spaces. Shade can be a good public investment because a) many attractive, protective designs are available and b) it requires less pre-planning than other sun protection practices (e.g., clothing and sunscreen). Differences in existing shade, amenities in the parks and near PRAs, and public sun safety campaigns may explain the unexpectedly higher use of shaded PRAs in Denver than Melbourne.

EFFECT OF AN INTERVENTION ON OBSERVED SUN PROTECTION BY VACATIONERS IN A RANDOMIZED CONTROLLED TRIAL AT NORTH AMERICAN RESORTS

David Buller, PhD[1], Peter A. Andersen, BA, MS, PhD[2], Barbara Walkosz, PhD[3], michael Scott, Phd[4], Larry Beck, Ph.D.[5], Gary R. Cutter, MS PhD[6]

[1]Klein Buendel, Inc., Golden, CO; [2]San Diego State Unversity, Jamul, CA; [3]Klein Büendel, Inc., Wheat Ridge, CO; [4]CSU, Chico, Santa Fe, NM; [5]San Diego State University, La Mesa, CA; [6]UAB School of Public Health, Vestavia Hills, AL

High-risk sun exposure often occurs during vacations. An intervention based on Transportation and Diffusion of Innovation Theories comprised of posters, brochures, audiovisual, and online (website and social media) messages promoting comprehensive sun protection (clothing, hats, sunscreen and reliable cues to solar UV) targeted vacationers. It was evaluated with a sample of 41 North American warm-weather destination resorts in 17 states enrolled in a pair-matched, group-randomized pretest-posttest controlled quasi-experimental design in 2012-14. Resorts were randomly assigned to receive the intervention or remain no-treatment controls. Sun protection practices were observed in cross-sectional samples of vacationers who appeared 18 or older at pretest (n=4,347) and posttest (n=3,986) by trained research staff during two-day visits to resorts. Vacationers' sun protection (i.e., composite z-score measure of body coverage and use of shade) did not differ by experimental condition ($p>0.05$) or extent of intervention implementation ($p>0.05$). However, recreation venue moderated intervention impact. The intervention improved comprehensive sun protection at waterside (pools and beaches) recreation venues (intervention pre=-22.74, post=-15.77; control pre=-27.24, post=-23.24) but not at non-waterside (golf, courts, and dining) venues (intervention pre=20.43, post=20.53; control pre=22.94, post=18.03, p pre=-25.45, post=-14.05; low implementation pre=-24.70, post=-21.40) compared to non-waterside (high implementation pre=14.51, post=19.98; low implementation pre=24.03, post=18.98, $p < 0.01$) recreation venues. The intervention was effective with vacationers in recreation venues with the highest-risk sun exposure, waterside venues. However, it was not broadly effective throughout the resorts possibly due to the sun-seeking desires of vacationers, information overload at resorts, and constraints on clothing styles and sun protection practices by recreation activities.

PHYSICAL, EMOTIONAL AND SITUATIONAL PREDICTORS OF DIETARY LAPSES IN WEIGHT LOSS TREATMENT

Cara Dochat, B.A.[1], Stephanie Goldstein, M.S.[1], Evan M. Forman, PhD[1], Meghan L. Butryn, PhD[1], Stephanie Manasse, MS[1], Ross D. Crosby, PhD[2], Graham Thomas, PhD[3]

[1]Drexel University, Philadelphia, PA; [2]Neuropsychiatric Research Institute, Fargo, ND; [3]Brown University & The Miriam Hospital, Providence, RI

Frequency of lapsing from a prescribed weight loss diet predicts weight loss treatment failure, yet inconsistent findings about factors preceding lapsing have prevented effective treatment targeting. Lapses are categorically heterogeneous and as such may have unique internal and external antecedents. The current study uses ecological momentary assessment (EMA) to examine predictors of three lapse types—eating more than intended, eating a forbidden food, and eating when not intended—in adults (n=189; 82.0% female; 70.9% Caucasian; M_{age} = 51.81 ±9.76 years; M_{BMI} = 36.93 ±5.83 kg/m^2) enrolled in a 12-month randomized controlled trial comparing the effectiveness of standard behavioral weight loss treatment to an acceptance-based condition. At baseline, participants completed 14 days of EMA in which they indicated whether and what type of lapse had occurred since the last prompt, and responded to questions assessing current physical (hunger, tiredness), environmental (presence of delicious foods), and affective (loneliness, sadness, stress, boredom, feelings of deprivation) states. Because lapse frequency did not differ by study condition, conditions were combined for the following analyses. Separate generalized estimating equations were used to examine whether each state prospectively predicted lapse occurrence at the next survey. The majority of lapses were categorized as eating a forbidden food (44%), followed by eating when one had not intended (28%) and eating a larger portion than planned (27%). Results indicate that likelihood of eating a forbidden food was greater for those who reported more frequent aversive physical states ($p < .05$), and for all participants when delicious foods were present ($p < .01$). Likelihood of eating larger portions was greater for those reporting more frequent negative affective states ($p < .01$). Eating when not intended was more likely to occur following momentary aversive affective and physical states for all participants ($p < .01$). Results support the theory that distinct lapse types exist, and that lapse types can be predicted by both momentary conditions and individual tendencies toward certain physical and affective states. Identifying individual differences in tendencies toward sadness,

tiredness, and hunger, might help participants anticipate conditions for lapsing and develop specific strategies for their most common lapse types. Future research should examine how lapse types uniquely affect weight loss outcomes.

A RANDOMIZED TRIAL OF AN ACCEPTANCE BASED BEHAVIORAL INTERVENTION FOR WEIGHT LOSS IN PEOPLE WITH HIGH INTERNAL DISINHIBITION

Jason Lillis, Ph.D.

Brown Medical School, Rocklin, CA

Background: Most individuals completinga behavioral weight loss program achieve weight loss of approximately 7-10% over 6-9 months and then gradually regain weight thereafter. Innovative approaches are needed to improve long-term weight control otucomes. Standard interventions typically include cognitive and emotional control strategies (e.g. thought replacement, distraction, relaxation) to support weight loss efforts. However excessive attempts to change or control thoughts, feelings, or bodily sensations, referred to as experiential avoidance, could paradoxically make it more difficult for individuals with obesity to cope with food cravings and instead lead to greater caloric consumption. Alternative treatment components may be necessary to help individuals cope with situations that can interfere with successful weight loss maintenance. Acceptance-based approaches (e.g. Acceptance and Commitment Therapy; ACT) may provide a viable alternative thorugh the use of mindfunlness and acceptance-based strategies that focus on improving felxibile responding to unwanted thoughts, feelings, and cravings. The aim of this study was to determine whether an Acceptance-Based Behavioral Intervention (ABBI) produces better weight losses than standard behavioral treatment (SBT) among individuals reporting high internal disinhibition.

Methods: Participants were 162 adults with overweight or obesity (mean BMI 37.6) randomly assigned to ABBI or SBT. Intervention was one year with a fading contact schedule and counterbalanced interventionists. Both interventions provided the same calorie intake target, exercise goal, and self-monitoring skills training. SBT incorporated current best practice interventions for addressing problematic thoughts and emotions. ABBI utilized acceptance-based techniques based on Acceptance and Commitment Therapy. ABBI and SBT were compared on weight change and disinhibition change over 24 months.

Results: Mixed models analysis showed mean weight loss at 24 months was -4.1% (*SE*=0.88) for ABBI and -2.4% (*SE*=0.87) for SBT (*p*=.204). Secondary analyses showed that the ABBI group regained less weight from the end of treatment to the final follow-up (4.6 vs. 7.1kg;

p=.005), and that a significantly higher proportion of ABBI participants achieved a 5% weight loss (38% vs. 25%; *p*=.038) at 24 months.

Conclusions: Taken together, results suggest that ABBI had a positive impact on weight outcomes by reducing the magnitude of weight regain after treatment ended, suggesting that ABBI could be helpful for improving the maintenance of weight loss for individuals who report high internal disinhibition. The results of this trial also point to gaps in our current knowledge of the utility of using mindfulness and acceptance strategies for improving weight control (e.g. when is the best time to introduce these strategies/ who is a good fit?).

TIME DELAYS PROMOTE HEALTHIER VENDING MACHINE SNACK CHOICES

Brad Appelhans, PhD[1], Simone French, PhD[2], Lisa Powell, PhD[3], Imke Janssen, Ph.D.[1], Elizabeth Avery-Mamer, MS[4]

[1]Rush University Medical Center, Chicago, IL; [2]Div. Epidemiology & Community Health, Minneapolis, MN; [3]University of Illinois at Chicago, Chicago, IL; [4]Rush University Medical Center, Morton Grove, IL

In environments replete with palatable foods, a preference for immediate gratification can frequently outstrip inhibitory control during food choice. Research on delay discounting suggests that delaying access to tempting high-calorie foods could potentially shift choice to healthier (though less desired) options. We tested this principle in the context of a novel vending machine intervention called DISC (Delays to Influence Snack Choice), which selectively delays the delivery of less healthy snacks. When less healthy snacks are purchased, DISC retains the purchased snack on a platform until the specified time delay expires. This ecological study used a repeated-measures design to test the effects of a 25-second time delay on purchasing rates for healthy snacks in three vending locations at an urban medical center. The proportion of total sales from healthy snacks was compared for the following conditions: 1) no intervention, 2) 25-s time delay on less healthy snacks, 3) 25-cent discount on healthy snacks, 4) a 25-cent tax on less healthy snacks, 5) 25-s time delay plus 25-cent discount, 6) 25-s time delay plus 25-cent tax. Each condition ran for roughly one month in each location. Healthy snacks met ≥5 of 7 nutritional criteria and composed 50% of items sold in each machine. The proportion of total sales from healthy snacks in each condition was compared through generalized estimating equations with 31,827 sales. Relative to no intervention, 25-s time delays yielded a 1.6% to 5.4% absolute increase ($p < .001$) in the proportion of total purchases from healthy snacks, depending on location. Healthy snack purchasing also increased under both 25-cent discounts and taxes (p’s < .001). Combining time delays with the discount doubled its impact ($p < .0001$). None of the interventions involving time delays led to a significant reduction in overall vending sales volume. Brief time delays influence food choice at the point of decision, do not harm vending revenues, and may augment differential pricing interventions. Future research should test DISC in a larger multisite trial, and explore the potential impact of time delays on food choice in other

contexts such as fast food restaurants and online grocers. Funded by R21HL121861. NCT02359916.

ACCEPTANCE-BASED BEHAVIORAL TREATMENT OUTPERFORMS STANDARD BEHAVIORAL TREATMENT AT POST-TREATMENT AND LONG-TERM FOLLOW-UP

Evan M. Forman, PhD[1], Meghan L. Butryn, PhD[2], Stephanie M. Manasse, MS[2], Ross D. Crosby, PhD[3], Graham Thomas, PhD[4]

[1]Drexel University, philadelphia, PA; [2]Drexel University, Philadelphia, PA; [3]Neuropsychiatric Research Institute, Fargo, ND; [4]Brown University & The Miriam Hospital, Providence, RI

Acceptance-based behavioral treatments (ABTs; i.e., approaches that fuse behavioral strategies with tolerance of difficult internal experiences and loss of pleasure, mindful decision making and commitment to valued behavior) have been recognized as potential enhancements to the efficacy of gold standard behavior treatment (SBT) for weight loss. However, only one full randomized controlled trial testing this hypothesis has been published to date, and no long-term follow-up has been conducted. The NIH-funded Mind Your Health Project randomly assigned overweight and obese participants (n = 190) to 25 sessions of either SBT or ABT. At the 1-year (post-treatment) and 2-year (1-year follow-up) assessments, and using maximum likelihood imputation, ABT produced significantly greater percent weight loss (1-year: 13.3% ± 0.83, 2-year: 7.3% ± 0.88) than did SBT (1-year: 9.8% ± 0.87, 2-year: 4.6% ± 0.92; linear effect of treatment condition p = .04). Weight regain from 1 to 2 years was equivalent by condition. Results support the long-term efficacy of ABT. Mediation effects support the postulated mechanisms of ABT, and moderation effects suggest that those with greater impulsivity would especially benefit from assignment to ABT. Future directions include examining outcomes at an even longer follow-up period and examining whether post-treatment booster sessions strengthen and/or extend the advantage of ABT.

USING MACHINE LEARNING AND JUST IN TIME ADAPTIVE INTERVENTION TO PREDICT AND PREVENT DIETARY LAPSES: THE DIETALERT APP

Evan M. Forman, PhD[1], Stephanie P Goldstein, M.S.[2], Adrienne S. Juarascio, Ph.D.[1], Meghan L. Butryn, PhD[1], Pramod Abichandani, PhD.[1]

[1]Drexel University, Philadelphia, PA; [2]Drexel University, Philadelphi, NJ

Lack of success in weight loss programs can be largely attributed to dietary lapses, i.e., specific instances of inadherence to dietary recommendations. Lapses have been linked to a select group of internal and external cues, suggesting that lapse prediction and prevention are possible, given sufficient data. As such, we have set out to create a smartphone-based system called DietAlert that utilizes machine learning to predict lapse behavior with increasing accuracy, and to deliver tailored, momentary interventions designed to prevent lapses from occurring during a period of elevated risk. This presentation describes four phases of development and evaluation which involved overweight participants using DietAlert while following a Weight Watchers weight loss plan. First, we will describe the development of an experience sampling component of the app, and will report user compliance (94.6%) and user-rated satisfaction (6.42/7.00). Second, we will describe the creation and evaluation of a machine learning predictive model of lapses (e.g., the maximizing of sensitivity without unacceptably low specificity). As such, we will report the final model's strongest predictors of lapse (e.g., socializing, affect, tiredness), sensitivity (70%) and specificity (72%). Third, we will report on the development of 159 tailored micro-interventions, and implementation of these interventions in DietAlert. Fourth, we report on an effectiveness trial in which participants (current n=20; projected n=40) used a full version DietAlert that included experience sampling, risk alerts, and momentary and tailored micro-interventions. Preliminary results suggest that DietAlert is reducing lapse frequency (M = -3.00, SD=5.55) and enhancing weight loss (M = 3.7%, SD=1.6%) versus weight watchers alone (M ~ 2% in an independent sample), though the uncontrolled nature of the study makes this conclusion temporary.

YOUTH WITH TYPE 1 DIABETES: PSYCHOSOCIAL PREDICTORS OF RISK FACTORS AND DIABETES-RELATED COMPLICATIONS 11 YEARS LATER

Vicki Helgeson, PhD[1], Howard Seltman, Ph.D.[1], Trevor Orchard, M.D.[2], Dorothy Becker, M.D.[3], Ingrid Libman, M.D.[3]

[1]Carnegie Mellon University, Pittsburgh, PA; [2]University of Pittsburgh, Pittsburgh, PA; [3]Children's Hospital of Pittsburgh, Pittsburgh, PA

The goal of this study was to examine the extent to which psychosocial variables measured during adolescence predicted risk factors and early indicators of diabetes-related complications at age 22. We followed 132 youth with type 1 diabetes, average age 12 at study entry, for 11 years with 81% retention. At age 22, we obtained measures of glucose control (HbA1c), cardiovascular risk factors (BMI, cholesterol, blood pressure) and indicators of diabetes-related complications (nephropathy [albuminuria], autonomic neuropathy [heart rate from inhalation and exhalation], peripheral neuropathy [from vibratory readings]). Lower parental social status at study entry and minority race were related to several risk factors and complications. Current education achieved predicted outcomes: higher education by age 22 was associated with better glycemic control, lower cholesterol, and lower autonomic and peripheral neuropathy. Thus, we statistically controlled for parent social status, sex, race, and current educational achievement in all analyses presented below. Overall quality of relationship with mother and father predicted multiple risk factors, but there were more consistent links to father relationship. Higher father relationship quality was associated with lower BMI ($B = -1.18$, $p < .05$), lower levels of non-HDL cholesterol ($B = -16.11$, $p < .01$), and marginally higher autonomic neuropathy ($B = .06$, $p < .10$). Friend support at age 12 did not predict risk factors or complications, but friend conflict did. Friend conflict predicted higher HbA1c (.42, $p < .10$), higher autonomic neuropathy ($B = -.09$, $p < .05$) and higher peripheral neuropathy ($B = .40$, $p < .05$). Greater depressive symptoms and lower feelings of self-worth at age 12 predicted increased albuminuria ($B = 59.78$, $p < .05$; $B = -27.0$, $p < .05$) and peripheral neuropathy ($B = 1.32$, $p < .05$; $B = -.59$, $p < .10$). These results suggest that youth with type 1 diabetes who are having difficulties in relationships and experiencing psychological distress are more likely to experience poor health outcomes many years later. There are a number of potential pathways by which psychosocial variables at age 12 impact physical health 11 years later.

Paper Session 42: Advancing Care for Type 1 Diabetes 3:19 PM-3:36 PM

INCONSISTENT SLEEP IS LINKED WITH POOR DIABETES MANAGEMENT AND GLYCEMIC CONTROL IN ADOLESCENTS

Niral J. Patel, MPH, Kimberly L. Savin, BA, Lauren A. Williams, BS, Beth A. Malow, MD, MS, Sarah S. Jaser, PhD

Vanderbilt University Medical Center, Nashville, TN

Background: Prior research has focused on improving adherence and glycemic control in adolescents with type 1 diabetes (T1D), but the effect of sleep on these outcomes has received little attention. Adolescents, in general, have difficulty meeting sleep recommendations (8-10 hours/night) due to changes in circadian rhythms paired with early school start times, and increased time spent on schoolwork, extracurricular activities, and peer relationships. Insufficient sleep may have serious consequences for adolescents with T1D due to its link to poor diabetes management. This study aims to examine the links between inconsistent and insufficient sleep, measured by objective actigraphy data, and measures of adherence and glycemic control in adolescents with T1D.

Methods: Participants (n = 64, age 13-17 years, 52% female, mean A1C = 8.9±1.5%) wore actigraphs for 7 nights. Actigraphy data were analyzed using Philips Actiware software. Sleep inconsistency was calculated using the standard deviation of total sleep time across 7 nights, representing the variation in sleep from night to night. Average daily blood glucose monitoring (BGM), average blood glucose levels (BG), and percent of blood glucose readings within target range were obtained through 30 day glucometer downloads. A1C was obtained from medical charts and adherence was measured using the Self-Care Inventory (SCI).

Results: Bivariate analysis revealed a significant association between inconsistent sleep and daily BGM ($r=-0.27$, $p < 0.05$), such that more inconsistent sleep was associated with less frequent BGM. Further, inconsistent sleep was correlated with A1C ($r=0.34$, $p < 0.01$) and BG ($r=0.30$, $p < 0.05$), such that participants with greater sleep inconsistency had higher levels of A1C and BG. Additionally, sleep consistency was associated with percent of blood glucose levels within range ($r =-0.26$, $p < 0.05$), indicating that greater sleep inconsistency was linked with fewer blood glucose levels within a specified target range. Inconsistent sleep was not significantly associated with other measures of adherence such as the parent-report or self-report SCI. Average total sleep time was not significantly associated with adherence or glycemic control.

Discussion: In our sample, inconsistent sleep patterns were associated with poorer glycemic control and less frequent BGM in adolescents with T1D. These findings provide novel insights

into the importance of sleep in youth with T1D, suggesting that inconsistent sleep may be more detrimental than total sleep time, and that clinicians should consider sleep patterns as a factor that might affect adherence and glycemic control. Future research should aim to determine the directionality of the relationship between sleep patterns and diabetes-related outcomes through longitudinal studies, and to understand the role of sleep in adolescents' ability to successfully manage T1D.

PERFORMANCE-BASED AND QUESTIONNAIRE MEASURES OF EXECUTIVE FUNCTION LINKED TO DIABETES OUTCOMES

Emily R. Hamburger, MEd, Niral J. Patel, MPH, Sachini N. Kahanda, BA

Vanderbilt University Medical Center, Nashville, TN

Background: Type 1 diabetes (T1D) is one of the most prevalent medical conditions affecting teens. A complex treatment regimen is needed to maintain glycemic control, which requires components of executive function (EF), such as the ability to shift attention, regulate emotions, and initiate behavior. Although past studies have focused on EF deficits in teens with diabetes, our study is unique and expands upon current literature, incorporating both performance-based and parent-reported measures of EF in relation to glycemic control, treatment adherence, and fear of hypoglycemia.

Methods: Teens with T1D (n=65, age 13-17, 52.3% female, 87.1% White, mean A1c=8.85%) and their caregivers completed the Self Care Inventory (SCI), a measure of diabetes management behaviors where higher scores indicate greater adherence. Parents reported on their teen's EF using the Behavior Rating Inventory of Executive Function (BRIEF), with higher scores indicating greater dysfunction. Teens completed the Fear of Hypoglycemia Survey (FHS), which assesses behaviors and worries related to hypoglycemia. After teens checked their blood sugar, the Delis–Kaplan Executive Function System (D-KEFS) Trail Making subtest, a performance-based measure of EF, and the Working Memory Index (WMI) of the Wechsler Intelligence Scale for Children were administered. Clinical data (i.e., A1c) were collected from medical charts.

Results: Bivariate analysis showed significant relationships between the Worry subscale on the FHS and the D-KEFS Trail Making (r=-.282, $p < .05$), and the Behavior Regulation Index (BRI) on the BRIEF (r=-.273, $p < .05$). These relationships were not present for the Behavior subscale of the FHS. The Emotional Control scale on the BRIEF was found to be significantly associated with A1c (r=.287, $p < .05$). Several BRIEF subscales, as well as the BRI (r=-.325, $p < .05$) and Global Executive Composite (r=-.308, $p < .05$) were significantly correlated with the parent report SCI. These relationships were not observed with the self-report SCI. WMI was not related to any outcomes.

Discussion: As teens become more responsible for their diabetes care and management, the role of EF in treatment adherence becomes more important. This study reveals that lower levels of EF are related to worse treatment adherence, and worries about hypoglycemia are linked to worse performance on an EF task. EF deficits may make it more difficult for teens to

adhere to their treatment plans and maintain glycemic control. Our study is unique in its multimethod assessment of EF, using performance-based and questionnaire measures, which provide valuable and complementary information regarding separate facets of diabetes management. Worry's relation to EF is a novel finding, and warrants further investigation. Future research will need to identify which EF components are most important to specific health behaviors.

Paper Session 42: Advancing Care for Type 1 Diabetes 3:55 PM-4:12 PM

MULTIMETHOD SLEEP ANALYSIS OF ADOLESCENTS WITH TYPE 1 DIABETES

Kimberly L. Savin, BA, Sachini N. Kahanda, BA, Gray A. Lochbihler, BA, Beth A. Malow, MD, MS, Sarah S. Jaser, PhD

Vanderbilt University Medical Center, Nashville, TN

While sleep's effect on psychosocial and cognitive functioning is well-established, few researchers have described sleep habits in adolescents with type 1 diabetes (T1D) and few clinicians regularly assess sleep habits. This study aimed to provide an in-depth description of adolescents' sleep on school nights and weekend nights using a multimethod (actigraphy, questionnaire, daily diary self-report) approach to measuring sleep habits.

Participants included adolescents with a diagnosis of T1D for at least 1 year (N=65, mean age=15.0, mean HbA1c=8.9%, 52.3% female). Participants completed the Pittsburgh Sleep Quality Index (PSQI), wore an actigraph and kept daily diaries recording sleep, activity, mood, and blood glucose monitoring (BGM) habits for at least 7 days. Actigraphy was analyzed using Philips Actiware software. Data were analyzed for each participant for one school night and one weekend night.

On school nights, actigraphy revealed average bed time was 10:55 PM (range: 8:19 PM-2:51 AM) and average wake time was 6:34 AM. Actigraphy showed only 5.8% of participants slept for ≥8 hours on school nights, while 38.8% self-reported ≥8 hours of sleep. School night diary data revealed 52.3% of the sample slept with ≥1 electronic device in the room, 60% reported nighttime BGM, and 76.9% reported morning BGM. On weekend nights, actigraphy revealed average bedtime was 11:53 PM (range: 9:21 PM-5:06 AM) and average wake time was 8:46 AM. Actigraphy showed 33.3% of participants slept for ≥8 hours on weekend nights, while 55.8% self-reported ≥8 hours of sleep. Weekend night diary data revealed that 60% of the sample slept with ≥1 electronic device on in the room, 72.3% reported nighttime BGM, and 83.1% reported morning BGM. Using PSQI data, 41.7% self-reported clinically significant poor overall sleep quality.

Paired t-tests revealed that participants slept more on weekend nights than on school nights, using both actigraphy (7:31 on weekends, 6:32 on school nights; $p < .001$) and daily diaries (8:45 on weekend nights, 7:45 on school nights; $p < .005$). Bivariate analysis revealed that greater actigraphy sleep time was correlated with less caffeine intake on the weekend ($r=-.27$, $p < .05$). Additionally, using PSQI report, better overall sleep quality was correlated with less stress on school nights ($r=.34$, $p < .05$) and better mood on the weekend ($r=.26$, $p < .05$).

These findings suggest that few adolescents with T1D meet sleep recommendations on school or weekend nights regardless of sleep measure used, though they tend to sleep longer and report BGM more regularly on weekends than school nights. Clinicians could consider assessing adolescents' sleep habits, particularly on school nights, and encouraging earlier bedtimes and less caffeine intake. Future studies utilizing objective BGM data would elucidate the relationship between sleep and diabetes management habits.

PATIENT-PROVIDER COMMUNICATION IN PEDIATRIC TYPE 1 DIABETES CLINICAL CARE

April Idalski Carcone, PhD, Deborah Ellis, PhD

Wayne State University, Detroit, MI

Although widely studied in adult health care, few studies have examined patient-provider communication(PPC) in pediatric medical care and almost none describe PPC in pediatric chronic illness. A few pediatric PPC studies in primary care and one recent study in chronic illness describe a pattern of low child participation(age=10.3±1.1 years, 53% female, 62% Caucasian, diagnosed 5.1±2.2 years, 61% insulin pump, M_{HbA1c}=9.2%±1.4, 74% 2-parent homes, Mdn_{income}=$50-59K). Three coders used an adapted version of the Turn Allocated System to characterize who initiated a given communication and who the intended recipient was(e.g., physician speaks to patient). We coded 10,341 speaking turns; 20% of each recording was co-coded to assess inter-rater reliability(κ=.680). Patients' speaking turns comprised only 12% of the interactions whereas caregivers represented 39% and physician 48%, a pattern consistent with previous research. Sequential analysis suggested a significant pattern of conversational turn-taking. Physicians responded directly to patients' physician-directed turns 63% of the time overall with a pattern of increasing response as patients' age increased: physicians responded directly to 45% of 8-9yr olds' communications, 63% of 10yr olds', 64% of 11yr olds', and 75% of 12yr olds'. A similar pattern emerged for patient-directed physician turns and parent interruptions of these turns. Patients responded to physicians 53% of the time overall with an increasing pattern as patient age increased: 8-9 year olds responded 42% of the time, 10yr olds responded 44% of the time, 11yr olds responded 58% of the time, and 12yr olds responded 72% of the time. Parents "interrupted" these turns 17% of the time overall, 26% of the time with 8-9yr olds, 21 with 10yr olds, 14% with 11yr olds, and 8% with 12yr olds. These data provide preliminary information on patterns of PPC in pediatric specialty care. Further research is needed to understand the content and purpose of parent "interruptions", how PPC varies over time, and how to optimize PPC patterns that promote patient health outcomes in children with chronic health conditions.

CAN "SMARTER" MHEALTH PROGRAMS IMPROVE ENGAGEMENT, ADHERENCE, AND SMOKING CESSATION OUTCOMES?

Jennifer McClure, PhD[1], Melissa Anderson, MS[1], Kathy Bradley, MD, MPH[1], Larry An, MD[2], Sheryl Catz, PhD[3]

[1]Group Health Research Institute, Seattle, WA; [2]University of Michigan, Ann Arbor, MI; [3]University of California - Davis, Sacramento, CA

Most mHealth smoking cessation apps are not particularly 'smart.' Their content does not follow best practice clinical guidelines and they do not take advantage of smartphone capabilities to adaptively tailor content or allow two-way communication between users and clinicians. We developed a comprehensive, interactive mHealth smoking cessation and medication adherence program (MyMAP; My Mobile Advice Program) that combines standard cognitive-behavioral self-help with real-time adaptively tailored cessation and adherence support/advice, and ability to exchange secure messages with a cessation counselor. MyMAP was pilot tested (n=66; 56% female) against an identical mHealth program minus the interactive and adaptive support/advice and secure messaging features when both were paired with varenicline. Those randomized to MyMAP completed self-initiated and prompted brief check-in surveys about smoking status, cessation medication use, motivation/confidence for quitting, and common adverse events (AEs; withdrawal symptoms/medication side-effects). Participants then received tailored support/advice based on this information. Secure messages were initiated by participants or by counselors, in response to reported AEs, as needed. Outcome measures of engagement, adherence, and cessation were all positive at 5 months. MyMAP was used more often than the control program (10.6 vs. 2.7 mean log-ins, P =.0001), driven by use of the experimental features (tailored support/advice and secure messaging). Experimental participants received help managing 258 withdrawal symptoms/medication side-effects and exchanged 130 secure messages (22 message strings initiated by smokers; 44 message strings initiated by clinicians in response to concerns raised during check-in surveys). Most thought MyMAP could help others quit smoking (92%), consistently take their medication (97%), and would recommend it (87%). More MyMAP participants tended to be 'optimally' adherent (36% vs. 24%) and quit smoking (36% vs. 24%; ORs for each: 1.79; CI: 0.61-5.19). In sum, MyMAP's proactive, adaptive and interactive treatment approach showed promising effects on engagement, adherence and cessation. Results have implications for designing future mHealth cessation programs.

SMOKERS WHO ARE NOT MOTIVATED TO QUIT ARE MORE LIKELY TO QUIT SMOKING WITH MORE INTENSIVE VS. LESS INTENSIVE INTERVENTIONS.

Romano Endrighi, PhD[1], Shira Dunsiger, PhD[2], Belinda Borrelli, PhD[3]

[1]Boston University Henry M. Goldman School of Dental Medicine, Boston, MA; [2]The Miriam Hospital and Brown University, Portsmouth, RI; [3]Boston University, Henry M. Goldman School of Dental Medicine, Boston, MA

Parents who smoke and are not motivated to quit are an important group for intervention, particularly if they have a child with asthma. Previous research indicates that smokers who are not motivated to quit will be less responsive to intensive smoking interventions, although motivation by treatment interactions have not been directly tested. The current study is a secondary analysis examining whether motivation to quit among parents with asthmatic children moderates the effect of a smoking cessation induction intervention. We hypothesized that smokers who were not motivated to quit would be more likely to quit smoking and reduce secondhand smoke exposure (SHSe) in a more intensive intervention vs a less intensive one.

Parents had a child with an asthma episode requiring urgent care. They were told that they would receive two home-based asthma education visits and discuss their smoking, but they did not have to want to quit smoking to enroll. Home visits included asthma education, motivational interviewing (MI) for smoking cessation and feedback on child SHSe. After the home visits, participants were randomized (n=339, 79.6% female) to receive either enhanced-PAM (Precaution Adoption Model; 6 counseling calls using MI for cessation induction and repeated SHSe feedback) or PAM (6 contact control calls with checks on asthma status) over 4 months. Motivation to quit within 30-days (yes/no) was assessed at baseline. Outcomes were bioverified 7-and 30-day point prevalence abstinence (PPA) at 6 months, and SHSe was measured by passive dosimetry (very low/undetectable vs moderate/high).

At baseline, 38.9% were not motivated to quit. There was a significant treatment group by motivation interaction: Not-motivated smokers in enhanced-PAM were 3-4 times more likely to be abstinent vs. not-motivated smokers in PAM (7-day PPA OR=3.71, 95%CI=1.06, 12.99; 30-day PPA OR=4.15, 95%CI=1.20, 14.35). Smoking outcomes did not significantly differ between treatment arms among motivated smokers. Not-motivated smokers in enhanced-PAM were more than 4 times as likely to have very low/undetectable SHS at follow-up vs not-motivated smokers in PAM (OR=4.46, 95%CI=1.31, 15.15). SHSe did not significantly differ between treatment arms among motivated smokers.

Thus, parents who were not-motivated to quit achieved better outcomes with the more intensive treatment. It cannot be assumed that smokers who are unmotivated to quit will not be responsive to intensive interventions.

IMPLEMENTATION OF MHEALTH TECHNOLOGY FOR HIGH-RISK INPATIENT UNITS: TECHNOLOGY INPATIENT PROGRAM FOR SMOKERS (TIPS)

Amanda Blok, PhD, MSN, PHCNS-BC[1], Rajani Shankar Sadasivam, PhD[2], Thomas Houston, MD, MPH[3]

[1]University of Massachusetts Medical School, Cambridge, MA; [2]Univ of Massachusetts Medical School, Worcester, MA; [3]University of Massachusetts Medical School, Worcester, MA

Background. Tobacco use increases the likelihood of hospitalization for cardiac and pulmonary patients. Hospital stays for these conditions are teachable moments, representing “windows of opportunity” for patients to address their risk behavior. The Technology Inpatient Program for Smokers (TIPS) is a short messaging system (SMS) texting program with motivational messages for hospitalized smokers. The TIPS implementation program included 1) engaging hospital stakeholders and 2) motivating TIPS usage through a promotional poster campaign. The goal of this project was to evaluate the implementation.

Methods. The implementation was evaluated quasi-experimentally for 15 weeks on 2 hospital wards at each of 2 sites. Process measures of the implementation program included weekly site observation and stakeholder meetings on the wards participating. Reach was calculated using admission rates of current smokers from electronic medical records and centralized logs of text messages. Administrative documents were used for a cost analysis.

Results. Posters were hung in patient rooms and hallways on wards by hospital staff. On weekly rounds, a mean of 10.2% (SD: 8.7%) posters went missing from patient rooms and had to be replaced. ***Implementation*** challenges included coordinating the poster campaign and establishing leadership buy-in, but were not detrimental to overall Program rollout. Per hospital floor, 29 to 51 smokers (Mean: 34.7, SD: 8.8) were admitted per week. After 15 weeks, 30 smokers enrolled in the system. Thus, estimating total smokers admitted in 15 weeks, 5.7% (30/520) enrolled in the system. The initial sunk ***cost*** of the TIPS intervention, including posters and stakeholder meetings, was $2238.89. There was a small marginal cost per smoker of $6.32 ($189.49/30).

Discussion. Smokers participated in TIPS with only limited interventional effort and small marginal costs, although proportionately few smokers signed up for TIPS. Further research will be conducted to examine the effects of more intensive implementation efforts, including incorporation of a TIPS Program orientation into nurse workflow.

PROJECT CONNECT: HELPING TOBACCO USERS STAY QUIT AFTER DISCHARGE WITH BEDSIDE VISITS FROM TRAINED VOLUNTEERS

Denise S. Taylor, MS, RD[1], Elisabeth G. Bradley, MS, APRN, AGPCNP-BC, ACNS-BC[2], Dominique Comer, PharmD, MS[3], Adebayo Gbadebo, MBA[3], Zugui Zhang, PhD[3], Claudine Jurkovitz, MD, MPH[3], Freda Patterson, PhD[4], Edward Goldenberg, MD[1]

[1]Christiana Care Health System, Wilmington, DE; [2]Christiana Care Health System, Lincoln University, PA; [3]Christiana Care Health System, Newark, DE; [4]University of Delaware, Newark, DE

In-patient hospital care represents a window of opportunity to initiate smoking cessation. However, a lack of cessation support upon discharge limits the extent to which initial abstinence becomes sustained cessation. To address this gap in care, the current study evaluated the efficacy of a systems-based smoking cessation program – *Project Connect*- designed to provide a continuity of smoking cessation care from the bedside back to the community. Between February and June, 2016, hospital-trained volunteers (former smokers, former nurses, health behavior science students) administered a brief, smoking cessation protocol based on the ASK-ADVISE-CONNECT model to active smokers admitted to any cardiology unit of a single large hospital. If the patient accepted, a fax-referral form was submitted to the Delaware state quitline to initiate quitline cessation services within 72 hours of discharge. A total of 434 patients across 462 admissions were included in the study. The sample was 40% female, 75% white, and on average 57.5 years of age. Across admissions, 30% resulted in a fax referral to the quitline. Of the patients with complete 90-day follow up data, 50% (122/244) indicated they were ready to quit in the next 6 months. Of those, 49 (40%) accepted services and enrolled in treatment. To date, 77 patients have reported not using tobacco within the past 30 days at 90 days post discharge. *Project Connect* is a novel approach to help link patients to evidence-based treatment for their tobacco use. Costs are kept low by using trained volunteers and connecting patients to a state-funded Quitline that offers free choice of seven FDA-approved cessation medications and coaching over the telephone or in person. *Project Connect* represents a value-based approach by treating tobacco use as a chronic disease that is addressed in the hospital and managed through referral to free resources in the community.

INCENTIVES FOR HELPING MEDICAID RECIPIENTS QUIT SMOKING: A RANDOMIZED CONTROLLED TRIAL

Shu-Hong Zhu, PhD[1], Christopher M. Anderson, BA[1], Sharon E. Cummins, PhD[1], Anthony C. Gamst, PhD[1], Neal D. Kohatsu, MD[2]

[1]University of California San Diego, La Jolla, CA; [2]California Health and Human Services Agency, Sacramento, CA

Medicaid recipients smoke at nearly double the rate of the general population and have more difficulty quitting. Treatment for smoking-related disorders costs Medicaid over $40 billion/year. CMS launched an initiative to examine incentives for the prevention of chronic disease. This study was part of that initiative and examined the effect of providing incentives to help Medicaid smokers quit smoking; the study was embedded in the California Tobacco Quitline.

Quitline callers with Medicaid who consented to the study (N=3,816) were randomly assigned to: Usual Care (UC), Nicotine Patches (NP), or NP plus Incentives (NP+I) using a ratio of 1.0:1.4:1.4. All groups were provided standard quitline counseling. UC subjects could receive free nicotine patches by taking a doctor's prescription to their pharmacy. NP subjects were sent free nicotine patches directly to their home by the quitline to minimize barriers. NP+I subjects were mailed patches directly and were provided with small monetary incentives to participate in counseling (up to $60 for a complete course of 5 counseling sessions).

Subjects were evaluated on quit attempts made, self-reported prolonged abstinence (30-day abstinence at 2 months and 180-day abstinence at 7 months), and use of nicotine patches and other quitting aids.

Incentives increased the median number of counseling sessions delivered by 1. Mailing patches directly increased use of quitting aids from 68.4% to over 90%. Quit attempt rates were 88.3%, 91.8%, and 94.5% for the UC, NP, and NP+I groups, respectively. At 7 months, prolonged abstinence rates were 14.1%, 15.8%, and 19.3%, for the three groups, respectively. For both quit attempt rates and prolonged abstinence rates, the difference between UC and NP+I was significant. Results for NP were not significantly different from either condition.

Barrier free access to patches and small monetary incentives for counseling increase quit attempts and success for Medicaid recipients. The policy implications of these findings will be discussed.

Supported by the Centers for Medicare and Medicaid Services (Grant #1B1-CMS330883)

DEPRESSIVE SYMPTOM PROFILES, CARDIOMETABOLIC RISK AND INFLAMMATION: RESULTS FROM THE MIDUS STUDY

Diana A. Chirinos, PhD[1], Kyle W. Murdock, PhD[2], Angie S. LeRoy, MA[1], Ryan L. Brown, N/A[3], Christopher P. Fagundes, PhD[1]

[1]Rice University, Houston, TX; [2]Rice University, Houson, TX; [3]Bryant University, Houston, TX

Depression is an important predictor of cardiometabolic risk; however; the presentation of depressive symptoms can be highly heterogeneous. In this study, we used latent profile analysis (LPA) to (1) provide a comprehensive characterization of depressive symptoms profiles in a healthy sample of adults, and (2) examine their association with cardiometabolic outcomes, including metabolic syndrome (MetS) and obesity. Participants were 1180 adults enrolled in the MIDUS-II biomarker study. We used LPA to derive depressive symptom profiles using subscales of the Mood and Anxiety Symptom Questionnaire, the Center for Epidemiologic Studies Depression Scale subscales and the Pittsburgh Sleep Quality Index. Blood was drawn to assess C-reactive protein as a marker of inflammation. Four depressive symptom profiles were identified. The “Low Symptoms” subgroup (56.66% of the sample) had low scores across all subscales. The “Somatic Complaints” subgroup (25.93%) was characterized by lower scores across indicators, with subscales measuring somatic symptoms being the highest *within* group. The “Negative Affect” subgroup (11.78%) had high scores across subscales with those measuring negative affect/loss of interest being the highest. Finally, the “Acute Symptoms” subgroup (2.63%) was characterized by high scores on all subscales. After controlling for sociodemographic characteristics, membership to both the “Somatic Complaints” and the “Negative Affect” subgroups was associated with greater odds of presenting MetS (OR_{Som}=1.384, *p*=0.037; OR_{NegA}=2.088, *p*=0.001) and obesity (OR_{Som}=1.392, *p*=0.032; OR_{NegA}=1.934, *p*=0.001). Inflammation partially attenuated the association between the “Somatic Complaints” subgroup and cardiometabolic outcomes, while associations for the “Negative Affect” subgroup remained independent. This is the first study to identify empirically-derived depressive symptom profiles among healthy mid-life adults in the US and link them to cardiometabolic outcomes. Future work should examine potential differential pathways to increased risk across depressive symptom profiles and examine whether tailored interventions have an impact on cardiometabolic risk.

PREOPERATIVE DEPRESSION AND STRESS PREDICT POSTOPERATIVE CARDIOVASCULAR EVENTS IN PATIENTS UNDERGOING VASCULAR SURGERY

Mallory Rutigliano, N/A[1], Tanya Spruill, PhD[1], Yu Guo, MA[2], Adriana Perez, N/A[3], Maya Rubin, BA[4], Caron Rockman, MD, FACS[5], Jeffrey S. Berger, MD, MS[1]

[1]NYU School of Medicine, New York, NY; [2]New York University school of medicine, New York, NY; [3]N/A, New York, NY; [4]New York Medical College, Valhalla, NY; [5]New York University Langone Medical Center, New York, NY

Preoperative depression and stress predict postoperative cardiovascular events in patients undergoing vascular surgery

Background: Depression and psychosocial stress are associated with cardiovascular morbidity and mortality, including negative outcomes following cardiac surgery. Hypothesized mechanisms include poor lifestyle, high blood pressure and increased platelet activity These mechanisms are also involved in peripheral vascular disease, but little is known about the effects of psychosocial factors on vascular surgery outcomes. We examined the association between depressive symptoms and psychosocial stress and cardiovascular events 30 days after vascular surgery.

Methods: The study sample included 181 adult patients with vascular disease undergoing non- emergent vascular surgery at NYU Medical Center and Bellevue Hospital. Validated single item measures of depressive symptoms, perceived stress at home or work, and financial stress were administered preoperatively and were dichotomized (high versus low) for this analysis. The two stress items were combined to provide a measure of elevated stress of any kind. The primary outcome was the 30-day event rate, a composite of stroke/transient ischemic attack, myocardial infarction, death and troponin elevation.

Results: Mean age was 70 ± 9 and the sample included 29.3% females and 17.7% racial/ethnic minorities. The 30-day composite event rate was 21.1%. Prior to surgery, 54.2% of participants reported high depressive symptoms and/or high stress. These participants had almost twice as many postoperative events as those reporting low depression and low stress (24.2% vs. 13.2%, p=.07). After adjusting for age, sex, race/ethnicity, body mass index, smoking status, type of surgery and prior coronary artery disease or myocardial infarction, high stress/depression was associated with higher odds of postoperative events (OR 3.44, 95% CI, 1.28 to 9.24). The odds were similar in participants reporting both elevated stress and depression 3.61 (0.9, 14.55) and those reporting elevated stress or depression 3.38 (1.2, 9.54), compared with those reporting low stress and low depression.

Conclusions: These results support the hypothesis that high pre-operative stress or depressive symptoms may increase risk for negative outcomes after vascular surgery.

IMPACT OF ANTIDEPRESSANTS ON RISK FOR MAJOR ADVERSE CARDIOVASCULAR EVENTS IN PATIENTS WITH AND WITHOUT CARDIOVASCULAR DISEASE

Kim L. Lavoie, PhD[1], Nicola J. Paine, PhD[2], Roxanne Pelletier, PhD[3], Andre Arsenault, MD[4], Tavis Campbell, PhD[5], Louise Pilote, MD, MPH, PhD[6], Simon L. Bacon, PhD[2], Jean G. Diodati, MD[7]

[1]University du Quebec a Montreal, Montreal, PQ, Canada; [2]Concordia University, Montreal, PQ, Canada; [3]Research Institute McGill University Health Centre, Montreal, PQ, Canada; [4]Montreal Behavioural Medicine Centre, Montreal, PQ, Canada; [5]University of Calgary, Calgary, AB, Canada; [6]McGill University, Montreal, PQ, Canada; [7]Hopital Sacre Coeur de Montreal, Montreal, PQ, Canada

Background: The American Heart Association (AHA) has endorsed depression as a cardiac risk factor and recommends screening as part of routine practice. This has been met with controversy due to a paucity of data linking depression treatment to better cardiovascular outcomes. This study prospectively assessed the association between antidepressant treatment (defined as being prescribed antidepressants) and major adverse cardiovascular events (MACE) in men and women undergoing exercise stress tests.

Methods: 2385 participants were recruited on the day of their exercise stress test between 1998 and 2002, and were followed for 8.8yrs. Participants underwent a sociodemographic, medical, and psychiatric interview (PRIME-MD) and completed the Beck Depression Inventory (BDI). Antidepressant use was self-reported and verified via chart review. Outcomes included MACE from administrative databases.

Results: A total of 39% (n=921) of the sample had depression and 8% (n=190) were taking antidepressants at baseline.Adjusted cox regression analyses revealed that antidepressant use was associated with a 30% reduced risk of MACE (HR=0.697; 95%CI =0.504–0.964; *p*=.029). There was no significant interaction between antidepressant use and sex (β = -0.07, 95%CI; (β) = -0.73 – 0.60; *p*=.85).

Conclusions and Relevance: Findings indicate a cardio-protective effect of antidepressants on risk for MACE over an 8.8-year follow-up among patients presenting for exercise stress tests

independent of traditional risk factors, CVD history and baseline depression, which did not differ by sex.

CLUSTERING OF SOMATIC SYMPTOMS OF DEPRESSION, HRV, AND INFLAMMATION IN PATIENTS WITH ASYMPTOMATIC HEART FAILURE

Laura Redwine, Ph.D[1], Kathy Wilson, MS[1], Meredith A. Pung, Ph.D[1], Brook Henry, Ph.D.[1], Suzi Hong, Ph.D.[2], Paul Mills, Ph.D[1]

[1]University of California, San Diego, La Jolla, CA; [2]University of California San Diego, La Jolla, CA

Stage B, asymptomatic heart failure (HF) presents a therapeutic window for attenuating disease progression and development of HF symptoms, since mortality rates increase dramatically when there is progression to symptomatic HF. By identifying biomarkers that cluster with somatic symptoms of depression, interventions may be developed to target this high risk group. Methods. Participants were 44 patients with Stage B HF (mean age = 66.2 +/- 7.6 and left ventricular ejection fraction (LVEF%) = 62.8 +/- 8.48) assessed for somatic and cognitive symptoms of depression, Beck Depression Scale (BDI), heart rate variability (HRV) (EquaVital, EQ01 heart rate monitor) and plasma inflammatory biomarker, c-reactive protein (CRP). Results. Regression analyses, adjusting for EF revealed that elevated somatic symptoms of depression predicted increased HRV measures, RMSSD (delta R2 = .104, p = .037) and HF (delta R2 = .145, p = .02), and inflammation biomarker CRP (delta R2 = .072, p = .042). A hierarchical cluster analyses was performed whereby a Dendrogram using Ward Linkage showed that indeed somatic but not cognitive symptoms of depression clustered with HRV and CRP. Conclusions. In patients with Stage B heart failure, somatic symptoms of depression were associated with increased HRV and a marker of inflammation. Somatic symptoms of depression, potentially denoting sickness behavior associated with increased inflammation, may result in increased parasympathetic activity to conserve energy.

Paper Session 44: Correlates of Cardiovascular Disease 4:13 PM-4:30 PM

CHILDHOOD TRAUMA, PERCEIVED STRESS, AND HAIR CORTISOL IN ADULTS WITH AND WITHOUT CARDIOVASCULAR DISEASE

Stéphanie Bossé[1], Bianca D'Antono, PhD[2]

[1]Montreal Heart Institute/Université de Montréal, Montréal, PQ, Canada; [2]Montreal Heart Institute/Université de Montréal, Ste-Julie, PQ, Canada

Background: Traumas experienced in childhood have been associated with greater psychological or physical morbidity, including a greater risk of developing cardiovascular disease (CVD). It has been hypothesized that this may reflect, at least in part, disturbances in how stress is later perceived and regulated.

Objective: To examine the associations of childhood trauma with perceived stress over the past two years and 3-month hair cortisol levels in adults with and without CVD. Whether associations differ as a function of sex, age or CVD status is also examined.

Methods: 745 men and 453 women (Age=65 ± 7 years) with and without (N=581) CVD completed the Childhood Trauma (CTQ) and Perceived Stress Questionnaires. Cortisol concentrations from 3-cm segments of hair were assessed in 642 participants. Analyses involved Pearson correlations and hierarchical regressions that controlled for pertinent covariates.

Results: Moderate to severe childhood trauma was experienced by 374 participants, and was reported to a similar extent irrespective of sex, age, or CVD status. Women reported more stress but had lower hair cortisol levels compared to men (all $p < 0.001$). Those with CVD exhibited greater cortisol ($p < 0.001$) but similar stress levels compared to participants without CVD. Childhood trauma was associated with higher perceived stress levels over the past two years ($r=0.344$, $p=0.01$; $\beta=0.309$, $p < 0.001$), but not with hair cortisol concentration in both univariate and multivariate analyses. Age moderated the relation between childhood trauma and perceived stress ($\beta=-0.061$, $p=0.023$).

Conclusion: Younger individuals who experienced trauma in their youth reported more chronic stress in late adulthood. However, childhood trauma was not associated with greater accumulation of cortisol in hair over the past 3 months. Whether this reflects more or less intact HPA regulation in those having lived trauma in childhood or reflects the characteristics

of our sample (e.g. 81.1% over the age of 60, 94.5% with at least one illness) requires further investigation.

Keywords: cardiovascular disease, childhood trauma, hair cortisol, perceived stress

RACIAL ATTITUDES AND NONVERBAL CONVERGENCE IN RACIALLY DISCORDANT ONCOLOGY INTERACTIONS

Lauren M. Hamel, PhD[1], Mark A. Manning, PhD[2], Louis A. Penner, PhD[1], Robert Chapman, MD[3], Terrance L. Albrecht, PhD[1], Eggly Susan, PhD[1]

[1]Wayne State University/Karmanos Cancer Institute, Detroit, MI; [2]Karmanos Cancer Institute/Wayne State University School of Medicine, Detroit, MI; [3]Josephine Ford Cancer Center, Detroit, MI

Background: Patient and physician racial attitudes (e.g., physician implicit racial bias; patient suspicion of medical care racial/ethnic minorities receive) affect perceptions of communication in racially discordant (Black patients, non-Black physicians) medical interactions. Racial attitudes are likely expressed and reinforced through nonverbal behaviors. The Communication Accommodation Theory predicts that nonverbal convergence/divergence reflects relational convergence/divergence over time in interpersonal interactions. However, prior research has not investigated the association between nonverbal convergence/divergence and racial attitudes. We investigated the relationship between patient and physician racial attitudes and the convergence/divergence of nonverbal behaviors in racially discordant oncology interactions.

Method: Data were 99 racially discordant video-recorded oncology interactions. Five one-minute slices from each interaction were extracted, randomized, and coded by trained coders (N=495 slices). Coded behaviors were selected based on the research literature and community members' input. The coding system assessed frequency/duration of facial behaviors (e.g., smiling, eye gaze) and body behaviors (e.g., lean, orientation to the other, and openness). Longitudinal dyad discrepancy score modeling (i.e., scores nested within patient-physician dyads) was used to determine discrepancy in nonverbal behaviors between patients and physicians. A three-level longitudinal multilevel model (i.e., time nested within patient, patient nested within physician) was used to determine to what extent racial attitudes influence nonverbal convergence/divergence across each oncology interaction for each behavior.

Findings: Results showed that racial attitudes of patients and physicians influenced the degree of convergence of facial, but not body, behaviors across the oncology interactions. Physicians

lower in implicit racial bias converged with their patients more on frequency of smiling than physicians higher in implicit bias ($p < .05$). Patients higher on medical suspicion converged more with their physicians on duration of eye gaze than patients lower on medical suspicion ($p = .07$). No significant relationships were found between racial attitudes and body behaviors.

Discussion: Findings suggest racial attitudes may manifest in facial behaviors, lending partial support to the Communication Accommodation Theory. Next steps including applying the final phase of the coding system, identification of paraverbal behaviors, to further determine to what extent racial attitudes impact nonverbal convergence/divergence throughout oncology interactions, and to link nonverbal behaviors to interaction outcomes.

Paper Session 45: Racial Concordance and Provider Communications 3:19 PM-3:36 PM

RACE, AGE, AND GENDER DIFFERENCES IN CLINICAL TRIAL AWARENESS, PARTICIPATION, AND SOCIAL SUPPORT IN A SAMPLE OF U.S. ADULTS

Aisha T. Langford, PhD, MPH, Azizi Seixas, PhD, MS

New York University School of Medicine, New York, NY

Background: Historically, racial/ethnic minorities, older adults, and women have been underrepresented in clinical trials (CTs) and health research studies. Limited knowledge and awareness, medical mistrust, logistical barriers, and lack of invitation are some of the commonly cited reasons for these disparities. However, it is not clear how, if at all, these factors may differ by demographics.

Objective: To assess race, age, and gender differences in awareness, participation, and social support for CT participation in an online sample of adults across the United States.

Methods: Black (n=1513) and white (n=361) adults were recruited through Survey Sampling International and completed an online survey about diabetes, health behaviors, CT awareness and participation, and attitudes about research. Age range of participants was 30 to 85. With regard to gender, 910 were male and 949 were female. Chi-square tests were conducted for the following items: 1) Have you ever participated in a research study; 2) Have you ever heard of a CT; 3) Have you ever been asked by a healthcare provider to participate in a CT; 4) Have you ever tried to participate in a CT but told that you were not eligible; 5) If you could guess, how many of your friends and family would participate in a CT (none, some, most, all); and 6) If you decided to participate in a CT, how many of your friends and family would support that decision (none, some, most, all)?

Results: There were significant differences between whites and blacks for having heard of a CT (86% vs. 81%), $\chi^2(df=1,N=1865)=4.5$, $p=.03$. There were also racial differences for how many friends and family would support one's decision to join a CT, $\chi^2(df=3,N=1863)=24.75$, $p < .001$, with whites reporting a higher percentage of “most” compared with blacks. Among blacks exclusively, there were significant age differences. Compared with younger black adults, older black adults were more likely to answer “yes” to the following items: having participated in a research study, $\chi^2(df=1,N=1481)=4.81$, $p=.02$; heard of a CT, $\chi^2(df=1,N=1482)=36.59$, $p < .001$; ever asked by a provider to participate in a CT, $\chi^2(df=1,N=1480)=26.85$, $p < .001$; and tried to participate in a CT but told you were not eligible, $\chi^2(df=1,N=1474)=3.93$, $p=.04$. Additionally, perceptions of how many friends and family would participate in CTs (i.e., "most" or "all") was

higher among younger black adults compared with older black adults, $\chi^2(df=3, N=1483)=23.12$, $p < .001$. There were no differences between black men and women for any of the items evaluated.

Conclusion: More research on the role of social support on CT decision making is needed. Efforts to raise CT awareness and improve participation of diverse groups may benefit from targeted approaches that incorporate demographic, health literacy, and psychosocial factors.

THE INFLUENCE OF HEALTH PROFESSIONAL CONTROL AND QUALITY OF CARE ON WELL-BEING AMONG BREAST CANCER SURVIVORS

Alexis D. Abernethy, PhD[1], Leah S. Fortson, MA[2], Nathan Flores, BA[3], Kimlin Ashing, Ph.D[4]

[1]Travis Research Institute/ Fuller Theological Seminary, Pasadena, CA; [2]Fuller Graduate School of Psychology, Pasadena, CA; [3]Fuller Theological Seminary - Graduate School of Psychology, Pasadena, CA; [4]City of Hope National Medical Center, Duarte, CA

Recent work on locus of health control has clarified the role of both passive and active dimensions of external locus of control in African American cancer survivors. Locus of control and perceptions of professional care were examined in African American and Latina breast cancer (BC) survivors. The hypotheses were as follows: compared to individuals low on quality of professional care, individuals high on quality of professional care will endorse greater well-being; and individuals who endorsed higher professional control and higher internal control (for both control scores, lower scores = higher control) will endorse higher quality of professional care. This study used baseline data from a parent study examining the effects of a psychosocial intervention to reduce distress. Participants were recruited from state and local hospital cancer registries, including the City of Hope cancer registry. The sample included 320 women, 28% African American and 73% Latina, age 26 – 89 years, and 1-5 years post BC diagnosis. High quality of professional care was associated with greater well-being ($\beta = .67$, $p < .001$). Professional control was correlated with professional care. BC survivors who viewed their doctors as being less in control of their health endorsed greater quality of professional care ($r = .15$, $p < .01$). Internal control was inversely correlated with professional care as survivors who had high internal control reported greater quality of professional care ($r = -.25$, $p < .001$). There was no significant interaction between professional care and professional control on well-being. Professional care varied by ethnicity, $F(1, 311) = 18.99$, $p < .001$, as African American survivors endorsed higher quality of professional care than Latina survivors. English speakers endorsed higher quality of professional care than Spanish speakers, $F(1, 311) = 24.25$, $p < .01$. These results may be partially explained by language differences and Latina BC survivors' lower scores on professional care. These findings support the relationship between internal control and professional care, but the findings on professional control and care are unexpected and may provide important insights for care delivery to Latina BC survivors.

Paper Session 45: Racial Concordance and Provider Communications 3:55 PM-4:12 PM

THE IMPACT OF BLACK PATIENTS' RACE-RELATED ATTITUDES ON THE QUALITY OF RACIALLY DISCORDANT ONCOLOGY INTERACTIONS

Louis A. Penner, PhD[1], Felicity Harper, PhD[2], Terrance L. Albrecht, PhD[1], Eggly Susan, PhD[1]

[1]Wayne State University/Karmanos Cancer Institute, Detroit, MI; [2]Karmanos Cancer Institute/Wayne State University, Detroit, MI

In a seminal report on “Unequal Treatment,” the IOM panel identified both provider and patient attitudes as contributing to racial disparities in the quality of healthcare. Subsequently, considerable attention has been given to the impact of providers’ racial attitudes in racially discordant medical interactions. The racial attitudes of Black patients have received much less research attention. The present study explores how different facets of Black cancer patients’ race-related attitudes and beliefs affect patients’ behavior in racially discordant oncology interactions and also patients’ and oncologists’ post-visit perceptions.. Black patients (n=114) completed baseline measures of perceived past discrimination, trust of physicians, healthcare suspicion, and racial identity. Approximately one week later, patients had initial visits with an oncologist (n=18). Ninety-nine of these interactions were recorded and assessed for patients’ verbal activity (e.g., how much they talked). Finally, both patients and oncologists completed post-interaction questionnaires regarding perceptions of each other and of the interaction. Despite their conceptual similarity, patient attitudes and beliefs were weakly intercorrelated and showed different effects. Multi-level regression models were conducted, to account for patients being nested in physicians. Past discrimination was strongly positively associated with patient verbal activity, but was not associated with patient perceptions. Suspicion was negatively associated with patients’ perceptions of oncologist patient-centeredness, trust in the oncologist, confidence in recommended treatments, and ability to complete treatments. Suspicion was also negatively associated with physicians’ perceptions of patient education. A mediational analysis showed that perceived educational level led oncologists to believe higher suspicion patients were less likely to follow treatment regimens and tolerate their treatments. Thus, Black patients’ race-related attitudes and beliefs, which are grounded in history and in current experiences as Black people living in the US, play an important role in racially discordant medical interactions. These attitudes and beliefs can contribute to racial disparities in patient and physician treatment decisions and adherence. Differences among patients in these attitudes and beliefs must be considered in attempts to reduce racial disparities in healthcare.

INFLUENCE OF RACE OF PRINCIPAL INVESTIGATOR ON STUDY PARTICIPATION OF AFRICAN AMERICANS

Martinus Evans, B.S., M.S.[1], Christine May, PhD[2], Molly E. Waring, PhD[1], Danielle E. Jake-Schoffman, PhD[3], Amanda Okpoebo, BS[4], Sherry Pagoto, PhD[1]

[1]University of Massachusetts Medical School, Worcester, MA; [2]University of Massachusetts Medical School, Fiskdale, MA; [3]University of Massachusetts Medical School, Worcest, MA; [4]UMass Medical School- Preventive Behavioral Medicine, Leominster, MA

African Americans continue to be underrepresented in clinical research studies. This study aimed to investigate if the race of the principal investigator (PI) would influence African Americans' motivation to participate in research studies, how to convey the race of the PI, and factors that would help build trust when the PI is not African American. We conducted in-depth semi-structured interviews (n=4) and two focus groups (n=6) with adults who self-identified as African American or multiracial African American. Interviews and focus groups were recorded and transcripts were coded using an inductive method. We conducted a content analysis on all questions of using an inductive method using two coders. Participants (n=10) were on average 35 (SD=6.0) years old and 80% were college educated. Results revealed that for the majority of the participants (n=9), their motivation to participate in a study would be enhanced if they knew that the PI was African American (kappa =1.0). When asked what would the best way to convey the PI was African American, a face-to-face approach was the most common recommendation reported by 4 participants. Other recommendations included putting a picture of the PI on the recruitment flyers (n=3), and stating "by black people for black people" on recruitment materials (n=1) (kappa=.7). Several themes emerged about how to build trust when the PI is not African American (kappa= .8): having a presence in the community (n=6), showing transparency in the research process (n=4), acknowledgement of the African American struggle (n=2), and hiring diverse staff (n=1). Increasing the diversity of research investigators and research workforce as well as changes in recruit strategies may increase African American participation in research studies. Further research is needed to explore which strategies are to increase participation of African Americans in research studies.

USING MACHINE LEARNING TO IDENTIFY SOCIAL DETERMINANTS THAT PUT VETERANS AT HIGHEST RISK FOR POOR DIABETES OUTCOMES

Leslie Hausmann, PhD[1], Joshua THORPE, PhD, MPH[1], Maria K. Mor, PhD[1], John Cashy, PhD[2], Amresh Hanchate, PhD[3]

[1]VA Pittsburgh Healthcare System, Pittsburgh, PA; [2]VA Pittsburgh Health System, Pittsburgh, PA; [3]Boston University School of Medicine, Boston, MA

Social determinants of health contribute to disparities in diabetes. Whether or how multiple social determinants combine to put patients at highest risk for poor diabetes management is unknown. We used classification and regression trees (CART) methods in a national cohort of 188,743 Veterans with type 2 diabetes in 2008 to identify combinations of key social determinants that predict two indicators of poor diabetes management: diabetes-related preventable hospitalizations and mortality. Using Veterans Affairs and US Census data, we computed 45 individual and zip-code level indicators of social determinants of health, including individuals' sociodemographic (e.g., race, marital status, homelessness) and clinical (e.g., mental illness, HIV) characteristics and their neighborhood's socioeconomic status, safety, racial/economic diversity, internet connectivity, and grocery stores. In 2009, 0.7% of the sample were hospitalized and 3.6% died. CART identified 4 individual-level variables that combined into 5 risk factor profiles for hospitalizations (range: 0.3% to 3.1% hospitalized). Area under the receiver-operator characteristic (ROC) curve for these 4 predictors was 0.64. Highest hospitalization rates were among married Veterans with a history of homelessness (3.1%) and unmarried Veterans (1.2%). Among those remaining, the highest rate was among black Veterans under age 65 or over 74 (1.0%). For mortality, CART identified 4 individual and 2 neighborhood variables that combined into 8 risk profiles ranging from 1.8% to 6.6% in the youngest and oldest age groups, respectively (ROC=0.66). In the middle age groups, those who were unmarried, had hepatitis or used tobacco, and lived in areas with high poverty and unemployment had increased risk of death. From the 45 possible risk factors, CART analysis identified a small subset of key social determinants that predicted poor diabetes outcomes in Veterans. Additionally, these risk factor combinations would be difficult to detect using traditional statistical methods and can enable interventions to be targeted towards particularly at-risk populations.

CHARACTERISTICS OF ARMY RESERVE FAMILIES WHO USE FAMILY READINESS PROGRAMS

Erin M. Anderson Goodell, SM[1], D. Lynn Homish, BS[2], Gregory G Homish, PhD[2]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; [2]University at Buffalo, Buffalo, NY

Background: Previous research suggests that families of Reserve/National Guard (R/NG) personnel are less integrated into military life compared to active duty families. Special family readiness programs (FRPs) exist to address this issue, but limited research has been conducted to examine who uses them. This study uses the Andersen Behavioral Model (ABM) to examine characteristics of Army R/NG families who access FRPs.

Methods: Data are cross-sectional from Operation: SAFETY (Soldiers And Families Excelling Through the Years), an ongoing longitudinal study of US Army R/NG Soldiers and their partners (N=411 couples). The ABM was used to frame predisposing, enabling, and need-based factors that may influence use of FRPs. Logistic regression models assessed the likelihood of the respondent or an immediate family member accessing an FRP based on selected variables.

Findings: Predisposing factors that may influence a family to access FRPs include having more children (OR=1.14 [1.01-1.30], $p < 0.01$). A military-specific predisposing factor is a family experiencing at least 1 deployment (OR=3.18 [2.08-4.85], $p < 0.001$). Furthermore, having two spouses who have deployed, as in dual-military couples, also increases the likelihood of accessing an FRP (OR=4.95 [1.91-12.84], $p < 0.01$). For enabling factors, families with members who have longer time in military service are more likely to access FRPs (OR=1.12 [1.07-1.16], $p < 0.001$), while families with the wife as the military spouse results in lower likelihood of accessing FRPs, compared to husband-only and dual-military families (OR=0.26 [0.12-0.57], $p < 0.01$ and OR=0.33 [0.12-0.93], $p < 0.05$, respectively). For need factors, mental health status (depression, hazardous drinking, and PTSD), of either military or civilian spouse, is not related to the outcome. However, physical intimate partner violence perpetrated by the husband is marginally significantly related to accessing an FRP (OR=1.68 [1.00-2.82], $p=0.05$).

Conclusions: Findings shed light on the types of military families that may or may not access FRPs, which might guide future efforts to link underserved families to resources. Future research should focus on understanding need-based factors and the impact that FRPs might have on such needs.

Paper Session 46: Health Profiles of Veterans 3:37 PM-3:54 PM

LONGITUDINAL EXAMINATION OF RESILIENCE AMONG 3 SAMPLES OF MILITARY PERSONNEL

Gabriel De La Rosa, NA[1], Jennifer Webb-Murphy, PhD[2], Scott Johnston, CAPT, PhD[2], Jeffrey Millegan, MD, MPH[2]

[1]Naval Center for Combat and Operational Stress Control, San Diego, CA; [2]Naval Center for Combat & Operational Stress Control, San Diego, CA

After exposure to potentially traumatic events (PTEs) some individuals experience great hardship while others return to normal functioning. This ability to “bounce back” after exposure to PTEs characterizes psychological resilience. Given the importance of resiliency in contributing to individual wellbeing, several researchers have noted a need for considering the temporal nature of this construct. Research into the stability of resiliency over time is limited and can provide mixed conclusions. To help add to this growing literature base, the current study investigates the stability of resiliency among three samples of military personnel. Sample 1 includes 873 personnel on a combat deployment. Sample 2 includes 177 personnel participating in a training initiative. Sample 3 includes 611 military personnel presenting for mental health treatment. *Resilience* was measured using the Response toStressful Experiences Scale (RSES), a 22-item scale emphasizing coping processes. Longitudinal growth models using a multilevel random coefficient modeling framework were employed to examine trajectories of resilience over time (Raudenbush & Bryk, 2002). Results suggest that from 49% to 64% of variance in resilience scores were explained by between person differences. Results suggest that lowest initial RSES scores were found among the sample of treatment seeking military personnel while the highest initial RSES scores were found among the personnel participating in a training initiative. The treatment seeking sample displayed the strongest increase in resilience scores over time while the deployed Marine sample displayed the lowest increase in resilience scores over time. Results from the treatment seeking sample may suggest that clinicians can provide personnel with the resources and confidence needed to address future stressors. Results of the current study suggest that over time, resilience scores are more likely to increase (or remain stable) than to decrease. This is evidenced by the significant positive relationship between time and resiliency scores and the positive relationship between age and overall resiliency scores. Even throughout a stressful combat deployment, resiliency scores tended to increase over time.

12-MONTH WEIGHT LOSS OUTCOMES AMONG VETERANS WITH PREDIABETES IN AN ONLINE DIABETES PREVENTION PROGRAM

Tannaz Moin, MD, MBA, MSHS[1], Mona AuYoung, PhD, MS, MPH[2], Laura Damschroder, MS, MPH[2], Caroline Richardson, MD[3]

[1]VA Greater Los Angeles Healthcare System, David Geffen UCLA School of Medicine, Los Angeles, CA; [2]VA CCMR, Ann Arbor, MI; [3]University of Michigan, Ann Arbor, MI

There is a significant evidence base supporting the effectiveness of the Diabetes Prevention Program (DPP), a lifestyle management program to reduce incidence of diabetes, which has been translated to multiple settings. Online adaptations of the DPP may enhance reach by allowing individuals to participate in DPP at the time and location of their choosing. However, most programs have been limited to face-to-face or phone-based modes of delivery. Thus, the goal of this study was to assess the effectiveness of an online version of the DPP among Veterans with prediabetes.

Eligible Veterans with prediabetes were invited to enroll in an online DPP, which was added to an ongoing trial of two in-person programs as an additional parallel, non-randomized arm. The analytic sample included consented patients who had 12-month weight outcomes available (via wireless scales or clinical administrative data). Mixed effects models were used to assess 12-month weight change, controlling for demographic factors.

Based on preliminary analyses, on average, online DPP participants (n=268) lost 6.25 lbs ($p < 0.001$) from baseline to 12 months. This was comparable to the average weight loss of 7.5 lbs ($p < 0.001$) among participants of the in-person DPP that was part of the ongoing trial within the VA. These preliminary findings suggest that online delivery of DPP is feasible and that results may be comparable to a group-based in-person program for Veterans with prediabetes.

Paper Session 46: Health Profiles of Veterans 4:13 PM-4:30 PM

LIFESTYLE FACTORS AND RISK OF OBESITY AMONG US VETERANS

Deborah B. Bookwalter, ScD[1], Isabel G. Jacobson, MPH[1], Ben Porter, PhD[1], So Yeon Kong, PhD[1], Alyson J. Littman, PhD[2], Rudolph P. Rull, PhD[1], Edward J. Boyko, MD, MPH[3]

[1]Naval Health Research Center, San Diego, CA; [2]VA Puget Sound Health Care System and the University of Washington, Seattle, WA; [3]VA Puget Sound Health Care System, Seattle, WA

Research suggests US veterans have a higher prevalence of obesity (body mass index [BMI] ≥30 kg/m^2) than those with no prior military service and weight gain is particularly high around the time of military discharge. Despite an established link between individual lifestyle factors and weight gain, few studies have assessed the combined influence of multiple factors on obesity risk. This study examined the cumulative effect of several lifestyle factors on risk of new-onset obesity after separation from the military using data from the Millennium Cohort Study, an ongoing prospective study designed to investigate health effects associated with US military service. Participants complete surveys triennially that collect information on demographics, service-related and lifestyle factors, and physical and mental health. Participants' self-report of lifestyle factors of interest (physical activity, sedentary time, sleep duration, fast food intake, alcohol use) were dichotomized into "healthy" and "unhealthy" categories (e.g., fast food intake < 1 vs. ≥1 times per week). Multivariable Cox models estimated hazard ratios (HR) and 95% confidence intervals (CI) for incident obesity in relation to the number of healthy lifestyle factors (0 to 5). Among 16 432 participants with a BMI of 18.5 to 29.9 kg/m^2 at baseline, 16% became obese over a mean follow-up of 4.8 years. Obesity risk decreased with an increasing number of healthy lifestyle factors, with a 51% lower risk for those with all 5 vs. 0 healthy lifestyle factors (HR 0.49; 95% CI 0.34 to 0.69); evaluated ordinally, risk was 14% lower for each additional healthy lifestyle factor (HR 0.86; 95% CI 0.83 to 0.90; *P*, trend < 0.001). Estimates were similar by sex but less precise among women. The population attributable risk for having 1 or more of the 5 unhealthy lifestyle factors compared with none was 30% (95% CI 1% to 48%), an estimate of the proportion of individuals with new-onset obesity that would have been prevented if the entire study population had all 5 healthy factors. The present findings suggest the adoption of an increasing number of healthy lifestyle factors is associated with an additive reduction in risk of obesity among veterans.

STRESS REACTIVITY MEDIATES THE WITHIN-DAY LINK BETWEEN SLEEP QUALITY AND DEPRESSION IN FIBROMYALGIA

Dhwani J. Kothari, M.A., Crystal T. Rivers, J.D., M.A., Mary C. Davis, Ph.D.

Arizona State University, Tempe, AZ

Poor sleep quality is a common correlate of chronic pain. Not only does poor sleep exacerbate ongoing pain, but it can also impair psychological functioning through heightened symptoms of depression. The within-day mechanisms linking a night of poor sleep to increased depression the next day have not been examined. Therefore, the current study examined the within-day relations among morning reports of sleep quality on the previous night, late afternoon reports of stress reactivity, and nighttime reports of depressive symptoms. Stress reactivity was expected to mediate the link between sleep quality and symptoms of depression. Electronic daily diary data were collected for 21 days from 220 individuals with fibromyalgia, a chronic pain condition. Multilevel Structural Equation Modeling was performed to estimate the mediation model at the within-person level. Results demonstrated that stress reactivity significantly mediated the relation between sleep quality and depressive symptoms. Specifically, higher than usual morning reports of poor sleep quality on the previous night predicted greater than usual late afternoon stress reactivity, which subsequently predicted higher than usual levels of depressive symptoms reported at nighttime. Further, a secondary within-day analysis showed that nighttime reports of depressive symptoms did not predict sleep quality reported the next morning. Overall, the findings suggest that a night of poor sleep may heighten same-day depression in chronic pain individuals by interfering with their ability to manage stressors that day. There was no evidence to suggest carryover effects of depression on sleep, suggestive of a “vicious cycle,” on subsequent days.

BRIEF BEHAVIORAL THERAPY FOR CANCER-RELATED INSOMNIA: EFFECT ON QUALITY OF LIFE AND HEART RATE VARIABILITY DURING CHEMOTHERAPY

Oxana Palesh, PhD[1], Michelle Janelsins, PhD, MPH[2], Caroline Scheiber, PhD[1], Mary Melissa. Packer, MA[3], Shelli Kesler, PhD[4], Richard Gevirtz, PhD[5], Joseph J. Guido, MS[2], Charles E. Heckler, Ph.D., M.S. [2], Karen Mustian, PHD, MPH, MS[2]

[1]Stanford, Stanford, CA; [2]University of Rochester Medical Center, Rochester, NY; [3]Stanford University, Burlingame, CA; [4]MD Anderson, Houston, TX; [5]Alliant International University, San Diego, CA

Quality of Life (QOL) is negatively impacted in breast cancer (BC) patients receiving chemotherapy, and diminished QOL exacerbates psychological and physiological symptoms. Reduced vagal tone, as indicated via lower heart rate variability (HRV), is hypothesized to influence the pathophysiology of impaired QOL. To date, there are no effective brief behavioral interventions that are deliverable to cancer patients in the clinic while they are receiving chemotherapy. As QOL and HRV are heavily influenced by sleep quality, we aimed to evaluate the efficacy of a novel intervention, Brief Behavioral Therapy for cancer-related insomnia (BBT-CI), for improving QOL and HRV in BC patients undergoing chemotherapy.

In our phase II, 2-arm, randomized controlled trial, 71 BC patients (mean age=52.5, SE=1.16; 96% Caucasian) who reported moderate insomnia were randomized to: 1) BBT-CI (2 face to face sessions + 4 phone calls) or 2) a healthy eating behavioral control (HEAL). BBT-CI and HEAL were delivered over 6 weeks by trained nurses or clinical research assistants in the chemotherapy infusion clinic at 5 NCI-funded Community Oncology Research Program (NCORP) clinical practices across the U.S. QOL was measured via the Functional Assessment of Cancer Therapy – General (FACT-G) and FACT-B, a specific subscale for patients with BC, as well as HRV via an ambulatory heart-rate device (Firstbeat Bodyguard 2) at baseline and post-intervention. HRV was measured using time (SDNN, rMSSD) and frequency indices.

The study showed excellent feasibility and acceptability of conducting BBT-CI in the infusion clinic with a recruitment rate of over 75% of eligible participants and an intervention adherence of 74%, with 75% of intervention components successfully delivered by trained community research staff. Analysis of covariance showed that patients who received BBT-CI exhibited improvements in their QOL compared to those receiving HEAL at 6 weeks (FACT-G, p=0.009; FACT-B, p=0.016). Furthermore, there was a significant treatment effect in HRV indices of both time and frequency in which patients receiving BBT-CI remained stable in contrast to patients receiving HEAL whose HRV declined (SDNN, p=0.047; rMSSD, p=0.040; HF, p=0.018).

BBT-CI rendered greater improvements than HEAL on QOL and HRV, demonstrating efficacy in the community oncology setting. BBT-CI is a novel intervention that can yield additional psychophysiological benefits to patients during their infusion sessions. Bringing efficacious behavioral interventions to the oncology clinic can change the paradigm of clinical practice, ameliorating patients' burden and symptoms.

SLEEP QUALITY INFLUENCES NEXT-DAY AFFECT AND EMOTION REGULATION: A DAILY DIARY STUDY OF HIV-POSITIVE GAY AND BISEXUAL MEN

Brett M. Millar, MA[1], Jeffrey T. Parsons, PhD[2], H. Jonathon Rendina, PhD, MPH[3]

[1]Graduate Center, City University of New York, New York, NY; [2]Hunter College and The Center for HIV Educational Studies and Training, New York, NY; [3]Hunter College of the City University of New York (CUNY), New York, NY

Background: Previous studies have uncovered the impact of poor sleep quality on subsequent affect and emotion regulation in the general population. Daily diary studies on gay and bisexual men have also observed event-level associations between both anxious affect and sexual activation and increased sexual risk-taking. The current study sought to explore links between sleep quality and daily affect and emotion regulatory capacity amongst HIV-positive gay and bisexual men using event-level data from an online daily diary study. **Method:** We analyzed 798 daily reports from 53 HIV-positive gay and bisexual men enrolled in a 21-day online diary study. Multilevel logistic modeling was used to test whether previous night's sleep quality predicted affect (depressive, anxious, anger, fatigue, and sexual, separately) and emotion regulation. Models were fit with an AR(1) covariance structure and random intercept. Daily reports of previous night's sleep quality were disaggregated into individual-level averages and situational fluctuations around one's average, and were used to predict current-day affect and emotion regulation. **Results:** The sample was diverse with regard to race/ethnicity (75% men of color), and had a mean age of 38 years. Daily sleep quality was significantly associated with each affective outcome, such that an individual having lower-than-average sleep quality on a given day also reported higher levels of depressive ($B = -0.08$, $p < 0.001$), anxious ($B = -0.04$, $p = 0.02$), and angry ($B = -0.05$, $p < 0.01$) affect, as well as greater fatigue ($B = -0.08$, $p < 0.001$) and emotion dysregulation ($B = -0.04$, $p< 0.01$). Lower-than-average sleep quality on a given day was also marginally associated with increased sexual activation ($B = -0.05$, $p = 0.06$). **Conclusions:** Individuals experiencing daily disruptions in sleep quality reported increased negative emotionality, which is consistent with previous research on various populations. The current study highlights poor sleep quality as an important lifestyle variable in these men's emotional and sexual lives--increasing negative affect and potentially sexual activation, while also decreasing the individual's capacity to regulate these affective states. Implications for the development of sleep-related interventions to improve mood and daily coping, and to potentially reduce sexual risk-taking, will be explored.

SLEEP DISRUPTION AMONG CANCER PATIENTS FOLLOWING AUTOLOGOUS HEMATOPOIETIC CELL TRANSPLANTATION (HCT)

Ashley M. Nelson, MA[1], Heather Jim, PhD[2], Brent Small, PhD[3], Brian D. Gonzalez, Ph.D.[4], Taiga Nishihori, MD[5], Julie Cessna, M.P.H., M.A.[6], Kelly Hyland, B.A.[6], Meredith Rumble, PhD[7], Paul B. Jacobsen, PhD[8]

[1]University of South Florida & Moffitt Cancer Center, Tampa, FL; [2]Moffitt Cancer Center, Tampa, FL; [3]University of South Florida, Tampa, FL; [4]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; [5]H. Lee Moffitt Cancer Center and Research Institute, Tampa, FL; [6]University of South Florida/Moffitt Cancer Center, Tampa, FL; [7]University of Wisconsin, Madison, WI; [8]National Cancer Institute, Bethesda, MD

Background: Sleep disruption is a commonly reported quality of life concern among cancer survivors following HCT. Despite the high prevalence of sleep disruption in HCT recipients, relatively little research has investigated sleep disruption or explored relationships with psychological factors such as cognitive or behavioral factors. In addition, no studies have used actigraphy to characterize sleep disruption in this population.

Method: Autologous HCT recipients who were between 6 to 18 months post-transplant completed self-report measures of cancer-related distress, fear of cancer recurrence, dysfunctional sleep cognitions, and maladaptive sleep behaviors upon enrollment. Patients then wore an actigraph and completed a sleep log for the next 7 days and completed a self-report measure of sleep disruption on day 7 of the study.

Results: Patients were 84 autologous HCT recipients (age M = 60, 45% female, 69% multiple myeloma). Forty-one percent met criteria for sub-clinical or clinical insomnia based on patient self-report (ISI ≥ 8). Examination of actigraphy data indicated that, on average, sleep was disturbed (e.g., wake after sleep onset M = 66 minutes; total sleep time M = 6.5 hours). Cancer-related distress, fear of recurrence, dysfunctional sleep cognitions, and maladaptive sleep behaviors were related to self-reported sleep disruption (p's < .05), but were not related to objective sleep indices. The cognitive and behavioral factors accounted for 27% of the variance in subjectively reported sleep disruption compared to 7% of variance accounted for by cancer-related distress and fear of recurrence.

Conclusion: Results suggest that many HCT recipients experience sleep disruption during the post-transplant survivorship period. Cancer-related distress, fear of recurrence, dysfunctional

sleep cognitions, and maladaptive sleep behaviors are related to self-reported sleep disruption and can be considered targets for intervention.

Paper Session 47: Behavioral Medicine in Sleep and Insomnia Research 4:13 PM-4:30 PM

MIND-BODY-SPIRITUAL PROGRAM REDUCES INSOMNIA IN FEMALE VETERANS WITH PTSD: A RANDOMIZED PILOT

Jill E. Bormann, PhD, RN, FAAN[1], Danielle J. Beck, MPH, CCRC[2], Teresa Gacnik, MSN, RN[3]

[1]VA San Diego Healthcare System Center of Excellence for Stress and Mental Health (CESAMH), San Diego, CA; [2]VA San Diego Healthcare System, San Diego, CA; [3]VA San Diego Healthcare System, Carlsbad, CA

Objectives: Prior research on outcomes of the Mantram Repetition Program (MRP) in 80 women has shown significant posttreatment reductions in perceived stress and improvements in quality of life. The majority of women, however, did not have history of trauma. This study explored the outcomes of MRP versus Present Centered Therapy (PCT) in female Veterans diagnosed with PTSD.

Methods: A randomized trial compared the MRP with PCT in 173 Veterans. Of these, 26 were women randomly assigned to either 8-weeks (1 hour/week) of individual MRP (*n*=16) or PCT (*n*=10). Insomnia Severity Index (ISI), Clinician-Administered-PTSD Scale-version-4 (CAPS), and PTSD Checklist-version 4 (PCL) were administered at pre-, post-, and 2-month follow-up. Data were analyzed using mixed effect models.

Results: Participants' average age was 39.5±11.6 ranging from 25 to 65 years old. Fifty-four percent (*n*=14) were White, 23% (*n*=6) were married/partnered, and 27% (*n*=7) were employed full-time. There was a significant group by time interaction effect for ISI, *F*(2,32)=3.70, *p*=.036, indicating the MRP group had a significantly greater decrease in ISI at 2-month follow-up (*M*=18.94±6.3 to 12.5±9.5) versus PCT group (*M*=18.0±6.4 to 16.4±7.0). There was strong trend for a group by time interaction effect on the CAPS, *F*(2,34)=3.08, *p*=.059, showing MRP group with a greater decrease at 2-month follow-up (*M*=81.50±18.9 to 50.30±20.5) compared with PCT (*M*=76.90±20.4 to 60.33±27.5). There were significant time effects for CAPS in both groups, *F*(2,34)=12.43, *p*=.001. There were significant time effects for PCL *F*(2,45)=16.12, *p*=.0001 with MRP group reporting a slightly greater decrease in PCL at follow-up (*M*=60.07±11.7 to 41.10±12.8) compared with PCT (*M*=60.50±15.5 to 49.50±16.3).

Conclusions: The MRP, a non-trauma-focused, complementary program for PTSD, may significantly reduce insomnia in female Veterans with PTSD. Despite the small sample size, these findings are promising and support future research to determine the full effect of the MRP for PTSD symptoms.

CHANGES IN NURSE-CAREGIVER COMMUNICATION IN CANCER HOME HOSPICE VISITS OVER TIME

Maija Reblin, PhD[1], Seth Latimer, MStat[2], Margaret Clayton, PhD[2], Lee Ellington, PhD[2]

[1]Moffitt Cancer Center, Tampa, FL; [2]University of Utah, Salt Lake City, UT

Background

Cancer patients often decline quickly at end of life and many choose home hospice care. In home hospice, family caregivers (CGs) have primary responsibility for patients' day-to-day symptom, psychosocial, and emotional care with support from a nurse-led interdisciplinary team. Little systematic research has been conducted on nurse-CG communication in home hospice and thus it is unknown how nurse-CG communication changes with patient decline. Our goal was to identify the trajectory of home hospice nurse-CG visit communication.

Methods

As part of a large prospective, multi-site observational study, 537 nurse home visits to 101 spouse cancer CGs were audio-recorded from hospice enrollment to patient death. Communication in physical, psychosocial, and emotional domains were identified for both nurses and CGs. Linear mixed modelling was conducted on communication domain using visit as a random effect and CG and nurse as fixed effects.

Results

CG M age=65.6 years (SD=10.2) and 60% were female. Nurses were 90% female and M years practicing in hospice=4.5 (SD=4.9). Visits averaged 40 minutes and length did not significantly change over time. Physical care talk was the most common for nurses on average (M=55%, SD=23%) and CG (M=46%, SD=28%). Psychosocial talk averaged 11% of nurse talk (SD=10%) and 21% for CGs (SD=19%); emotional talk averaged 12% for nurses (SD=8%) and 8% for CGs (SD=11%). Over time nurses had significantly less psychosocial (t=-2.56, p.05).

Discussion

Findings suggest that nurses and CGs co-construct communication in home hospice over time, with small but significant changes as patient death approaches. CG physical care talk increases as their psychosocial and emotional talk is maintained, suggesting CGs are reporting more physical changes with patient decline. Despite this, nurse physical care talk remains stable. The reduction in nurse psychosocial and emotional talk frequency may suggest lessening priority of these domains or providing more space for CGs. Our findings demonstrate a first step in future research to demonstrate how CG needs are met over time and the impact this has on patient and CG outcomes.

FEASIBILITY AND ACCEPTABILITY OF A COMMUNICATION INTERVENTION FOR COUPLES COPING WITH HEMATOPOIETIC CELL TRANSPLANTATION

Shelby L. Langer, PhD[1], Joan M. Romano, PhD[2], Stephanie Lee, MD[3], Tracey Godlewski, PA-C[3], Melissa DuPen, BS[2], Laura Porter, PhD[4]

[1]Arizona State University, Phoenix, AZ; [2]University of Washington, Seattle, WA; [3]Fred Hutchinson Cancer Research Center, Seattle, WA; [4]Duke University, Durham, NC

Hematopoietic cell transplantation (HCT) is an aggressive form of cancer treatment with medical and psychosocial sequelae. Caregiving partners are also impacted, reporting elevated levels of distress. Patient-partner communications, moreover, are characterized by avoidance of treatment-related concerns. This study assessed acceptability and feasibility of a 5-session couple-based intervention to optimize communication between HCT patients and partners. Of 89 couples approached and deemed eligible, 40 (45%) consented. Demographic characteristics were: M (SD) age = 55.9 (12.3), 38% female, 5% Hispanic and 92% White [patients]; M (SD) age = 54.2 (11.9), 62% female, 8% Hispanic and 92% White [partners]. Eligible and consenting patients did not differ from eligible and refusing patients on these characteristics ($p > .05$). All enrolled patients and partners completed baseline assessments prior to HCT. Thirty reached the intervention (TX) phase 1 month post-HCT; 4 patients died prior to this phase and one was deemed no longer eligible for transplant. All 30 commenced TX and 25 completed TX and follow-up questionnaires; two remain in treatment (90% retention). Process data collected after each session revealed that ratings of self-disclosure and partner responsiveness were high, with means ranging from 4.45 (0.66) to 4.80 (0.35) on a 1-5 scale. These findings suggest that the intervention facilitated communication as intended. Number of sessions completed was positively associated with partner ratings of the extent to which they felt close to and understood/ validated/ accepted by the patient during the sessions (r values ranging from 0.40 to 0.54, p values < .05), and unassociated with baseline demographic or psychosocial characteristics ($p > .05$). Program evaluation ratings support acceptability: M (SD) = 4.50 (0.59) and 4.17 (0.72) on a 1-5 scale for satisfaction with services reported by patients and partners, respectively; and 4.17 (0.70) and 4.22 (0.80) for usefulness of the program. Findings indicate that HCT patients and partners can be recruited and retained for this intervention, and found it acceptable and useful. Perceived partner responsiveness may be important for continued retention.

COPING WITH HOME HOSPICE CANCER CAREGIVING: EMOTIONAL SCAFFOLDING IN NURSE-CAREGIVER COMMUNICATION

Maija Reblin, PhD[1], Janella N. Hudson, PhD[1], Margaret Clayton, PhD[2], Lee Ellington, PhD[2]

[1]Moffitt Cancer Center, Tampa, FL; [2]University of Utah, Salt Lake City, UT

Background

Cancer caregiving can be stressful for families, especially in home hospice as end of life approaches and more demands are placed on family caregivers (CGs). CGs of home hospice patients are often dependent on their hospice nurse for guidance in providing patient care and in helping CGs emotionally cope with the stress of care and an impending loss. Much is known about how nurses support CGs in providing patient symptom management, but little research has addressed nurse strategies for scaffolding CG emotional coping during distress. This study examines the communication strategies utilized by hospice nurses to support emotional expression and coping and the responses from informal spouse caregivers.

Methods

Data were taken from a larger study of audio recorded nurse visits to families in cancer home hospice. Using transcripts of recordings, trained coders identified verbal behaviors representing various types of nurse emotional scaffolding and CG emotional expression. Using an iterative process of constant comparison, coders inductively categorized the instances of nurse and CG communication behavior into overarching themes.

Results

19 visits were selected (representing 7 hospice agencies). Average nurse age was 42.5 (SD=8.9), 90% white, 100% female. CGs were spouses of patients (average years in relationship=35.9, SD=20.0), average age=68.1 (SD=10.6), 100% white, 84% female). Nurses scaffolding was more common than CG emotional expression. Nurses scaffolding included encouragement of emotional expression and modeling emotional coping strategies. CGs expressed positive emotion (e.g. gratitude, humor) and frustration. Common thematic

strategies included positive reframing (e.g. seeking to see the positive side), building emotional rapport (e.g. using humor to connect), and venting (e.g. giving permission, providing a safe space, or airing concerns).

Discussion

Emotion-focused coping can reduce stress and improve psychological and physical health. Nurses provide emotional scaffolding that encourages some CGs to express emotions during distress, but more research is needed to determine longer-term impacts on CG coping or CG health outcomes and patient care. These findings may inform educational materials for nurses or future communication interventions.

SOCIAL SUPPORT FOR LATINO CAREGIVERS

Isabela Marques, BS, Guilherme Balbim, MS, Melissa Magallanes, MS, Judith Rocha, LCSW, David Marquez, PhD

University of Illinois at Chicago, Chicago, IL

Alzheimer’s disease and related dementia (ADRD) affect 11% of people age 65 and older in the US. Latinos are a growing segment of the population and it is expected that by 2050, 128 million Latinos will account for 29% of the population. Loneliness and low levels of support from family, friends and social groups are important predictors of disease outcomes in older adults. Latinos report greater social isolation than non-Latino whites, exposing them to greater risk of chronic diseases. The purpose of this study was to identify the different groups that provide social support for Latino caregivers, and to understand how the four kinds of social support (emotional, appraisal, informational, and instrumental support) are offered for Latino caregivers. Interviews were conducted with Latino caregivers (N=16, 12 females; 4 males), 50 years and older, caring for a relative with ADRD a minimum of 4 hours daily for the past 6 months. Eight interviews were conducted in Spanish and eight in English. Interviews about the caregiver role, family and social support, and health behaviors were recorded, transcribed, translated and coded according to the directed content analysis. Caregivers mentioned that social support was provided by family, friends, therapist, homemakers, governmental aid, and organizations. The four types of social support were identified: emotional, appraisal, informational, and instrumental support. Caregivers reported receiving emotional support from family and friends; appraisal support from family and therapist; informational support was provided by family and organizations; and instrumental support from family, friends, homemakers, organizations, and governmental aid. Family members were cited as vital piece in caregiving, providing all four types of support. Instrumental support was mentioned as a needed type of support, mainly offered by family members, homemakers, and governmental aid. Interventions must consider the Latino family structure in offering assistance for caregivers, and also the crucial instrumental help desired to reduce caregivers’ responsibilities.

ENGAGEMENT IN PLEASANT LEISURE ACTIVITIES AND BLOOD PRESSURE: A 5-YEAR LONGITUDINAL STUDY IN ALZHEIMER'S CAREGIVERS

Taylor Bos, MA[1], Brent Mausbach, PhD[2], Igor Grant, MD[2]

[1]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA; [2]University of California San Diego, La Jolla, CA

Objective: Elevated blood pressure is a significant public health concern, particularly given its association with cardiovascular disease risk, including stroke. Caring for a loved one with Alzheimer's disease has been associated with physical health morbidity, including higher blood pressure. Engagement in adaptive coping strategies may help prevent blood pressure elevation in this population. This 5-year longitudinal study examined whether greater participation in pleasant leisure activities was associated with reduced blood pressure in caregivers.

Methods: Participants were 126 in-home spousal Alzheimer caregivers (mean age = 74.2 ± 7.9 years) that completed five yearly assessments. Linear mixed effects models analysiswas used to examine the longitudinal relationship between pleasant leisure activities and caregivers' blood pressure, after controlling for demographic and health characteristics.

Results: Greater engagement in pleasant leisure activities was associated with reduced mean arterial blood pressure (MAP; $p = 0.037$). Follow-up analyses indicated engagement in activities was significantly associated with reduced diastolic ($p = 0.031$) but not systolic blood pressure ($p = 0.097$). In addition, MAP was significantly reduced when caregiving duties ended because of placement of care recipients in nursing homes ($p = 0.005$) or death of the care-recipient ($p = 0.019$).

Conclusions: Greater engagement in pleasant leisure activities was associated with lowered caregivers' blood pressure over time. Participation in pleasant leisure activities may have both cardiovascular and psychological health benefits for Alzheimer's caregivers.

MERITORIOUS AWARD WINNER

THE IMPACT OF AGE ON THE ASSOCIATIONS BETWEEN DRUG USE DURING SEX AND HIV RISK BEHAVIORS AMONG BLACK MEN WHO HAVE SEX WITH MEN

Jessica L. Maksut, M.A.[1], Elizabeth J. Siembida, Ph.D.[2], Lisa Eaton, PhD[3], Kate E. Dibble, M.A.[1]

[1]University of Connecticut, Storrs, CT; [2]University of Connecticut, Bethesda, MD; [3]InCHIP, Storrs, CT

Background: The associations between drug use during sex, age, and HIV risk remain understudied among samples of exclusively Black MSM (BMSM). Younger BMSM are at highest risk for HIV infection, and so understanding the influence of age on HIV risk behavior patterns among BMSM is critical.

Method: 812 BMSM (*M* age = 33.28 years, *SD* = 11.15 years) in Atlanta, GA completed a quantitative assessment via computer-assisted personal interviewing (CAPI). Negative binomial regression was employed to model the association of number of male partners with whom condomless anal intercourse (CAI) was had, number of female partners with whom condomless vaginal intercourse (CVI) was had, depressive symptoms, problem drinking, HIV treatment optimism, and age with frequency of drug use during sex in the past 3 months.

Results: Of the BMSM who reported drug use during sex (n = 399, 49.14%), the average number of sex acts under the influence of drugs was 6.28 (*SD* = 20.47). BMSM's drug use during sex was positively associated with the number of female partners with whom UVI was had (AOR = 1.61; 95% CI = 1.39-1.88, p = 0.001), depressive symptoms (AOR = 1.06; 95% CI = 1.01-1.10, p = 0.006), and problem drinking (AOR = 2.00; 95% CI = 1.55-1.58, p = 0.001). In contrast, HIV treatment optimism (AOR = 0.68; 95% CI = 0.54-0.87, p = 0.002) and younger age (AOR = 0.95; 95% CI = 0.92-0.98, p = 0.001) were negatively associated with drug use during sex. The interactions between CAI × age (AOR = 1.02; 95% CI = 1.01-1.04, p = 0.003), CVI × age (AOR = 0.98; 95% CI = 0.97-0.99, p = 0.001), and HIV treatment optimism × age (AOR = 1.02; 95% CI = 1.01-1.04, p = 0.002) were significant. As age decreased, the association between CVI with drug use during sex became stronger. Conversely, as age increased, the associations between CVI and HIV treatment optimism with drug use during sex were strengthened.

Discussion: Age is key to understanding the relationships between drug use during sex, CAI, CVI, and HIV treatment optimism. Future HIV prevention efforts may consider tailoring their content to address specific age-related risks for their BMSM clients.

ASSOCIATION BETWEEN ATTACHMENT AND RISK FACTORS FOR ENGAGEMENT IN RISKY SEXUAL BEHAVIORS AMONG AFRICAN AMERICAN WOMEN

Nicole Gause, M.A.[1], Jennifer L. Brown, N/A[2], Sarah Whitton, PhD[1], Ralph J. DiClemente, PhD[3], Kristen E. Jastrowski Mano, PhD[1]

[1]University of Cincinnati, Cincinnati, OH; [2]University of Cincinnati College of Medicine, Cincinnati, OH; [3]Rollins School of Public Health, Atlanta, GA

Background: The study assessed whether attachment-related constructs, *working model-self* (WMS) and *working model-other* (WMO), are associated with risky sexual behaviors, and whether WMS and WMO are associated with risk factors for sexual behaviors commonly targeted by HIV prevention interventions for African American women (e.g., fear of condom negotiation). Furthermore, the study evaluated whether risk factors partially mediate the hypothesized association between WMS and WMO and risky sexual behaviors among African American women.

Methods:560 African American females (age 18-24) reported attachment style, condom use for vaginal and anal sex, and alcohol use prior to sexual encounters during the past 3 months. A subset of women in relationships reported condom use at most recent sexual encounter with boyfriend/main sexual partner.

Results: Neither WMS nor WMO were associated with the following outcomes: (a) proportion condom use for vaginal sex; (b) any condom use for anal sex; (c) condom use at most recent sexual encounter with boyfriend/main sexual partner; and (d) consuming alcohol prior to any sexual encounters. As such, no partial mediation hypotheses were supported. However, WMS was associated with all risk factors for risky sexual behaviors (mediators): partner communication self-efficacy (for example, in relation to this construct, $\beta = 0.26$, $p > .001$); fear of condom negotiation; peer norms for risky sexual behaviors; partner trust; and sex-related alcohol expectancies. Participants with lower WMS had (a) lower partner communication self-efficacy, (b) more fears related to condom negotiation, (c) greater endorsement of peer-norms for risky sexual behaviors, (d) lower levels of partner trust, and (e) greater sex-related alcohol expectancies.

Discussion: Future research should examine whether women with lower WMS benefit from more intensive HIV prevention interventions to effectively change these risk factors and, whether they reduce engagement in sexual risk behaviors.

GENDER COMPARISONS OF CONDOMLESS SEX INTENTION AMONG COLLEGE VARSITY ATHLETES IN TAIWAN USING THE THEORY OF PLANNED BEHAVIOR

Jiun-Hau Huang, S.M., Sc.D., Chia-Hsien Hsu, B.S.

National Taiwan University College of Public Health, Taipei, N/A, Taiwan (Republic of China)

Background: Prior research has found that the prevalence of unprotected sexual behavior in male college athletes was higher than that in female athletes. However, given the different socio-cultural context in Taiwan, little is known about whether and how male and female athletes differ in their condomless sex intention (CSI) and associated factors. Hence, this study aimed to systematically examine the theory-based factors influencing CSI among college athletes using the Theory of Planned Behavior (TPB).

Methods: A total of 1,652 anonymous survey responses were collected from college varsity athletes in Taiwan. After excluding non-heterosexual athletes (n=270) and incomplete responses, a final sample of 1,348 was included in the multivariate logistic regression analyses to examine the TPB-based factors related to higher CSI (rated on a 7-point scale and dichotomized by the median). Items derived from the 3 constructs of TPB (Attitude Toward the Behavior, Subjective Norm, and Perceived Behavioral Control) were factor-analyzed to form 5 factor-based subscales, whose scores were trichotomized using tertiles as cutoffs.

Results: In this study, male college athletes reported significantly greater prevalence of higher CSI (53.6%) than their female counterparts (31.7%). In regard to the 5 TPB subscales, males tended to rate significantly more positively than females concerning attitudinal evaluations of positive CSI outcomes, subjective norm, and perceived ease of CSI under constraining conditions. Among male athletes, those perceiving relatively neutral (AOR=1.66) and relatively positive (AOR=2.59) attitudinal evaluations of positive CSI outcomes were more likely to have higher CSI. By contrast, females had elevated CSI only when they had relatively positive evaluations (AOR=3.75). Further, males with relatively neutral (AOR=1.68) and relatively supportive (AOR=3.22) norm had higher CSI, whereas females reported higher CSI only when perceiving relatively supportive norm (AOR=3.04). Notably, males perceiving relatively intermediate level of control over CSI under facilitating conditions (AOR=0.62) had lower CSI. Lastly, males with relatively high level of control over CSI under constraining conditions (AOR=1.66) had higher CSI.

Conclusions: In conclusion, male college athletes in this study had higher CSI than their female counterparts. Using TPB as a framework, this study found that males reported elevated CSI if they had relatively neutral or higher levels of attitudinal evaluations of positive CSI outcomes

and supportive norm, while females only reported higher CSI if they had relatively positive evaluations and supportive norm, suggesting a threshold for CSI in female athletes. These findings along with other differential patterns and associations warrant gender-specific sexual health education tailored for male and female college athletes in the future.

Paper Session 49: Sexual Behaviors Across Populations 3:55 PM-4:12 PM

EXAMINING THE SYMPTOM NETWORK OF DEPRESSION AND PTSD IN RELATION TO SEXUAL RISK BEHAVIOR IN MSM WITH CHILDHOOD SEXUAL ABUSE

Karmel W. Choi, MA, PhD Candidate[1], Abigail W. Batchelder, Ph.D., M.P.H.[2], Michael Boroughs, PhD[3], Peter P. Ehlinger, B.A.[4], Conall O'Cleirigh, PhD[1]

[1]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital/ Harvard Medical School, Boston, MA; [3]University of Windsor, Windsor, ON, Canada; [4]Fenway Community Health, Cambridge, MA

Background: Histories of childhood sexual abuse (CSA) are disproportionately common among men who have sex with men (MSM) and predict high rates of depression and PTSD, which are known to contribute to sexual risk behavior. To date, research has examined influences of depression and PTSD on sexual risk at the level of disorders, rather than individual symptoms. Moreover, while depression and PTSD frequently co-occur, their symptoms are expected to be meaningfully distinct in presentation and behavioral impact. This study sought to use a novel network approach to (1) visualize how symptoms of depression and PTSD are inter-related in MSM with CSA histories, and (2) explore which symptoms of depression and PTSD are most related to sexual risk behavior.

Methods: In a cross-sectional sample of 296 urban MSM with CSA histories, depressive symptoms were assessed using the Centre for Epidemiological Studies Depression Scale, and PTSD symptoms were assessed using the frequency scale of the Davidson Trauma Scale. Sexual risk behavior was indexed by self-reported frequency of unprotected sex in the past three months. Network analyses were performed in R using mixed graphical modeling to account for different variable types.

Results: The resulting network structure showed complex associations (1) between symptoms across depression and PTSD, and (2) in relation to sexual risk behavior, even when accounting for the influence of all other variables in the network. While depression and PTSD symptoms mainly clustered within their respective disorders, they were connected at symptom nodes related to sleep disruption, concentration difficulties, and limited life outlook. Moreover, specific symptoms of depression (e.g., trouble keeping mind on things, feeling disliked by others) and PTSD (e.g., painful reminders of the event, reliving event) were linked to sexual risk behavior while other symptoms were not.

Conclusions: Network analyses allow associations to be simultaneously mapped according to

the strength and relevance of these relationships. Consistent with existing literature, depression and PTSD showed some degree of connectivity (comorbidity) across expected symptoms domains. Of note, this analysis has identified symptoms of depression and PTSD that may particularly influence sexual risk in MSM with CSA histories, and illustrates a promising method to refine clinical targets affecting health risk behavior.

“SEX ED IS NOT A THING!”: EARLY HEALTH SEEKING BEHAVIORS AMONG MEN WHO HAVE SEX WITH MEN IN RURAL AREAS

Danielle N. Lambert, MPH, CHES[1], Natalia Truszczynski, MPH[2], Anne Marie Schipani-McLaughlin, MPH[2], Carolyn Lauckner, PhD[2], Nathan Hansen, PhD[2]

[1]University of Georgia, Atlanta, GA; [2]University of Georgia, Athens, GA

Background: Men who have sex with men (MSM) are disproportionately affected by HIV and STIs. Although at increased risk for negative health outcomes, relatively few sexual health education curriculums are inclusive to the health needs of men identifying as gay, bisexual, or queer. This is especially true in rural areas where stigmatization of sexual minorities is even more prevalent. Thus, in the absence of appropriate programming, little is know about where and from whom MSM in rural areas seek out and learn sexual education.

Methods: Semi-structured qualitative interviews were conducted with 20 respondents ranging from 18-60 years old from July 2015 to June 2016. Respondents were eligible for participation if they identified as a man who dates or has sex with other men, resided in a non-metropolitan area of the United States, and were at least 18 years old. Interviews were transcribed verbatim and analyzed by a diverse coding team in NVivo 11 using grounded theory approaches.

Results: The majority of the respondents sought sexual health information from three sources: the Internet, their social network, and LGBT resource centers. Geographic isolation and low population density forced many young MSM to turn to the Internet for information related to HIV/STIs, condom use, and PrEP. While some recognized the CDC and WHO websites as trusted forms of information, many did not know where to start searching for health information on the Web and therefore ended up reviewing non-validated sites, such as blogs. Web-based social networking platforms, such as dating websites or support groups, were a way for respondents to obtain health advice from other MSM in rural areas where inclusive social venues were uncommon. For many respondents, LGBT resource centers located on college campuses were a key source of health information. They provided educational materials to improve safe sex behaviors, guidance in accessing healthcare, free testing, and confidential services in a trusted environment.

Conclusions: The lack of tailored sexual health education for MSM speaks to an immediate need for more reliable programming and inclusive resource centers. Understanding the barriers to receiving sex education, and the ways in which MSM are currently obtaining sexual

health information, can help practitioners relay accurate sexual health information to channels and organizations commonly accessed by MSM.

THE IMPACT OF HOPE ON QUALITY OF LIFE IN LUNG CANCER

Laurie E. Steffen, PhD[1], Kevin E. Vowles, PhD[2]

[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]University of New Mexico, Albuquerque, NM

Goal-setting, problem-solving, and values-based action are common components of quality of life interventions for cancer (Graves, 2003). These components are sometimes referred to as “hope,” which has been associated with quality of life across multiple types of cancer. The utility of hope has not, however, been tested longitudinally in lung cancer where quality of life is a key treatment outcome given low survival rates and high symptom and treatment burden. The goal of this study was to study relations between hope and quality of life (e.g., social functioning, palliative wellbeing) in lung cancer patients undergoing treatment. Patients with higher hope were expected to report better quality of life and daily levels of hope were hypothesized to predict daily quality of life. Fifty lung cancer patients (58% female, 78% non-small cell, 66% metastatic disease, average age = 68.66, SD = 8.78) completed a baseline questionnaire and 21 daily assessments (M = 20.3 days, SD = 1.3; 1,042 days of data). Multilevel modeling was used to analyze same-day and next-day relationships. Pre-specified models controlled for disease (e.g., time since diagnosis, treatment type, daily disease symptoms) and psychological (e.g., depression, daily affect) factors. Intra-class correlations ranged from 0.64 to 0.75. Patients with higher levels of hope reported higher social and role functioning (estimate = 3.37, SE = 0.90, 95% CI = 1.60, 5.14) and higher palliative wellbeing (estimate = 0.88, SE = 0.24, 95% CI = 0.40, 1.35). On days where patients reported higher hope, they reported higher social and role functioning (estimate = 2.36, SE = 0.70, 95% CI = 1.00, 3.73), better physical functioning (estimate = 2.27, SE = 0.81, 95% CI = 0.68, 3.87), and higher palliative wellbeing (estimate = 0.91, SE = 0.13, 95% CI = 0.66, 1.16). Daily hope appeared to attenuate the negative impact of treatment days on functioning (estimate = 3.33, SE = 1.25, 95% CI = 0.88, 5.77). Daily hope did not, however, predict quality of life in any next-day models. Daily hope was not predicted by cancer symptoms, which suggests that hope may support quality of life regardless of symptom burden.

A HEALTH MESSAGE INTERVENTION FOR INCREASING PHYSICAL ACTIVITY IN EMERGING ADULTS AT-RISK FOR DIABETES

Stephanie R. McDonough, M.A., Lillian Slaughter, BA, Barbara A. Stetson, Ph.D.

University of Louisville, Louisville, KY

Background: Millions of adults in the U.S. have type 2 diabetes (T2D), a disease largely preventable with health behavior change. Rates continue to rise, even among younger populations. Emerging adulthood (18-25) is an important point in development for establishing healthful behavior; however most do not meet CDC guidelines for physical activity (PA). Framed health message interventions may provide an effective and easily implemented avenue for increasing PA motivation and behavior in emerging adults.

Aim: This pilot study tests the effectiveness of a framed health message intervention focusing on increasing PA in emerging adults at-risk for T2D.

Method: Ss were 51 sedentary emerging adults with a family history of T2D (68.6% White, 84.3% Female). At baseline and 2-week follow-up, Ss completed validated self-report measures assessing exercise behavior (SDSCA) and motivation (exercise intention). Ss were randomly assigned to receive a gain (n=22) or loss (n=29) framed health message to promote regular PA in an effort to reduce T2D risk. Exercise intention and behavior scores at baseline and follow-up were compared using paired sample t-tests. Change scores from baseline to follow-up were calculated and compared by type of framed message using independent sample t-tests.

Results: *Intention* to increase exercise was higher at follow-up (*M*=5.43, *SD*=1.31), when compared to baseline (*M*=4.95, *SD*=1.52), *t*(50)=-2.009, *p*=.050. Frequency of exercise *behavior* also increased from baseline (*M*=2.82, *SD*=1.20) to follow-up (*M*=3.78, *SD*=1.64), *t*(50)=-3.663, *p*=.001. However, no significant differences emerged by frame of message for exercise intention [Gain: *M*=.011, *SD*=1.91; Loss: *M*=-.853, *SD*=1.46, *t*(49)=1.833, *p*=.073], or exercise behavior [Gain: *M*=-.75, *SD*=1.46; Loss: *M*=-1.12, *SD*=2.14, *t*(49)=.733, *p*=.467].

Conclusion: Findings suggest that health messages may be an effective strategy for increasing exercise motivation and behavior in sedentary emerging adults at-risk for T2D, regardless of message valance. Consistent with previous literature, it was expected that gain-framed messages would promote greater exercise intention when compared to loss. However, no differences by message valence emerged. It is possible that simply bringing T2D risk to awareness, coupled with concrete behavioral suggestions for reducing disease onset, may be sufficient for promoting health behavior change. More research examining framed health messages in emerging adults is needed, including exploration of potential mediators and moderators. Development of efficacious interventions promoting health behavior change in emerging adults is crucial for reducing disease risk.

A TOBACCO-FREE CAMPUS POLICY REDUCES CIGARETTE SMOKING AND USE OF ELECTRONIC NICOTINE DELIVERY SYSTEM DEVICES

Sumner Sydeman, Ph.D., Donna Zastrow, Student, Kevin Madden, Student

Northern Arizona University, Flagstaff, AZ

Cigarette smoking is the number one preventable cause of death and disease in the United States; 90% of all adult smokers start smoking in their teens (Bach, 2016; USDHHS, 2014). As part of tobacco prevention efforts, college campuses in the United States have started to implement smoke-free policies in an effort to reduce cigarette smoking and use of Electronic Nicotine Delivery System (ENDS) devices (e.g., electronic cigarette, electronic hookah). The purpose of the current research project was to examine the effect of a tobacco and smoke-free campus policy on cigarette smoking and ENDS use in college freshman living on campus at a state university in the Southwest United States. Self-report data from 1,419 freshmen (median age 18, 84% female) were collected the year before the policy took place (Fall 2015 semester) and immediately after the policy was enacted (Fall 2016 semester). The prevalence rate of cigarette smoking (past 30-day use) dropped from 6.4% in Fall 2015 to 4.0% in Fall 2016, a statistically significant reduction ($p = .048$). Past 30-day ENDS use decreased from 18.1% in Fall 2015 to 11.7% in Fall 2016, which was also statistically significant ($p = .001$). These results provide empirical support that a campus-wide tobacco and smoke-free policy resulted in less cigarette smoking and ENDS use by freshman living on campus. These findings are important because smoking has negative effects on health, and these data suggest that enacting smoke-free policies on college campuses can reduce smoking and ENDS use.

AMBIVALENCE MODERATES THE EFFECT OF MOTIVATIONAL INTERVIEWING ON THE PROMOTION OF INTERNAL MOTIVATION TO DONATE BLOOD

Kristen R. Fox, M.S.[1], Christopher France, PhD[1], Janis France, PhD[1], Bruce Carlson, PhD[1], Lina Himawan, M.A.[1], Victoria Frye, MPH, DrPH[2], Louisa Duffy, B.A.[3], Debra Kessler, MSRN[3], Mark Rebosa, MBA[3], Beth Shaz, MD[3]

[1]Ohio University, Athens, OH; [2]City University of New York School of Medicine, New York, NY; [3]New York Blood Center, New York, NY

BACKGROUND: Having a strong internal motivation to donate blood is positively associated with donation intention and behavior. At a group level, participation in a brief motivational interview designed to bolster individual autonomy related to the decision to donate has been shown to increase internal motivation, donation intention, and actual donation behavior. However, at an individual level, donation-related ambivalence may moderate the effect of a motivational interview as individuals who hold ambivalent attitudes may be more amenable to change. Accordingly, the present study sought to determine if individual differences in ambivalence moderate the effect of a motivational interview on internal motivation to donate blood.

METHODS: A sample of recent blood donors (N = 299) was randomly assigned to receive an intervention that either did or did not contain a brief, telephone-based motivational interview aimed at enhancing individual autonomy related to the decision to donate blood. Measures of ambivalence and autonomy to give blood were administered at least one week before and after the interview.

RESULTS: Consistent with a moderation effect, regression analyses revealed a significant interaction between baseline ambivalence and interview group on post-intervention autonomy, while controlling for baseline autonomous motivation ($p < .05$). Specifically, compared to no-interview controls, participation in a motivational interview was associated with significantly higher levels of autonomous motivation among donors with high initial ambivalence (1 SD above the mean) or average levels of initial ambivalence, but no significant differences were observed among donors with low initial ambivalence (1 SD below the mean).

CONCLUSIONS: Ambivalent donors appear to derive more benefit from a brief motivational interview designed to enhance autonomous decision making regarding future blood donation.

Additional research is needed to determine whether the promotion of internal motivation among ambivalent donors is related to significant changes in donation intention and behavior.

BREAST CANCER SURVIVORS' ATTRIBUTIONS OF LACK OF EXERCISE AS CAUSES FOR CANCER DIAGNOSIS AND RECURRENCE RISK

Rachel Hirschey, RN, PhDc[1], Isaac Lipkus, PhD[2]

[1]Duke University, Durham, NC; [2]Duke University School of nursing, Durham, NC

Regular exercise (i.e., ³ 150 vigorous/moderate intensity weekly minutes) is associated with and thus recommended to decrease breast cancer diagnosis and recurrence risk. However, most breast cancer survivors (BCS), do not meet this recommendation. Understanding the extent to which BCS attribute exercise influencing their diagnosis and especially recurrence can inform how to motivate exercise. Thus we explored the extent to which BCS attribute lack of exercise to their initial cancer diagnosis and possibility of cancer recurrence, and how the latter attributions are related to perceived recurrence risk and levels of exercise.

BCS 2 months - 10 years post treatment were recruited through oncologist referral by mail or in person, at regular follow-up visits. BCS completed online questionnaires. Exercise was measured using the Godin scale. Attributions for initial diagnosis and recurrence were assessed by "What do you think caused you to be diagnosed with breast cancer?" and "What if anything may cause your breast cancer to come back?". Risk recurrence perceptions were assessed by "What do you think is your chance that your breast cancer will come back in your lifetime if you do not exercise?" (1=no chance – 7=certain to happen) and "Compared to other breast cancer survivors your age and race, what do you think is your chance that your breast cancer will come back in your lifetime if you do not exercise?" (1=much below average – 7=much above average).

The sample (n=111) mean age is 57 (SD=10), mean exercise is 147 min/wk (SD=210), is 87% Caucasian, and most (81%) have some college education. The two most common attributions for initial diagnosis were stress and genetics (both cited by 24% of sample); lack of exercise was mentioned by only 8% (n=9) of the sample. With respect to recurrence risk, lack of exercise was the second most common attribution reported by 22% of the sample, behind only diet, mentioned by 26%. Of import, BCS who mentioned lack of exercise as increasing recurrence risk reported exercising more weekly minutes than survivors who did not mention lack of exercise (169 (SD=229) vs. 68 (SD=86), p

BCS attribute lack of exercise as a more frequent cause for possible recurrence than initial diagnosis. This attribution, along with diet, suggests that BCS perceive causes more under their control for recurrence than for an initial event. This may serve the purpose of empowering BCS to believe they have control over lowering their recurrence risk. The heightened perceptions of recurrence risk among those who mentioned versus did not mention lack of exercise may serve as a motivational cue. Further studies are needed to determine how best to incorporate attributions of recurrence risk to motivate exercise.

CHANGES IN BMI, SELF-REPORTED FAMILY NUTRITION, PHYSICAL ACTIVITY, AND SEDENTARY BEHAVIORS IN THE E.P.I.C. KIDS STUDY

Bonita Sur, M.S.[1], Kathylynn Saboda, M.S.[1], Scott Going, PhD[1], Denise Roe, DrPH[1], Craig S. Stump, MD, PhD[2], Randa Kutob, MD, MPH[3], Melanie D. Hingle, PhD, MPH, RD[1]

[1]University of Arizona, Tucson, AZ; [2]University of Arizona College of Medicine, Southern Arizona VA Health Care System, Tucson, AZ; [3]University of Arizona College of Medicine, Tucson, AZ

The prevalence of overweight and obesity in youth continues to be high (Ogden et al., 2016). Obesity in youth is strongly associated with obesity into adulthood, as well as increased risk for chronic diseases, including type 2 diabetes (T2D) (Field, Cook, & Gillman, 2005; Herman, Craig, Gauvin, & Katzmarzyk, 2009). Parents shape their children's home nutrition and physical activity environments, making them central agents for prevention and treatment of weight-related problems. However, few effective community-based programs aimed at reducing obesity prevalence and diabetes risk within the family environment exist. In EPIC Kids, we tested the effect of a 12-week family-focused YMCA-based lifestyle intervention in forty-eight 9-12-year-old obese children at risk of T2D and their parents, on behavioral, anthropometric, and environmental T2D risk factors. We hypothesized that a supportive home nutrition, physical activity, and media environment would be associated with a lower child BMI Z score. Child height and weight was measured by trained technicians. Age and sex specific BMI percentiles were determined using CDC growth charts. Self-reported family food, physical activity, and media environment was assessed at baseline and follow-up using the Family Nutrition and Physical Activity (FNPA) questionnaire, a 20-item survey completed by parents focusing on nutrition, physical activity, and sedentary behavior. Descriptive statistics and t-tests were calculated. Difference scores were calculated as week 12 minus baseline scores. BMI Z scores are age and gender standardized using CDC standards. Regression methods were used to explore the relationship between BMI Z scores and FNPA scale and sub scales. Thirty-six families completed post-intervention (12-week) measurements. Improvement (reduction) in BMI Z score ($p = 0.02$) and in family nutrition ($p = 0.0001$) and physical activity ($p = 0.002$) behaviors were observed from baseline to 12 weeks. No significant changes in sedentary behaviors were observed ($p = 0.063$). Similar to previous research using the FNPA instrument (Ihmels, Welk, Eisenmann, Nusser, & Myers, 2009), baseline FNPA scores trended toward predicting change in BMI Z scores although did not achieve significance ($p = 0.241$). Limitations include potential measurement error from self-report and small sample size. These preliminary findings demonstrate the potential for a

YMCA-based lifestyle intervention to improve child BMI Z score, and parent-reported health behaviors, although change in BMI Z score did not predict changes in health behaviors.

EXAMINING FAMILY AND GROUP-LEVEL DIFFERENCES ASSOCIATED WITH SELF-MONITORING IN THE FAMILIES IMPROVING TOGETHER (FIT) TRIAL

Tyler C. McDaniel, M.S., Allison Sweeney, PhD, Dawn K. Wilson, PhD, Juanita Hawkins, B.S.

University of South Carolina, Columbia, SC

The Families Improving Together (FIT) for Weight Loss Project is a randomized controlled trial testing the efficacy of a motivational and family-based program for improving weight loss among underserved African American adolescents and their parents. Project FIT integrates face-to-face and online sessions to build skills around sustaining healthy lifestyle improvements, including self-monitoring and goal-setting. Parents and adolescents are encouraged to monitor and track their caloric intake and energy expenditure. Intervention facilitators review and provide feedback on participants' self-monitoring logs. Although numerous studies have shown that self-monitoring is a critical behavior-change skill, relatively little is known about the conditions under which people are most likely to self-monitor. The present research extends past research by examining how: 1) aspects of the family structure (including marital status and education-level of the parent) and 2) a facilitator's ability to implement behavioral skills training in a given cohort (as assessed by independent process evaluators) impact self-monitoring among parents and adolescents. A self-monitoring score was created by summing the total number of weeks (range: 0- 6) that participants reported engaged in self-monitoring. Among parents ($N = 72$, $M_{\text{age}} = 43.77$, 93% female, $M_{\text{BMI}} = 37.85$, $M_{\text{income}} \leq \$40,000$), those who were married tracked significantly more weeks ($M = 2.90$ weeks) compared to those who were not married ($M = 2.00$; $p < .05$). Teens ($N = 72$, $M_{\text{age}} = 13.12$, 69.4% female, $M_{\text{BMI\%}} = 97.02$) with parents that had at least a college degree tracked significantly more ($M = 2.60$ weeks) compared to those with parents that had two years of college or less ($M = 1.80$; $p < .05$). Furthermore, among cohorts with relatively high behavioral skills implementation, adolescents engaged in greater behavioral tracking ($M = 2.54$) than cohorts with relatively low behavioral skills implementation ($M = 1.76$; $p = .03$). There were no differences in self-monitoring by age, BMI, or sex. The present study provides preliminary evidence that aspects of the family structure as well as group-level factors contribute to self-monitoring. Given the importance of self-monitoring for promoting health behavior change, the present results suggest that family structure and parent capacity should be considered when designing future weight loss interventions for underserved African Americans.

C007 6:00 PM-7:00 PM

EXAMINING HEALTH LITERACY, SELF-EFFICACY, AND HEALTH BEHAVIORS IN COLLEGE STUDENTS WITH CHRONIC CONDITIONS

Jeremy Barsell, B.S., Samantha A. Miadich, M.A. , Michael Trujillo, M.A., Robin S. Everhart, PhD

Virginia Commonwealth University, Richmond, VA

To date, research on how students adapt to college life in the context of managing their illnesses and their experiences with a chronic condition are limited. In this study, health literacy and self-efficacy were examined in their associations with health behaviors (e.g., general behaviors, wellness maintenance, substance use). Health literacy, an understudied construct, has high relevance for college students considering many may have recently reached legal age and are now responsible for seeking and understanding how to use health services. Participants included 153 students with a chronic condition (18-37 years; 67% female; 40% White; 23% Black/African-American; 16% Asian; 26% asthma; 6% allergic rhinitis; 4% heart condition) who completed a series of online questionnaires. Health behaviors were categorized into general behaviors (e.g., “I get enough sleep”), wellness maintenance (e.g., “I see a doctor for regular checkups”), and substance use behaviors (e.g., “I do not drink alcohol”). General health behaviors were associated with each subscale of health literacy (functional, r=.253, p=.003; communicative, r=.459, p < .000; critical, r=.387, p < .000) and self-efficacy (management, r=.440, p < .000; general, r=.389, p < .000, outcomes r=.404, p < .000) .Wellness maintenance behaviors were associated with each subscale of health literacy (functional, r=.206, p=.014; communicative, r=.388, p < .000; critical, r=.485, p < .000), as well as self-efficacy (management, r=.424, p < .000; general, r=.340, p < .000, outcomes r=.314, p < .000). Fewer substance use behaviors, however, were only associated with communicative health literacy (r=.193, p=.023), critical health literacy (r=.277, p=.001), and self-efficacy to achieve outcomes (r=.233, p < .000). Findings suggest that higher levels of both health literacy and self-efficacy may have an impact on general health and wellness maintenance behaviors in college students with chronic conditions. On the other hand, fewer substance use behaviors were associated with only one dimension of self-efficacy and two dimensions of health literacy. It may be that in college, students engage in substance use behaviors to appear more normative to peers, regardless of their own self-efficacy. More research is needed on college students with chronic conditions in order to elucidate the mechanisms by which health literacy and self-efficacy can reduce substance use, and also improve positive health behaviors.

INTERVENTION MEDIATORS IN AN RCT TO INCREASE COLONOSCOPY UPTAKE AMONG THOSE AT INCREASED RISK FOR FAMILIAL COLORECTAL CANCER

Barbara H. Brumbach, Ph.D.[1], Wendy C. Birmingham, PhD[2], Watcharaporn Boonyasiriwat, N/A[3], Scott Walters, PhD[4], Anita Y. Kinney, Ph.D.; RN[1]

[1]University of New Mexico Comprehensive Cancer Center, Albuquerque, NM; [2]Brigham Young University, Provo, UT; [3]Chulalongkorn University, Bangkok, N/A, Thailand; [4]University of North Texas Health Science Center, Ft. Worth, TX

Background: Understanding pathways by which interventions achieve behavioral change is important for optimizing intervention strategies. The Extended Parallel Process Model and implementation-intention strategies were theoretical guides to the development and implementation of the intervention. **Purpose:** We examined mediators of behavior change in a tailored-risk communication intervention that increased guideline-based colorectal cancer (CRC) screening among individuals at increased familial risk. **Methods:** Using a population-based recruitment strategy, participants at increased familial risk for CRC (N=481) were randomized to one of two intervention arms: 1) remote, tailored-risk communication (TeleCARE) or 2) mailed educational brochure. **Results:** A mediation model showed that the intervention lead to increased colonoscopy uptake through several constructs (threat, efficacy, emotions, knowledge, intentions). Structural equation modeling showed that TeleCARE participants were more likely to get a colonoscopy. The effect was partially mediated through threat perceptions ($\beta=0.12$, pConclusion: Evaluating mediating variables between an intervention (TeleCARE) and a primary outcome (colonoscopy) contributes to understanding underlying mechanisms that lead to health behavior change, thus leading to better informed future interventions.

MATERNAL BMI CHANGE LINKED TO CHILD ACTIVITY CHANGE IN FAMILY-BASED BEHAVIORAL INTERVENTIONS FOR PEDIATRIC WEIGHT MANAGEMENT

Ashleigh A. Pona, MA[1], Jordan A. Carlson, PhD[2], Robin P. Shook, PhD[2], Meredith L. Dreyer Gillette, PhD[3], Ann M. Davis, PhD, MPH, ABPP[4]

[1]University of Missouri - Kansas City, Kansas City, MO; [2]Children's Mercy Hospital, Kansas City, MO; [3]Children's Mercy Kansas City, Kansas City, MO; [4]University of Kansas Medical Center, Kansas City, MO

Objective: Family-based behavioral interventions (FBBIs) for pediatric weight management encourage weight loss through modification of the family’s nutritional intake and physical activity (PA) habits using behavioral techniques. Studies on FBBIs typically focus on child weight change as the primary outcome. Little is known about factors associated with change in PA in FBBIs, but evidence suggests that parent modeling and family environment influence children’s overall diet and PA habits and are critical components in FBBIs. We investigate whether change in maternal body mass index (BMI) is associated with change in child’s moderate to vigorous PA (MVPA), prolonged sedentary behavior (PSB), and BMIz during the course of FBBIs for pediatric weight management.

Methods: Youth (*n*=126) ages 5-13 (mean age=9.03±1.7) years with a baseline BMI ≥ 85th percentile (mean BMI%=94.66±4.6) and their families were enrolled in one of three similar FBBIs for pediatric weight management and followed over a period of 6-12 months, depending on length of the FBBI. Child and maternal height and weight were measured by trained clinicians using standardized procedures. Activity data were collected via accelerometers. Residualized change scores were computed for each variable of interest (dependent variables: children’s BMIz, minutes/day of MVPA, proportion of day consisting of PSB; independent variables: maternal BMI) and each covariate (total wear time, weekdays worn, weekend days worn) by regressing follow-up (T2) score on baseline (T1) score. Other covariates included child age, gender, race, study, length of FBBI, and treatment session attendance.

Results: From T1 to T2, maternal BMI decreased from 30.47±6.3 to 30.25±6.0 (*p*=.26), child BMIz decreased from 1.80±.5 to 1.76±.5 (*p*=.04), child MVPA decreased from 36.67±23.4 to 32.09±19.1 minutes/day (*p*=.02), and proportion of day consisting of child PSB increased from 12.06±8.0% to 14.78±11.3% (*p*=.01). Regression analyses indicated a decrease in maternal BMI attenuated both the decrease in child MVPA, *B*=2.77, *p*=.048, and the increase in

proportion of day consisting of child PSB, *B*=-.02, *p*=.02, from T1 to T2. Change in maternal BMI was not associated with change in child BMIz (*B*=.03, *p*=.29) from T1 to T2.

Discussion: Improvement in maternal BMI showed important positive associations with child MVPA and PSB over the course of FBBIs for pediatric weight management. Our findings support the theoretical construct that enabling mothers to improve their weight status via health behavior changes as part of a pediatric weight management intervention is important in supporting healthy behavior change in their children. Future research should consider directly measuring maternal PA and/or target maternal health habits more directly.

MOTIVATIONAL PROCESSES AND HEALTH BEHAVIOR OUTCOMES AMONG HIGH-RISK LATINAS PARTICIPATING IN A LIFESTYLE INTERVENTION

Kelly Biegler, PhD[1], Mienah Sharif, PhD[1], Laura Arias, BA[1], Camila Aguilar, Undergraduate Student[1], Jennifer Escareno, Undergraduate Student[1], Emily Dow, MD[1], David Kilgore, MD[1], Margaret Schneider, PhD[2], Karen S. Rook, PhD[1], Dara H. Sorkin, PhD[3]

[1]UC Irvine, Irvine, CA; [2]University of California, Irvine, Irvine, CA; [3]University of California Irvine, Irvine, CA

Purpose: Mexican-American women have one of the highest lifetime risks for developing diabetes, which may stem, in part, from high levels of obesity and physical inactivity. Research to date has focused on behavioral, socioeconomic, or environmental risk factors, while few studies have examined the motivational systems underlying poor health behaviors.

Behavioral inhibition and activation are two discrete, opposing motivational systems that are posited to underlie behavior and mood, and have been widely used as a framework for examining health behaviors associated with obesity and chronic disease. The behavioral inhibition system (BIS) promotes avoidance of punishment or negative emotions, and has been associated with higher levels of anxiety. The behavioral activation system (BAS) promotes goal directed behavior and is sensitive to reward, and has specifically been implicated in increased intake of high-sugar, high-fat foods and obesity.

We completed a randomized trial testing the effectiveness of a dyadic weight loss intervention in Mexican-American mothers with type 2 diabetes and their obese, adult daughters. Despite high rates of perceived stress in this population, no study has considered the complex interplay between motivation, stress, social relationships and health characteristics of two individuals pursuing a shared health behavior change in the context of a weight loss intervention in this under-resourced, high-risk population.

Objective: The study examined baseline associations between mothers' and daughters' ratings of BIS/BAS and: (1) measures of perceived stress and positive and negative social interactions; and (2) self/other health behavior characteristics (i.e., nutrition intake, BMI).

Method: Data was derived from 89 mother-daughter Mexican-American dyads (N=178).

Results: Higher BIS scores were associated with higher levels of perceived stress ($r=0.30$, $p < 0.001$). However, higher BAS scores were associated with lower levels of perceived stress (r=-

0.23, p=0.02) and negative social interactions (r=-0.26, p=0.007). In addition, higher BAS scores were associated with greater saturated fat intake (r=0.21, p=0.01). Additional analyses examined the differential associations between mother/daughter ratings' of self and other health behaviors

Discussion: The findings from this study highlight the importance of considering motivational states in characterizing risk factors of chronic disease and improving health outcomes in this high-risk population.

NUTRITION-BASED HEALTHY LIFESTYLE PILOT PROGRAM FOR FEMALE HOSPITAL EMPLOYEES

Iva Greenshtein-Littman, MPH[1], Donna Zwas, MD, MPH[2]

[1]Hadassah Hospital, Jerusalem, Yerushalayim, Israel; [2]Cardiology Department, Hadassah University Medical Center, Jerusalem, Yerushalayim, Israel

Background: Behavioral risk factors for chronic disease (i.e. smoking, unhealthy diet, sedentary lifestyle) are prevalent in hospital employees (HE). Female HE are at a particular risk given shift work and stressful work environment. Gender-tailored interventions may improve outcomes. Identifying effective methods for increasing HL among HE can inform public health interventions in hospital-based and employee interventions worldwide.

Objectives: This study explored a gender-tailored nutrition-based healthy lifestyle (HL) program for female HE in a Jerusalem hospital, assessing outcomes of health behaviors and BMI. It consisted of 8 weekly sessions on the Mediterranean diet and HL monitoring, including physical activity (PA), with emphasis on providing tools likely to improve outcomes in women (social support, social and emotional eating, etc.). Participants completed surveys (asking about nutrition, PA and other HL parameters) and had BMI and blood pressure measured before and after the program. Program objectives included increased adherence to the Mediterranean diet, increased PA, reduced smoking, and reduced BMI.

Results: 48 women (ages 36-67) completed surveys. 46% were nurses and 25% from hospital administration. They reported increased consumption of vegetables (29.8%, p2 (p

Conclusions: This gender-tailored HL pilot program was effective in helping female HE improve adherence to the Mediterranean diet, reduce smoking, and achieve healthier BMIs. Tailoring HL programs to women may increase HL in female HE.

Main Messages:

- Gender-tailored nutrition-based healthy lifestyle programs can be effective at empowering female hospital employees to adopt healthy behaviors.

PATTERNS OF TOTAL AND SATURATED FAT CONSUMPTION AND THEIR ASSOCIATIONS WITH WEIGHT CHANGES OVER A 12-MONTH WEIGHT LOSS STUDY

Yaguang Zheng, PhD, RN[1], Susan Sereika, PhD[2], Qianheng Ma, MS[2], Cynthia Danford, PhD[2], Christopher Imes, PhD[2], Yang Yu, MSN[2], Ran Sun, MSN[2], Rachel Goode, MSW[2], Juliet Mancino, MS[2], Lora Burke, PhD, MPH[2]

[1]Boston College, Chestnut Hill, MA; [2]University of Pittsburgh, Pittsburgh, PA

Background: Established guidelines recommend restriction of total fat intake to 20-35% and saturated fat to < 10% of total calories for both general public and those in weight loss studies. To date, no study has examined temporal patterns of fat intake change. Our aim was to identify distinct trajectories of total and saturated fat intake and their associations with weight change.

Methods: This was an analysis of data from a 12-month behavioral weight loss study where participants were asked to reduce total fat intake to ≤25%. Dietary intake was recorded using the Lose It! app on a smartphone and averaged weekly. Weight was measured via a digital scale every 6 months. Group-based trajectory and mixed modeling were used for analyses.

Results: The sample (N=148) was 90.5% female, 81.1% White, with a mean age (±SD) of 51.3±10.1 years and a mean BMI of 34.1±4.6 kg/m^2. Three trajectory groups were found for % calories from total fat: *recommended & decreasing* (n=46, 22.4-26.3%); *recommended & increasing* (n=68, 28.9-33.0%); *high & increasing* (n=34, 32.7-42.5%). For % calories from saturated fat, 3 trajectory groups were found: *recommended* & *consistent* (n=35, 5.3-7.3%), *recommended & increasing* (n=89, 8.6-10.0%); *high & increasing* (n=24, 11.1-16.5%). Significant differences in % weight change were found among total fat trajectory groups (p=.04), with mean % weight losses of -10.6±7.4 for the *recommended & decreasing* group, -9.1±8.8 for *recommended & increasing* group and -5.8±-6.7 for the *high & increasing* group. We found no differences in % weight loss among saturated fat trajectory groups (p=.54).

Conclusions: Nearly one third of sample consistently followed recommendations for fat intake and had greater weight loss. Those consuming fat in excess of recommended levels had less weight loss and could benefits from additional strategies to assist in the development of skills and habits to lower fat intake to support weight loss and improve cardiovascular health.

PILOT TEST OF A SUN SAFETY PROGRAM FOR THE TATTOO COMMUNITY

Robert Dellavalle, MD, PhD, MSPH[1], Barbara Walkosz, PhD[2]

[1]University of Colorado Denver, Denver, CO; [2]Klein Büendel, Inc., Wheat Ridge, CO

Sun Safety Ink! (SSI!) is a skin cancer prevention program developed for the tattoo community. Over 5.4 million cases of non-melanoma skin cancers occur annually and melanoma rates continue to increase. Invasive melanoma of the skin is the third most common cancer among adolescents and young adults (ages 15-39). Concurrently, the popularity of tattoos continues to grow in the U.S. and among members of the military. One in four American adults (23%) have a tattoo, and younger adults, [38% of the Millennial Generation and 32% of Generation X] are more likely to have tattoos than older adults. Tattooed individuals need to take extra precautions not only to protect themselves from UVR but also to reduce damage to and preserve their tattoos. Sun safety is sometimes promoted with tattoo aftercare instructions.

The *SSI!* program included a training for tattoo artists with information on skin cancer and tattoo rates, the relationship of UV and the skin, and skin cancer risk factors and prevention strategies along with a tip card to be distributed with the tattoo studio's aftercare instructions.

55 tattoo studios were invited to participate. 18 (32%) enrolled, 5 (9%) refused, and 32 (55%) did not respond. [4 dropped out after enrollment and randomization]. 14 tattoo studios (6 intervention [I], 8 control[C]) participated. 77 clients completed posttest surveys after receiving a tattoo. Most tattoos were on the arms (50%) and upper torso (47%). 80% reported a sunburn in the past 12 months; sun protection practices were low (1= never to 3=always): sunscreen, M=2.16; wide-brimmed hat, M= 1.53; long sleeve shirts and pants, M=1.69; sunglasses, M=2.57; seek shade, M=1.90. 15.5% engaged in indoor tanning. Strong tanning preferences were reported.

85% (87% Intervention[I] v. 80% Control [C]) received sun protection information in the studio: verbal message from tattoo artist: 93% (95%I v. 86%C]; written aftercare instruction: 92% (90%I v. 100 %C), studio website: 54% (50%I v. 61%C): social media, poster or sign: 51% (55%I v 41%C), tip card brochure, 73% (76%I v. 64%C).

59% (56%I v. 68% C) of respondents said messages were about protecting tattooed skin and 40% (44%I v. 31% C), about protecting all of your skin. The results of pilot study support the need and feasibility to move forward to further test *SSI!*

POSITIVE MOOD IS ASSOCIATED WITH DAILY FRUIT AND VEGETABLE CONSUMPTION DURING AN INCENTIVE INTERVENTION

Casey K. Gardiner, MA, Angela D. Bryan, PhD

University of Colorado Boulder, Boulder, CO

Monetary incentive interventions to promote health behavior change have gained recent popularity in both academic research and public health practice, and they have been deemed effective in numerous health domains. However, much remains unknown regarding the effects of these interventions on psychosocial factors associated with overall health and well-being, including affect and perceived stress.

The present research explores these relationships in the context of a brief randomized controlled trial designed to promote fruit and vegetable (FV) consumption using monetary incentives. Participants (n = 60) were randomized to receive either daily incentives, delayed lump sum incentives, or no incentives based upon their FV consumption. Over the course of 21 days, they completed daily reports of their FV consumption, affect, and stress.

Multilevel modeling was employed to examine within- and between-participant relationships between intervention condition, health behavior engagement (i.e., FV consumption), affect, and stress. Results demonstrated a significant relationship between affect and FV consumption both within and across days, over and above the effect of intervention condition ($\beta = 0.90$, $p = .02$). Specifically, on days when participants reported more positive affect, they consumed more FV ($\beta = 0.07$, $p = .04$). Additionally, participants who experienced more positive affect across days also consumed more FV ($\beta = 0.52$, $p = .04$). Daily stress, however, was not significantly associated with FV consumption overall, though a stress X condition interaction reached a trending level ($\beta = 0.08$, $p = .10$), such that an effect of reduced FV consumption on days when participants reported more stress was less strong for participants receiving incentives than those in the control condition.

In sum, this research presents a first examination of the within- and across-day effects of monetary incentives, affect, and stress on FV consumption. Notably, participants' mood was positively associated with their FV consumption both within and across days, indicating that healthier behavior is linked to more positive affect, and these relationships were not adversely affected by the presence of incentives.

POTENTIAL DRIVERS OF DIETARY CHANGE IN AFRICAN AMERICAN CONGREGANTS

Elizabeth Lynch, PHD[1], Laurin Mack, PHD[1], Yamin Wang, MS[1], Elizabeth Avery-Mamer, MS[2]

[1]Rush University Medical Center, Chicago, IL; [2]Rush University Medical Center, Morton Grove, IL

Introduction: Cardiovascular morbidity and mortality are higher in African Americans than whites, partly due to differences in diet quality. African Americans tend to have poorer diet quality than whites, and in particular, eat fewer vegetables. Increased vegetable consumption is associated with decreased cardiovascular and all-cause mortality. The ALIVE intervention is a church-based intervention, designed by a partnership among researchers, pastors and church leaders, to increase vegetable consumption among African Americans. A pilot study showed that ALIVE was successful at increasing average vegetable consumption by one serving over 9 months. The purpose of the current analysis is to investigate individual and social factors related to increased vegetable consumption.

Method: The ALIVE study was a 9-month single-arm trial that was conducted in 5 African American churches. Participants were exposed to both church-wide and individual-level intervention components and completed assessments at baseline and 9 months, including 24-hour dietary recalls and measures of self-efficacy, nutrition knowledge, social norms, and social support. We measured associations between these psychosocial variables and whether participants increased vegetable intake by ≥ 1 servings per day.

Results: Across the five participating churches, participants (n=206) were mostly female with a range of socioeconomic status (25% below poverty). 182 participants (88%) completed at least one dietary recall at 9-month follow-up. Vegetable consumption increased by ≥ 1 serving in 46.6% of participants. Self-efficacy, nutrition knowledge, social norms and social support increased during the intervention (all ps

Discussion: These findings suggest that clinically significant changes in vegetable consumption may be related to both individual-level and social factors. Interventions that focus solely on individual-level factors may be failing to leverage the importance of social norms in driving dietary behavior.

PRECONCEPTION HEALTH (PCH) BEHAVIORS: EXAMINING THE GAP BETWEEN KNOWLEDGE AND INTENTIONS

Kirsti Toivonen, HBA[1], Kirsten Oinonen, PhD[1], Katelyn Duchene, MA[1], Rosemary Scofich, RN[2]

[1]Lakehead University, Thunder Bay, ON, Canada; [2]Thunder Bay District Health Unit, Thunder Bay, ON, Canada

Background: Positive PCH behaviors (i.e., health changes made before pregnancy) are important to maximize offspring health. While studies suggest the general public has knowledge of the importance of PCH behaviors, even many of those with planned pregnancies do not engage in them. Little research has examined the intention to engage in specific PCH behaviors. Intentions may represent an intermediate step between PCH knowledge and behavior change and may help explain the knowledge-behavior gap.

Methods: As part of a larger study on PCH knowledge and behaviors, 170 women from Thunder Bay, Canada between the ages of 18 and 45 were surveyed regarding their knowledge of the importance of, and the intention to engage in, 12 different PCH behaviors prior to a potential future pregnancy (i.e., avoiding alcohol, tobacco, second-hand smoke, toxic chemicals, personal care products with parabens/phthalates, toxic-cleaners, and fish high in mercury; reducing stress and caffeine; improving sleep and physical activity; and taking folic acid). Women were asked whether they intend to engage in the behaviors: *in the months before pregnancy*, *when they begin to attempt to conceive*, *when they know they are pregnant*, *later in pregnancy*, or *not at all*.

Results: Across the 12 behaviors studied, a mean of 86% of women reported knowledge of the importance of engaging in them (ranging from 63 to 94%, who knew they should avoid personal care products with parabens/phthalates and get adequate sleep, respectively). Of the women with knowledge of the importance of each behavior before pregnancy, a mean of 72% of women reported the intention to engage in each behavior in the months before a potential pregnancy (ranging from 59 to 82%). Of the women with knowledge, a mean of 28% did not intend to engage in PCH behaviors in the months before conception (18% endorsed waiting until trying to conceive, and 10% endorsed waiting until they know they are pregnant, later in pregnancy, or not engaging in the behavior at all).

Discussion: Although most women report knowing the importance of engaging in positive PCH behaviors before a potential pregnancy, a mean of 28% of women with knowledge reported no intention to engage in specific behaviors in the months before attempting conception.

Results indicate that having PCH knowledge does not necessarily lead to intentions. This may in part explain the ‘knowledge-behavior gap’ observed in PCH. Future research should examine reasons for this gap.

PROMOTING PATIENT PARTICIPATION IN HEALTHCARE INTERACTIONS THROUGH COMMUNICATION SKILLS TRAINING: A SYSTEMATIC REVIEW

Thomas A. D'Agostino, PhD, Thomas M. Atkinson, PhD, Lauren E. Latella, MS Ed, Madeline Rogers, BA, Dana Morrissey, MPH, LMSW, Antonio DeRosa, MLIS, Patricia A. Parker, PhD

Memorial Sloan Kettering Cancer Center, New York, NY

Background: Communication training is a potentially effective tool for promoting patient participation in care and helping patients to get the most out of their visits. Previous reviews of patient communication training literature are either outdated or topical reviews. The purpose of the current systematic review was to present an overview of the status of patient communication training research. Our goal was to examine the content and structure of existing training programs, the design of intervention studies, and evidence concerning the impact of training on patient behavior, communication process, and other important outcomes.

Methods: Systematic searches were conducted in six databases: MEDLINE (via PubMed), Embase, The Cochrane Library, Web of Science, PsycINFO (via OVID), and ERIC (Education Resource Information Center). References were screened for inclusion through title, abstract, and full text review phases by a team of five researchers. Extracted data included intervention study design, sample characteristics, content and structure of training programs, outcomes assessed, and findings reported.

Results: A total of 32 unique intervention studies met inclusion criteria. Most targeted primary care (50%) or cancer patients (28%) and used a randomized controlled design (59%). Interventions used a variety of training formats (i.e., materials only, materials plus individual coaching, and group-based) and modes of delivering educational material (e.g., written, face-to-face, and web-based). Reported findings suggest that communication training is an effective approach to increase patients’ total level of active participation in healthcare interactions and that some communication behaviors may be more amenable to training (e.g., expressing concerns). Trained patients do not have longer visits and tend to receive more information from their providers. Most studies have found no link between communication training and improved health, psychosocial wellbeing, or treatment-related outcomes.

Conclusions: We cannot conclude that a superior patient communication training program exists or that one method for delivering educational materials is best. If anything, the findings of our review indicate that there are many different ways of increasing patient participation

through communication skills training. More work is needed to determine the most efficacious training programs with the strongest potential for dissemination.

PSYCHOSOCIAL MEDIATORS OF PHYSICAL ACTIVITY ADOPTION IN A RCT OF AN INTERNET-BASED INTERVENTION FOR LATINAS

Shira Dunsiger, PhD[1], Dori Pekmezi, PhD[2], Beth C. Bock, PhD[3], Britta Larsen, PhD[4], Sheri J. Hartman, PhD[5], Sarah Linke, PhD, MPH[6], Kim M. Gans, PhD,MPH[7], Andrea S. Mendoza-Vasconez, MPH[8], Bess H. Marcus, Ph.D.[9], Becky Marquez, PhD, MPH[10]

[1]The Miriam Hospital and Brown University, Portsmouth, RI; [2]University of Alabama at Birmingham, Birmingham, AL; [3]Brown Medical School, Providence, RI; [4]University of California, San Diego, San Diego, CA; [5]Department of Family Medicine and Public Health, UC San Diego, La Jolla, CA, USA, La Jolla, CA; [6]UC San Diego, La Jolla, CA; [7]University of Connecticut, Storrs, CT; [8]University of California San Diego, San Diego, CA; [9]University of California, San Diego, La Jolla, CA; [10]University of California San Diego, La Jolla, CA

Theory- and Internet-based interventions have shown great promise in improving physical activity (PA) among Latinas, a group disproportionately affected by PA-related conditions (obesity, diabetes). A better understanding of the theoretical constructs driving PA behavior change in this at-risk group is needed. Pasos Hacia la Salud tested a culturally adapted, theory-based, individually tailored, Internet-based Spanish language PA intervention vs. an Internet-based Wellness Contact Control condition among 205 under-active Latinas. For both objective (accelerometer) and subjective (7-Day PA Recall Interview) measures of PA (minutes/week), the Intervention group had significantly greater increases in PA than controls. The current study explores potential psychosocial mediators (self-efficacy, behavioral and cognitive processes, social support and enjoyment) of the intervention effect on both self-reported and objectively measured PA. A multiple mediation approach was used based on the product of coefficients method with bootstrapped standard errors (one model for each of the primary PA outcomes). There were significant *a* path coefficients (effects of intervention on mediators) for self-efficacy, (a=.43, SE=.15,p=.004); behavioral (a=.64, SE=.14, pb paths (effect of mediator on outcome) such that higher self-efficacy (b=24.54, SE=10.98, p=.03), social support (friends, b=2.36, SE=1.23, p=.04) and to some degree enjoyment (b=.74, SE=.42, p=.08) were associated with higher mean min/week of self-reported PA. The only significant *b* path for objectively measured PA was for self-efficacy (b=22.36, SE=11.25, p=.04). For both PA outcomes, there was an indirect effect of the intervention on PA through increases in self-efficacy (*ab*=10.49, CI:2.46-24.54 for self-report; *ab*=11.11, CI:1.37-32.72 for objectively measured). For self-reported outcomes, there was a significant indirect effect of enjoyment (*ab*=7.30, CI: 0.92-21.78). Results indicate that self-efficacy and enjoyment are key

psychosocial mediators of PA change in Latinas and have important implications for future intervention targets.

QUALITY OF SLEEP AFFECTS SELF-EFFICACY FOR ADHERING TO A HEALTHY LIFESTYLE PLAN

Lora Burke, PhD, MPH[1], Eileen Chasens, phd[2], Christopher Imes, PhD[1], Christopher Kline, phd[2], Lynn Baniak, phd[2], Dara Mendez, PhD[1], Stephen Rathbun, phd[3]

[1]University of Pittsburgh, Pittsburgh, PA; [2]university of pittsburgh, pittsburgh, PA; [3]University of Georgia, pittsburgh, PA

Background: Prior research suggests that sleep affects adherence to a healthy lifestyle. We conducted a 12-month behavioral weight loss intervention study and used ecological momentary assessments (EMA) to collect data about behaviors and emotions. This study is a secondary analysis of the relationship between self-efficacy (SE) for adherence to a healthy lifestyle plan and quality and quantity of self-reported sleep.

Methods: Using a smartphone, participants completed a beginning of the day (BOD) survey reporting quality and quantity of sleep and random assessments of their level of SE for following a healthy lifestyle. All 12 months of data were used for each participant. Linear mixed effects models were fit including subject-dependent random effects of intercept, each sleep variable, and study interval.

Results: The sample (*N* = 150) was primarily female (90.7%), White 80.7%), middle-aged (51.1(10.2) years of age), and obese (BMI = 34.0 (4.6) kg/m^2). Participants completed 99.6% of the 44,917 BOD assessments on sleep. They reported a mean of 6.9 (1.3) hrs of sleep and 1.6 (3.5) awakenings. On a 0-10 scale, they rated “how well slept” as 6.5 (2.1) and “trouble falling asleep” as 3.1(2.6), and feeling tired 42% of the days. SE was assessed in 133,508 random assessments and was rated as 7.0 (2.1) on a 0-10 scale. Neither trouble falling asleep nor hours slept were significantly related to SE; however, SE increased by 0.02 points for each unit increase in “how well slept”, increased by 0.15 points when subjects reported that they were not feeling tired, and decreased by 0.02 points for each awakening the previous night.

Conclusions: While participants averaged nearly 7 hours of sleep per night, they reported feeling tired over 40% of the mornings. Sleep duration did not affect SE; however, how well a person slept and not feeling tired increased SE ratings, and awakenings reduced SE ratings. The mean SE score of 7 suggests that confidence in adhering to the lifestyle met the minimum level for engaging in adherence to lifestyle behaviors, based on the theoretical basis of the SE construct. However this level of SE does not ensure they will sustain this behavior in the face

of challenges. Future work needs to focus on strategies to improve sleep quality among individuals aiming for weight loss and weight loss maintenance.

REACHING THE HARD TO REACH

Tricia K. Gatlin, PhD[1], Michael Johnson, Ph.D., RN[2]

[1]University of Nevada, School of Nursing, Las Vegas, NV; [2]University of Nevada, Las Vegas, Henderson, NV

Introduction/Background: ‘Hard-to-reach’ is a term that has been primarily used by researchers to describe groups of people who have been historically difficult to find or contact. The group could be hard to reach for a myriad of reasons, such as geographical location or social and economic situation, concealment of identity due to fear, social pressure, or stigma or social invisibility. The term, ‘hard-to-reach’, implies that the only barrier to recruiting the population is reaching or accessing them. Researchers know that is not the case though. After reaching the hard-to-reach, researchers often encounter challenges in recruiting and retaining participants. It is important for public interest to include members of ‘hard-to-reach’ in research because not including certain sub-populations in research diminishes the ability to identify groups that potentially have the highest burden of illness and to develop an understanding of why group differences exist. Thus, the purposes of this presentation are to: 1) describe the challenges in recruiting hard-to-reach population in two separate research studies, 2) discuss the strategies that were used to overcome those challenges, and 3) provide recommendations for researchers.

Methods: The authors used two of their own research studies involving hard-to-reach populations as case studies for this paper. The research studies used in these case studies involved two very different hard to-reach groups, (1) low-income ethnic minorities who were un- or under-insured, and (2) lesbian and bisexual women and transgender men. Each author was able to access their respective population but encountered numerous challenges in recruiting participants and in collecting all of the data necessary for their study. Several creative recruiting strategies were utilized to gain adequate sample size for these 2 populations.

Results: Through open discussion between the two authors regarding the challenges to reaching their ‘hard-to-reach’ populations, two overarching themes were identified as barriers to ‘reaching’ the population of interest: (1) *gaining interest* and (2) *building trust*. These themes add to the literature regarding the multi-prong approach that is needed to recruit members of hard-to-reach populations. We found that despite having buy-in from stakeholders and a multi-prong recruiting approach, gaining interest of potential participants included barriers such as language in recruitment flyers, competing demands for time, and

transportation to the data collection site. Building trust with interested study participates was also a large issue noted between both studies; especially concerning sensitive questions or cultural barriers regardless of the reliability and validity of the tools used in the study.

Discussion: It is widely believed that underserved populations are ‘hard to reach’ however, it is because they are unwilling or it is it because we don’t know how to reach them? ‘Reaching’ the population of interest means that you take into consideration the opportunity to participate. Gaining interest and building trust with your population of interest is key. Recruiting in rich environment with known high numbers of the potential participants can yield low sample size if one does not take the time to consider how to adequately gaining interest and build trust with potential or actual research subjects.

RECIPROCAL RELATIONSHIP BETWEEN SEDENTARY BEHAVIOR AND MOOD IN YOUNG ADULTS

Madison M. DeMello, Ph.D. [1], Shira Dunsiger, PhD[2], Bernardine M. Pinto, Ph.D.[3], Gregory Hand, PhD MPH[4], Steven N. Blair, PED[3]

[1]College of Nursing, University of South Carolina, Columbia, SC; [2]The Miriam Hospital and Brown University, Portsmouth, RI; [3]University of South Carolina, Columbia, SC; [4]West Virginia University, Morgantown, WV

With the increasing development of technology, a variety of leisure activities are spent in sedentary or seated behavior. Numerous associations between sedentary behavior and mental health outcomes such as mood have been reported, however none have looked at the reciprocal relationship between mood and sedentary time. The purpose of this study is to examine the relationship of sedentary behavior with mood and health status in young adults.

Methods: A sample of 430 adults (49.3% male) between the ages of 21-35 provided valid objective activity data in addition to an assessment of their wellbeing in a year-long observational study. For the purpose of this study, sedentary behavior is defined as less than 1.5 METS and was measured using a SenseWear mini-armband. The armband was worn for a period of 10 days (compliance of 7 days), with at least 21 hours of verifiable wear time per day. In addition, participants' mood status and quality of life were assessed by the Profile of Mood State (POMS) and SF-36 questionnaire respectively. Specifically, this study used the Total Mood Disturbance (TMD) score from the POMS questionnaire to assess mood. Assessments of sedentary behavior were conducted at baseline and then quarterly for one year duration, while assessments of mood and health status were conducted at baseline and one year.

Results: A cross-lagged, autoregressive clustered model was used to examine simultaneous changes over time in both mood and sedentary behavior allowing for both clustering and adjustment of covariates over time. Data suggests that TMD score decreased significantly over one year, suggesting improvement in mood ($p=0.01$). Furthermore, there were positive associations between sedentary time and TMD; this association increased over time ($p=0.001$). Specifically, higher sedentary time was associated with more distress and this association intensified over time. Mean sedentary time remained stable over the course of the study ($p=0.29$). However, higher TMD scores (more distress) were associated with greater mean sedentary time ($p=.03$), and this association remained stable over the study period ($p=0.51$). Taken together, results suggest significant reciprocal associations (cross-lagged

effects) between mood and sedentary time, with the stronger predictive associations of mood on sedentary time. Similar patterns of change over time in health status and its' reciprocal relationship with sedentary time will also be presented.

Conclusion: These results indicate a reciprocal relationship between mood and sedentary time, that is a decrease in sedentary time should improve mood status, likewise, an improved mood may decrease time spent sedentary. However, the stronger association is mood status predicting time spent sedentary in young adults. By identifying predictors of seated behavior, researchers can better understand ways to reduce time spent sedentary.

REVERENCE—A PREOPERATIVE POSITIVE EMOTION PREDICT POST-OPERATIVE LENGTH OF HOSPITALIZATION

Amy L. Ai, PhD[1], Paul Wink, PhD[2]

[1]Florida State University, Tallahassee, FL; [2]Wellesley College, Wellesley, MA

There has been growing diversification of the American religious landscape (Pew Forum, 2008), which call for research on its behavioral health implications. Aa a cardinal virtue deeply rooted in Western and Eastern civilization, reverence is a sacred positive emotion. Reverence is defined as “feeling or attitude of deep respect, love, and awe, as for something sacred,” which can bestow meaning and purpose in life within different worldviews. In this interdisciplinary study, we investigated the predictive value of traditional religiousness and of experiencing reverence in religious and secular (e.g., naturalistic, moralistic) contexts in postoperative hospital length of stay among patients undergoing open-heart surgery 400+. *Method*: Information on demographics, faith factors, sense of reverence, mental health, and medical comorbidities was collected from 400+ patients (age 62+12) around two weeks before surgery via personal interview. Measures included depression, social support, optimism, religiousness, spirituality, and reverence. Standardized medical indices, including hospital length of stay, were retrieved from the Society of Thoracic Surgeons' national database. *Results*: Hierarchical multiple regression associated secular reverence and shorter hospitalization, after controlling for demographics, medical indices, depression, and psychosocial protectors. Other hospital length of stay predictors included female gender, age, medical comorbidities, low left ventricular ejection fraction, perfusion time, and coronary bypass graft surgery. *Conclusion*: Secular reverence exerts a protective role in an objective measure of cardiac health. More investigation is warrant on naturalistic view of spirituality in patients with diverse beliefs. If the finding is replicated, health providers may integrate a naturalistic perspective of spirituality in cardiac behavioral care.

RISK PERCEPTION UNCERTAINTY MATTERS: GREATER UNCERTAINTY PREDICTS A LOWER LIKELIHOOD OF BEHAVIOR CHANGE.

Caitlin Biddle, MA, MS[1], Jennifer L. Hay, Ph.D.[2], Marc T. Kiviniemi, BA, PhD[1], Erika A. Waters, PhD, MPH[3], Heather Orom, PhD[1]

[1]University at Buffalo, Buffalo, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Washington University in St. Louis, St. Louis, MO

Purpose: The association between perceived risk and behavior is often surprisingly weak given the intuitive nature of the relationship. It is possible that important dimensions of risk perception have been neglected. We propose that uncertainty about risk perception, or people’s low confidence in the accuracy of their risk perception appraisals, may also influence behavior change. This may be the case if uncertainty is indicative of lack knowledge about risk factors that would guide behavior change or can be used defensively to justify non-action. The purpose of this study was to test whether risk perception uncertainty predicts health behavior change.

Methods: Participants were 255 MTURK workers (median education = some college; 83% White; mean age = 34(SD = 9)) who completed an on-line cross-sectional survey. We used four logistic regression models to test whether level of uncertainty about perceived risk for heart disease predicted behavior change, controlling for level of perceived risk. In the first model we regressed change in diet on perceived conditional absolute risk and associated uncertainty about risk. In the second, we regressed change in diet on perceived conditional comparative risk and uncertainty. Corollary models were tested for change in exercise. We controlled for age, gender, race/ethnicity, education, income, insurance status, and healthcare provider access.

Results: For conditional comparative and conditional absolute risk uncertainty, 29%-31% of participants reported being very uncertain or uncertain. Three out of 4 tests supported the hypothesis that greater uncertainty about perceived risk is associated with lower likelihood of health behavior change. Participants who were more uncertain about their perceived conditional absolute, and comparative risk were less likely to have changed their diet (OR = 1.7, p = .04; OR = 1.6, p = .02). Participants who were more uncertain about their perceived conditional comparative risk were less likely to have changed their physical activity (OR = 1.5, p = .048). However there was no association between conditional absolute risk uncertainty and change in physical activity. Only one of the four perceived risk measures was associated

with health behavior change: a higher conditional absolute risk perception of heart disease was associated with a greater likelihood of diet change (OR = 1.6, p = .03).

Discussion: Risk perception uncertainty predicts health behavior change even when controlling for level of risk perception. In fact, it was a more reliable predictor of behavior change than level of perceived risk itself. Dissemination of risk estimation tools that help people understand their personal risk profiles may help people assess their risk with greater certainty, and therefore may improve our ability to promote health behavior change.

SELECTING MOBILE APPS FOR DISTRACTION AND RELAXATION TO HELP SMOKERS DEAL WITH CRAVINGS

Ariana Kamberi, MBA[1], Amanda Blok, PhD, MSN, PHCNS-BC[2], Daniel Amante, MPH[1], Rajani Shankar Sadasivam, PhD[3], Angela DiBenedetto, MA[1], Thomas Houston, MD, MPH[1]

[1]University of Massachusetts Medical School, Worcester, MA; [2]University of Massachusetts Medical School, Cambridge, MA; [3]Univ of Massachusetts Medical School, Worcester, MA

Background.

Smart phone mobile applications (or Apps) available at the point-of-need may help smokers in their quit attempts. Cravings are a major problem for smokers trying to quit. Relaxation and distraction activities can be used to assist smokers in managing cravings. We identified existing relaxation Apps and distraction game Apps. Using formative evaluation techniques, we evaluated smoker's preferences for these Apps.

Methods.

Our study was conducted in two phases. **Phase1:** We conducted a search to identify a set of relaxation and distraction Apps (iOs and Android) for usability testing. To select a subset of Apps for patient review, the investigators conducted a heuristic criteria evaluation. Criteria used included: evidence based Apps that are compatible to both Apple and Android phones, free to the consumer, frequently downloaded, and low complexity (duration of 2-7 minutes).

Phase 2: We recruited smokers to participate in a think-aloud usability testing. Testing sessions were coded for thematic content.

Results.

Phase 1: Our search yielded 15 Apps (9 relaxations and 6 distractions). Based on the heuristic evaluation criteria, a subset of 7 Apps was selected.

Phase 2: Participants (N=8) preferred various relaxation Apps based on their visuals and sounds. Example Comments were: visual ***("I like scenery, like beach, lakes"),*** and sound ***("I like sound of rain, ocean, beach and water running. I love sounds")***. Among distraction Apps, a major theme was that users found some distraction games too challenging and frustrating *(**"This game gives me frustration"**).* Further themes included that engagement was key to game preference ***("Game it's very engaging, it keeps my mind alert")***. Also some smokers commented that game was of appropriate duration to manage a craving ***("This game is long enough, it keeps me distracted and away from smoking").***

Discussion/Conclusions.

Participants revealed a wide range of personal preferences for both current relaxation and distraction. Further evaluation of these Apps for current smokers will continue in the larger randomized trial.

STRATEGIC SELF-PRESENTATION AND BMI: THE IMPACT OF SOCIAL AND PHYSICAL COPING STRATEGIES IN THE ACTIVE BY CHOICE TODAY TRIAL

Allison Sweeney, PhD, Dawn K. Wilson, PhD, Nicole Zarrett, PhD

University of South Carolina, Columbia, SC

This study examines the role of social cognitive and motivational theories on increasing motivation for physical activity (PA) in underserved adolescents. One motivational strategy known as Strategic Self-Presentation (SSP), involves making a public commitment to an action-plan and coping strategies. SSP is based on a theoretical framework that integrates elements from role-playing and commitment, cognitive dissonance theory, and self-perception theory, all of which predict that a person’s public display has a strong impact on one’s self-perceptions and subsequent actions. Past studies have found that SSP facilitates greater coping skills among chronic disease patients, and positive changes in diet and PA among minority youth. Despite preliminary support for the efficacy of SSP, few studies have implemented SSP as a behavioral strategy in a randomized controlled trial. The present study extends past research by examining the effects of an SSP intervention module of a larger school-based PA trial on: 1) changes in body mass index (BMI) from pre-to-post intervention; and 2) the relations of different SSP-derived youth coping strategies on post-intervention BMI. SSP was an intervention component in the Active by Choice Today (ACT) trial, a 17-week randomized school-based trial evaluating the efficacy of motivational intervention on increasing PA among sixth-graders. The SSP task involved completing a video-taped interview about one’s personal coping strategies for overcoming PA barriers and for enlisting peers in PA. To further induce public commitment, students were allowed to view and revise the video. SSP interviews (N = 301, 95.7% female, 36.2% African American) were coded by two raters using a standardized coding scheme ($\kappa = 0.75$), such that strategies used to enlist peers in PA were separated into six categories: psychological (greater confidence), emotional (feel good), social (be with friends), physical (increased ability), health (reduce heart-risk), academic, and other. Sex, race, baseline PA, and baseline BMI were included as covariates. A linear regression indicated that generating a greater number of social and physical strategies was associated with a lower post-intervention BMI, $B = -.220$, $SE = .10$, $t = 2.21$, $p = .028$. The results of this study indicate that social and physical coping strategies are especially impactful for helping underserved adolescents to overcome PA barriers, and should be considered in future interventions.

THE EFFECTIVENESS OF HEALTH COACHING: A SYSTEMATIC REVIEW

Jaime M. Hughes, PhD, MPH, MSW[1], David Edelman, MD[2], Jennifer McDuffie, PhD[2], Hayden Bosworth, PhD[2], Eugene Oddone, MD[2], Shannon S. Taylor, Ph.D.[3], Cindy Swinkels, PhD[4], Andrzej Kosinski, PhD[5], Jennifer M. Gierisch, PhD, MPH[6]

[1]Center for Health Services Research in Primary Care, Durham VA Health Care System, Cary, NC; [2]Center for Health Services Research in Primary Care, Durham VA Health Care System, Durham, NC; [3]Durham VA Medical Center, Durham, NC; [4]Durham VA Health Care System, Durham, NC; [5]Department of Biostatistics and Bioinformatics, Duke University, Durham, NC; [6]Duke Univeristy, Durham, NC

Health coaching is an emerging patient-centered, collaborative intervention where coaches work with patients to identify goals and action plans to maximize personal well-being and overall health. This systematic review evaluated health coaching effectiveness among adults with chronic medical conditions on clinical, behavioral, and self-efficacy outcomes. We searched multiple databases for health coaching RCTs, screened studies, and abstracted data based on pre-determined criteria. When meta-analysis was feasible, we computed summary effect estimates via standardized mean differences or mean differences in random-effects models with Knapp-Hartung confidence interval correction. We grouped analyses based on active (eg, counseling) or inactive (eg, usual care) comparator. When meta-analysis was infeasible, we synthesized qualitatively. Compared to inactive comparators, health coaching had a statistically significant effect on A1c (MD -0.30; 95% CI -0.50,-0.10); physical activity (SMD 0.29; 0.15, 0.43); BMI reduction (MD -0.52; -0.91, -0.14); fat reduction (SMD -0.21; -0.31, -0.10); and self-efficacy (SMD 0.41; 0.21, 0.62). Only change in physical activity had sufficient studies to compare effects with active comparators. When compared to active controls, physical activity change was not significant (SMD 0.17; -0.32, 0.67). Estimates exhibited moderate to high statistical heterogeneity ($I^2 \geq 50\%$). In qualitative syntheses, results were mixed or inconclusive for health coaching on functional status, smoking, and medication adherence. We explored potential sources of heterogeneity including population characteristics, intervention dose, intervention delivery mode, coach type, and concordance with key elements of health coaching. None of these factors were robust predictors of heterogeneity suggesting that high heterogeneity in pooled estimates may be driven by a combination of intervention characteristics. These results suggest that health coaching has the potential to produce significant changes in clinical, behavioral, and psychosocial outcomes. Changes compared to usual care were similar to published results for other

counseling or self-management interventions. Variability in what is considered health coaching may contribute to the overall inconsistency and heterogeneity of effects. Additional research is warranted on the impact of health coaching and the central elements that distinguish it from other behavioral counseling and self-management approaches.

ASSOCIATIONS BETWEEN MEETING COMBINED EXERCISE-ONCOLOGY GUIDELINES AND QUALITY OF LIFE IN KIDNEY CANCER SURVIVORS

Dominick Strom, Bachelor of Science in Kinesiology[1], Kerry S. Courneya, PhD[2], Linda Trinh, PhD[3]

[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]University of Alberta, Edmonton, AB, Canada; [3]University of Illinois at Urbana Champaign, Urbana, IL

Background: Kidney cancer survivors (KCS) are advised to engage in both aerobic and strength exercise. It is unclear, however, if meeting the combined exercise guidelines confers any additional quality of life (QoL) benefits compared to meeting only one of the exercise guidelines.

Purpose: To estimate the prevalence of adherence to the combined exercise guidelines and determine any associations with QoL.

Methods: All 1985 KCS diagnosed between 1996 and 2010 were identified through a Canadian Provincial Registry and mailed a survey including the Godin Leisure Time Exercise Questionnaire and several Functional Assessment of Cancer Therapy QoL scales. Self-reported demographic and medical variables were collected.

Results: Completed surveys were received from 703 (43%) of the 1,654 KCS that received the survey. Only 71 KCS (10.1%) reported meeting the combined exercise guidelines, 112 (15.9%) were meeting the aerobic guideline only, 62 (8.8%) were meeting strength guideline only, and 458 (65.1%) were meeting neither guideline. Analyses of covariance indicated a dose–response association between the exercise guidelines and most QoL outcomes ($p < 0.001$). For the primary QoL outcome of the trial outcome index-fatigue (TOI-F), meeting the combined exercise guidelines was superior to meeting: a) neither guideline (mean difference = 11.8 points; 95% CI: 7.1–16.3, $p < 0.001$), b) the strength only guideline (mean difference = 5.4 points; 95% CI: 0.7–10.1, $p = 0.025$), and c) the aerobic only guideline (mean difference = 6.1 points 95% CI: 2.4–9.8, $p = 0.001$). The aerobic and strength exercise only guidelines were superior to meeting neither guideline ($p = 0.025$ for aerobic; $p = 0.001$ for strength) but were not different from each other ($p = 0.80$).

Conclusions: Meeting the combined exercise guidelines is associated with significantly and meaningfully better QoL in KCS. However, only a small percentage of KCS are meeting the

combined guidelines. Efforts are needed to encourage KCS to adopt the combined exercise guidelines to optimize QoL.

BENEFIT FINDING AND HEALTH BEHAVIORS ONE YEAR AFTER HEMATOPOIETIC STEM CELL TRANSPLANT

Lisa M. Gudenkauf, Ph.D., Shawna Ehlers, Ph.D., Christi A. Patten, Ph.D., Tabetha A. Brockman, M.A., James Cerhan, M.D., Ph.D., Dennis Gastineau, M.D.

Mayo Clinic, Rochester, MN

Background/Objectives. The ability of cancer survivors to find benefits in the midst of crisis has been increasingly recognized. Less is known about benefit finding (BF) among cancer survivors receiving hematopoietic stem cell transplant (HSCT), especially in association with health behaviors of prognostic significance and at long-term follow-up. Exercise in particular has been associated with better mood, fatigue, and speed of rehabilitation post-treatment. Better understanding of the relationship between BF and health behaviors may suggest interventions to improve health behaviors as prognostic factors and long-term quality of life among cancer survivors. **Method.** 667 adults completed a survey of benefit finding and health behaviors one year after HSCT. Benefit finding was assessed using the Benefit Finding Scale (Antoni et al., 2001; Tomich & Helgeson, 2004) 17-item mean score. Multivariate analyses were used to determine associations between BF and health behaviors. Age ranged from 18 to 78, with an average age of 55. 21. This sample consisted of 60. 4% male, 80. 1% married, and 69. 7% Caucasian survivors. Most received autologous HSCT (79. 9%). **Results.** BF was higher among women than men ($F(1, 665)= 8. 716$, $p = 0. 003$) and among those in remission at one year follow-up ($F(1,663) = 5. 359$, $p = 0. 021$). BF was not associated with age at time of treatment, marital status, or type of transplant. In examination of health behaviors, BF was associated with eating more servings of fruit per day ($r = 0. 081$, $p = 0. 038$) but was not associated with servings of vegetables or with current exercise at one-year follow-up. BF was also associated with greater perceived importance of diet ($r = 0. 124$, $p = 0. 001$), but not importance of exercise. BF was associated with intention to change/improve health behaviors, such that those who intended to improve both diet ($F(1,645) = 38. 755$, $p < 0. 001$) and exercise ($F(1,636) = 4. 087$, $p = 0. 044$) reported higher BF compared to those who did not intend to improve these health behaviors. Finally, BF was associated with greater self-efficacy for behavior change, including patients' confidence in their ability to improve nutrition ($r = 0. 237$, $p < 0. 001$) and exercise more ($r = 0. 079$, $p = 0. 046$). Associations remained significant when controlling for gender and remission status, except that BF was no longer associated with eating more fruits per day. **Conclusions.** While BF was not generally associated with current exercise and diet behavior one year after HSCT, BF was associated with intention to improve health behaviors as well as greater self-efficacy for health behavior change. Future work should examine whether interventions could capitalize on patients' ability to find

benefits in the cancer experience as well as their intention and self-efficacy for health behavior change to promote improved health behaviors among HSCT populations.

CLINIC VISIT WAIT TIME: ADVANCED CANCER PATIENT AND CAREGIVER DISCUSSIONS

Jiayun Xu, PhD, RN[1], Lauren Kane, BS[2], Echo L. Warner, MPH[3], Maija Reblin, PhD[4], Margaret F. Clayton, PhD[2], Kathleen Mooney, PhD, RN, FAAN[2], Anna Beck, MD[5], Lee Ellington, PhD[2]

[1]University of Utah, Rockville, MD; [2]University of Utah, Salt Lake City, UT; [3]Huntsman Cancer Institute, Salt Lake City, UT; [4]Moffitt Cancer Center, Tampa, FL; [5]University of Utah, Huntsman Cancer Institute, Salt Lake City, UT

Background

In an effort to become more patient and family centered, cancer outpatient care is moving towards increased consolidation of multiple provider consultations (e.g. oncologist, pharmacist) into a single visit. For patients with advanced cancer and their family caregivers, it is especially important that their time is used wisely, focusing on what matters most for them today and for the remainder of the patient's life. Our objective was to describe the length of wait times and the content of family communication during outpatient oncology appointments. This information can direct future structuring of appointments in cancer centers to better meet the needs of families.

Methods

We recorded and analyzed 21 outpatient clinic visits where at least one family caregiver was present with an advanced cancer patient. Wait times were identified, timed, and patient and family dialogue was analyzed using an iterative, inductive coding process.

Results

Most patients were female (71.4%) with a mean age of 64.6 (SD=11.7) years; family caregivers were mostly female (66.7%) averaging 56.3 (SD=16.9) years old and 50% were spouses. Visits averaged 61.3 (SD=30.5) minutes, with an average of 29.3 (SD=11.2) minutes spent with a healthcare provider and 25.2 (SD=22.7) total minutes spent waiting. On average 13.1 minutes of wait time was uninterrupted (range=50 seconds to 81 minutes). All visits except for two had at least 9.8 minutes of uninterrupted time. During wait times, families spent 53.5% of time discussing their health care. For example: medication management, the current appointment or treatment, caregiving responsibilities, and completing clinical or research paperwork. 46.5% of wait time was spent discussing everyday life such as meals, shopping, and grandchildren.

Conclusion

We found advanced cancer patients and their family caregivers spend approximately half of their appointment time waiting for providers. Approximately half of their waiting time is spent discussing health-care related topics and half on everyday life. Cancer centers may consider

restructuring appointment timing to further consolidate time with providers, or provide guidance for discussions during wait times to provide more support to families. Examples include interventions to facilitate family decision making, sharing values and goals, and care management problem solving, which have been shown to be an under-addressed need for advanced cancer patients and families.

DESIGNING PHYSICAL ACTIVITY INTERVENTIONS BASED ON FAMILY CAREGIVERS' PERSPECTIVES: RESULTS FROM THE RECHARGE TRIAL.

Colleen A. Cuthbert, PhD[1], Kathryn King-Shier, PhD[1], Nicole Culos-Reed, PhD[1], Dean Ruether, MD[2], Dianne Tapp, PhD[1]

[1]University of Calgary, Calgary, AB, Canada; [2]Alberta Health Services, Calgary, AB, Canada

Background: Research activity on physical activity (PA) interventions to support cancer family caregiver health and wellbeing has increased over the last 5 years. Recent studies on PA in cancer caregivers have demonstrated significant effects of exercise on physical health, psychological health, PA levels, and physical fitness. Very few studies have used qualitative inquiry to gather the caregivers' perspectives about this type of intervention.

Method: This qualitative inquiry was part of a larger mixed methods investigation of a randomized controlled trial exercise intervention for cancer family caregivers (the RECHARGE trial). Caregivers participated in group based resistance training classes as well as independent aerobic sessions over 24 weeks. Our goal was to examine cancer family caregivers' perspectives about their participation in the exercise program. Semi-structured face-to-face interviews were completed and analyzed using the method of Interpretive Description.

Results: 20 participants were interviewed. The following themes characterized the caregivers' experience of participating in the exercise program. The context of caregiving is an important component of caregivers' ability to regularly exercise, therefore, timing of when caregivers can participate in PA is highly variable. Caregivers were motivated to participate for many reasons, including wanting to feel better mentally and physically, and wanting to engage in a healthier lifestyle with their entire family. Caregivers preferred exercising with other caregivers in a group based format. The caregivers preferred instructor led (versus independent) exercise as it meant one less thing to worry about or plan. The resistance training format was important as it allowed caregivers to focus on one thing and was a distraction from their worries. Having fun and doing something positive for their own health was an important benefit of regular exercise.

Conclusions: Our findings highlight important aspects of the design of an exercise program based on caregivers' perspectives. Future research on PA interventions in caregivers should include qualitative inquiry to better understand how to design interventions based on caregiver preferences, what outcomes to measure, how to reach more caregivers, and how to sustain PA programs in the changing context of the caregiving situation.

EFFECTS OF A TXT INTERVENTIONS ON PSYCHOSOCIAL OUTCOMES FOR BREAST CANCER PATIENTS RECEIVING CHEMOTHERAPY: A RCT STUDY

Kuang-Yi Wen, PhD[1], Suzanne M. Miller, PhD[2], Rita Smith, BS[3], Jennifer WINN, MD[4], Lori Goldstein, MD[3]

[1]Fox Chase Cancer Center, Cheltenham, PA; [2]Fox Chase Cancer Center/Temple University Health System, Philadelphia, PA; [3]Fox Chase Cancer Center, Philadelphia, PA; [4]Fox Chase Cancer Center, Lansdale, PA

As a core component of cancer care, the use of chemotherapy in the ambulatory care setting is likely to increase considerably with projected increases in the incidence of breast cancer. Chemotherapy may improve overall survival; it is also often associated with substantial treatment-related toxic effects that negatively affect HRQOL. Patients are responsible for making complex decisions about what to do or when to contact the providers in the event of new, escalating or unexpected side-effects. To fill this void, we are in the process of evaluating an innovative and automated text messaging program, designed to facilitate breast cancer patient's self-management in the home setting during adjuvant chemotherapy. The theory-based mChemoCoping text messaging-based intervention was developed through an iterative formative evaluation process with targeted population. Using a RCT design, 34 women were assigned to a control group with a patient education booklet and 31 were assigned to the mChemoCoping intervention group in the ongoing study. During the 4-month intervention, participants in the mChemoCoping condition receive one chemotherapy coping tip text message in the morning and one topic inquiry tip (to generate user-initiated text) in the afternoon. All participants complete a baseline survey and 4 monthly follow-up survey. For the 1-month follow-up complete data, Intervention feasibility and acceptability scores are above average and satisfaction feedback from intervention participants is highly positive through qualitative interviews. A total of 1649 text messages are sent by intervention participants and the most prevalent topics requested by the participants are emotional coping, fatigue, and body changes. The intervention had positive effects on self-efficacy ($F = 9.9$, $p < 0.05$) but not symptom distress ($F=0.9$, $p=0.35$) at 1-month follow-up. This innovative mHealth intervention has potential for improving women's coping skills to manage chemotherapy in the ambulatory care setting.

Background: Many cancer survivors experience financial hardship, particularly individuals under age 65. This study examined qualitative responses of cancer survivors under age 65 to a survey item requesting description of financial sacrifices associated with cancer.

Methods: We examined data from adults aged 18-64 years with a history of cancer who responded to a 2012 LIVESTRONG Survey on experiences with cancer. The online survey contained a section dedicated to the effects of cancer on finances, including borrowing money, filing for bankruptcy, and “other” financial sacrifices. Among 4484 survey participants aged 18-64 years, approximately 37% (n=1656) responded to the survey item “Have you or your family had to make any other kinds of financial sacrifices because of your cancer, its treatment, or the lasting effects of that treatment?” and completed the open-ended question describing these financial sacrifices. For the qualitative assessment, a codebook was developed based on initial review of the open-ended responses. Two trained staff classified each individual response, using codes that were applied as content dictated. We assessed the frequency of financial sacrifice and examined differences between two reported levels of medical debt (≥\$10,000 vs. 2 tests. The n’s indicate the frequencies of coded financial sacrifices.

Results: Among the 1656 respondents, a majority were women (71%), non-Hispanic white (87%), between the ages of 40-54 (50%), and married (68%). Approximately 33% of respondents reported medical debt ≥\$10,000. The most commonly described financial sacrifices included: cutbacks/significant budgeting (n=796); health care insurance/costs (n=406); career impacts (n=316); asset depletion/reduction (n=273); inability to pay bills (n=263); family/relationship burden (n=220); housing challenges (n=216); and increased debt/borrowing (n=184). The type of financial sacrifices differed by level of medical debt. A significantly greater proportion of respondents with debt ≥\$10,000 experienced inability to pay for bills and services, housing challenges, family/relationship burden, and increased debt/borrowing compared to those with debt

Conclusion: Findings provide insight into financial sacrifices made by cancer survivors under age 65 and underscore the sociocultural, individual, interpersonal impact on those who experience financial hardship.

EXPLAINING THE EFFECTS OF MINDFULNESS BASED STRESS REDUCTION ON FATIGUE IN CANCER SURVIVORS

R. Brian Giesler, PhD[1], Shelby Eaton, BA[1], Natalie Nusinow, BA[1], Shelley A. Johns, PsyD, ABPP[2]

[1]Butler University, Indianapoils, IN; [2]Indiana University School of Medicine, Indianapolis, IN

Cancer-related fatigue (CRF) is a significant problem for cancer survivors. In a recent, randomized, controlled pilot study, Mindfulness-Based Stress Reduction (MBSR) was compared to an
education/support control group to assess MBSR’s capacity to provide relief from fatigue. Breast (n=60) and colorectal (n=11) cancer survivors (stage 0-III) with persistent, moderately severe CRF were randomized to MBSR or ES. Outcomes, which included vitality, were assessed at baseline (T1), post-intervention (T2) and again 6 months later at follow-up (T3). Complete results are reported elsewhere (Johns, et al., 2016), but by T2, MBSR participants reported significantly greater vitality (p=0.003) compared to ES participants. To examine the possible mechanisms behind this difference, several potential mediating variables were identified on theoretical grounds, including self-regulatory ability, depressive symptoms, pain, attentional function, and the variables assessed by the Five Facet Mindfulness Questionnaire (FFMQ). Each potential mediator variable was tested using boot-strap procedures: indirect effects and the 95% confidence interval were computed for each of 5,000 bootstrapped samples. These procedures identified one significant mediator: attentional function. For attentional function, assessed by the Attentional Lapse Subscale of the Attentional Function Index (AFI), the indirect effect was 2.2602 and the 95% confidence interval ranged from .1147 to 6.9203. These findings suggest that relative to ES, MBSR exerted its effects, in part, by improving the attentional function of participants.

FACTORS ASSOCIATED WITH TELEVISION VIEWING TIME AMONG BREAST, PROSTATE, AND COLORECTAL CANCER SURVIVORS

Bennett R. McDonald, MPH[1], Corinne Leach, MS PhD MPH[2], Elizabeth Fallon, Ph.D.[1]

[1]American Cancer Society, Atlanta, GA; [2]American Cancer Society's Behavior Research Center, Atlanta, GA

Introduction: Sedentary behavior is a distinct risk factor for poor physical and mental health outcomes independent of moderate to vigorous physical activity (MVPA). Television (TV) viewing time has been linked to increased risk of cancer mortality. Because cancer survivors are at higher risk for chronic disease morbidity and mortality and are more likely to be sedentary compared to individuals without a cancer history, there is need to examine correlates of TV viewing time in cancer survivors.

Methods: Data from 852 breast, prostate, and colorectal cancer survivors within their first year post-treatment were analyzed. Hierarchical ordinal regression was used to assess demographic (age, gender/cancer type, race, education, marital status), medical (months since treatment completion, treatments received, cancer stage, number of comorbidities, physical symptom prevalence), behavioral (smoking status, BMI, MVPA), and psychosocial predictors (depressive symptoms, social support, fear of recurrence) of elevated TV viewing time per day over the past month (< 2, 2-4, or >4 hours/day).

Results: 26.2% of participants reported viewing less than 2 hours, 41.2% reported 2-4 hours, and 32.6% reported more than 4 hours of TV viewing time per day. The odds of reporting elevated TV viewing time were significantly higher among non-whites compared to whites (OR=1.48; 95% CI=1.01, 2.18) and those with no college education compared to at least some college (OR=0.69; 95% CI=0.52, 0.92). Obese survivors compared to those of normal weight (OR=1.67; 95% CI=1.20, 2.33), current smokers compared to never smokers (OR=2.05; 95% CI = 1.27, 3.31), those not meeting MVPA guidelines compared to survivors who did (OR=1.66; 95% CI = 1.26, 2.18), and those with more comorbid conditions (OR=2.51; 95% CI = 1.61, 3.90) also reported higher odds of elevated TV viewing time.

Discussion: Subgroups of cancer survivors who have recently completed treatment may be at higher risk of deleterious physical and mental health outcomes due to elevated TV viewing time. Future research should validate these findings with objective measures. Modifiable risk factors, including smoking status, obesity, and MVPA should be considered when developing interventions aimed at reducing TV viewing among cancer survivors. Further, interventions

should consider targeting survivors with higher odds of TV viewing, including racial/ethnic minorities, non-college educated individuals, and/or those with multiple comorbid conditions.

GOAL DISRUPTION IN EARLY-STAGE BREAST CANCER SURVIVORS: AN EXAMINATION OF PREDICTORS AND CORRELATES

Marcie D. Haydon, M.A.[1], Annette L. Stanton, Ph.D.[2], Patricia A. Ganz, M.D.[1], Julienne Bower, PhD[3]

[1]University of California, Los Angeles, Los Angeles, CA; [2]UCLA, Los Angeles, CA; [3]UCLA Departments of Psychology and Psychiatry/Biobehavioral Sciences; Cousins Center for Psychoneuroimmunology, Los Angeles, CA

Background: Disruption in meaningful life goals is common in cancer patients and has been shown to predict long-term decrements in well-being. However, to date, few studies have examined the factors that contribute to goal disruption, particularly in cancer survivors. To address this gap, we examined the relationship between demographic variables, cancer- and treatment-related factors, behavioral symptoms (depressive symptoms, fatigue, pain, and cognitive complaints), and cancer-related goal disruption in early-stage breast cancer survivors 1 year after the completion of primary treatment.

Methods: A cohort of early-stage breast cancer survivors (n = 190; M_{age} = 51.75) completed assessments following primary treatment with surgery, radiation, and/or chemotherapy, and again 6-months and 1-year later. We focused on the 1-year post-treatment assessment (n = 175) when participants were asked if they had experienced a cancer-related goal disruption. Behavioral symptoms included depression (Beck Depression Inventory-II), fatigue (Multidimensional Fatigue Symptom Inventory), pain (RAND SF-36 Pain Subscale), and cognitive complaints (Patients Assessment of Own Functioning Inventory). These symptoms were computed as a composite measure and also analyzed individually.

Results: Approximately 27% of women reported a goal disruption due to their cancer diagnosis. Cross-sectional analyses indicated that both receipt of chemotherapy and behavioral symptoms were significantly associated with goal disruption; no other demographic or disease-related factors were associated with goal disruption. In multivariate analyses, women were more likely to report a goal disruption if they had received chemotherapy (OR = 3.32, p = .003) and reported greater overall behavioral symptoms (OR = 1.26, p = .004); $\chi^2(2)$ = 26.03, p < .001. When analyzed separately, each behavioral symptom significantly predicted the likelihood of experiencing a goal disruption (ps ≤ .01), holding chemotherapy constant.

Conclusions: Many women reported a cancer-related goal disruption, even a year after treatment completion. Disrupted goals were reported as highly meaningful and spanned various life domains. Chemotherapy and behavioral symptoms were unique predictors,

suggesting that the impacts of chemotherapy extend beyond its influence on persistent behavioral symptoms. This is one of the first studies, to date, to examine goal disruption in early breast cancer survivorship.

HEALTH BEHAVIOR ENGAGEMENT, OBESITY, AND SYMPTOM MANAGEMENT IN LATINA BREAST CANCER SURVIVORS: A QUALITATIVE STUDY

Gloria Juarez, RN, PhD[1], Dara H. Sorkin, PhD[2], Mienah Sharif, PhD[3], Dana B. Mukamel, PhD[4], Yunan Chen, PHd[2], Alfred Kobsa, PhD[4], Alice Police, MD[4], Sadeeka Al-Majid, PhD[5], Kelly Biegler, PhD[4]

[1]UC Irvine, SanPedro, CA; [2]University of California Irvine, Irvine, CA; [3]University of California Irvine, irvine, CA; [4]UC Irvine, Irvine, CA; [5]California State University, Fullerton, Fullerton, CA

Background: Breast cancer survivors are at risk for weight gain, obesity, and diabetes. Relative to other ethnic groups, Latinas are at even greater risk of diabetes and obesity, and are more likely to experience other breast cancer-related symptoms, including fatigue and negative mood. Symptom burden is further compounded in this population by lower socio-economic status and limited access to resources (e.g., car transportation, specialty medical care). Importantly, engaging in health behavior change to achieve weight loss can significantly reduce the number symptoms and their severity among breast cancer survivors. Thus, understanding the complex interplay of obesity, health-behavior engagement, and symptom experience among a group of high-risk, under-resourced Latina breast cancer survivors is a critical next step for addressing this disparity.

Purpose: To obtain an in-depth understanding of Latina breast cancer survivors' perception of factors that contribute to their own health, and the potential connection between their engagement in particular health behaviors and whether these behaviors alleviated symptoms.

Methods: We conducted 17 focus groups in both English and Spanish with 70 Latina women who had undergone treatment for breast cancer to further understand the role of Hispanic culture in the breast cancer survivor experience, cultural-specific motivators and barriers, as well as symptom burden, to engaging in a healthy lifestyle during survivorship.

Results: A common theme that emerged from the focus groups was that a healthy lifestyle helped alleviate some of their symptoms. Some quotes to provide direct examples include: *"For me, the more that I exercise the more active I feel. I also want to be healthier and to feel better. When I do not exercise I feel more fatigued, more tired. The body is not the same after you have been through a lot."* In response to asking what made her start walking another patient said: *"Well, because I was feeling like I was not feeling good with myself. I was feeling*

bloated and the doctor said that it would probably help….So I did and I just felt better, you know. I know, so I started walking a lot and like 30-40 minutes a day.”

Conclusions: Findings suggest under-resourced, high-risk Latina breast cancer survivors recognize a potentially important link between healthy behavior and symptom management. This awareness has to potential be leveraged to create meaningful lifestyle modification programs.

HEART DISEASE VERSUS CANCER: UNDERSTANDING PERCEPTIONS OF POPULATION PREVALENCE AND PERSONAL RISK

Jennifer K. Scheideler, BA[1], Jennifer M. Taber, PhD.[2], Rebecca A. Ferrer, PhD. [1], Emily Grenen, MPH[3], William Klein, PhD.[4]

[1]National Cancer Institute, Bethesda, MD; [2]Kent State University, Kent, OH; [3]ICF, Washington, DC; [4]National Cancer Institute, Rockville, MD

Americans are more likely to be diagnosed with and die from heart disease than cancer. However, many believe that cancer is the more common disease, and may regard their personal risk of cancer to be higher than their heart disease risk. Using the nationally representative 2013 iteration of the National Cancer Institute's Health Information National Trends Survey (HINTS 4 Cycle 3), we examined the prevalence of both of these relative risk beliefs (i.e., relative population prevalence estimates and disease-relative personal risk perceptions). Additionally, we examined sociodemographic (i.e. race, gender, age, education) and psychosocial (i.e., perceptions of ambiguity and fatalism) factors, as well as health behaviors (i.e., physical activity, colorectal cancer screening, fruit/vegetable consumption, soda consumption, sunscreen use, and mammography) associated with these beliefs. Consistent with past work, 42.81% of participants rated cancer as more common than heart disease. Moreover, 78.45% rated their own cancer risk as equal to or exceeding their heart disease risk. These beliefs were only modestly correlated ($r = 0.10$, $p = .013$), and correlates of the two beliefs differed. Specifically, beliefs about population prevalence were associated with fatalism (i.e., thinking about cancer leads to thoughts of death; $B = .16$, $p < .001$) and perceived ambiguity of cancer messages (i.e., perceive cancer recommendations as ambiguous; $B = .022$, $p < .001$), whereas perceived personal risk was not. Less educated ($r = -.14$, $p < .001$) and non-White individuals ($M_{non\text{-}White} = 2.50$, $M_{white} = 2.22$, $p < .001$) rated cancer as more common. Individuals who thought their personal risk of cancer was greater consumed more fruit ($B = .13$, $p = .002$) and vegetables ($B = .09$, $p = .04$), whereas those who believed cancer to be more common consumed more soda ($B = .12$, $p = .039$) and engaged in less physical activity ($B = .20$, $p = .013$). Overall, accuracy in beliefs about cancer and heart disease relative risk and prevalence is low. Future longitudinal research should explore the antecedents and consequences of these beliefs and explore *why* some people think their risk of cancer is greater than their risk of heart disease.

INCREASING PHYSICAL ACTIVITY AND CHANGES IN COGNITIVE FUNCTIONING IN BREAST CANCER SURVIVORS: A RANDOMIZED CONTROLLED STUDY

Sheri J. Hartman, PhD[1], Sandahl H. Nelson, MS[2], Emily Myers, MPH[2], Loki Natarajan, PhD[1], Dorothy Sears, PhD[2], Barton Palmer, PhD[2], Barbara Parker, MD[2], Ruth Patterson, PhD[2]

[1]Department of Family Medicine and Public Health, UC San Diego, La Jolla, CA, USA, La Jolla, CA; [2]University of San Diego, California, La Jolla, CA

Introduction: Increasing physical activity can improve cognition in healthy and cognitively impaired adults. However, the benefits of physical activity for cancer patients' cognition have not been previously reported.

Methods: Sedentary breast cancer survivors with cognitive difficulties were randomized to an Exercise intervention (n=43) or Control arm (n=44). At baseline and 12-weeks participants wore an accelerometer to measure activity and completed the NIH Cognitive Toolbox providing 9 scores (composite fluid and crystalized ability scores and scores for seven component tests). Intervention effects for change in each score over 12 weeks were tested using linear mixed effects regression models.

Results: Participants (n=87) were a mean of 57 years (SD=10.4), diagnosed with breast cancer 2.5 years ago (SD=1.3); 53% had chemotherapy and 70% were taking hormone therapy. At 12 weeks, 60% of the Exercise arm met the study goal of 150 min/week of moderate to vigorous physical activity (MVPA). Relative to Control, the Exercise arm had greater increases in MVPA (mean min/day increase 14.2 vs. -0.7, b=7.24, $p < .001$) and total activity (mean min/day increase 27.4 vs. 4.9, b=10.05, p=.02).

Of the NIH Toolbox's 9 scores, only the Oral Symbol Digit (a measure of processing speed) had significant improvement in the Exercise vs. Control (b=2.01;$p < .05$). The Exercise arm increased an average of 7 points while the Control arm increased an average of 3 points. There appeared to be an interaction between time since diagnosis and Oral Symbol Digit scores (p=.07). Participants ≤2 years from diagnosis had significantly more improvement in the Exercise vs. Control (b=4.00, $p < .01$); there was no significant improvement in patients who were >2 years post-diagnosis (b=-1.19, p=.40). No modification effect was found for BMI, years since diagnosis, chemotherapy or hormone therapy.

Within the exercise arm there was a significant dose response with greater increases in MVPA

associated with greater increases in Oral Symbol Digit (b=2.0, p=.02). Also, greater total activity was associated with greater increases in the Fluid Composite score (b=0.03, p=.04) and Picture Sequence (memory; b=0.04, p=.04).

Conclusion. Among breast cancer survivors, the exercise intervention only significantly improved processing speed. Moderator and dose-response analyses suggest that future trials should aim for greater increases in physical activity and target women closer to diagnosis to impact cognition.

INFLAMMATORY BIOMARKERS ARE ASSOCIATED WITH CHANGE IN SKELETAL MUSCLE MASS AND STRENGTH IN EXERCISING PROSTATE CANCER PATIENTS

Calvin L. Cole, PhD[1], Ian Kleckner, PhD[2], Po-Ju Lin, PhD, MPH, RD[3], Charles Kamen, PhD, MPH[2], Luke J. Peppone, PhD, MPH[4], Michelle Janelsins, PhD, MPH[2], Charles E. Heckler, Ph.D., M.S. [2], Karen Mustian, PHD, MPH, MS[2], Sarah Kerns, PhD MPH[2], Matthew Asare, PhD, MBA, CHES[1]

[1]University of Rochester, Rochester, NY; [2]University of Rochester Medical Center, Rochester, NY; [3]University of Rochester Medical Center, Department of Surgery-Cancer Control, Rochester, NY; [4]University of Rochester, Wilmot Cancer Institute, Rochester, NY

BACKGROUND: Decreases in skeletal muscle mass (SMM) and muscular strength are debilitating side effects of cancer and its treatments and are independently predictive of mortality. Recent studies suggest a negative association of inflammatory cytokines with SMM and strength. Exercise has been shown to positively regulate pathways that govern SMM and strength. This research study attempted to identify any associations among declines in SMM and strength and inflammatory biomarkers and to determine if exercise has an effect on these associations. **PURPOSE:** The purpose of this study was to assess the relationship among inflammatory biomarkers, indices of SMM and strength, and engagement in exercise among prostate cancer patients**. METHODS:** A secondary data analysis was performed on a two-arm randomized clinical trial examining the influence of a 6-week home-based aerobic and resistance exercise program. Participants included 57 sedentary prostate cancer patients aged 67 ± 8.05 years, who were undergoing cancer treatment or had been previously treated with hormone therapy and/or radiation therapy. Each participant was randomly assigned to usual care or usual care with exercise. SMM and muscular strength were measured along with biomarkers of inflammation (IL-6, IL-1b, IFN$_{\gamma}$, IL-10, IL-8, and TNFR1 proteins) at baseline and post-intervention. Pearson correlations and linear regressions were used to analyze the relationship among these variables. **RESULTS:** In the exercise group, changes in IFN$_{\gamma}$ and IL1b showed a moderate association with changes in SMM (IFN$_{\gamma}$ r =.442, p = .016, IL-1b, r = .543, p = .002) where increases in IFN$_{\gamma}$ (p =.016) and IL-1b (p = .002) explained 20% and 30% of the change in SMM, respectively. A trend towards a moderate relationship between IL-10 and leg muscle strength (r = -.348, p = .081) was found where decreases in IL10 explained 12% of the change in leg strength. No significant associations among any of these variables were found in the usual care group**. CONCLUSION:** Changes in IFN$_{\gamma}$, IL-1b and IL-10 may be associated with changes in SMM and strength in exercising prostate cancer patients.

INFORMATION AND SUPPORT NEEDS AMONG YOUNG ADULT RELATIVES OF BRCA 1/2 MUTATION CARRIERS

Chalanda N. Evans, BS[1], Rebekah J. Hamilton, RN PhD CNL FAAN[2], Kenneth P. Tercyak, PhD[3], Beth N. Peshkin, MS, CGC[4], Sue Friedman, DVM[5], Claudine Isaacs, MD[4], Suzanne O'Neill, PhD[4]

[1]Georgetown University/ Lombardi Comprehensive Cancer Center, Washington, DC; [2]Rush University College of Nursing, Chiacgo, IL; [3]Georgetown University Medical Center, Lombardi Comprehensive Cancer Center, Washington, DC; [4]Georgetown University, Washington, DC; [5]Facing Our Risk of Cancer Empowered (FORCE), Tampa, FL

Background: Young women from hereditary breast and ovarian cancer (HBOC) families face a unique set of challenges in managing their HBOC risk where obtaining essential information to inform decision making is key. Previous work suggests that the need for specific health information related to risk also comes at a time of heightened distress and greater individuation from family. Our study sought out to assess the information needs in this population and correlates of greater need.

Method: One hundred young women (M age= 25 years) who were first or second degree relatives of *BRCA1/2* carriers participated. Participants ages 18-30 were recruited through research registries and a national non-profit organization for a telephone interview. Using multivariable linear regression, we examined the association between clinical (age, tested status, number of cancer-affected relatives and age of youngest affected relative) and psychosocial (familial disruption, peer support, cancer-related distress and perceived cancer risk) variables and our outcome of information need.

Results: One third of the sample endorsed wanting HBOC information that they did not know how to obtain and 63% endorsed unmet HBOC information needs. Multivariate regression model results revealed that greater information need was associated with being untested (β=.30, p=.004) and greater familial disruption (β=.41, p=.002) and cancer-related distress (β=.21, p=.04).

Conclusion: Our results suggest that young adult women from HBOC families have unmet cancer genetic information needs. Untested women, as well as those with higher levels of distress and poorer familial connections, are specifically in need of support. Social support can mitigate distress and supplement familial relationships. Our results suggest that young adult relatives could benefit from a structured peer-led intervention that provides needed support and targets psychologic distress. Trained peers can offer structured social support guidance and assist with objectively weighing the pros/cons of personal HBOC risk management choices and lifecycle issues relevant to women in their 20's and 30's.

INTEREST IN WEIGHT LOSS AMONG FEMALE CANCER SURVIVORS WITH OVERWEIGHT OR OBESITY

Christine May, PhD[1], Molly E. Waring, PhD[2], Martinus Evans, B.S., M.S.[2], Sherry Pagoto, PhD[2]

[1]University of Massachusetts Medical School, Fiskdale, MA; [2]University of Massachusetts Medical School, Worcester, MA

Obesity increases risk of cancer recurrence and decreases survival, yet many female cancer survivors are overweight or obese. We surveyed adult female cancer survivors with overweight or obesity via the internet on their awareness of the link between obesity and cancer recurrence and preferences in various intervention modalities (in-person, telephone, Facebook, Twitter, private website) and interest in 12 components of a Facebook-delivered intervention. Responses dichotomized as not at all/a little bit, neutral vs quite a bit/extremely interested. Survivors also reported preferred group composition (any cancer type, same cancer type, not focused on survivors, no preference). An open-ended question assessed interest in other weight loss group features. We conducted a content analysis of responses with two coders (kappa=0.84). Survivors (N=96) were on average 54.3 (SD: 9.6) years old, 89% white, with average BMI of 32.7 (SD: 5.8) kg/m^2; 87% tried to lose weight in the last year. Just over half (54%) reported that their weight at least somewhat affects their likelihood of cancer recurrence. Most (81%) reported being quite a bit/extremely interested in a program delivered via Facebook or private website (71%), while fewer were interested in telephone (37%) or in person delivery (34%). About three-quarters were interested in having a weight loss counselor lead the group (78%), healthy recipe links (73%), and free exercise videos (72%); interest in other program components ranged from 35%-69%. Survivors suggested features including information on effects of cancer treatment on weight (25%), a calorie tracker (21%), and exercise modifications for cancer survivors (17%). Almost half (43%) preferred a group with cancer survivors (19% same cancer type, 3% not focused on survivors, 33% no preference). Nearly half of survivors were not aware of the link between obesity and cancer. Survivors were interested in a weight loss program that addresses their specific weight loss needs, and the majority liked the idea of a Facebook-delivered program. Social media delivered weight loss interventions for female cancer survivors should incorporate information on the obesity-cancer link and features that address specific needs of this population.

IS ANTICIPATED REGRET A SEPARATE AND UNIQUE THEORETICAL CONSTRUCT FROM MOTIVATION IN THE CONTEXT OF HPV VACCINATION?

Catherine Rochefort, MS[1], Austin S. Baldwin, PhD[1], Deanna Denman, MA[1], Amy McQueen, PhD[2], Jasmin A. Tiro, PhD[3]

[1]Southern Methodist University, Dallas, TX; [2]Washington University, School of Medicine, St. Louis, MO; [3]University of Texas Southwestern Medical Center, Dallas, TX

Objective: Anticipated regret, a negative emotion stemming from the ability to reason counterfactually, has been shown to be a key predictor of various health behaviors (Brewer et al., 2016), but no studies have demonstrated that it is a unique construct from motivation. Anticipated regret is conceptually similar to introjected motivation from self-determination theory (i.e., motivation to avoid guilt and shame). In the context of HPV vaccination, we hypothesized that anticipated regret about not vaccinating a child would load more strongly on a factor with introjected motivation than autonomous motivation (i.e., motivation to engage in behaviors that reflect personal values). **Methods**: We collected data via telephone questionnaires from 223 parents of unvaccinated adolescents attending safety-net clinics. We assessed parents' anticipated regret, introjected and autonomous motivation, and intentions to vaccinate. **Results**: Using confirmatory factor analyses, a four-factor model including autonomous motivation (4 items), introjected motivation (2 items), external motivation (2 items), and 1 anticipated regret item provided a good fit to the data (TLI= .971, CFI= .983, RMSEA= .053, 90% CI: .013, .085). The anticipated regret item did not load significantly onto introjected motivation (.26) or autonomous motivation (.49). In a univariate regression model, anticipated regret predicted intentions to vaccinate (ß= .243, $p < .001$). A multivariable model containing introjected motivation and anticipated regret showed both to be significant predictors of intentions, but when tested simultaneously with autonomous motivation, anticipated regret was no longer a significant predictor of intentions. **Conclusion**: Anticipated regret is a distinct construct from motivation, and loads more strongly on a factor with autonomous motivation than introjected motivation for HPV vaccination. In addition, anticipated regret did not explain any variance in HPV vaccination intentions that is not shared with autonomous motivation. Implications for these findings will be discussed.

KNOWLEDGE, ATTITUDES, AND BELIEFS ABOUT HPV, GARDASIL, AND ACCESS DIFFER AMONG LATINOS IN A SMALL RURAL NEW DESTINATION SETTING

Jason Daniel-Ulloa, PhD, MPH[1], Laura Seegmiller, MPH[1], Barbara Baquero, PhD, MPH[1], Gregory Steckel, MDiv[2], Marlén Mendoza, HS[1], Ana Duarte, HS[1], Christine Harb, BA[1]

[1]University of Iowa College of Public Health, Iowa City, IA; [2]St. Joseph Catholic Church, West Liberty, IA, West Liberty, IA

The target vaccine coverage rate for HPV set by Healthy People 2020 is 80%. However, few if any communities meet this goal, yet. Latino populations in rural new destination settlements (areas in which Latino communities are growing rapidly) present unique challenges for local providers and public health staff (e.g., language capacity, cultural competence). To provide better information on the knowledge, attitudes and beliefs about HPV, Gardasil, and access to vaccines among Latinos in a new destination area in a rural Midwestern state, we conducted 72 intercept interviews with representatives of Latino households. Surveys were conducted at a local Catholic Church, a small Latino owned grocery store, a large grocery store, two Latino Festivals, a bakery and a restaurant. The survey included items assessing age, gender and vaccine status for all household members 9-26 years old, knowledge of HPV and Gardasil, best places to get vaccinated, trusted sources for health education and the best way to contact individuals for reminders. The sample was mostly female (67%), born in Mexico (59%) or the US (24%). Mean age was 39 (13.1), and average number of years lived in the US was 24 (13.2). A majority of households (57%) included at least one vaccine eligible female and 61% included an eligible male. A higher percentage of females (80%) reported knowing about HPV than males (57%). Of those that were familiar with HPV, 89% of females and 82% of males were familiar with Gardasil. Access to the vaccine was rated highest at the mobile clinic overall. The nearest pharmacy, (one town over) received significantly higher access ratings ($p < .05$) by individuals that were born outside the US but immigrated as minors (< 18). Churches and beauty salons received highest ratings as places to provide education. Beauty salons were rated higher by US born than minor ($p < .001$) and adult ($p < .003$) immigrants. Participants reported similar ratings for calls, texts, emails and postcards. Reaching and educating Latino populations in rural areas will be important in achieving vaccine coverage objectives in the Midwest. However, in predominantly white states, local efforts may focus more on larger non-Latino communities, further complicated by a lack of information about how these new communities access information about cancer and cancer prevention. This exploratory study can help inform useful strategies and tactics to reach these Latinos for HPV vaccine education and initiation.

LESSONS LEARNED: ASSESSING GRIP STRENGTH AND MOBILITY FUNCTIONS IN A BREAST CANCER SUPPORT GROUP SETTING

Maria Swartz, PhD, MPH, RD, LD[1], Rachel R. Deer, PhD[2], Eloisa Martinez, BS, CCRP[3], Zakkoyya Lewis, BS[4], H. Colleen Silva, MD[5], Elizabeth J. Lyons, PhD[5]

[1]UTMB, Missouri City, TX; [2]UTMB, Galveston, TX; [3]University of Texas Medical Branch-Galveston, Texas City, TX; [4]University of Texas Medical Branch, Bellflower, CA; [5]The University of Texas Medical Branch, Galveston, TX

Background: Functional impairments are associated with reduced quality of life and survival in breast cancer survivors. Currently, self-reported measures are most often used to screen survivors for functional deficits, and community-based measurement is rare. However, objective measures may better capture complex constructs, and community-based assessment would potentially allow earlier discovery of deficits in a broader population than is currently screened. Thus, the aim of this study was to evaluate the feasibility of using objective functional measures within a community setting of a breast cancer support group.

Methods: Baseline information from a 12-week pilot breast cancer support group intervention was used to evaluate participants' function. Grip strength—assessing muscular strength—was evaluated using the Jamal dynamometer and mobility function was assessed using the Short Physical Performance Battery (SPPB). Feasibility was evaluated based on number of participants completing both assessments and time required to conduct both assessments. Descriptive statistics were conducted.

Results: Nineteen survivors completed the grip strength and SPPB assessments. The majority of the participants were White (68%) with a mean age of 55±12 years and mean BMI of 32.4±7.9 kg/m^2. All participants completed three grip strength evaluations for both right and left hands despite 32% reporting peripheral neuropathy. Seven participants had grip strength below norms. All attempted the entire SPPB assessments with a mean score of 10±1.3 out of 12, indicating high functioning. However, 9 of 19 participants completed the 10 seconds tandem balance test with some difficulty. Approximately 25 minutes per person were required to complete both assessments using standardized protocols.

Discussion: Overall, we found that it is feasible to conduct grip strength and SPPB assessments in a breast cancer support group setting. Despite 47% of participants experiencing difficulty during the 10 seconds tandem balance test, the mean SPPB score was

high. This indicated a ceiling effect. A protocol modification to increase hold time from 10 seconds to 30 seconds may eliminate the ceiling effect we found and to help capture possible balance issues.

LIFESTYLE BEHAVIORS AND PSYCHOSOCIAL OUTCOMES AMONG LONG-TERM CANCER SURVIVORS

Errol J. Philip, PhD[1], Thomas V. Merluzzi, PhD[2], Steven Grapperhaus, BBA[3], Brian Lewis, BS[4]

[1]Laboratory for Psychooncology Research at the University of Notre Dame, Brea, CA; [2]University of Notre Dame, Notre Dame, IN; [3]California State University - Fullerton, Fullerton, CA; [4]California State University - Fullerton, San Diego, CA

Purpose: Cancer survivors represent a vulnerable population at increased risk of recurrence and poor physical and psychosocial long-term effects. These individuals are recommended to adopt healthy lifestyle behaviors that may reduce the risk of recurrence of certain cancers and improve overall health status. Further, it is often believed that a cancer diagnosis can represent a ‘teachable moment’ and prompt individuals to adopt healthy behavior changes. Despite this, there exists a paucity of research examining adoption of potentially protective lifestyle behaviors among long-term survivors, and how such behaviors may be associated with psychosocial outcomes.

Method: 407 long-term cancer survivors (73.3% female, average age 63.3 years, average time since diagnosis 14.6 years, 77.1%, White/European American, 19.1% African American) reported adoption of recommended lifestyle behaviors (regular exercise, non-smoking status, non-obese weight status) and measures of quality of life (FACT-G), and depression/anxiety (HADS). Survivors were further divided into groups based on their degree of adoption of protective health behaviors.

Results: Among a sample of long-term cancer survivors, 80.2% reported regularly exercising, 91.5% were non-smokers and 60.8% were not obese. Overall, 25.6% engaged in all three recommendations, while 3.9% engaged in none. Importantly, nearly 40% of the sample were obese and 8.5% reported currently smoking. Further analyses revealed that survivors who engaged in two or more of the recommended lifestyle behaviors had significantly better quality of life (114.36 vs. 106.49 $p < .001$) and fewer symptoms of anxiety (3.99 vs. 5.43, $p < .001$ and depression (2.86 vs. 4.33, $p < .001$) compared to those who engaged in one or zero behaviors. Further preliminary analyses revealed weight status and exercise to be primarily responsible for observed differences in psychosocial outcomes.

Conclusion: The importance of health promotion in cancer survivorship is becoming increasingly recognized. Among a sample of long-term survivors, approximately one-quarter of those surveyed had adopted general health recommendations, with greater engagement

associated with improved quality of life and lower rates of anxiety and depression. While encouraging, a number of challenges remain; nearly 10% of the sample still smoked and 40% were obese, with weight management continuing to be a critical challenge among survivors and the general population alike. Further research is needed to maximize engagement in healthy behaviors and enable professionals to actively and effectively promote lifestyle change among cancer survivors.

LIFESTYLE INTERVENTION EFFECTS ON MOBILITY AND BODY COMPOSITION IN PROSTATE CANCER PATIENTS ON ANDROGEN DEPRIVATION THERAPY

Brian Focht, N/A[1], Alexander R. Lucas, PhD[2], Elizabeth Grainger, PhD[3], Christi Simpson, BA[4], Ciaran FAIRMAN, M.S.[1], Jennifer M. Thomas-Ahner, PhD[1], Steven K. Clinton, MD, PhD[1]

[1]The Ohio State University, Columbus, OH; [2]Wake Forest School of Medicine, Winston Salem, NC; [3]The Ohio State University Comprehensive Cancer Center, Columbus, OH; [4]The Ohio State University Comprehensive Cancer Center, Dayton, OH

Although exercise consistently results in significant improvements in clinically relevant outcomes in prostate cancer (PCa) patients undergoing androgen deprivation therapy (ADT), the synergistic benefits of promoting concomitant change in both exercise and dietary behavior could represent an optimal lifestyle intervention approach for offsetting the adverse effects of ADT on mobility performance and body composition experienced by PCa patients. The purpose of the single-blind, randomized controlled Individualized Diet and Exercise Adherence-Pilot (IDEA-P) trial is to evaluate the preliminary efficacy of a combined exercise and dietary (EX+D), implementing a group-mediate cognitive behavioral (GMCB) approach, relative to standard of care (SC) treatment upon change in mobility performance and body composition among PCa patients undergoing ADT. A total of 32 PCa patients (*M* age = 65 years) on ADT were randomly assigned to the EX+D (n = 16) or SC (n = 16) interventions. Measures of mobility and body composition were obtained at baseline and 2 and 3 month follow-up assessments. Results of intention to treat ANCOVA analysis of residualized change scores yielded a significant Treatment main effects for 400M Walk ($p < 0.01$) and stair climb ($p < 0.01$) performance and body composition ($p < 0.05$). Results of intention to treat analysis yielded a significant Treatment main effects for 400M Walk ($p < 0.01$) and stair climb ($p < 0.01$) performance and body composition ($p < 0.05$). The EX+D intervention resulted in superior improvements in mobility performance relative to SC at 2 and 3 months. Additionally, the EX+D intervention yielded significantly greater improvements in body weight, body fat percentage, and fat mass relative to the SC intervention at 3 month follow-up. Findings from the IDEA-P trial suggest that the EX+D intervention, implementing a GMCB approach designed to promote adoption and adherence to lifestyle behavior change, resulted in superior changes in mobility performance and body composition relative to a SC approach. These results underscore the utility of promoting concomitant change in both exercise and dietary behavior for enhancing mobility and body composition among PCa patients undergoing ADT.

LONGITUDINAL ANALYSIS OF THE PERCEIVED STRESS OF A NEW CANCER DIAGNOSIS AND PTSD-LIKE SYMPTOMS AT ONE YEAR FOLLOW-UP

Hannah-Rose Mitchell, MPH[1], Amanda Ting, BS[1], Melanie McKenna, N/a[2], William F. Pirl, M.D., MPH[3], Youngmee Kim, PhD[2]

[1]University of Miami, Miami, FL; [2]University of Miami, Coral Gables, FL; [3]Sylvester Cancer Center, University of Miami Miller School of Medicine, Miami, FL

Cancer patients are at risk for psychological distress, including post-traumatic stress disorder-like (PTSD) symptoms reaching clinical levels of impairment. There is a lack of prospective studies examining early predictors of PTSD in cancer patients. The current longitudinal study examined the relationship between the appraisal of stress around the time of diagnosis and the onset of PTSD symptoms around the time of completion of treatment.

Colorectal cancer patients (*N=54;* stages I-IV, 61% female, 59% Hispanic, *M*=55 years old) completed questionnaires at around 3 and 12-months post-diagnosis. At the baseline assessment, patients completed the Perceived Stress Scale (PSS) measuring their perception of stress. The Impact of Event Scale (IES) measure of PTSD was administered at both time points and served as the outcome. Age, gender, ethnicity, and cancer stage were covariates.

Relatively small-to-moderate number of patients reported clinical levels of PTSD symptoms at 3-months and 12-months (13% at both times) post-diagnosis. On the other hand, the majority reported normative levels of perceived stress around the time of diagnosis (*M*=14.2, *SD*=5.94). Hierarchical linear regression revealed that after controlling for covariates, higher perceived stress around the time of diagnosis related to higher levels of PTSD symptoms around the completion of treatment (*B*=0.90, *p* < .01).

These longitudinal findings suggest that appraisal and perceptions of stress around the time of a cancer diagnosis may manifest into sub-clinical or clinical levels of psychological disorder in patients by the time they complete treatment. The results suggest the need for early psychosocial assessment to identify patients with high stress appraisals who could benefit from interventions aimed at stress management and cognitive restructuring.

MEDICAL TOURISM: A GOOD THING OR A BAD THING

Linda Ko, PhD

Fred Hutchinson Cancer Research Center, Seattle, WA

Background:Colorectal cancer (CRC) remains the most commonly diagnosed cancer among Korean Americans (KAs) in part due to low screening rates. Recent studies suggest that some KA patients engage in medical tourism and receive medical care in their home country. The impact of medical tourism on CRC screening is unknown. The purpose of this paper was to

1) investigate the frequency of medical tourism, 2) examine the association between medical tourism and CRC screening, and 3) characterize KA patients who engage in medical tourism.

Methods: This is a community-based, cross-sectional study involving self-administered questionnaires conducted from August 2013 to October 2013. Data was collected on 193KA patients, ages 50-75, residing in the Seattle metropolitan area. The outcome variable is up-to-date with CRC screening, defined as having had a stool test (FOBT or FIT) within the past year or a colonoscopy within 10 years. Predictor variables are socio-demographics, health factors, acculturation, knowledge, financial concerns for medical care costs, and medical tourism.

Results:In multi-variate modeling, medical tourism was significantly related to being up-to-date with colorectal screening. Participants who engaged in medical tourism had 8.91 (95% CI: 3.89-23.89) greater odds of being up-to-date with CRC screening compared to those who did not travel for healthcare. Factors associated with engaging in medical tourism were lack of insurance coverage (P=0.008), higher levels of education (P=0.003), not having a usual place of care (P=0.002), older age at immigration (P=0.009), shorter years-of-stay in the US (P=0.003), and being less likely to speak English well (P=0.03).

Conclusions: This study identifies the impact of medical tourism on CRC screening and characteristics of KA patients who report engaging in medical tourism. Healthcare providers in the US should be aware of the customary nature of medical tourism among KAs and consider assessing medical tests done abroad when providing cancer care.

METABOLIC SYNDROME AMONG OVERWEIGHT/OBESE AFRICAN-AMERICAN BREAST CANCER SURVIVORS VS. MATCHED NON-CANCER CONTROLS

Patricia Sheean, PhD, RD[1], Huifang Liang, PhD, MD[2], Linda Schiffer, MS, MPH[3], Claudia Arroyo, MPH[3], Melinda Stolley, MA, PhD[4]

[1]Loyola University Chicago, Maywood, IL; [2]Takeda Development Center Americas, Deerfield,, IL; [3]University of Illinois at Chicago, Chicago, IL; [4]Medical College of Wisconsin, Milwuakee, WI

Background: Metabolic Syndrome (MetS) predicts multiple chronic diseases and is predominant in those who are overweight/obese, as well as minority populations. Emerging data now suggests MetS may also predict breast cancer (BC) recurrence and overall decreased survival; however, African-American (AA) BC survivors have been analyzed in aggregate.

Purpose: Therefore, the primary aim of this study was to establish the prevalence of MetS among an exclusive cohort of AA BC survivors and to compare these estimates with matched non-cancer population controls. This approach allowed us to assess the impact of BC treatment on the occurrence of MetS and to generate prevalence estimates affording comparisons with other BC populations.

Methods: We employed a case-control design. For the cases, we utilized baseline data from a behavioral weight loss intervention conducted in overweight/obese AA BC survivors (R01CA154406). To represent non-cancer population controls, we used cross-sectional data from the National Health and Nutrition Examination Survey. Overweight/obese AA women with treated Stage I-IIIa BC were matched 1:1 on age, race, sex and body mass index (BMI) category with non-cancer population controls (n=444 or 222 pairs). All measurements were procured by trained study personnel and certified clinical laboratories. Three of the following conditions were used to define MetS: HDL cholesterol < 50 mg/dL (1.3 mmol/L), serum triglycerides ≥ 150 mg/dL (1.7 mmol/L), blood glucose ≥ 100 mg/dL (or on treatment), waist circumference ≥ 88 cm, or ≥ 130 mm Hg systolic or ≥ 85 mm Hg diastolic blood pressure (or on treatment). Matched-pairs analyses were conducted.

Results: For BC cases, most women had self-reported Stage I (n=76) or Stage II (n=91) disease and were 6.9 (± 5.2) years post-diagnosis. Compared to non-cancer population controls, BC cases were more educated ($p < 0.001$) and had greater access to health insurance, specifically private insurance (< 0.001). MetS was significantly less frequent among BC survivors vs. non-population cancer controls (43.2% vs. 51.4%, respectively; $p < 0.05$) and did differ significantly

across any BMI category (Overweight 25.0% vs. 37.9%; Class 1 Obesity 38.1% vs. 44.8%; Class 2 Obesity 64.3% vs. 53.6% and Class 3 Obesity 39.0% vs. 73.2%, respectively.) However, a lower prevalence of ≥ 2 risk factors was observed for all BC cases vs. non-cancer population controls (80.2 % vs. 85.6%, $p < 0.05$).

Conclusions: While MetS occurred less frequently in our BC cases vs. non-cancer population controls, these estimates are nearly two times those reported in other BC investigations, suggesting important racial/ethnic differences that merit attention and greater intervention efforts. The prognostic implications of MetS among AA BC survivors remain unknown.

MINDFULNESS MEDIATES ASSOCIATION BETWEEN AGE AND DEPRESSIVE SYMPTOMS IN EARLY STAGE BREAST CANCER PATIENTS

Melissa Janson, BA[1], Kate R. Kuhlman, PhD[2], Julienne Bower, PhD[3]

[1]UCLA, Cousins Center for Psychoneuroimmunology, Northridge, CA; [2]UCLA, Cousins Center for Psychoneuroimmunology, Los Angeles, CA; [3]UCLA Departments of Psychology and Psychiatry/Biobehavioral Sciences; Cousins Center for Psychoneuroimmunology, Los Angeles, CA

Mindfulness mediates association between age and depressive symptoms in early stage breast cancer patients

BACKGROUND: Diagnosis with breast cancer is highly stressful and is associated with elevated risk for depression, with negative implications for quality of life, treatment adherence, and other outcomes. Younger women are at elevated risk for depression in the aftermath of a breast cancer diagnosis. However, the underlying mechanisms that contribute to age differences in depressive symptoms in breast cancer patients have not been determined. Research suggests that acceptance of negative emotional experiences increases with age and may contribute to lower negative affect. Acceptance is closely related to mindfulness, the state of being attentive to and aware of one’s present moment experience in a nonjudgmental manner. In the present study, we examined whether dispositional mindfulness mediated the link between age and depression in women recently diagnosed with early stage breast cancer.

METHODS: 271 women diagnosed with Stage 0-III breast cancer (mean age=56.2 years, SD=11.5) were assessed after diagnosis but before starting adjuvant treatment (radiation, chemotherapy, endocrine therapy). Participants completed the Center for Epidemiologic Studies Depression Scale (CESD) to assess depressive symptoms in the past week, and the Mindful Attention Awareness Scale (MAAS) to assess trait levels of mindfulness. We used multiple linear regression models to examine the association between age and depression, as well as whether mindfulness mediated this relationship. All analyses controlled for potential confounds including disease characteristics, ethnicity, education, and income.

RESULTS: Older age was associated with lower depressive symptoms (B=-.24, SE=.06, $p < .001$) and with higher levels of dispositional mindfulness (B=.016, SE=.01, p=.002). Higher levels of mindfulness were associated with lower depressive symptoms (B=-5.00, SE=.70, $p < .001$), and mindfulness partially mediated the association between age and depressive symptoms, Sobel Test =2.87, SE=0.025, p=.004.

CONCLUSION: The findings suggest that mindfulness may increase with age and therefore be protective against depressive symptoms following breast cancer diagnosis. Mindfulness interventions may be aptly targeted toward younger breast cancer patients.

PATIENT-REPORTED AND GENETIC RISK FACTORS FOR CHEMOTHERAPY-INDUCED NAUSEA IN CANCER PATIENTS

Kelly A. Hyland, B.A.[1], Ashley M. Nelson, MA[2], Gillian Bell, PharmD[3], Jhanelle Gray, MD[4], Richard Kim, MD[4], Paul B. Jacobsen, PhD[5], Howard L. McLeod, PharmD [4], Heather Jim, PhD[4]

[1]University of South Florida/Moffitt Cancer Center, Tampa, FL; [2]University of South Florida & Moffitt Cancer Center, Tampa, FL; [3]Mission Health, Asheville, NC; [4]Moffitt Cancer Center, Tampa, FL; [5]National Cancer Institute, Bethesda, MD

Purpose: Chemotherapy-induced nausea (CIN) is common among cancer patients even when anti-emetic prophylaxis is provided in accordance with clinical practice guidelines. Early identification of patients at risk for CIN may help physicians to better personalize anti-emetic therapies and reduce this undesirable side effect. The current study examined patient-reported and genetic risk factors for CIN.

Methods: Eligible individuals were a) age > 18, b) English or Spanish-speaking, c) chemotherapy naïve cancer patients, and d) scheduled to receive highly- or moderately-emetogenic intravenous chemotherapy for solid tumors at Moffitt Cancer Center. Participants completed a baseline sociodemographic questionnaire and provided a blood sample to measure genetic variants in *ABCB1* (rs1045642) and *HTR3B (*rs45460698)as well as *CYP2D6* activity score. Participants also completed a self-report risk factor questionnaire the morning of the first infusion and the MASCC Antiemesis Tool (MAT) 24 hours and 5 days post-infusion to assess the severity of acute and delayed CIN.

Results: Participants were 107 patients (50% male, *M*=61 years). Twenty-three percent of participants experienced acute CIN and 55% experienced delayed CIN. In univariate analyses, younger age, fewer hours slept the night prior to infusion, and a history of morning sickness with pregnancy were associated with more severe acute CIN; fewer hours slept the night prior to infusion and receipt of highly emetogenic chemotherapy were associated with more severe delayed CIN (*p*'s < .05). Of genetic variants assessed in 77 patients, only that in *ABCB1* was associated with acute CIN, with heterozygotes reporting more severe acute CIN. In multivariate analyses, *ABCB1* added an additional 4% predictive value beyond the 10% variance explained by patient-reported risk factors (*p* = .067). No genetic variants were associated with delayed CIN.

Conclusions: The current study identified patient-reported and genetic factors that may place

patients at risk for acute CIN despite receipt of anti-emetic prophylaxis. Additional studies examining other genetic variants are needed.

PATTERNS OF EXPERIENTIAL AVOIDANCE AND MISCARRIED HELPING IN PARENTS OF CHILDREN WITH CANCER

Leah McDiarmid, B.A.[1], Casiana Warfield, B.S. [2], Kristina Brookshire, M.S.[3], Rachel Kentor, M.S.[3], Michelle Byrd, Ph.D., L.P.[4], Megan N. Perez, M.S., M.B.A.[5], Lauren Ostarello, M.S.[3], Kristin Kullgren, Ph.D.[6], Flora Hoodin, Ph.D.[3], Gregory Yanik, M.D.[6]

[1]Eastern Michigan University, Waterford, MI; [2]Eastern Michigan University, Belleville, MI; [3]Eastern Michigan University, Ypsilanti, MI; [4]Department of Psychology, Eastern Michigan University, Ypsilanti, MI; [5]Oklahoma State University, Guthrie, OK; [6]University of Michigan Health System, Ann Arbor, MI

Family expressiveness and conflict are known to affect child psychosocial adjustment to cancer. Two potentially pertinent interactional constructs yet to be examined in pediatric cancer populations are Experiential Avoidance in Parenting (EAP) and Miscarried Helping (MH). Higher EAP, parental inability to tolerate negative child affect, predicts poorer psychosocial outcomes in general clinical and pediatric samples. Higher MH, the more well-intentioned parental efforts to assist their ill children are met with child resistance, reflects more family conflict. This study of parent-child communication aimed to explore whether groups of caregivers differ meaningfully in patterns of EAP and MH.

Caregivers (*n*=161, *M* age=41, 86% female) of children with cancer (*M* age=9, 58% male) completed an electronic survey of self-reported medical background, the Parental Acceptance and Action Questionnaire (PAAQ; Cheron et al., 2009) and the Helping for Health Inventory (HHI; Harris et al., 2008), assessing EAP and MH, respectively. A two-step cluster analysis was conducted to create clusters based on PAAQ and HHI z-scores. Group differences were examined in follow-up one-way ANOVAs.

The average silhouette measure of cohesion and separation was 0.5, demonstrating that four clusters were a good fit. Parents in cluster 1 (*n*=28) were high in both MH (*M*=1.16, *SD*=.68) and EAP (*M*=1.28, *SD*=.65). Parents in cluster 2 (*n*=45) demonstrated higher MH (*M*=.47, *SD*=.54) than EAP (*M*=-.43, *SD*=.52). Parents in cluster 3 (*n*=56) exhibited higher EAP (*M*=.42, *SD*=.42) than MH (*M*=-.55, *SD*=.62). Parents in cluster 4 (*n*=31) were low in both MH (*M*=-.89, *SD*=.44) and EAP (*M*=-1.33, *SD*=.47). One-way ANOVA($F_{(3,\ 156)}$=6.60, *p*=.000) and post-hoc analyses indicated parents in cluster 1 perceived the probability of cure for their child as less likely than parents in cluster 2 (*p*=.002) and 4 (*p*=.018). Parents in cluster 3, too, perceived their child as less likely to be cured than parents in cluster 2 (*p*=.008).

This exploratory cluster analysis yielded 4 groups of caregivers. The group perceiving the worst medical outcome for their child had least tolerance for child negative affect and most parent-child conflict. The group perceiving the best probability for good outcome was moderately low in intolerance of child negative affect and moderately high in parent-child conflict. Future research into EAP and MH and their configuration may suggest productive new directions for interventions in clinical care.

POSITIVE AFFECT AND SLEEP QUALITY MEDIATE THE RELATIONSHIP BETWEEN STRESS AND DEPRESSION AMONG LUNG CANCER PATIENTS

Alyssa K. Choi, B.A. (in progress)[1], Timothy J. Williamson, M.A., MPH[1], Julie C. Kim, B.A.[1], Annette L. Stanton, Ph.D.[2]

[1]University of California, Los Angeles, Los Angeles, CA; [2]UCLA, Los Angeles, CA

Background: Stress and depression evidence a robust association, and poor sleep and low positive affect (PA) have been hypothesized as mechanisms through which stress predicts depression. Although some researchers posit that poor sleep more strongly predicts low PA than the reverse, no studies have examined these variables as sequential mediators explaining the association between stress and depression. Lung cancer patients report high levels of stress, sleep disturbance, and depressive symptoms, and it is important to identify putative mechanisms, which can be harnessed for preventive efforts to reduce depression in this population. The present study tested two models of serial mediation to illuminate the role of poor sleep and low PA in explaining the relationship between stress and depression. **Method:** Participants (n=33) undergoing treatment for lung cancer completed a daily diary at home for seven days. Participants reported perceived stress and PA (i.e., happy, calm) at the end of each day, sleep quality each morning, and depressive symptoms at the end of the week. Serial mediation was conducted to compare two models: 1) Model 1 tested whether high stress predicts poor sleep quality, which in turn predicts low PA, which then predicts more depressive symptoms; 2) Model 2 assessed whether the results differed if low PA preceded poor sleep quality rather than vice-versa. **Results:** Low PA significantly mediated the association between stress and depressive symptoms (b = 5.68, SE = 1.79, 95% CI [2.42, 9.55]), but sleep quality did not (b = -.79, SE = 1.02, 95% CI [-3.55, .83]). Furthermore, low PA explained significant variance in the relationship between stress and sleep quality (b = -14.74, SE = 5.99, 95% CI [-29.07, -5.66]). Results from serial mediation analyses demonstrated that Model 1 (b = 2.14, SE = 1.16, 95% CI [.32, 4.97]), but not Model 2 (b = -.77, SE = 1.06, 95% CI [-3.50, .85]), significantly explained the relationship between stress and depressive symptoms. Unexpectedly, poor sleep quality was unrelated to depressive symptoms. **Conclusion:** Low PA mediated the relationship between stress and depressive symptoms and between stress and sleep quality. Future research should target PA to mitigate the effects of stress on depressive symptoms in adults diagnosed with lung cancer.

POSTOPERATIVE QUALITY OF LIFE IN PATIENTS AFTER BOTH TOTAL GASTRECTOMY AND ESOPHAGECTOMY

Shin Saito, MD[1], Yoshinori Hosoya, MD[2], Misuzu Nakamura, Ph.D[3], Takashi Ui, MD[4], Kentaro Kurashina, MD[5], Shiro Matsumoto, MD[2], Rihito Kanamru, MD[6], Joji Kitayama, MD[7], Alan Lefor, Ph.D.[8], Naohiro Sata, MD[2]

[1]Departmet of surgery, Jichi medical university, Shimotsuke, Tochigi, Japan; [2]Department of surgery, Jichi medical university, shimotsuke, Tochigi, Japan; [3]Department of nursing, Jichi medical university, simotsuke, Tochigi, Japan; [4]Department of surgery, Jichi medical university, Shimotsuke, Tochigi, Japan; [5]Department of surgery, Jichi medical university, simotsuke, Tochigi, Japan; [6]Department of surgery, jichi medical university, shimotsuke, Tochigi, Japan; [7]Department of surgery, JIchi medical university, shimotsuke, Tochigi, Japan; [8]Department of surgery, Jichi Medical University, Shimotsuke, Tochigi, Japan

Background: Patients with esophageal cancer and a history of previous gastrectomy or synchronous gastric cancer have neither an esophagus nor stomach after surgery. Few studies have evaluated quality of life (QOL) in these patients objectively. Health-related QOL includes physical, social, and psychological aspects, and can be assessed quantitatively. The Dysfunction After Upper Gastrointestinal Surgery (DAUGS) score was used to evaluate postoperative QOL in patients undergoing both esophagectomy and gastrectomy.

Methods: From January 1999 to December 2015, 41 patients underwent esophagectomy with previous or concurrent total gastrectomy at our institution. The proximal jejunal flap was brought up in a Roux-en-Y fashion subcutaneously together with a vascular pedicle and the divided vessels anastomosed to the internal thoracic vessels. Of these, 25 patients were surveyed because they were without recurrence and did not receive chemotherapy within three months of the survey. Patients were sent a DAUGS questionnaire, rating 20 items in seven categories related to postoperative dysfunction on a scale of 0 to 5, with higher scores indicating more dysfunction.

Results: A total of 19 patients (76%) completed and returned the questionnaire. Of these, 11 patients had a previous gastrectomy (mean 20.8 years before), and 8 patients underwent simultaneous esophagectomy and gastrectomy. The mean (±standard deviation) DAUGS20 score in these 19 patients is 25.1±14.0. Weight loss after surgery was 10.6±6.5 (%).

Conclusion: Previous reports describe a mean DAUGS20 score after gastrectomy alone of 27.8 and after esophagectomy alone of 36.1. Patients in this study had lower DAUGS scores (less dysfunction), despite resection of both esophagus and stomach, for which there are several possible explanations. The reconstruction used may reduce reflux symptoms. The majority (11/19) of these patients had undergone gastrectomy and were already impaired when they underwent esophagectomy. In addition, some patients may be satisfied with their postoperative QOL and dysfunction, simply by surviving their disease.

PREDICTORS OF HPV VACCINE INITIATION AMONG LOW INCOME, ETHNIC MINORITY ADOLESCENTS IN CALIFORNIA

Beth Glenn, PhD[1], Roshan Bastani, PhD[1], Rita Singhal, MD, MPH[2], Catherine M. Crespi, PhD[1], Jennifer Tsui, PhD, MPH[3], Alison Herrmann, PhD, MS[1], Narissa Nonzee, MA[1], Li-Jui Cindy. Chang, MS[1], Victoria Taylor, MD, MPH[4]

[1]University of California Los Angeles, Los Angeles, CA; [2]LA County Department of Public Health, El Monte, CA; [3]Rutgers Cancer Institute of New Jersey, New Brunswick,, CA; [4]University of Washington, Seattle, WA

Prophylactic HPV vaccines have been widely heralded as a breakthrough in cancer prevention. However, uptake of the vaccine in the US remains disappointingly low. As part of a randomized trial to improve HPV vaccination rates among low income, ethnic minority adolescents in Los Angeles County, we conducted telephone interviews with caregivers of never-vaccinated adolescents (10-17 years) at baseline and 9-months post intervention (n = 211). The intervention, targeted to caregivers of adolescents and delivered through a telephone hotline operated by the county health department, demonstrated no significant effect on HPV vaccine initiation. Therefore, we examined baseline characteristics of caregivers (demographics, health care access, HPV-related knowledge/attitudes) and adolescents (demographics, health care access) that might predict vaccine initiation over the study period. The following caregiver factors predicted a greater likelihood of vaccine initiation at follow-up in bivariate analyses: Latino ethnicity, less than college education, Medicaid managed care insurance, having a usual source of care, higher perceived HPV risk, stronger beliefs about vaccine effectiveness, lower cost concerns, feeling sufficiently informed to make a decision about vaccination, higher self-efficacy to have child vaccinated, previous provider recommendation for HPV vaccination, and intention to have child vaccinated within 6 months ($p < .05$). No child-level factors were associated with HPV vaccination. These results suggest subgroups of caregivers that might be targeted for intervention (e.g., non-Latino caregivers). In multivariate analyses including study condition, demographics, and significant bivariate factors, only intention to have child vaccinated in the next 6 months (OR = 4.8, $p < .01$) and having received a previous provider recommendation for vaccination (OR = 4.5, $p < .01$) were significant. Results underscore the critical influence of behavioral intentions and provider recommendation on receipt of preventive health services. Only 18% of caregivers in our sample had received a provider recommendation for HPV vaccination for their child despite the fact that 90% reported their child had a usual source of care. These findings suggest that interventions targeting health care providers to reduce missed opportunities during health

care encounters may be an especially important strategy in efforts to improve HPV vaccine uptake.

PRELIMINARY FEASIBILITY OF A WEB-BASED COGNITIVE BEHAVIORAL THERAPY FOR INSOMNIA INTERVENTION DURING CANCER TREATMENT

Amma Agyemang, PhD, MPH

Virginia Commonwealth University Medical Center, Richmond, VA

BACKGROUND: Insomnia is common in cancer, especially around the time of cancer diagnosis and at the onset of cancer treatment. Yet it is often unrecognized and untreated. Cognitive Behavioral Therapy for Insomnia (CBT-I) is gold standard for treating insomnia in cancer. Previous studies have largely used homogenous samples of White, well-educated women with breast cancer who are years post-treatment. CBT-I dissemination in oncology is further limited by a lack of available providers and resources needed to implement standard face-to-face treatment. A solution is to abbreviate standard CBT-I into low-intensity modalities that can be self-administered online. The current pilot study examined the feasibility, acceptability, and efficacy of implementing a 6-module online self-administered CBT-I intervention, Sleeping Healthy Using the Internet (SHUTi), with optional clinician support, during cancer treatment.
METHODS: Twenty-eight individuals who were on average 2 months post-cancer diagnosis (36% breast, 25% gastrointestinal, 21% head and neck) and met DSM-IV criteria for insomnia were randomized to treatment at usual (TAU) (n=14) or SHUTi (n=14). Participants were undergoing chemotherapy and/or radiation with curative intent, at an NCI-designated cancer center that is also a safety net hospital (mean age = 47; 79% female; 64% White, 32% Black; 54% reported income < $30,000; 18% were uninsured/indigent, 18% on Medicaid; 25% had only completed high school or less). Pre- and post-sleep diaries, and self-reported global sleep disturbances, psychological distress, and health-related quality of life were collected.
RESULTS: Over an 8-month period, 83% of individuals approached about the study were screened and 100% of individuals meeting study eligibility consented to participate. The overall retention rate was 84% with similar attrition for both the TAU (20%) and SHUTi (13%) groups. On average, participants completed the study in four months, due to delays before (13%) and during (37%) cancer therapies. In the SHUTi group, 91% of participants who completed all six modules accessed clinician support; Black participants and those who were unemployed or on disability more readily accepted clinician support. SHUTi participants rated the program moderately acceptable (M=3.6; 1-5 scale), easy to use (M=4.1) and easy to understand (M=4.8). Compared to TAU, SHUTi participants reported greater decrease in global insomnia severity ($p < 0.05$; d=0.60), subjective time awake after sleep onset ($p < 0.05$; d=0.49), and depressive symptoms ($p < 0.05$; d=0.43) post-intervention.
CONCLUSIONS: There is preliminary support for the feasibility and efficacy of addressing

insomnia during cancer treatment with a web-based CBT-I program. Some form of clinician support may be critical for patients, especially those from underserved groups, as they navigate unexpected delays during cancer treatment.

PREVALENCE AND CORRELATES OF SKIN CANCER SCREENING AMONG INDOOR TANNERS AND NON-TANNERS

Carolyn Heckman, PhD[1], Elizabeth Handorf, PhD[2], Melissa Auerbach, PhD in Social and Health Psychology[3]

[1]Fox Chase Cancer Center, Philadelphia, PA; [2]Fox Chase Cancer Center, philadelphia, PA; [3]Fox Chase Cancer Center/Temple University Health System, Williamstown, NJ

Introduction:

Millions of Americans who have indoor tanned are at much higher risk of melanoma than the general population. The FDA recommends indoor tanners be screened regularly for skin cancer. Very little research has examined the association between indoor tanning and skin cancer screening.

Methods:

This study used data from the 2015 National Health Interview Survey (NHIS). NHIS methodology is described in detail elsewhere (https://www.cdc.gov/nchs/nhis/). Potential correlates of skin cancer screening included demographic factors, skin cancer risk factors, and health care access variables. Multiple logistic regressions were conducted separately for indoor tanners and non-tanners, with potential correlates included as independent variables and skin cancer screening as the outcome. Analyses used survey weights to provide results representative of the US population.

Results:

The sample included 30,352 participants, excluding individuals with prior skin cancer. 16% reported ever having indoor tanned, and 22% of these had indoor tanned in the last year. 30% of ever indoor tanners, 20% of never indoor tanners, and 21% of the overall sample had ever been screened for skin cancer. Based on the multivariate logistic regressions, significant correlates of skin cancer screening for both ever indoor tanners and non-indoor tanners were older age, non-Hispanic ethnicity, higher income, looking up health information on the internet in the last year, sunscreen use, and receipt of a spray-on tan at a salon in the last year. In non-indoor tanners only, white race, health insurance, not worrying about paying bills, and sun-burning easily were also significantly related to skin cancer screening.

Discussion:

The likelihood of having been screened for skin cancer was higher among indoor tanners than non-indoor tanners. Screeners in both groups were older and more likely to engage in sun protection using sunscreen than non skin cancer screeners. Some never indoor tanners who are at risk for skin cancer have insurance/financial barriers to skin cancer screening. Findings suggest that: 1) high-risk individuals who do not use sunscreen need to be targeted for skin cancer screening, and 2) insurance, financial, and information barriers to screening may also need to be addressed.

PREVALENCE AND PREDICTORS OF HEALTH ANXIETY IN LYNCH SYNDROME PATIENTS

Tae Hart, PhD[1], Jenna Albiani, PhD[1], Lindsey Torbit, MA[1], Crystal Hare, BA, BSc[1], Melyssa Aronson, MSc[2], Kara Semotiuk, MSc[2], Spring Holter, MSc[2]

[1]Ryerson University, Toronto, ON, Canada; [2]Sinai Health Care System, Zane Cohen Centre for Digestive Diseases, Toronto, ON, Canada

Background: Health anxiety (HA) is characterized by fear or worry about ill health, ranging from a sense of indifference to intense health-related concerns (Salkovskis & Warwick, 1986). In particular, elevated HA has been frequently reported in individuals diagnosed with cancer (e.g., Grassi et al., 2004). However, little data exist on those at high-risk for *developing* cancer, such as Lynch syndrome, which is a genetic predisposition to adult onset cancers. Individuals with Lynch syndrome have a 60-80 percent chance of developing colorectal cancer in their lifetime (Aarnio et al., 1999). This study examined the severity of and predictors associated with health anxiety in Lynch syndrome patients.

Methods: Participants (N=209) were recruited from a genetic cancer registry and completed self-report measures assessing health anxiety (Short Health Anxiety Inventory; Salkovskis et al., 2002), depression and anxiety (Hospital Anxiety and Depression Scale; Zigmond & Snaith, 1983), cancer worry interference (Trask et al., 2001) and coping (Coping with Health Problems Inventory; Endler et al., 1998). Hierarchical multiple regression analyses were conducted to examine predictors of elevated HA.

Results: Results indicated that 30% of participants reported clinically significant levels of health anxiety. After controlling for gender, time since LS diagnosis, prior cancer diagnosis, and number of first-degree relatives with cancer, regression analyses indicated younger age, $\beta=-.12$, $p=.046$, increased use of the coping strategy of emotional preoccupation, $\beta=.28$, $p=.001$, more anxiety, $\beta=.25$, $p=.001$, more depression, $\beta=.18$, $p=.02$, and more worry interference, $\beta=.20$, $p=.002$, were all significantly associated with greater HA, $F(8, 180)=20.28$, $p=.001$.

Discussion: Findings suggest that health anxiety is of clinical significance for individuals with Lynch syndrome. Moreover, our results suggest that risk factors for high HA include younger patients who are struggling with general anxiety, depression, and cope with their problems using worry and rumination strategies. People with hereditary cancer conditions often feel like health care providers do not understand the negative impact of living with their condition

(e.g., Sheppard et al., 2013). Disseminating these findings to physicians and genetic counselors working with Lynch patients is critical, which will help to identify and health anxiety among this population. We will discuss avenues to disseminate information to both providers and patients, as well as future directions aimed at reducing the distress among Lynch syndrome carriers.

PREVENTIVE HEALTH BEHAVIOR PERCEPTIONS AMONG PARENTS OF YOUNG CHILDHOOD CANCER SURVIVORS

Justin Wilford, PhD

University of California, Irvine, Santa Ana, CA

Background: Childhood cancer survivors (CCS) face a lifetime of significantly elevated risks for a variety of chronic and life-threatening illnesses. A consensus has emerged on the need for preventive health behavior education to reduce long-term health risks among CCS, and yet little is known about preventive health behavior promotion upon completion of treatment and in follow-up care, especially regarding parents of young and adolescent CCS.

Methods: A cross-sectional survey of 114 parents of young and adolescent (< 13 years) childhood cancer survivors was used to assess perceptions of preventive survivorship health behavior promotion. Recruitment was conducted through the online social network communities of two childhood cancer non-profits that focus on parent wellbeing. The novel online survey given to parents included 15 questions about receiving survivorship-related preventive health behavior promotion from medical professionals, the extent to which parents perceive specific health behaviors to be important for survivorship preventive health, and the degree to which parents want help with these specific health behaviors.

Results: The percentage of parents reporting receiving any specific preventive health behavior advice from medical professionals (doctors, nurses, or other) ranged from 54% (promotion of “healthy diet”) to 20% (promotion of “healthy sleep habits”). Nevertheless, parents strongly endorsed specific health behaviors as being “very important” for survivorship health, ranging from 75% of parents for “healthy diet” to 63% for “healthy sleep habits.” However, fewer parents wanted “quite a bit” or “a lot” of help with changing specific preventive health behaviors, ranging from 44% for “healthy diet” to 33% for “physical activity.” Parents who reported receiving survivorship-related “healthy diet” promotion from a medical professional were more likely to report that each specific health behavior is important for survivorship health (for “healthy diet”, $p=.002$; for “physical activity”, $p=.009$; for “healthy sleep”, $p=.059$; for “stress management, $p=.035$; for “social support”, $p < .000$). Parents who reported receiving survivorship-related health behavior promotion were no more likely to want help changing any of the specific health behaviors.

Conclusions: Despite inordinate and lifelong chronic disease risks among childhood cancer survivors, parents do not report receiving uniform preventive health behavior promotion from medical professionals. When parents receive such promotion, they may be more likely to

believe specific preventive health behaviors to be important for their child’s long-term health.

PROMOTING CANCER LIFE MANAGEMENT VIA INTEGRATIVE HEALTHCARE: EFFECTIVENESS IN IMPROVING EMOTIONAL HEALTH AND IMMUNE FUNCTION

Rebecca L. Shorter, M.A.[1], Kerry M. Cannity, M.A.[1], Heather C. Zapor, M.A.[1], Jerika C. Norona, M.A.[1], Patricia N.E. Roberson, Ph.D.[1], John L. Bell, MD[2], Gregory L. Stuart, Ph.D.[1]

[1]University of Tennessee-Knoxville, Knoxville, TN; [2]University of Tennessee Medical Center, Knoxville, TN

Up to 50% of cancer patients experience significant depression, anxiety, and stress (Hopko et al., 2016). Depressed and anxious cancer patients experience decreased quality of life and immune system functioning, more rapid progression of cancer, more pain, and possibly increased mortality relative to non-depressed patients (Reddick et al., 2005; Spiegel & Giese-Davis, 2003). Among novel treatments developed to ameliorate the psychosocial impact of cancer is integrative healthcare (IH), which combines conventional Western medicine with adjunctive, complementary treatments (Deng & Cassileth, 2005). There is some evidence to indicate short-term benefits of IH usage for cancer patients (Helyer et al., 2006); however, the long-term efficacy of IH has not been systematically studied. The current study examines the effectiveness of IH for cancer patients, relative to treatment as usual (TAU), in reducing emotional and physical symptoms and improving immune functioning. Patients were recruited from the University of Tennessee Medical Center's Cancer Institute (n = 106) and were eligible to participate irrespective of cancer diagnosis and stage. Patients opted to continue TAU or engage in an IH program (services include: psychotherapy, massage therapy, reiki, acupuncture, yoga, and mind-body skills training). A subset of the sample (29%; n = 31) was randomized to a blood draw condition. Outcome variables included Patient Health Questionnaires (PHQ-9, GAD-7, and PHQ-15) and plasma cytokine levels (C-Reactive Protein [CRP] and Interleukin-6 [IL-6]). Patients were assessed at three intervals (baseline, 3-month and 12-month follow-up). 15% of the sample utilized IH services between baseline and 12-month follow-up, attending IH services an average of 4.31 times (SD = 6.81, range: 1 – 29). Latent growth curve models (LGCM) revealed patients utilizing IH services (0 = no usage; 1 = 1+ times) generally presented with higher anxiety and depression ($p < .05$). Reductions in depression occurred more rapidly with IH usage ($r = -.05$, $p < .05$), while change in anxiety was only marginally associated with IH usage ($r = -.05$, $p = .07$). IH usage was not significantly correlated with change in physical/somatic symptoms. Preliminary analyses did not offer support for change in plasma cytokines over time. Overall, findings offer preliminary support for long-term benefits of IH in reducing depression and anxiety in cancer patients. Study limitations and implications will be discussed.

PSYCHOLOGICAL DISTRESS AFTER PELVIC EXENTERATION FOR RECURRENT GYNECOLOGIC CANCER

Kristine A. Donovan, PhD, MBA[1], Ashley M. Nelson, MA[2], Alyssa L. Fenech, BA[1], Alexandra Albizu-Rivera, MPH[1], Hye Sook Chon, MD[1], Robert M. Wenham, MD[1]

[1]Moffitt Cancer Center, Tampa, FL; [2]University of South Florida & Moffitt Cancer Center, Tampa, FL

Background Pelvic exenteration (PE) has been performed historically in women with gynecologic cancer for palliation of recurrent disease. With advances in chemotherapy agents and operative methods, PE in the well-selected patient now produces 5-year survival rates as high as 60%. Thus, a greater proportion of women are living longer with a wide range of physical and psychological issues. Despite the recent increase in rate of PE performed for curative intent, there is a paucity of data on the long-term effects of PE. In the current study, we sought to characterize women's long-term psychological health after PE for recurrent gynecologic cancer and examine its associations with overall quality of life (QOL).

Methods As part of a larger mixed-methods study of the effects of PE on QOL, 21 women who underwent PE between 6 months and 10 years previously completed the Impact of Event Scale-Revised (IES-R), Center for Epidemiologic Studies-Depression Scale (CES-D), and EORTC-Quality of Life questionnaire.

Results Participants ranged in age from 43 to 75 years (mean=58) and were a mean of 4 years (range=0.7-8.8) post-PE. Mean IES-R total score was 21.2+19 and ranged from 0 to 69. Nearly one-third exceeded the cut-off for clinically significant distress. Mean subscale scores were 5.8+6 for hyperarousal, 6.7+6 for avoidance and 8.3+8 for intrusion. On the CES-D, 71% exceeded the cut-off for clinically significant depressive symptoms (CES-D total= 19.8+9; range=3-39). Participants reported above average physical functioning on the EORTC-QLQ (69+23; range=27-100). Self-reported global QOL was below average (42.5+22; range=0 to 66.7). In regression analysis, psychological health accounted for 49% of the variability in QOL.

Conclusions Findings suggest women's psychological health after PE is relatively poor and accounts for considerable variability in overall QOL. Findings suggest targets for clinical interventions to improve psychological well-being and enhance QOL in long-term survivors. This study highlights the need for clinicians to attend not just to women's physical symptoms following this life-altering surgery but to monitor and attend to women's psychological health

as well.

PSYCHOMETRIC PROPERTIES OF A 47-ITEM DISTRESS SCREENING TOOL FOR CAREGIVERS OF CANCER PATIENTS IN A COMMUNITY-BASED SAMPLE

M Longacre, PhD[1], M F. Miller, PhD, MPH[2], M Golant, PhD[2], V Kennedy, LCSW[2], A Zaleta, PhD[2], J Buzaglo, PhD[2]

[1]Arcadia University (affiliation was CSC at time of work), Washington, DC; [2]Cancer Support Community, Washington, DC

Background. The landscape of cancer care is changing with patients living longer and healthcare trending towards outpatient treatment. Consequently, family caregivers face their own distress. While validated distress screening for patients is essential to quality care, there’s an absence of validated measures to identify and address unmet psychosocial needs of caregivers. We developed and tested the psychometric properties of CancerSupportSource-Caregiver (CSS-CG), a 47-item web-based distress screening and referral instrument, including a 4-item depression subscale. **Methods.** Family caregivers rated their concerns about self-care (27 items), caregiving tasks (11 items), and patient care (9 items). Concurrent validity was determined by correlations with the Distress Thermometer (DT), the Center for Epidemiologic Studies Depression Scale (CES-D), the SF-12 mental and physical component scores (MCS, PCS), the Zarit Burden Interview (ZBI), and the Caregiver Reaction Assessment Scale (CRA). ROC curve analysis was used to determine sensitivity and specificity for a 4-item depression subscale compared to the CES-D. Test-retest reliability was assessed in a subsample (n=115) using the intra-class correlation coefficient (ICC). **Results.** Participants included 246 caregivers (median age 54 y) from 10 affiliates of a community-based organization. The 47-item tool and depression subscale demonstrated high internal consistency (Cronbach's alpha=0.96 and 0.79, respectively). The total distress score created using summed item scores correlated substantially (pConclusion. The CSS-CG shows strong psychometric properties and can be considered a valuable community-based instrument to screen for distress. Next steps include reducing the number of screening items to facilitate implementation and dissemination.

PUTTING EMOTIONS IN CONTEXT: FEASIBILITY, ACCEPTABILITY, AND VALIDITY OF AN EMOTION REGULATION ASSESSMENT FOR CANCER PATIENTS

Claire C. Conley, MA, Barbara L. Andersen, PhD

The Ohio State University, Columbus, OH

Objective: Authors have called for the study of emotion regulation (ER) in health psychology and psycho-oncology. However, self-report measures of ER may not be appropriate for cancer patients. ER assessment methodologies that incorporate specific contextual demands may perform better in this population. Thus, the purpose of the present study was to assess the feasibility and acceptability of a frequently-used assessment paradigm from the affective science literature in a sample of cancer patients.

Methods: Cancer patients (N=13) completed an ER task frequently used among samples of healthy young adults. Participants recalled 4 specific situations in which they had experienced emotions: (1) non-cancer, moderate intensity emotions; (2) non-cancer, high intensity emotions; (3) cancer-specific, moderate intensity emotions; and (4) cancer-specific, high intensity emotions. Participants then rated their use of 11 ER strategies (i.e., reappraisal, problem-solving, suppression, acceptance, etc.) in each of these situations. Following completion of the task, participants were asked for feedback on its acceptability (e.g., ability to comprehend instructions, ease of completion, etc.).

Results: For 52 prompts, 51 examples were generated (98% completion rate), indicating that the task is feasible and easy to complete. All patients reported that the task was pleasant. Minimal changes (e.g., providing instructions prior to session to facilitate situation recall) were suggested. Use of suppression differed between cancer and non-cancer situations (t=1.7, df=49, p < .05), such that participants suppressed emotions less frequently in cancer-related situations. Use of acceptance differed between moderately and highly intense situations (t=-2.3, df=49, $p < .05$), such that participants accepted emotions more frequently in highly intense situations.

Conclusions: Use of a context-specific ER task among cancer patients is feasible. Patients found the task acceptable and, consistent with validity hypotheses, demonstrated differences in ER strategy use depending on situation type and intensity. Future research should establish the reliability of this task.

QUALITY OF LIFE OF POSTMENOPAUSAL WOMEN WITH BREAST CANCER TREATED WITH ADJUVANT ENDOCRINE THERAPY

Keith M. Bellizzi, Ph.D., MPH[1], Pamela Taxel, M.D.[2], Kate E. Dibble, M.A.[1], Elizabeth J. Siembida, Ph.D.[3], Linda S. Pescatello, Ph.D., FACSM[1], Elizabeth D. Schifano, Ph.D.[1], Samantha Guarneri, B.A.[4], Susan H. Tannenbaum, M.D.[2]

[1]University of Connecticut, Storrs, CT; [2]UConn Health, Farmington, CT; [3]University of Connecticut, Bethesda, MD; [4]University of Connecticut, Stamford, CT

Background: Breast cancer is the most common cancer in women with an estimated 246,660 new cases to be diagnosed in 2016, joining the over 3 million women living with the disease (ACS, 2016). To reduce cancer recurrence, postmenopausal women (highest incidence and prevalence of breast cancer) who test positive for hormone receptors in the tumors, are candidates for adjuvant endocrine therapy (i.e., aromatase inhibitors (AI)). Despite the benefits of AIs in the treatment for breast cancer, many women are at risk for complications, including osteoporosis and fractures all of which can adversely affect health-related quality of life (HRQOL). **Methods:** Postmenopausal women with breast cancer (n=174), ages 50 – 95 (*M*= 68.5), diagnosed with stage 1-3 disease, forty one percent on AIs, were recruited from an academic medical center in the Northeast. Demographic and quality of life data (Functional Assessment of Cancer Therapy-Breast (FACT-B) was collected via patient self-report and clinical data (AI use, bone health, comorbid conditions) was abstracted from patient medical records. **Results**: Preliminary analyses suggest women with a history of adjuvant AI therapy (compared to those without history of adjuvant therapy use) report better physical and emotional well-being. **Discussion**: Despite the well-known clinical benefits of AI therapy for disease recurrence, it is possible that particular QOL outcomes (i.e., physical, emotional) may also be positively affected. However, a diagnosis of osteopenia or osteoporosis and bone fractures, potential side effects of AI use, may put patients at higher risk for worse functional well-being. The benefits and risks (potential side effects that may affect QOL) of AI use should be discussed with patients.

RELATIONSHIP OF WORRY ABOUT CANCER TO PERCEIVED RISK AND POSITIVE AND NEGATIVE EFFECTS OF CANCER

Salene Jones, PhD[1], Rebecca Ziebell, BS[2], Rod Walker, MS[2], Larissa Nekhlyudov, MD, MPH[3], Borsika Rabin, Phd, PharmD, MPH[4], Stephanie Nutt, MA, MPA[5], Monica Fujii, MPH[2], Jessica Chubak, PhD[2]

[1]Group Health Research Institute, Steilacoom, WA; [2]Group Health Research Institute, Seattle, WA; [3]Harvard Medical School, Department Population Medicine, Boston, MA; [4]Kaiser Permanente Colorado, Denver, CO; [5]University of Texas Austin, Dell Medical School, Austin, TX

Background: Worry is associated with negative effects of cancer, such as worse physical functioning and higher perceived risk of disease progression, but associations with positive changes post-cancer, such as benefit-finding, have been studied less. We examined the relationship of worry about cancer to negative and positive effects of cancer and perceived risk of progression to inform whether worry may lead to negative effects after cancer.

Methods: We invited 1,376 long-term survivors (5–10 years post-diagnosis) to complete the survey and 615 (46%) were eligible and completed the survey. Of the 615, 594 survivors of cancer (breast, prostate, colorectal, lung, melanoma) completed the relevant questions. Respondents answered questions regarding worry about cancer recurrence/progression, negative effects of cancer on mental and physical function, perceived risk of recurrence/progression and benefit-finding (being a stronger person, coping better, making positive changes). Multivariable regressions estimated associations of worry with negative effects of cancer, perceived risk and benefit-finding.

Results: Worry was related to greater odds of negative effects of cancer (odds ratio (OR) range: 1.40 to 1.46, all all p’s < .01) and to higher perceptions of recurrence/progression risk (b=0.69, p < .01). Worry about cancer was unrelated to benefit-finding (all *p’s* >.10).

Conclusions: Worry about cancer is related primarily to negative, but not necessarily positive, effects of cancer and is related to greater perceptions of disease progression. More research on effective treatments for worry about cancer is needed.

SEDENTARY LIFESTYLE AND GREATER SYMPTOM BURDEN IN PATIENTS DIAGNOSED WITH ADVANCED CANCERS

Jennifer Steel, PhD[1], David Geller, M.D.[1], Michael Antoni, Ph.D.[2], Lauren Terhorst, PhD[3], Frank Penedo, PhD[4], Lora Burke, PhD, MPH[5], Allan Tsung, MD[1]

[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]University of Miami, Coral Gables, FL; [3]University of Pittsburgh, pittsburgh, PA; [4]Northwestern University, Chicago, IL; [5]University of Pittsburgh, Pittsburgh, PA

Background: Physical activity has been shown to improve symptoms such as depression, fatigue, insomnia, and pain. The aims of this study were to examine the link between physical activity and symptom burden in patients diagnosed with cancers affecting the hepatobiliary and pancreatic system.

Methods: Participants were administered a battery of questionnaires that included the Center for Epidemiological Studies-Depression (CESD) Scale, Brief Pain Inventory, Pittsburgh Sleep Quality Index, Functional Assessment of Cancer Therapy (FACT)-Fatigue, FACT-Hepatobiliary, and the International Physical Activity Questionnaire (IPAQ). The IPAQ can be categorized into sedentary, moderate and vigorous physical activity. Analyses included descriptive statistics and Analysis of Variance was performed to test hypotheses.

Results: Of the 395 patients enrolled in the study, the mean age at cancer diagnosis was 62 (SD=11); the majority were male (61.7%) and Caucasian (91.1%). Patients who reported sedentary lifestyle reported the highest levels of depressive symptoms (M=16.61, SD=11.2) vs those with moderate (M=13.64, SD=8.4) or vigorous physical activity (M =11.83, 9.9); F(2,394)=6.267, p=0.002. Patients who were sedentary also reported significantly higher levels of fatigue (M= 23.60, SD=13.1) when compared to those who were moderately active (M=19.70, SD=11.3) or vigorously active (Mean=16.95, SD=12.0), F(2,370)=9.390, $p < 0.001$. Levels of physical activity were not associated with pain (p=0.770) or sleep quality (p=0.524). Sedentary patients reported poorer overall quality of life (M=70.9, SD=17.2) vs those who were moderately (M=75.01, 14.3) or vigorously physically active (M=80.0, SD=16.6), F(2, 386)=10.607.

Conclusions: Sedentary lifestyle after a diagnosis of cancer was associated with increased symptom burden that was both statistically and clinically meaningful. Dissemination and

implementation of effective interventions to increase physical activity in cancer patients are warranted to decrease symptoms burden and improve quality of life

SUICIDAL IDEATION AMONG VETERANS LIVING WITH CANCER

Candice C. Johnson, Psy.D., Kristin M. Phillips, Ph.D., Stephanie N. Miller, Ph.D.

James A. Haley Veterans Hospital, Tampa, FL

Background: Subgroups of Veterans (e.g., those with PTSD, depression, or pain) are at increased risk for suicide. Suicide rates are also higher among individuals living with cancer compared to the general population. A recent study of people with metastatic cancer found factors associated with suicidal ideation (SI) include race, PTSD, Panic Disorder, lack of spirituality, limited support, not feeling well physically, and seeking psychotherapy. However, little is known about SI among Veterans with cancer. *Objectives:* Identify factors associated with SI among Veterans with cancer. *Method:* Veterans with cancer (N = 101) who were referred for mental health evaluation completed a clinical interview and questionnaires, including Pain Numeric Rating Scale (PNS), Insomnia Severity Index (ISI), Patient Health Questionnaire (PHQ-2), Generalized Anxiety Disorder (GAD-7), and PTSD Checklist (PCL). SI was defined by endorsing "Thoughts that you would be better off dead or of hurting yourself in some way" on paper-and-pencil questionnaire or thoughts of killing oneself during clinical interview. *Results:* 29% reported SI. Compared to those without SI, Veterans with SI had higher ratings on PNS (t= 2.46, p= 0.016), PHQ-2 (t= 5.36, p< .001), GAD-7 (t= 4.41, p< .001), and PCL (t= 2.61, p= .011); they were also more likely to have a history of suicide attempt (χ^2 = 3.85, p= .050). There were no group differences on disease stage, ISI, race, social support, or religious prohibition against suicide (p-values >.05). To determine which factors account for the greatest proportion of variance in SI, a logistic regression was performed with history of attempts, PHQ-2, GAD-7, PCL, and PNS entered as predictors in separate blocks. The omnibus model was significant (p < .001). However, only PHQ-2 had a statistically significant contribution to the model (β = 0.56, p= .008). *Conclusion:* Although previous studies of SI among Veterans have emphasized the importance of pain and PTSD, this study is consistent with the literature showing the link between pain and suicide and PTSD and suicide disappear when depressive symptoms are considered. Results suggest that pain, PTSD, history of suicide attempts, and anxiety (including worry and fear) are important to consider when treatment planning for Veterans with cancer. However, anhedonia and hopelessness explain the greatest proportion of variance in thoughts of being better off dead or wanting to die and should be the focus of intervention.

ACTIGRAPHY-ASSESSED SLEEP EFFICIENCY IS ASSOCIATED WITH AMBULATORY BLOOD PRESSURE IN A COMMUNITY SAMPLE

Caroline Doyle, BA[1], Melissa Flores, MS[2], Matthew Allison, M.D., MPH[3], Timothy Smith, PhD[4], Joshua Smyth, Ph.D[5], Daniel J. Taylor, Ph.D.[6], Bert N. Uchino, PhD[7], John M. Ruiz, Ph.D.[8]

[1]University Of Arizona, Tucson, AZ; [2]The University of Arizona, Tucson, AZ; [3]University of California at San Diego, San Diego, CA; [4]University of Utah, Park City, UT; [5]The Pennsylvania State University, University Park, PA; [6]University of North Texas, Denton, TX; [7]University of Utah, Salt Lake City, UT; [8]University of Arizona, Tucson, AZ

High blood pressure is a leading risk factors for overall disease burden, including cardiovascular disease. Likewise, emerging evidence suggests that various dimensions of sleep health are associated with cardiovascular health. However, less is known about the relationship between measures of sleep quality and blood pressure with much of the current literature reliant on self-reported sleep ratings. The aim of this study was to examine the association of actigraphic sleep efficiency and both ambulatory day and night-time blood pressure.

Participants were a community sample of 300 healthy adults (150 men, 150 women) ages 21 to 70 years enrolled in the North Texas Heart Study. The sample was stratified by age within gender and race/ethnicity, and the mean age at enrollment was 42.44 years (SD=12.76).

Actigraphy using AW Spectrum Actiwatches and sleep diary data were collected over a 48-hour period. Actigraphic sleep efficiency was defined as the ratio between total sleep time and time in bed. Ambulatory blood pressure (ABP) was collected at random times during 45-minute intervals over the corresponding 48-hour period, including one night. Person/day averages were calculated within day (7:00am to 10:00pm) and night (12:00am to 5:00am).

Higher average sleep efficiency over the two nights was associated with lower average nighttime systolic and diastolic ABP on the second night, all b’s < -0.44, t(208) = -4.05, p < .001. A temporal trend was also observed where higher sleep efficiency on night one predicted lower average systolic and diastolic ABP during the subsequent day, all b’s< -.17, t(245) = -2.29 , p < 05. All models were adjusted for age, race/ethnicity, gender, and BMI.

Although this study only provides a snapshot of sleep and blood pressure over a very limited period, the findings suggest that objectively assessed sleep efficiency may be related to cardiovascular disease risk through its effects on daily blood pressure. Studies using objective measures of sleep health and blood pressure are needed to further explore the role of sleep in cardiovascular disease risk.

ANGER STYLE AS A PREDICTOR OF 10-YEAR HEART ATTACK RISK

Ashley Peak, B.A., Tatiana Richard-Kassar, B.A., Lyssette Rodriguez, B.A., Sarah Schall, B.A., Luci Martin, Ph.D.

University of La Verne, la verne, CA

The connection between anger and cardiovascular disease has been inconclusive; however, demographic and moderating factors may explain these inconsistencies. The current study investigated whether varying styles of anger expression predict heart attack risk in a sample of university students. Data was collected across two phases: Phase 1 included a self-report survey (n = 505; 71% female; mean age 21.39, SD = 4.78) and Phase 2 included a physiological assessment (n = 258). Fifty-eight percent of the sample self-identified as European American, 19% African American, 12% Latino(a), 8% Asian American, and 4% other ethnicity. The State Trait Anger Inventory-2 was used to assess anger styles. A 10-year heart attack risk score was determined using age, gender, total and HDL cholesterol, smoker status, and systolic blood pressure. Age was entered as 45 years for males and 55 years for females. Anger controlled out (t = 2.93, p = .004) predicted 10-year heart attack risk (R^2 = .05, $F(6, 251)$ = 2.31, p = .03). Ethnicity was associated with the type of anger expression employed by participants, Pillai's Trace = .93, $F(18, 1403)$ = 1.93, p = .01. European Americans reported the lowest levels of both state and trait anger in comparison to African Americans and Latinos, respectively. Though females reported greater overall expression of anger, males reported greater anger control in and out. Mindfulness skills and coping styles were examined as moderators of anger style to inform clinical recommendations aimed at prevention.

ANXIETY SENSITIVITY AND MEDICATION NONADHERENCE IN PATIENTS WITH SUSPECTED ACUTE CORONARY SYNDROME

Othanya Garcia, B.A.[1], Marin Kautz, B.A.[1], Zunelly Velazquez, B.A.[1], Jenny Lee, MPH[1], Ian Kronish, MD, MPH[2], Carmela Alcantara, Ph.D.

[1]Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; [2]Columbia University Medical Center, Center for Behavioral Cardiovascular Health, New York, NY

Background: Anxiety sensitivity - distress over the physical, social, or cognitive consequences related to the awareness of anxiety – has been associated with increased risk for cardiovascular disease. Poor adherence to cardioprotective medications may underlie this association. We examined whether anxiety sensitivity was independently associated with self-reported medication nonadherence after discharge for a suspected ACS.

Methods: Between 2013 and 2015, a consecutive cohort of patients was enrolled from the emergency department of a tertiary care hospital in New York City. One month after discharge, patients were contacted by telephone to have anxiety sensitivity and medication nonadherence assessed. Anxiety sensitivity was assessed using the Anxiety Sensitivity Index (ASI-3); a score > 23 was classified as high anxiety sensitivity. Medication adherence was assessed by asking “How much of the time do you take your heart medications?” Patients who reported missing their medications at least some of the time were categorized as nonadherent. Logistic regression was used to determine the association between anxiety sensitivity and adherence after adjusting for age, sex, race, education, comorbidity (Charlson score), prior history of established coronary artery disease, discharge diagnosis (ACS vs non-ACS), and depressive symptoms (8-item Patient Health Questionnaire score ≥10).

Results: Among 434 patients with data on anxiety sensitivity and adherence, the mean age was 62.2 (SD 12.7) years, 44.7% were women, 58.2% Hispanic, and 25.0% had elevated depressive symptoms (PHQ>9). 39.2% of patients had a confirmed ACS hospitalization and 36.2% had a prior history of CAD. A greater proportion of patients with high anxiety sensitivity were nonadherent than patients without high anxiety sensitivity (20.3% vs 11.8%; p=.02). In the adjusted model, anxiety sensitivity was associated with increased odds of medication nonadherence (AOR 2.1, 95%CI 1.2, 3.9; p=.02). Education was the only other variable associated with nonadherence in this model, patients with less than high school education were less likely to be nonadherent (p=0.03). The same pattern was observed when entering anxiety sensitivity as a continuous measure (adjusted ß=1.02; 95%CI 1.00, 1.04; p=.03).

Conclusion: High anxiety sensitivity was associated with nonadherence to cardiac medications among patients recently discharged for a suspected ACS. Our results suggest that educating patients on strategies to reduce their anxiety sensitivity may be useful for improving their medication adherence, and their elevated cardiovascular risk.

ARE PATIENTS WHO RULE OUT FOR ACUTE CORONARY SYNDROME AT RISK FOR POSTTRAUMATIC STRESS DISORDER?

Zunelly Velazquez, B.A.[1], Donald Edmondson, PhD, MPH[2], Nathalie Moise, M.D., M.S.[1], Bernard Chang, MD, PhD[2], Ying Wei, PhD[3], David Lopez Veneros, M.A.[1], William Whang, MD, MS[1], Ian Kronish, MD, MPH[4]

[1]Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; [2]Columbia University Medical Center, New York, NY; [3]Columbia University Mailman School of Public Health, New York, NY; [4]Columbia University Medical Center, Center for Behavioral Cardiovascular Health, New York, NY

Background: Many patients diagnosed with acute coronary syndromes (ACS; unstable angina and myocardial infarction) develop posttraumatic stress disorder (PTSD) due to the experience. Less is known about risk for PTSD in patients who are ruled out for ACS during their hospital admission.

Methods: A consecutive sample of 500 patients presenting to an urban hospital emergency department (ED) with symptoms of a probable ACS were enrolled into an observational cohort study of PTSD after ACS. The reason for ACS symptoms at hospital discharge was determined through chart review. PTSD was assessed by telephone 1 month after discharge using the PTSD Checklist (PCL-S). Logistic regression was used to determine the odds of PTSD (PCL-S≥32), adjusting for demographics, coronary artery disease history, comorbidities, pre-existing psychiatric and psychosocial variables, and perceived threat in the ED.

Results: Compared to patients with a confirmed ACS, patients who ruled out for ACS had no significant differences in the presence of typical ACS somatic symptoms (p>0.1) or in perceived threat from the ACS symptoms (p=0.87). There were also no differences in the proportion of patients with and without a confirmed ACS who developed elevated PTSD symptoms (16.8% versus 19.3%; p=0.53), and risk for PTSD was no different in the adjusted model (adjusted OR 0.90, 95%CI 0.45, 1.78; p=0.77).

Conclusion: ED presentation with ACS symptoms is sufficient to trigger PTSD whether or not the etiology was truly due to a life-threatening ACS event. Patients ruled out for ACS should be targeted for interventions to decrease risk of PTSD.

ASSOCIATIONS OF GENDER IDENTITY AND SEX WITH INFLAMMATION LEVELS IN HYPERTENSIVE PATIENTS

Nicola J. Paine, PhD[1], Kim L. Lavoie, PhD[2], Andre Arsenault, MD[3], Simon L. Bacon, PhD[4]

[1]Concordia University & Hôpital du Sacré-Cœur de Montreal, Montreal, PQ, Canada; [2]University du Quebec a Montreal, Montreal, PQ, Canada; [3]Montreal Behavioural Medicine Centre, Montreal, PQ, Canada; [4]Concordia University, Montreal, PQ, Canada

Background: Elevated inflammation, as evidenced by increased C-reactive protein (CRP), has been associated with a greater risk of developing hypertension. Sex (a biological construct) is also a risk factor for hypertension, with men generally being at greater risk than women. However, women have been found to have higher levels of CRP compared to men. The aetiology of this difference is not well understood. It is possible that certain aspects of gender identity (a sociological construct), may explain this. We investigated the specific role of gender identity and sex on CRP levels in hypertensive patients.

Methods: A total of 798 hypertensive patients (54.3% women, mean ± SD age (yrs) =67.9 ± 8.72) undergoing pharmacological stress testing with self-reported, physician diagnosed hypertension participated in the study. Patients completed a series of questionnaires, measuring socio-demographics, health behaviours and gender identity, using the Bem Sex Role Inventory, to determine masculine and feminine gender identity. Blood samples were taken to assess CRP levels.

Results: Adjusting for age, waist circumference, alcohol consumption, smoking status, education level and physical activity, separate general linear model analyses revealed a significant main effect of sex with men having lower CRP levels (F=24.51, $p < .001$) but no effect of masculine gender identity (F=0.19, p=.66). There was no effect of feminine gender identity (F=0.28, p=.60) on CRP levels despite a main effect of sex with lower CRP in men (F=24.98, $p < .001$). Inclusion of a sex by gender identity interaction term revealed a significant masculine gender identity by sex interaction (F=4.20, p=.041), but not a feminine gender identity by sex interaction (F=0.76, p = .38). Post-hoc analyses revealed that for women, higher masculinity may be related to lower inflammation levels, which was not found in men - indicating that lower levels of masculine gender identity were associated with higher levels of CRP in women but not men. There was no relationship between feminine gender identity and CRP

Conclusion: Results indicate that in women, higher levels of masculine gender identity might be related to lower inflammation in patients with hypertension. However, given the complex nature of defining and assessing gender, and that our study only examined the role of gender identity, our results need to be interpreted with care. Others, who have used a more comprehensive assessment of gender by assessing gender roles and/or norms, rather than solely gender identity, have shown femininity to be predictive of CVD events. Our results need further investigation and replication with a more comprehensive assessment of gender, and highlight the need to consider all aspects of gender, not just gender identity.

CARDIOVASCULAR EMOTIONAL DAMPENING OF THREAT PERCEPTION: A PRELIMINARY STUDY OF BLOOD PRESSURE AND FINANCIAL RISK-TAKING

James McCubbin, PhD[1], Kenneth Whitesides, N/A[1], Jessica Tucker, N/A[1], Kyla Davis, N/A[1], Caitlyn Priddy, N/A[1], Rachel Basiura, N/A[1], Brooke Haile, N/A[1], Daniel H. Wood, PhD[2]

[1]Clemson University, Clemson, SC; [2]Federal Trade Commission, Washington, DC

Elevated resting blood pressure is associated with emotional dampening, including reduced responses to painful stimuli, emotionally evocative photographic scenes, and reduced perception of affect in facial expressions and written narratives. Several current models of health behavior suggest that perception of threat is a critical motivator in avoidance of risky health-damaging behavior. We hypothesize that that blood pressure-associated dampening of threat assessment may influence decision-making, and may be especially important in propensity for various risk-taking behaviors. Work from our lab has recently shown that increased resting blood pressure is associated with: 1) increased self-report of risky behavior from a modified National College Health Risk Behavior Survey, and 2) risky driving behavior assessed in a high fidelity driving simulator. We seek to build upon these results by assessment of the relationship between blood pressure and financial risk-taking using a simulated paired-choice lottery game.

Forty-one healthy, normotensive adults (11 men, 30 women) 18-43 years of age were recruited for a laboratory study of resting blood pressure and financial risk-taking behavior using a simulated paired-choice lottery task. Blood pressures were determined over a 10 minute rest period using a calibrated Dinamap V100 monitor. Participants then played a simulated lottery task involving ten paired-choice decisions to assess propensity for financial risk-taking.

Average resting systolic blood pressure was 110.7 +/- 1.41 mmHg (mean +/- SE) and diastolic blood pressure was 66.5 +/- .68. As in previous studies, systolic blood pressure was higher in men than in women (p=.001), but there were no other significant sex differences in blood pressure or risk behaviors. Multiple regression predicting lottery risk-taking from systolic and diastolic blood pressures indicated that higher resting systolic blood pressure was associated with increased risk-taking (B= -.075, t= -2.215, p= .033).

These data suggest that cardiovascular emotional dampening may be associated with increased finanacial risk-taking. The body of data suggests that CNS mechanisms associated with resting blood pressure levels are possibly associated with dampened perception of threat. This dampened threat perception may reduce motivation to avoid risk-taking behavior and thus lead to increased risk-taking behavior in multiple domains. Better understanding of the integration of CNS circuits that influence visceral, emotional, motivational and, hence, cognitive function may give more insight into individual differences in propensity to engage in risk-taking behavior. This approach to understanding risk-taking may provide new strategies for basic and translational research to reduce health-damaging behaviors, and thus reduce risk for multiple chronic diseases related to unhealthy lifestyle choices.

DEPRESSION IN CARDIAC PATIENTS AND RESULTING THREAT PERCEPTIONS IN THE EMERGENCY DEPARTMENT

Tara B. St. Onge, BA[1], Beatrice Konrad, BA[1], Gabriel Sanchez, B.A.[1], Amberle Cusmano, MS[1], Donald Edmondson, PhD, MPH[2]

[1]Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; [2]Columbia University Medical Center, New York, NY

Background: Patients that present to the emergency department (ED) with depression are more likely to develop posttraumatic stress disorder (PTSD) after an acute coronary syndrome (ACS) than their nondepressed counterparts. Threat perceptions during a traumatic event are associated with the severity of subsequent PTSD. Prior research, for example, suggests that depressed ACS patients are at increased risk of developing PTSD when they present to an overcrowded ED. However, no study has addressed the mechanism by which these ED threat perceptions influence PTSD risk. We tested whether depressed cardiac patients were more likely to perceive the emergency department as stressful during ED evaluation than nondepressed patients.

Methods: 581 patients being evaluated for acute coronary syndrome were enrolled in the Reactions to Acute Care and Hospitalization (REACH) study, an observational cohort study in the emergency department (ED), and provided complete data. Participants completed a baseline interview containing an Emergency Room Perceptions questionnaire that assessed perceptions of emergency room crowding, stress, and length of stay. They also completed the eight-item Personal Health Questionnaire Depression Scale (PHQ 8) to measure depression.

Results: Participants were 60.75 ± 0.6 years, 47% women, and 37.06% were depressed. Though perceptions of emergency room crowding did not differ [t= -1.292, p=.197], depressed patients perceived the ED as more stressful [t= -3.927, p=.000], perceived a one hour longer length of stay [t= -2.530, p=.012], and a 2.3 hour longer wait for a care plan [t= -2.701, p=.008].

Conclusion: Emergency Departments can be incredibly stressful environments and cardiac patients with depression are particularly vulnerable to the effects of ED perceptions. In this study, even though depressed patients did not perceive the ED as more crowded, they did perceive it as more stressful, their length of stay to be longer, and their wait for a care plan to be longer. This may be why previous research has found differential effects of ED crowding on depressed patients.

DEPRESSIVE SYMPTOMS AND MORTALITY IN HEART FAILURE: THE ROLE OF MEDICATION NON-ADHERENCE

Emily C. Gathright, M.A.[1], Mary A. Dolansky, RN, PHD[2], John Gunstad, PhD[3], Richard Josephson, MS, MD, FACC, FAHA, FACP, FAACVPR[4], Shirley M. Moore, PhD[2], Joel W. Hughes, PhD[3], Joseph Redle, MD[5]

[1]Kent State University, Providence, RI; [2]Case Western Reserve University, Cleveland, OH; [3]Kent State University, Kent, OH; [4]University Hospitals Health System, Cleveland, OH; [5]Summa Health System, akron, OH

Introduction

Approximately 20% of individuals with heart failure (HF) experience depression or depressive symptoms. Depression is detrimental to prognosis in HF, roughly doubling all-cause mortality risk. However, the mechanisms underlying this relationship are not fully known. Medication non-adherence may contribute, as depressed patients are less likely to adhere to medication regimens.

Purpose

The present study evaluated the role of medication non-adherence in the relationship between depressive symptoms and mortality risk in adults with HF.

Method

Participants were 303 HF patients in a longitudinal, observational study of self-care behaviors. Participants completed 21 days of medication monitoring using an electronic pillbox. Medication adherence was treated as a continuous variable. Depression was defined as Patient Health Questionnaires scores ≥ 5. Mortality data were obtained from the Centers for Disease Control and Prevention's National Death Index. Cox proportional hazards regression was used to assess the relationship between depressive symptoms and mortality, with and without adjustment for demographic and medical covariates, and medication non-adherence.

Results

After adjustment for covariates, depression was associated with increased all-cause (HR: 2.07; 95% CI: 1.02-4.17), but not cardiovascular, mortality risk. When medication non-adherence was added to the model, non-adherence (HR: 1.01; 95% CI: 1.002 – 1.02), but not depression, was associated with increased mortality risk.

Conclusion

Medication non-adherence appears to contribute to increased risk of all-cause mortality conferred by depressive symptoms in HF. Depression and medication adherence represent modifiable risk factors for poor prognosis. Future research is needed to understand whether interventions that concomitantly target these factors can improve outcomes.

ELIGIBILITY CRITERIA FOR HYPERTENSION-RELATED BEHAVIORAL INTERVENTIONS: ARE BLACKS INCLUDED?

Aisha T. Langford, PhD, MPH[1], Zhe He, PhD, MS[2]

[1]New York University School of Medicine, New York, NY; [2]Florida State University, Tallahassee, FL, FL

Background: Despite higher rates of hypertension (HTN) in blacks compared to other racial groups, blacks have historically been underrepresented in HTN-related clinical trials and health research studies. Behavioral interventions have been shown to improve HTN management among Americans in addition to, and sometimes in lieu of, drug therapy. However, it is not clear how often blacks are specifically mentioned in protocols for HTN-related behavioral interventions.

Objective: To quantify and describe HTN-related behavioral interventions registered with ClinicalTrials.gov that explicitly include “black” or “African American” as part of the eligibility inclusion criteria.

Methods: Using a novel database developed by Zhe He et al. that summarizes key attributes of ClinicalTrials.gov, “Commonalities in Target Populations of Clinical Trials (COMPACT),” we queried COMPACT for variables of interest. Broadly, there were 323 interventional HTN studies using behavioral interventions between 01/2005 and 08/2015. “Interventional HTN studies using behavioral interventions between 01/2005 and 08/2015 with ‘black’ or ‘African American’ in the eligibility criteria” yielded 28 studies. After qualitative review of the studies, two were dropped, leaving a total of 26 studies. Descriptive statistics were run in IBM SPSS 24 for gender, whether blood pressure was included as a primary outcome, minimum and maximum age for recruitment, focus of the behavioral intervention, and range of enrollment for the studies.

Results: With regard to gender, 22 (85%) of the studies recruited both men and women, while four studies (15%) only recruited men. Blood pressure was included a primary outcome in 21 studies (81%), while five studies (19%) had other primary outcomes (e.g., insulin sensitivity, dietary change, medication adherence, and feasibility assessment). The most common minimum age was 18 (50%), followed by 21 (23%), and 50 (8%). Other age minimums included 19, 35, 40, and 60. Regarding age maximums, 23 studies (89%) did not have an upper age limit, while two studies had 79 as the cutoff and one study had 80 as the cutoff. The focus of the interventions included six motivational interviewing (23%), three lifestyle

change/counseling (12%), two DASH diet (8%), two health/patient education or support (8%), two nursing (8%), and two multimedia/mhealth including DVDs and text messaging (8%). The nine “other” studies (34%) included blood pressure screenings, personal health records, group visits, self-affirmation, community health workers, health literacy, and pharmacy interventions. The enrollment targets ranged from 25 to 3698.

Conclusion: More research is needed on how eligibility criteria and the focus of behavioral interventions may affect black enrollment in HTN-related research studies.

EMOTION REGULATION AND ILLNESS PERCEPTIONS: IMPLICATIONS FOR ADHERENCE AND NEGATIVE CARDIAC EVENTS

Kelly L. Wierenga, PhD, MSN, RN

Case Western Reserve University, Holt, MI

African American women with heart failure (HF) have compounded stressors that negatively impact HF self-management and heighten the occurrence of negative cardiac events (visits to emergency departments, hospitalizations, and death for cardiac reasons). Perceptions of illness coherence and controllability and emotion regulation (the experiencing, processing, and modulating of emotional responses) are known to facilitate self-management in the face of stressors. Scant information exists to understand how cognitive and emotional components of illness may impact health disparities of African American women with HF. This prospective study examined the hypothesis that difficulties with emotion regulation and negative perceptions of illness coherence and controllability are detrimental to 1) HF self-management regimen adherence and 2) negative cardiac events in African American women with HF. African American women (n = 54) with HF ages 49 to 84 years participated in this longitudinal descriptive correlational study. Patients recruited from hospitals and heart failure clinics using convenience sampling completed interviews at intake and at 30 days, with medical records reviewed at 90 days. Linear and logistic regression models were used to assess predictors of HF regimen adherence and negative cardiac events. Of the 54 patients, 28 experienced a negative event for any reason over the 90 days, 57% of these being cardiac related. The only clear predictor of these events was greater New York Heart Association functional classification ($\beta = 1.47$, $p = .03$). No associations were found between predictors (emotion regulation, controllability, coherence, age, education) and HF regimen adherence. Despite the lack of significance with illness perceptions and emotion regulation, the individual impact on the outcomes prompts further inquiry. Emotion regulation showed a possible greater impact on negative cardiac events ($b = .80$, $p = .07$) than on HF regimen adherence ($b = -.10$, $p = .59$). Alternatively, perceived illness coherence showed less impact on negative cardiac events ($b = -.27$, $p = .51$) than on HF regimen adherence ($b = -.32$, $p = .08$). Findings indicated that a high percentage of women in this sample experienced negative cardiac events, with the hypothesized predictive factors remaining unexplained.

EXAMINING THE RELATIONSHIPS AMONG INFORMATION PRACTICES AND NEUROPROCESSING IN AFRICAN AMERICANS WITH PREHYPERTENSION

Lenette M. Jones, PhD, RN, Kathy Wright, PhD, RN, Shirley M. Moore, PhD, Jared Friedman, BA, Anthony I. Jack, PHD

Case Western Reserve University, Cleveland, OH

Title: Examining the Relationships Among Information Practices and Neuroprocessing in African Americans with Prehypertension

Background: Self-management of blood pressure requires patients to find, understand, and use information – to set goals and act on them. Understanding information practices (seeking, sharing, use) in which African Americans with prehypertension participate and associated underlying neurobiological mechanisms may be key to designing more effective self-management interventions to reduce blood pressure. Previous studies have shown that African American women who participate in information sharing, a social activity where one patient gives information about blood pressure management to another peer or peers, were more likely to report using information to self-manage their blood pressure. Studies have also shown those who are able to switch between two neurocognitive networks – the task-positive network (hypothesized to be involved with using analytic skills, knowledge for problem-solving and goal-directed action) and the default mode network (hypothesized to be involved with socio-emotional and motivational cognition) are better self-managers.

Purpose: To explore associations among information practices and the neuroprocesses associated with the task-positive network (TPN) and the default mode network (DMN) in African Americans with prehypertension.

Methods: Participants (N = 19; mean age = 53; 53% males) completed questionnaires assessing information practices related to self-management of blood pressure and underwent brain imaging (fMRI) to: (1) evaluate ability to switch between the TPN and DMN and (2) identify activation in the ventromedial prefrontal cortex (associated with emotional processing).

Results: Findings reveal that information sharing was positively associated with activation in the ventromedial prefrontal cortex ($r = .49$, $p = .03$) and ability to task switch ($r = .38$, $p = .10$). Information seeking and use were not associated with the neuroprocessing variables assessed.

Conclusions: Uncovering this brain mechanism associated with information sharing suggests that interventions based on information sharing by African Americans at risk for elevated blood pressure may be a fruitful blood pressure self-management strategy.

HOSTILITY, DEFENSIVENESS, AND TELOMERE LENGTH IN INDIVIDUALS WITH AND WITHOUT CARDIOVASCULAR DISEASE

Louisia Starnino, B.Sc[1], Gilles Dupuis, PhD[2], Bianca D'Antono, PhD[3]

[1]University of Quebec in Montreal/Montreal Heart Institute, Vaudreuil, PQ, Canada; [2]University of Québec at Montréal, Montréal, PQ, Canada; [3]Montreal Heart Institute/Université de Montréal, Montreal, PQ, Canada

Background: Shorter telomere length (TL) may indicate premature cellular aging and increased risk for disease. While individuals diagnosed with depression have been shown to possess shorter telomeres, data for potentially maladaptive personality traits related to cardiovascular disease (CVD), such as hostility and defensiveness, are sparse.

Objective: The purpose of this study is toevaluate the cross-sectional association of TL with hostility and defensiveness in individuals with and without CVD. Whether chronological age, sex and health status moderates the associations observed is also examined.

Methods: 781 men and women (M_{age} = 65.5 ± 6.8 yrs) with and without (N = 284) CVD completed the Marlowe-Crown Social Desirability Scale and the Cook-Medley Hostility Scale. Relative TL was measured via quantitative polymerase chain reaction of total genomic DNA samples. Hierarchical regressions were performed separately for hostility and defensiveness, and included interactions of hostility/defensiveness with age, sex, and CVD status (entered stepwise) in Block 3. Of the participants without CVD, only 37 were without other illnesses (i.e, were very healthy). These participants were examined separately in secondary analyses.

Results: As expected, women and younger individuals had longer TL compared to their counterparts (all *p*s < .05).In the primary analyses, defensiveness was not associated with TL. While no main effect of hostility emerged, a 3-way interaction of hostility with age and sex emerged ($\beta = -0.102$, $t=-2.820$, $p=0.005$). More specifically, greater hostility was associated with longer TL in older men and younger women, while in older women, the opposite was true. This effect remained significant after controlling for behavioural and physiological risk factors (e.g. smoking, exercise, IL6, systolic blood pressure).In healthy individuals, greater defensiveness was associated with shorter TL, though this did not reach significance due to lack of power ($\beta = -0.270$, $t = -1.701$, $p = 0.098$). This relation was not influenced by sex or age. Independence from covariates could not be examined given the sample size.

Conclusion: The association of hostility and defensiveness with telomere length was influenced by age, sex, and health status. Surprisingly, only a small fraction of the variance in TL was explained by the predictors and covariates included in the analyses. Whether this reflects disease spectrum bias or other factors remain to be determined, as does the implication of these relations for the progression of disease.

Key words: telomere length, hostility, defensiveness, age, sex , cardiovascular disease

'I BELIEVE HIGH BLOOD PRESSURE CAN KILL ME:' PATIENTS' PERCEPTIONS OF AN INTERVENTION TO CONTROL HYPERTENSION IN GHANA

Sarah Blackstone, MPH[1], Juliet Iwelunmor, PhD[1], Joyce Gyamfi, MSc.[2], Nana Kofi Quakyi, MPH[2], Gbenga Ogedegbe, MD[2]

[1]University of Illinois Urbana-Champaign, Champaign, IL; [2]New York University Langone Medical Center, New York, NY

Objectives: In Ghana, hypertension represents the second leading cause of out-patient morbidity and mortality. Regular screening for and early detection of hypertension are necessary for controlling the burden of the disease, yet are made difficult by the severe shortage of health care workers. Task-shifting strategy is one such approach to address hypertension in light of an under resourced health system. Currently in Ghana, there is an on-going TAsk- Shifting Strategy for Hypertension (TASSH) program in which nurses are trained in hypertension management. While this study will provide useful information on the viability of this approach, it is not clear how patients in the intervention perceive hypertension, the task-shifting strategy, and its effects on blood pressure management. The objective of this paper is to examine patients' perceptions of hypertension and hypertension management in the context of an on-going task-shifting intervention to manage hypertension in Ghana.

Design: Forty-two patients participating in the TASSH program (23 males, 19 females, and mean age 61. 7 years) completed in-depth, qualitative interviews. Interviews were transcribed, and key words and phrases were extracted and coded using the PEN-3 cultural model as a guide through open and axial coding techniques, thus allowing rich exploration of the data.

Results: Emergent themes included patients' perceptions of hypertension, which encompassed misperceptions of hypertension and blood pressure control. Additional themes included enablers (e.g. patients' degree of commitment to intervention) and barriers (e.g. financial difficulties in obtaining antihypertensive medication) to hypertension management, and how the intervention nurtured lifestyle change associated with blood pressure control.

Conclusions: This study offers a unique perspective of blood pressure control by examining how patients view an on-going task-shifting initiative for hypertension management. The results of this study will shed light on factors that can help and hinder individuals in low-resource settings with long-term blood pressure management.

LIFESTYLE BEHAVIORS, TYPE D PERSONALITY AND PARASYMPATHETIC FUNCTIONING FOLLOWING A SOCIAL AND COGNITIVE TASK

Kevin Tajii, M.S., Mariam Ter-Petrosyan, M.S., Luci Martin, Clinical Psychology, PhD

University of La Verne, La Verne, CA

Heart rate variability has a well-documented relationship with negative health outcomes including coronary heart disease and all-cause mortality. Lifestyle behaviors, such as diet, exercise and sleep may contribute to the development of negative health outcomes. Stable personality traits suggest a means to assess chronic attributes of individuals that may be at risk for disease. The purpose of this study was to examine whether lifestyle behaviors such as sleep, caffeine consumption, alcohol consumption and eating habits as well as the trait Type D Personality were associated with parasympathetic functioning in a diverse sample of young adults. Participants (n = 95, mean age = 20.77, SD = 4.97) completed self-report measures including a Lifestyle Behaviors questionnaire, the Type D Scale-14 and a physiological assessment to compute heart rate variability during a baseline imagery task and following a social and cognitive condition. Participants (80% female) self-identified as European American (40%), Latino/a (36%), African American (7%), and “other” (17%). Descriptive statistics were revealed for average hours of sleep (7-8 hours = 42.1%), quality of sleep (fairly good = 65.3%), alcoholic beverages consumed each day (M = .17, SD =.613), average daily caffeine consumption (M = 1.09, M = 1.203), eats 3-5 servings of fruits/vegetables a day (yes = 38.9%) and Type D personality (participants with Type D personality = 24.2%). Bivariate correlations revealed that following a regular exercise routine was associated with greater parasympathetic function at baseline (r = .204 p 2 =.09, F (3, 85) = 5.18, p < .01). Diet, sleep, alcohol consumption and Type D personality were not significantly associated with parasympathetic functioning within this sample; however, Type D was associated with lower quantity of sleep (r = -.295, p < -.01), lower quality of sleep (r = -.43, p < .001) as well as lower average exercise per day (r = -.216, p < .05). These results suggest that it is important to continue to examine the complex relationships between lifestyle behaviors, personality traits and heart rate variability, as these relationships may lead to better health outcomes.

PSYCHOSOCIAL FACTORS AND AMBULATORY BLOOD PRESSURE INDEXES

Amanda K. Small, B.A., Matthew J. Zawadzki, PhD.

University of California, Merced, Merced, CA

Ambulatory blood pressure (ABP) methods provide the opportunity to obtain robust BP data, including how BP may vary over the course of day and during sleep periods. However, in general ABP research has utilized largely mean measures, ignoring the oscillations in BP across the day. Given that both BP mean and variability independently predict morbidity and mortality, there is need to better what relates to ABP variability. The purpose of this study is to test the relationships between psychosocial factors and ABP measurements, comparing ABP mean with ABP variability and separately analyzing daytime and nighttime values. Community participants (*n*=291; 52.9% Male; age *M*=40.98; 59.4% Black/African America, 20.6% White, 7.3% Asian/Indian, 16.1% Latino/Hispanic; 63.3% Never married, 14.5% Married, 18.7% Divorced or Separated) completed measures of personality types, depression, rumination, anxiety, anger, and hostility. Afterward participants completed two 24-hour sessions of noninvasive ABP monitoring using Spacelabs 90207 ABP monitor spaced 2-4 months apart. Bivariate correlations tested the relationships between psychosocial factors and ABP measures (mean, standard deviation, and average real variability for systolic and diastolic BP). Mean measures (both day and night) related to more psychosocial factors than either variability measure, although the relationships were weak. During the day, openness to experience related to all three indexes although the relationship was inverse for mean and standard deviation but not average real variability. Hostility also related to both mean and standard deviation. Extraversion and Agreeableness related to mean only. Similar patterns were found in night time measures, although average real variability and mean measures showed more relationships to traits than during the day, included depression, rumination and anger. Several relationships exist between psychosocial traits and ABP indexes with mean measures related to the largest number and variety of traits. This is consistent with prior work and helps increase understanding about which personality traits relate to BP mean. Future work should address BP variability. Strong relationships between psychosocial factors and ABP variability were not identified. It is possible that while ABP mean does related to stable personality aspects, ABP variability may be better understood when considering considering context and potential state based psychosocial states rather than traits.

SOCIAL SUPPORT AND HEALTH BEHAVIORS IN CARDIAC REHABILITATION: ADHERENCE AND DEPRESSION AS MEDIATORS

Jillian Clark, M.A.[1], Kadie M. Harry, M.A.[2], Kalon R. Eways, M.A.[2], Alisha Howarter, PhD[3], Elizabeth J. Wilson, B.A.[2], Kymberley K. Bennett, Ph.D.[2]

[1]University of Missouri-Kansas City, San Diego, CA; [2]University of Missouri-Kansas City, Kansas City, MO; [3]Remington College, Kansas City, MO

Limited social support and psychological distress (i.e., depression) have been linked to negative outcomes, such as recurrence and mortality, following a cardiac event. Further, these constructs have been associated with health behaviors in both the general population and within samples of patients with cardiovascular disease (CVD). Using a conceptual model as a framework, the purpose of this study was to examine the relationship between social support and health behaviors in individuals with CVD, and the mediating roles adherence to cardiac rehabilitation (CR) and depressive symptoms may play in this relationship.

CR patients ($n = 83$) completed questionnaires at Time 1 (beginning of CR), Time 2 (end of CR), and Time 3 (18 months following the end of CR). Participants completed self-report measures assessing emotional social support (Time 1), depressive symptoms via the Beck Depression Inventory-II (Time 1 and 2), and adherence to recommended health behaviors (Time 3). Adherence to CR was measured by number of sessions completed. The mean age of participants was 63.9 years, the majority were male (63.9%) and European-American (92.7%)

A path analysis was estimated in MPlus, with social support as the exogenous variable, CR session and depressive symptoms as mediators, and health behavior adherence as the endogenous variable. The model controlled for Time 1 depressive symptoms, Time 1 health behaviors, and risk stratification. Overall, fit indices suggested poor model fit ($SB\chi2\ [6] = 79.36$, $p \leq .001$; RMSEA = .39, 90% RMSEA CI [.31, .46]; CFI = .73; SRMR = .07). Social support and adherence to CR were not significantly associated with any of the variables in the path model. Results did suggest that depressive symptoms at Time 2 was negatively associated with adherence to healthy behaviors at Time 3 ($\beta = -.29$, $p = .001$). There was no evidence of mediation. The model in its entirety explained 24.5% of Time 3 health behavior adherence.

Results suggest that CR practitioners should identify individuals who are experiencing greater depressive symptoms following a cardiac event and promote intervention methods to address their heightened psychological distress. This approach would be complementary to the ultimate goal of CR—lifestyle modification to adhere to recommended health behaviors to reduce the likelihood of cardiac event recurrence and cardiac-related mortality.

THE ASSOCIATION OF RELIGIOSITY AND BLOOD PRESSURE AMONG SEXUAL MINORITIES: RESULTS FROM A NATIONALLY REPRESENTATIVE SAMPLE

Kalina M. Lamb, B.A.[1], Kelsey A. Nogg, B.A.[2], Benjamin M. Rooney, B.A.[2], Aaron J. Blashill, Ph.D. [2]

[1]San Diego State University, San Deigo, CA; [2]San Diego State University, San Diego, CA

Objective: Hypertension is a major public health concern, given prevalence and morbidity. Among the general population, higher levels of religiosity have been associated with lower blood pressure (BP) compared to nonreligious individuals. However, no known studies have examined the relationship between religiosity and BP among sexual minorities (e.g., gay, lesbian, and bisexual individuals). Given that many world religions promote doctrines that include negative views toward sexual minorities, it is plausible that elevated religiosity among sexual minorities may be associated with increased BP.

Methods: The current study analyzed data collected from Wave IV of the National Longitudinal Study of Adolescent to Adult Health (Add Health), a publically available, nationally representative dataset. Participants were identified as a sexual minority if they identified themselves as 100% gay, mostly gay, or bisexual, or reported same sex attraction (N = 297, 25% Male, Mean age = 28.55, SD = 1.68 years). A religiosity variable was created by standardizing and averaging responses of two items assessing attendance of religious services and religious activities. BP was measured as systolic (SBP) and diastolic blood pressure (DBP) – each measured with three 30-second interval readings, with scores equaling the average of the second and third reading. Relevant covariates were controlled for in the models (i.e., age, gender, BMI, ethnicity, income, education, smoking and alcohol use).

Results: Complex Samples within SPSS (v23) was employed to account for the weighting, clustering, and stratification inherent to Add Health. Within Complex Samples, two separate General Linear Models were conducted, with SBP and DBP entered as outcome variables. Whilst controlling for relevant covariates, elevated religiosity was associated with increased SBP (b = 1.29, SE = .83, 95% CI: 0.35, 2.54, t = 2.045, p = .04) and DBP (b = 1.01, SE = 0.51, 95% CI: 0.003, 2.02, t = 2.00, p = .05).

Conclusions: Previous research has found religiosity to be a protective factor from hypertension among the general population. However, the results from the current study are the first to test and find an inverse effect among sexual minority individuals. There is a paucity of research examining the intersection of promoting health as a function of sexual orientation

and religion. Further research may benefit from examining the interaction of sexual orientation and religiosity in predicting hypertension.

NEW MOTHERS' USE OF NEW MEDIA FOR HEALTH INFORMATION & SUPPORT

Lorraine Walker, MPH, EdD[1], Michael Mackert, PhD[1], Misha Vaughan, PhD[2], Bobbie S. Sterling, RN, MSN, PhD[3], Sherry Hendrickson, PhD, APRN, CNS-BC[4], Sarah Guy, MSN, RN[5], Jisoo Ahn, MA[4]

[1]University of Texas at Austin, Austin, TX; [2]Oracle, Fremont, CA; [3]University of Texas at Austin, Georgetown,, TX; [4]The University of Texas at Austin, Austin, TX; [5]The University of Texas at Austin, Liberty Hill, TX

Electronic media are an important means for new mothers to obtain health information and support. Uses and Gratifications theory posits that needs of subgroups lead to differing media use. Understanding mothers' use of new media is key to patient education about electronic resources. The aim of this study was to determine new mothers' media use in 6 areas, and correlates (race/ethnicity, income, stress, emotional support, and number of children) of specific media use. Data for this study are from a random stratified survey sent to new mothers in Texas. Race/ethnicity and income level were stratifying variables. The adjusted response rate was 32%. Respondents had a mean age 31.4 y, SD = 5.4), were about 9 months postpartum, were African American (n = 35), Hispanic (n = 58), or White (n = 75), and most had between 1-3 children. The survey included items on demographic factors, perceived stress, emotional support, and mother- or baby-related media use. Data were analyzed by percentages and non-parametric tests (Kendall's tau, Kruskal-Wallis, and Friedman). Mothers' use of specific media was as follows: search for baby-related information (95%), search for mother-related information (87%), email to family or friends about baby (83%), read online sites for new mothers (78%), socialize on Facebook (77%), and watch YouTube videos on mother/baby care (46%). Types of media use differed significantly ($p < .001$). More often searching for mother- or baby-related information was correlated with having a lower number of children (-.30 and -.16, respectively). More frequent email use was significantly correlated with higher income (.33), lower stress (-.17), and lower number of children (-.17). Use of YouTube, Facebook, and online health reading had no significant correlates, indicating usage was relatively similar on correlate variables. Also, race/ethnicity and support were not related to media usage. In conclusion, these findings indicated that mothers' top media use was in searches about babies or mothers, with searches more frequent among those with fewer children. Race/ethnicity was not a factor differentiating use. These findings support patient education to identify credible sources (especially for first-time mothers) during health-related searches.

PARENT VERSUS CHILD PERCEPTIONS OF FEEDING CONTROL MECHANISMS

Caitlyn Murphy, Student Researcher[1], Marla Schroeder, Student Researcher[2], Allison Kiefner-Burmeister, Ph.D.[1]

[1]The University of Findlay, Findlay, OH; [2]University of Findlay, Sidney, OH

The parental feeding practices that contribute to childhood obesity are both important and commonly investigated (Goyder 2007; Musher-Eizenman & Kiefner, 2013). One understudied area of this line of research that may relate to food preoccupation is within the differentiation of overt and covert feeding practices (Ogden 2006). This descriptive study sought to investigate the differences in perception of control practices and eating attitudes of parents and their children. It was hypothesized that parental unhealthy eating attitudes would relate to the unhealthy attitudes of their children, and these attitudes would differ depending on parental control mechanisms. Participants were 25 parent-child dyads (92% White, 60% had an income of $100k or over, child age ranged from 12-14 years). Children participated in their sixth-grade classroom and parents filled out paper surveys at home. Measures included the EAT, the CHeat, the EEQ, the CFPQ, and the Overt and Covert feeding scales (Birch et al. 2001; Arnow, Kenardy, & Agras 1995; Musher-Eizemann & Holub 2008; Norwika, Flodmark, Hales, & Faith 2014).

Parents' unhealthy eating attitudes were related to their child’s unhealthy eating attitudes. There was a positive relationship between parent-reported covert feeding control and both parental dieting behaviors and restriction of their children’s food for weight control (dieting $r = .45$, $p < .05$; restriction $r = .57$, $p < .05$), such that the more parents control feeding covertly, the more they also show dieting behaviors themselves and restricted their child’s food based on their child’s weight. Parent-reported covert feeding was positively related to children’s preoccupation with food ($r = .54$, $p < .05$). These findings were not found with overt control. These findings suggest that covertly controlling practices may relate to children’s unhealthy relationships with food if the child perceives the covert behaviors. However, not all forms of covert practices related to negative attitudes. For example, there is a negative relationship between children who use food for emotional regulation and parents who use covert control ($r = -.42$, $p < .05$).

Children who perceived that parents encouraged a balanced diet with a variety of healthier food choices also reported parents who used more overt control behaviors ($r = .42$, $p < .05$). Overt control was also related to children’s reports that parents wanted them to be actively involved in food preparation and food choices in the household (r = .41, p < .05) and reports that parents wanted to teach them the reasoning behind overt control (r = .42, p < .05). Our preliminary study suggests that parent and child perceptions of the different types of control mechanisms used in a household may be just as important in relation to child attitudes toward food, dieting, and weight as the actual control mechanisms.

PARENTAL MONITORING IN THE LINK BETWEEN EARLY DATING INITIATION AND DATING VIOLENCE AMONG DIVERSE ADOLESCENTS

Ashley C. Baker, B.S.[1], Patricia Cabral, M.A.[2], Jan Wallander, PhD[3]

[1]University of California Merced, Merced, CA; [2]University of California, Merced, North Hollywood, CA; [3]Univ. California, Merced, Los Gatos, CA

Dating violence (i.e. emotional, physical, and sexual) is prevalent among adolescents and can differ across race/ethnicity. Unhealthy romantic relationships can start early and have long-term influence on adolescent outcomes (e.g. depression and suicidal behaviors). However, positive parenting practices, such as parental monitoring, may play a role in reducing the likelihood of dating violence (DV) among adolescents. Yet, the association between early dating initiation and subsequent DV across race/ethnicity has not been examined, nor has the role of parental monitoring in this association. Using data from 3,295 (51% female) Black (26%), Latino (54%), and White (20%) adolescent participants from the *Healthy Passages* longitudinal cohort study, we first examined the prevalence of DV experienced and committed across racial/ethnic groups by 10th grade. Next, we explored longitudinal associations between early dating behaviors by 5th grade and subsequent DV by 10th grade, followed by the moderation of this association by parental monitoring. Among boys and girls, Latino adolescents reported significantly more physical, emotional, and sexual DV than Black adolescents, who in turn reported significantly more physical and emotional DV experiences than White adolescents (*p*s < .01). Also, adolescents who initiated dating early were more likely to experience physical DV among Latino boys (OR = 2.28), Latina girls (OR = 2.28), Black boys (OR = 2.91), and Black girls (OR = 3.19). Among all groups, early dating initiation was significantly related to a greater likelihood of committing physical DV (OR = 2.11 - 6.59). Early dating initiation was also related to a greater prevalence of emotional DV experiences among Latino boys (OR = 2.34), Black boys (OR = 4.11), and Black girls (OR = 4.64), as well as a greater likelihood of committing emotional DV among Black boys (OR = 4.68) and girls (OR = 2.22). Whereas White adolescent boys who initiated early dating were more likely to experience sexual DV (OR = 1.65) and White girls were more likely to commit sexual DV (OR = 1.53). Moreover, parental monitoring moderated this association regarding physical DV committed and experiences of physical DV, emotional DV, and sexual DV (*p*s < .05), but in different ways for different racial/ethnic and gender groups. Findings may have important implications for parental interventions and approaches to child dating.

PARENTAL RELATIONSHIP QUALITY AND QUALITY OF LIFE AMONG YOUTH WITH AND WITHOUT CHRONIC MEDICAL CONDITIONS

Lauren E. Wisk, PhD, Elissa R. Weitzman, ScD, MSc

Boston Children's Hospital and Harvard Medical School, Boston, MA

Background: Family functioning is an important contributor to quality of life (QoL), particularly for families of youth with chronic conditions (YCC), as chronic conditions increase stress and distress for the affected individual and their family members. As family functioning and relationship quality may be particularly dynamic during adolescence and young adulthood, we evaluated trajectories of parental relationship quality (RQ) during this period for YCC compared to their healthy peers, and evaluated how these trajectories impacted individual QoL over time. **Methods:** Longitudinal data are from 3038 adolescents and young adults (ages 8-28 years) interviewed for the Panel Study of Income Dynamics, a national, population-based survey, between 2002 and 2013. We utilized multivariate generalized linear mixed models with natural cubic splines to model trajectories in RQ (MSALT scale, range 1-4) and their effect on QoL (MIDUS scales for emotional, social and psychological well-being, range 1-6) for youth with and without chronic conditions, adjusting for confounders. **Results:** Compared to their healthy peers, YCC (55% of sample) reported lower RQ with their mothers and fathers, particularly during late adolescence (2.86 vs 2.91, $p < 0.01$) and after age 20 (2.64 vs 2.73, $p < 0.01$) respectively. YCC also reported lower QoL than their peers across emotional, social and psychological domains (all $p < 0.01$); these difference persisted after adjustment for confounders. Better relationships with both mothers and fathers resulted in gains in all three domains of QoL and differences in QoL by parental RQ diminished with age. Nevertheless, disparities between YCC and their peers widened over time (particularly during emergent adulthood) for youth with lower parental RQ (e.g., average emotional QoL at age 16 was 0.24 (a quarter-SD) lower for YCC with low maternal RQ and 0.14 lower for those with high maternal RQ, but 0.36 lower at age 26 with low maternal RQ and 0.15 lower with high maternal RQ). **Conclusions:** Parent-child relationship quality appears to exert a significant effect on youth QoL well into young adulthood, especially so for YCC who may rely on support from their parents over a longer period of time than their peers. Practitioners and therapists may want to assess parent-child relationship quality to buttress resilience resources among patients with pediatric onset chronic disease.

PARENTING STYLES AND BODY MASS INDEX: A SYSTEMATIC REVIEW OF PROSPECTIVE STUDIES AMONG CHILDREN

Rebeccah L. Sokol, B.S. [1], Bo Qin, PhD[2], Jennifer Poti, PhD[3]

[1]Gillings School of Public Health, UNC Chapel Hill, Carrboro, NC; [2]Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; [3]University of North Carolina at Chapel Hill, Chapel Hill, NC

Parenting style is correlated with outcomes that impact eating and physical activity, and its classification schema provides a childhood obesity intervention target. Parenting style can be categorized into groups—authoritative, authoritarian, permissive, and neglectful—based on the response and demand dimensions. Reviews that evaluate the relationship between parenting style and weight have been largely based on cross-sectional studies, resulting in the inability to describe the interplay between parenting styles and obesity risk as children age. To address this, we systematically searched PubMed, Embase, and PsychInfo for studies published between 1995-2016 that evaluated the prospective relationship between parenting style and subsequent weight outcomes. We aimed to answer: 1) Is authoritative parenting associated with less body mass index (BMI) gains; and 2) Are there critical ages where parenting style has a more pronounced association with later weight outcomes?

We identified 11 prospective cohort studies. Among the 8 studies that categorized parenting style into groups, 5 provided evidence that authoritative parenting was associated with lower BMI gains. The 4 studies that conceptualized parenting styles along the response and demand dimensions offered less consistent evidence. Among the 6 highest quality studies, 4 suggested a protective role of authoritative parenting style against adverse weight outcomes. However, only one study controlled for a complete set of confounders. The small number of studies conducted within certain age groups precluded our ability to ascertain critical periods when parenting style is most strongly related to child weight. We found parents from minority populations were underrepresented, and all studies were conducted in the United States or Australia. Moreover, analyses in the included articles did not attend to the nuances of family structure, such as one-parent households, non-biological caregivers, or dual mother or father parenting, and only 4 studies measured paternal parenting style.

Authoritative parenting may be protective against later overweight and obesity, but to better define this relationship, future studies should consider paternal styles both independently and in combination with maternal parenting style, conduct studies of a longer duration to allow

the assessment of the critical period to intervene, more carefully control for child-related and parent-related confounding factors, and account for the nuances in family structure.

PARTICIPANTS’ EXPERIENCE AND ENGAGEMENT IN CHECK IT!, A POSITIVE PSYCHOLOGY INTERVENTION FOR ADOLESCENTS WITH TYPE 1 DIABETES

Erin M. Bergner, MPH, MA[1], Niral J. Patel, MPH[1], Kimberly L. Savin, BA[1], Emily R. Hamburger, MEd[1], Robin Whittemore, PhD, APRN, FAAN[2], Sarah S. Jaser, PhD[1]

[1]Vanderbilt University Medical Center, Nashville, TN; [2]Yale University, School of Nursing, Orange, CT

Problems with adherence are common among adolescents with type 1 diabetes (T1D). Adolescents and their families are responsible for managing a complex treatment regimen, which includes administering daily insulin, and monitoring blood sugar, diet, and activity levels. Positive psychology interventions are shown to improve health outcomes; however, they have not been used widely in pediatric populations. We tested the acceptability and feasibility of Check It!, a positive psychology intervention to improve adherence in adolescents with T1D.

Adolescents with T1D and their parents were randomized to a positive psychology intervention (via phone or text message) or an attention control (education) group. The intervention used positive psychology exercises, small gifts, and parent affirmations to increase positive affect (PA). Adolescents in both groups received education packets. Exit interviews and satisfaction surveys were conducted with adolescents and parents (n=58) to assess the acceptability and feasibility of Check it! from a representative sample of each group. Participants rated the acceptability of Check It! using a 5-point Likert scale, with higher scores indicating more favorable ratings. Interview transcripts were independently coded, and then reviewed to reach consensus. Adolescents were 15.4 ± 1.6 years old; 50% female; 8.6% non-White; 53.4% on insulin pump; with a T1D duration of 6.6 ± 4.1 years; and A1c of 9.1 ± .90%. Parents were 41 ± 9.7 years old; 85% female; 8.3% non-White; and 42% had annual family income >$80,000. Participants rated the helpfulness (3.4 ± 1.1) and enjoyment (3.5± 1.0) of Check It! favorably. Parents and adolescents indicated that the intervention provided support for the adolescent, offering the chance to discuss emotional topics in an age-appropriate way. Parents appreciated the reminders to provide affirmations to their children, as they offered an opportunity for self-reflection and helped the parent-child relationship. Adolescents also enjoyed the parental affirmations, and the opportunity to set adherence goals and learn about diabetes. However, feasibility of the phone delivery was low: fewer adolescents in the phone group completed PA phone interviews, as compared to those in the text group (14% vs. 67%; t=7.97, p < .001).Parents and adolescents reported that technical issues with cell phones, timing of calls and text messages, life events, and diabetes-specific factors presented challenges to participation. Participants rated Check It! favorably, but some feasibility problems were identified, particularly in the phone group. Adolescents and their parents enjoyed Check it! and found the intervention helpful. Findings indicate that text messages are more feasible than phone calls for interventions with adolescents, but determining optimal times to send text messages is important.

Introduction

Caregivers of children with chronic medical illnesses often experience posttraumatic stress symptoms (PTSS) as well as symptoms of depression in the wake of their child’s illness or its treatment. The potential effects of these symptoms on child medical outcomes have not been investigated prospectively. We evaluated whether caregiver PTSS and depression symptoms predict robust behavioral (adherence to medications) and medical (rejection) outcomes in a prospective, multisite study: Medication Adherence in Children who had a Liver Transplant (MALT).

Methods

Pediatric liver transplant recipients (n=400) ages 1-17 and their primary caregivers (n=386) were recruited from five pediatric liver transplant centers in the United States. Parents completed the Impact of Events Scale (IES) to measure caregiver distress and the Center for Epidemiologic Studies Depression Scale (CES-D) to measure caregiver depression. Patient medical variables and outcomes were followed for a two-year period. Medication Level Variability Index (MLVI), which is the level of variability of immunosuppressant levels in the blood, was used to determine adherence while centrally-read, biopsy-confirmed organ rejection was the primary medical outcome.

Results

There were no significant associations between IES (PTSS) scores and either adherence or rejection outcomes. In contrast, there were significant correlations between higher CES-D (depression) scores and higher MLVI (lower medication adherence); r=.13, p < .01). A trend towards higher scores on the CES-D was found among those whose children had experienced rejection (mean=12.4, SD=10.9) in comparison to those who did not (mean=9.1, SD=8.6; p=.07).

Conclusions

Caregivers' PTSS were not a risk factor for poor child outcomes in this cohort, whereas caregivers' depression symptoms were associated with nonadherence. These findings suggest that symptoms of depression as opposed to PTSS in caregivers confer greater risk for child well-being and therefore may be a priority for identification and intervention.

PREGNANT AND POSTPARTUM WOMEN'S AWARENESS OF EXISTING COMMUNITY SUPPORT PROGRAMS

Danae Dinkel, Ph.D., Kailey Snyder, MS, Sofia Jawed-Wessel, Ph.D.

University of Nebraska at Omaha, Omaha, NE

Background: Research consistently provides evidence that mothers have a critical role in the well-being of their children and the family as a whole. Specifically, a mother's mental and physical health is an integral component to her family's well-being. In order to ensure communities are providing programs that meet the mental and physical needs of mothers, it is imperative to understand perceptions of available programs for mothers as well as their desire for additional programs.

Purpose: The purpose of this study was to determine the awareness of existing community programs that pregnant and postpartum women are aware of and their desire for related programs.

Methods: Women who were pregnant or up to one-year postpartum (n=527) were recruited primarily through social media to complete a 32-question survey within a Midwestern community. The questionnaire contained several open-ended questions regarding use of current programs, awareness of other programs they did not use, and desired information they felt could help them to become better parents. Data were analyzed using a content analysis approach.

Results: Less than have of all mothers (43.8%) reported participating in a program that provides assistance or support to mothers who are pregnant or up to one year postpartum. Of those who participated, mothers primarily took part in governmental programs such as WIC (41.1%) or breastfeeding support groups (17.7%). A portion of women (26.1%) noted they were familiar with other programs (35.8%) but did not use them because their services were not needed (23.4%), they had no time (15.2%) or they didn't qualify (13.9%). Importantly, 46.8% of women reported not participating in any programs and 32.1% of women reported not being aware of any programs that provide support for this population. Almost a quarter of all women reported their primary needs for more information were in the areas of parenting concerns (e.g., discipline, starting solid foods) and mental or emotional support (e.g., stress management, support groups for single or working moms).

Discussion: A third of women were not aware of programs that could support them and their primary need for more information (parenting concerns and mental/emotional support) did not align with the programs that women were primarily aware of. Efforts are needed to ensure that 1) community programs are available that meet women’s needs and/or 2) women are aware that these programs exist.

PRELIMINARY EFFICACY OF A PILOT INTERVENTION FOR EMOTIONAL OVEREATING AND BINGE EATING AMONG ADOLESCENTS

Rebecca C. Kamody, M.S.[1], Idia B. Thurston, PhD[2], Elvin T. Burton, PhD, MPH[3]

[1]The University of Memphis, Memphis, TN; [2]University of Memphis, Memphis, TN; [3]Le Bonheur Children's Hospital / University of Tennessee Health Science Center, Memphis, TN

Background: Overeating to cope with stress develops in adolescence and may progress into binge eating disorder (BED) in early adulthood. Emotional overeating (i.e., eating in excess to soothe emotions) can be conceptualized as a subclinical symptom of BED that can lead to physical and mental health risks and thus it merits intervention among youth. The affect regulation model, in which overeating occurs in an attempt to regulate emotions, is an explanatory model for emotional overeating and binge eating (i.e., eating large amounts of food in a short time with loss of control). The model is consistent with a Dialectical Behavior Therapy (DBT) approach. In this study, we examined a DBT skills intervention for emotional overeating in adolescents and young adults (AYA).

Method: AYA aged 14-18 were recruited from a pediatric hospital to participate in a 10 week outpatient DBT skills group which introduced mindfulness, distress tolerance, emotion regulation, and interpersonal effectiveness, all in the context of emotional overeating. Three cycles were implemented (final post-attrition N = 9 [n per group = 3]; 100% Black, 67% Female; M_{age} = 15.22 years). AYA completed the Emotional Eating Scale for Children and Adolescents (EES-C), Eating Disorder Examination Questionnaire (EDE-Q), and Binge Eating Scale (BES) at baseline and post intervention.

Results: Baseline to post intervention means and standard deviations were compared. Mean scores on the EES-C decreased from 48.33 (SD = 16.45) to 44.33 (SD = 19.58; Cohen's d = 0.22), the EDE-Q Global Score decreased from 3.28 (SD = 1.20) to 2.71 (SD = 0.84; d = 0.55), and the BES decreased from 11.67 (SD = 10.10) to 8.33 (SD = 7.16; d = 0.38). Mean binges per month decreased from 6.00 (SD = 6.36) to 4.00 (SD = 6.10; d = 0.32), and the number of participants meeting BED criteria decreased from five to three.

Discussion: Findings support the preliminary efficacy of an outpatient DBT skills group for decreasing binge eating and emotional overeating in AYA. This streamlined modality provides opportunities for individuals with fewer economic resources to pursue needed treatment and

thus may increase scalability. Future directions include conducting a well-powered randomized controlled trial to determine intervention efficacy.

PRENATAL CARE AND PREGNANCY-RELATED OUTCOMES AT CHULA VISTA MEDICAL PLAZA

Nicole Villa, MPH

San Diego State University, San Diego, CA

ABSTRACT

Background: The CenteringPregnancy model is a nationally recognized prenatal care program that emphasizes education, risk assessment, and supportive care in a group environment. Assessing outcomes between women in CenteringPregnancy and women in traditional care will shed light upon the possible benefits of group prenatal classes for a population of predominantly Latina women. Previous research has found the CenteringPregnancy model to be associated with lower rates of preterm delivery, lower rates of low birth weight babies, and higher breastfeeding rates, when compared to traditional care. However, these findings have been mixed among Latina women.

Objective: To determine if women in the CenteringPregnancy program at Chula Vista Medical Plaza (CVMP) and women in traditional care at CVMP have different pregnancy outcomes.

Methods: Through an audit of electronic medical records (EMRs), outcomes between women in two different types of prenatal care were evaluated. Indicators and outcomes that were evaluated include: maternal weight gain, preterm delivery, infant birth weight, Apgar scores, feeding type at discharge, and feeding type at follow-up. Chi-squared and t-tests were used to test for differences between the two groups.

Results: Women in the two groups differed significantly in terms of risk level (*p*pp=.083), the percentage of low birth weight (LBW) infants (0.0% for Centering versus 10.2% for traditional care, *p*=.028), and exclusive breastfeeding at discharge (71.2% for Centering versus 39.0% for traditional care, *p*=.014). No significant differences were found between the two groups for preterm birth, Apgar scores, or breastfeeding rates at follow-up.

Conclusion: The CenteringPregnancy program may offer certain benefits to mothers and their infants. Future directions in this area should include a qualitative component that explores the opinions of the mothers and the providers involved in the CenteringPregnancy program.

Keywords: prenatal care, group prenatal care, CenteringPregnancy, pregnancy

MINDFULNESS, YOGA PRACTICE, AND WELL-BEING: PREDICTING SELF-REGULATION OVER A STRESSFUL TRANSITION

Lucy Finkelstein-Fox, B.A.[1], Crystal L. Park, PhD[2], Kelly Stoldt, Undergraduate Student[1]

[1]University of Connecticut, Storrs, CT; [2]University of Connecticut, Storrs Mansfield, CT

Mindfulness has been associated with well-being in many domains, and may be especially adaptive during periods of high stress and adjustment, such as the transition to college (Jimenez et al., 2010). Yoga practice, which often includes aspects of mindfulness, has also been suggested as a means of promoting well-being during periods of stress (Netz & Lidor, 2003). However, few studies have examined the roles of either mindfulness or yoga practice in reducing distress during stressful transitions. In order to better understand the connections between mindfulness, well-being, and experience with yoga in the context of stress, the present study examined these variables in a sample of first-year undergraduates.

Online surveys were administered to 157 undergraduates at the beginning and end of their first semester (M age=17.8; 80% female; 79% White). At semester start, students completed self-report measures of mindfulness (CAMS-R, Feldman et al., 2007), experience with yoga practice (yes/no and how often), and emotional (depression, anxiety, and stress; DASS-21, Lovibond & Lovibond, 1995) and spiritual (meaning/peace and faith; FACIT-Sp, Peterman et al., 2002) well-being. At semester end, well-being was re-assessed.

On average, emotional well-being did not change significantly across the semester, but average levels of meaning/peace and faith both decreased (ts (128) =2.20 and 2.16, ps= .03). Regression analysis revealed that mindfulness was negatively associated with individual increases in depression, anxiety, and stress (βs = -0.17, -0.17, and -0.16, ps< .05) over the semester, such that greater person-level mindfulness predicted smaller increases in symptomatology. In contrast, mindfulness was not associated with changes in spiritual well-being. Prior experience with yoga, reported by 55% of participants, was not associated with mindfulness or measures of well-being other than depression (β= -0.15, p < .05). Just 2% (N=3) of participants reported a current weekly yoga practice.

Despite its well-established association with well-being in the literature, mindfulness appeared to protect only against reductions in emotional, and not spiritual, well-being in our sample. Experience with yoga practice also appeared to protect against increases in depression, but was not strongly associated with mindfulness; however, very few participants had a regular weekly yoga practice, which may yield the greatest benefits for self-regulation.

The finding that mindfulness and experience with yoga were both somewhat predictive of emotional well-being over a period of stressful adjustment suggests that both may be helpful to include in interventions and programming targeted at new college students. These findings did not extend to spiritual well-being, however, and future research is needed to examine other variables that may promote resilience in spiritual domains.

NEUROPHYSIOLOGICAL INVESTIGATION ON DIFFERENTIAL EFFECTS OF COMPUTER-GENERATED-MODAL MUSIC – IMPLICATION FOR MUSIC THERAPY

Tadashi Kato, Ph.D., Timothy S. Rice, Shane M. Spencer, Dylan J. Thomas-Rogers, Kayla M. Kerns

Fairmont State University, fairmont, WV

Objective: The present study examined the neurophysiological effects of seven modal music (Ionian, Dorian, Phrygian, Lydian, Mixolydian, Aolian, & Locrian). **Method:** Thirty-three healthy adults (12 men & 21 women) listened to seven modal music generated by FractMus software (2-minute-long each) and their 16-channel-electroencephalogram (EEG), pulse wave, electrodermal activity, and respiration rates were measured. Fast Fourier Transformation (FFT) was applied to each of the EEG channels, leading to the mean power computation at alpha (8-13 Hz) and beta (13-30 Hz) frequency bands. FFT was also applied to pulse-wave interbeat intervals (IBIs) for the evaluation of autonomic nervous system, while pulse rate itself was also submitted to further analyses. Subjects rated their six basic emotions on 10-point-Likert scales (happiness, sadness, anger, surprise, fear, & disgust) before and after each music and the differences between pre- and post- ratings were computed. Mixed Design ANOVAs ('gender' as between and 'measurement stages' as within factors) were applied to each parameter. **Results:** Mixed Design ANOVAs for the mean power of alpha frequency bands elicited significant main effect on F7 (left frontal lobe) while listening to Ionian and its post-hoc-t-test with Bonferroni correction suggested that females had higher alpha power than males ($p < .05$). Mixed Design ANOVAs for the mean power of beta frequency band demonstrated a stage difference on T5 (left temporal lobe) where beta power was significantly higher during Locrian than during Mixolydian ($p < .05$). A Mixed Design ANOVA for pulse rate demonstrated a significant interaction between gender and measurement stages ($p < .05$) and its post-hoc t-tests with Bonferroni correction suggested that males had significantly lower pulse rate than females during both Phrygian and Aolian ($p < .05$). Further, Mixed Design ANOVAs for Basic Emotions demonstrated the main effects of 'Happiness' and 'Disgust' ratings ($p < .05$) and their post-hoc-t-tests suggested that ‘Happiness’ was higher in females than in males during Phrygian ($p < .05$) while ‘Disgust’ was lower in males than in females during Aolian ($p < .05$). **Discussion:** The results suggested differential physiological response depending on the musical modes, which also interacted with gender. Higher alpha power in females during Ionian suggested that women were more relaxed while listening to Ionian, whereas higher beta power during Locrian than during Mixolydian suggested that Locrian produced higher mental tension, regardless of gender. Higher pulse rate in females during Phrygian suggested higher excitement in women during Phrygian, while lower pulse

rate in males during Aolian implied the increased calmness in men during Aolian. Further investigation will be the key to a deeper understanding of the mechanism behind the effective music therapy.

YOGA OFF THE MAT: A DAILY DIARY STUDY EXAMINING THE EFFECTS OF YOGA TO ENHANCE SELF-COMPASSION AND SOCIAL CONNECTEDNESS

Moé Kishida, MS[1], Steriani Elavsky, PhD[2]

[1]The Pennsylvania State Univeristy, State College, PA; [2]Masaryk University, State College, PA

While the yoga literature has certainly proliferated over the past decades demonstrating a wide array of salutary benefits, there is a lack of research examining the relational outcomes that may be derived from yoga practice. Moreover, the majority of previous research has been conducted in lab-based contexts; hence, whether the benefits of yoga translate “off of the mat” in the context of one’s day-to-day life has yet to be determined. Through a daily diary approach, the overarching aim of the present study was to examine the daily effects of yoga practice on the relational variables of self-compassion and social connectedness. Community-dwelling yoga practitioners (N = 110; age range 18-76 years) with a yoga practice of at least once a week were recruited for a 21-day daily diary study. At the end of the day, practitioners were asked to complete daily Internet surveys which included questions in regards to one’s yoga practice and relational items of self-compassion and social connectedness. Multilevel analyses indicated substantial variability on self-compassion (ICC= .38) and social connectedness (ICC= .39) on a day-to-day basis at the within-person level. In concurrent models that controlled for weekend effects, mindfulness, and yoga experience, yoga practice days were associated with greater self-compassion (B=2.59, $p< .05$). A within-person association with the duration of yoga practice and self-compassion also emerged such that practitioners reported greater self-compassion on days in which one practiced more yoga (minutes) than what is compared to one’s usual (B=1.41, p < .05). In multilevel models predicting social-connectedness, yoga practice days and the duration of yoga practice demonstrated no effects on one’s daily social connectedness (B=.19, p=.76 ; B=.04, p=.92; respectively). In this community-based sample of yoga practitioners, these results suggest yoga practice has positive influences in boosting one’s self-compassion on a day-to-day basis, which may lead to enhanced health and wellbeing outcomes.

GOAL-SETTING IN DAFNE: CONTENT AND FIDELITY EXPLORATION OF THE GOAL-SETTING COMPONENT IN A TYPE 1 DIABETES EDUCATION PROGRAMME.

Milou Fredrix, BA, MsC[1], Molly Byrne, BA, MsC, PhD[2], Jenny McSharry, B.A., H.Dip., M.Sc., Ph.D[2]

[1]National University of Ireland, Galway, Galway, Ireland, Galway, Ireland; [2]National University of Ireland, Galway, Galway, Galway, Ireland

BACKGROUND

Type 1 diabetes (T1DM) is one of the most challenging public health issues (Guariguata et al., 2014). T1DM treatment includes continuous self-management by the patient (Ahola & Groop, 2013). To provide patients with knowledge, and skills, diabetes self-management programmes such as ‘The Dose Adjustment For Normal Eating (DAFNE)’ have been arising. The DAFNE programme is quickly becoming part of routine care globally, and is now available in Europe and Australia while looking into expanding to the United States. The programme includes 5 days of structured education in T1DM self-management, with an emphasis on insulin dose adjustment using flexible dietary intake and detailed estimation of dietary carbohydrate intake as the basis for insulin dosing. However, while DAFNE is well received, it often fails to help patients instil key self-management practices into their lives on a long term basis (Speight et al., 2010). A core component of DAFNE is goal setting. Goal setting can help facilitate long term behaviour change (Miller & Bauman, 2014). However, little is known about how the DAFNE goal setting component is delivered and received. To improve and further implement DAFNE, putting this goal setting session under a microscope and exploring its inner mechanisms could be beneficial. A first step in exploring the goal setting session, is assessing its content and levels of intervention fidelity (the extent to which an intervention is implemented as intended). Since DAFNE is delivered by different educators, variation in fidelity is expected. Therefore, we aimed to explore the content and the fidelity of delivery of the goal-setting session in DAFNE.

METHOD

The content of the goal setting session, as defined in the DAFNE handbook for delivering the intervention, was coded using a reliably taxonomy of behavioural change techniques (BCTs; Michie et al., 2013). A checklist was developed, listing the identified BCTs. To assess fidelity of delivery of the BCTs, a set number of DAFNE goal-setting sessions were observed and audio-recorded. Patient participation was observed and qualitatively described.

RESULTS
‘Problem solving’ and ‘action planning’ were the most frequently identified BCTs within the goal setting session. Preliminary results reveal different levels of intervention fidelity across various educators. Furthermore fidelity per BCT varied as certain BCTs had higher levels of fidelity than others.

CONCLUSIONS
This study showed that the content of the goal-setting component of DAFNE is relatively limited and could benefit from additional behaviour change techniques. Furthermore, the importance of fidelity checks for the delivery of interventions is highlighted, as differences in quality of intervention delivery increase the possibility of inconsistent intervention effects (Michie, Jochelson, Markham, & Bridle, 2009).

COMPARING DIABETIC & HEALTHY OLDER WOMEN ON DESIRE TO IMPROVE HEALTH, HEALTH SCREENING BEHAVIORS, AND COGNITIVE FUNCTIONING

Luciana Lagana, Ph.D.[1], Kimberly Arellano, Abigail Pajulas, none[2], Alberto Zacarias, Melissa Martinez, N/A[3]

[1]CSUN, Chatsworth, CA; [2]California State University Northridge, Glendale, CA; [3]California State University Northridge, Canyon Country, CA

The incidence of breast cancer peaks in late life; thus, breast cancer screening is important for older women, and particularly for those already living with a serious health condition such as diabetes. The latter increases the risk of breast cancer and breast cancer mortality, thus adequate breast cancer screening in older women with this condition is important. Moreover, establishing a significant relationship between diabetes and cognitive impairment would have important clinical and public health implications. The findings of published research suggest that diabetic as well as pre-diabetic older women often experience impaired cognitive performance and are at greater risk for developing cognitive impairment: this represents a significant threat to their ability to follow medical advice and to keep their diabetes in check. To our knowledge, there are no studies on diabetic versus healthy older women concerning receiving preventative medical services. To fill a gap in the literature, we compared 36 diabetic older women to 36 healthy older women (i.e., respondents who reported having no physical illnesses) on: desire to improve their health (hypothesized as being higher in the diabetes group), receiving mammograms and regular health screenings (analyzed without any hypotheses, due to the lack of evidence on this topic), as well as cognitive functioning (hypothesized as lower in the diabetes group, based on prior research findings). Participants (N=72, Mean age= 69.29, SD= 6.579, Age Range=50-90) were multiethnic, non-institutionalized women over the age of 50 residing in Los Angeles County who completed our research packet. The latter contained the first author's demographics List and the Older Women's Health - Qualitative Protocol, as well as the well-known MiniCog (Borson, 2000). The results of an ANOVA showed that, as hypothesized, diabetic women desired to improve their health more than the women in the control group [F (1,70)=11.87, $p < .05$, $\eta 2$=.15]. Additionally, upon implementing Chi-square analyses, we found that diabetic respondents were significantly more likely to receive mammograms [$X2$(1)=5.87, $p < .05$] and general health screenings [$X2$(1)=4.51, $p < .05$] than healthy respondents. Surprisingly, in contrast with prior literature's findings, cognitive health in the diabetic group obtained marginal significance in an ANOVA as being better than the cognitive health of the control group [F(1,68)=3.30, $p < .10$, $\eta 2$=.05].

DEPRESSION AND DIABETES SELF-CARE AMONG BLACK AMERICAN ADULTS: MODERATING EFFECTS OF REASONS FOR LIVING AND SPIRITUAL COPING

Rheeda Walker, Ph.D.[1], Mary O. Odafe, M.A.[2], Judy H. Hong, B.A.[1], David Talavera, MA[1], Chris Barr, Ph.D.[1], Aanand Naik, MD[3]

[1]University of Houston, Houston, TX; [2]University of Houston, TX, Houston, TX; [3]Baylor College of Medicine, Houston, TX

African Americans are significantly more likely than European Americans to be diagnosed with Type 2 Diabetes Mellitus (T2DM) and to experience severe diabetes-related complications; this is true also when SES is taken into consideration (Tull & Roseman, 1995). Compared to other ethnic groups, African Americans are significantly less likely to meet recommended blood pressure and LDL cholesterol goals (Casagrande et al., 2014).

Compared to non-diabetic adults, adults diagnosed with T2DM are also twice as likely to be depressed (Anderson et al., 2001; Nouwen et al., 2010). Importantly, higher levels of depression symptomatology are associated with decreased self-care behavior and considerably higher health care costs (Egede, Zheng, & Simpson,2002; Lustman et al., 2000). Among African Americans, depression is more debilitating in part because African American adults are among those least likely to seek clinical care for depression-related pathology (Williams et al., 2007).

Though there have been some efforts to address the dual need for integrated depression and diabetes care (Bogner et al., 2012), unique cultural factors associated with self-care among African Americans diagnosed with T2DM are understudied. We hypothesize that having “reasons” for living (RFL) buffers the association for depression symptomatology and self-care among African American adults.

Data were collected for 211 community-based, African American men and women (M_{age}=55.07, *SD*=8.79) who were prescribed medication or taking insulin for T2DM. Participants completed the Summary of Diabetes Self-Care Activities measure (SDSCA) as well as self-reported, well-validated measures of depression symptoms and reasons for living. The majority of participants (n=118; 51%) reported having graduated from high school or having some college or specialized training. Female participants were the majority (n=154; 73%) of the sample.

We found that higher ratings of depression symptoms were associated with poorer diabetes self-care for the total sample of African American women and men [b=-.31, p=.010]. Follow-up stratified analyses showed that, for women, there was a significant main effect for depression [b=-.32, p=.047] and a depression X RFL interaction predicting self-care that approached significance [b=.25, p=.074]. We followed up on this potential interaction effect by plotting self-care and depression symptoms for women who reported high and low RFL. Based on that plot, it appeared that depression was related to self-care for women who reported low [r=-.57, p < .001] but not high [r=-.06, p=.625] RFL. In stratified analyses, RFL did not moderate the depression - self-care association for African American men perhaps due to the limited sample size.

Future studies should examine how cognitive bias can impact self-care behavior particularly for African Americans who are diagnosed with T2DM.

EAT, MOVE, LIVE: A FEASIBILITY STUDY MEASURING BEHAVIORAL AND BIOLOGICAL OUTCOMES IN MEDICALLY VULNERABLE

Mayra Serrano, MPH[1], Marisela Huerta, CHES, BS [1], Kimlin Ashing, Ph.D[2], Katty Nerio, BS [1]

[1]City of Hope, Duarte, CA; [2]City of Hope National Medical Center, Duarte, CA

Background: Despite the tremendous need and enormous efforts to develop public health recommendations for appropriate exercise levels, especially among families at risk for diabetes, we still have no exact prescription to give the public. Obesity, unhealthy diet and physical inactivity are linked to increased diabetes and cancer risk. Our Eat Move Live (EML) program was implemented in collaboration with the City of Duarte and the Duarte Unified School District (DUSD). The goal of the program focuses on diabetes and chronic disease prevention through lifestyle, nutrition and physical activity. The program aimed to assess the possible positive effects of a nutrition and exercise intervention on metabolic components among underserved, Latino women at high-risk of diabetes.

Methods: The EML intervention is a series of weekly, culturally and community informed nutrition and physically activity workshops delivered by health educators. The target population is low-income Latina mothers who have elementary-aged children in the DUSD. Demographically matched schools were assigned to the intervention (n=2) or wait-list control (n=2). Participants were recruited through passive (fliers, home mailer) and active recruitment strategies. The intervention approach was community engaged, and school-based. The intervention design was a feasibility trial with a pre-test – post-test, wait-list control. Participant's weight and A1c was measured at baseline and following the 3month intervention.

Results: A total of 40 participants were enrolled in the study, 20 in the intervention and 20 in the wait list control conditions; there was just 1 attrition from the control-group. All participants reported elevated A1c and were at least over weight. As a result of participating in the EML program, 69% of intervention group saw a significant reduction of A1c compared to 28% control group (p

Conclusion: Our study shows that a community responsive approach implementing cultural exercise, nutrition, shopping and food preparation knowledge and skills combined with social support enhanced intervention acceptability and effectiveness. The results support our hypotheses that increasing level of exercise to CDC recommendations and providing nutrition

and physical activity skill-building workshops can improve A1c and BMI status among Latinas at high-risk of diabetes.

EFFECT OF DOSE OF BEHAVIORAL OBESITY TREATMENT ON HBA1C IN ADULTS WITH PREDIABETES

Vivian Bauman, B.S.[1], Aviva H. Ariel-Donges, M.S.[2], Eliza L. Gordon, M.S.[2], Kathryn Ross, PhD, MPh[2], Michael Perri, PhD, ABPP[2]

[1]Universtiy of Florida, Gainesville, FL; [2]University of Florida, Gainesville, FL

Introduction: Standard behavioral weight-loss interventions typically produce an 8-10% reduction in body weight and are associated with reduced diabetes risk. The optimal intensity (i.e., dose) of behavioral treatment for achieving maximum glycemic improvements remains unclear. Previous findings from the Rural LITE Trial indicated that moderate (16 sessions) and high (24 sessions) doses of treatment produced significantly larger weight losses at 6 months than low dose (8 sessions) treatment and a diet education control group (8 sessions). In this study, we examined the effect of dose of behavioral treatment on changes in HbA1c (A1c) and explored the mediating effect of weight loss.

Methods: The study included 315 adults with obesity (female=77%, Caucasian=78%; M±SD age=55±11 years, BMI=36.2±3.9 kg/m^2) who exhibited baseline A1c levels in the prediabetes range (5.7-6.4%). Intervention content was the same for the high, moderate, and low dose treatments. Participants in the control group received diet education without behavioral strategies. A1c and weight were measured at baseline and month 6. The effect of treatment dose on A1c was evaluated by a one-way ANOVA with Bonferroni adjusted post-hoc testing. The mediating effect of weight loss on A1c change was evaluated using the Preacher and Hayes model.

Results: There was a significant main effect of treatment dose on weight loss ($p < .001$) and on A1c (p=.005). A1c reductions were significantly greater in the high (-.131%) vs. the control (-.003%) conditions (p=.004). The association between treatment dose and A1c (p=.003) became non-significant when weight change was added to the model (p=.493). The indirect effect of dose through weight loss was significant (95% CI: .019-.043), suggesting full mediation.

Discussion: We found that a high dose of behavioral weight-loss treatment was required to achieve significant reductions in A1c compared to a diet education control group and that the relationship between treatment dose and A1c was fully mediated by weight loss. While most lifestyle interventions implement a moderate dose, these findings suggest that a higher dose of treatment resulting in greater weight loss may be necessary to maximize improvements in diabetes risk.

EXPLORATORY DEVELOPMENT OF A METHOD TO CLUSTER ADULTS WITH TYPE 2 DIABETES BASED ON SELF-MANAGEMENT STYLE

Bryan Gibson, DPT, PhD[1], Leah Yingllng, BS[2], Yue Zhang, PhD[1], Jorie Butler, PhD[3]

[1]University of Utah, Salt Lake City, UT; [2]University or Utah Department of Biomedical Informatics, Salt Lake City, UT; [3]University of Utah, SALT LAKE CITY, UT

Background: Adoption and engagement with Type-2 Diabetes (T2DM) self-management interventions vary across individuals. This may be related to the degree to which the intervention's mode of delivery and functions match the individual's self-management style.

The goal of this exploratory study was to determine whether a combination of a modified q-sort survey and k-means analysis could be used to develop a brief questionnaire that would cluster adults with Type 2 Diabetes according to their self-management style.

Methods: We conducted a web-based survey among adults with T2DM. Participants sorted 31 statements using a modified q-sort methodology. The first two sets of statements addressed intentions to change current self-management behaviors and individuals' desire for external support. The next five sets of statements addressed self-management functions that interventions often target: Teaching, Goal-setting and Planning, Feedback, Reminders, and Social Support. Participants sorted each statement to represent the degree to which the statement reflected their way of thinking on a bipolar scale (i.e., strongly agree to strongly disagree). For example, in the set of statements related to social support, participants sorted statements such as, "I am more likely to attend a support group to meet other people with diabetes;" and "I am more likely to join an online social network to meet other people with diabetes."

A k-means cluster analysis was performed to extract homogenous groups for each self-management function. The Big 5 Personality Traits and Regulatory Focus (collected at the start of survey) were assessed as cluster discriminators.

Results: For each self-management function, the k-means algorithm divided the cohort (n=1783, age= 59±10 years; 64% female; mean Hemoglobin A1c=7.4±1.6%) into two clusters: "Techie" and "Old style." Individuals were varied in their style: of the 64 possible permutations of Techie vs. Old style for each of 5 self-management functions, the ten most frequent clusters only accounted for 55% (n=977) of the sample. Interestingly, age,

socioeconomic status, personality traits and regulatory focus did not differ significantly between clusters.

Conclusions: A modified q-sort methodology combined with a k-mean clustering algorithm appears to capture individual differences in T2DM self-management style. Future work to test the resulting brief questionnaire will be discussed.

SLEEP DURATION, POSTPRANDIAL METABOLIC FUNCTION, AND THE ROLE OF INSULIN RESISTANCE IN NONDIABETIC INDIVIDUALS

Karin Garcia, M.S.[1], William Wohlgemuth, Ph.D.[2], Ele Ferrannini, M.D.[3], Andrea Mari, Ph.D.[4], Alex Gonzalez, B.A.[1], Theresa Dimascio, B.A.[5], Armando Mendez, Ph.D.[1], Ronald Goldberg, M.D.[1], Neil Schneiderman, Ph.D.[1], Barry Hurwitz, Ph.D.[1]

[1]University of Miami, Miami, FL; [2]Miami VA Healthcare System, Miami, FL; [3]University of Pisa, Pisa, N/A, Italy; [4]Institute of Neuroscience- National Research Council, Padua, N/A, Italy; [5]University of Miami, Coral Gables, FL

In preclinical diabetic dysmetabolism, there is an insulin secretion upregulation during postprandial periods to compensate for diminished insulin sensitivity. It is not known whether there is an association of shortened sleep duration with elevated postprandial insulin secretion in nondiabetic persons, or whether this relationship is moderated by insulin sensitivity. This study examined these interrelationships, while controlling for age, sex and cardiovascular risk factors (smoking status, visceral adiposity volume, systolic blood pressure, triglycerides, total cholesterol/HDL ratio), and postprandial metabolic indices (β-cell glucose sensitivity, early insulin secretion rate sensitivity, and insulin secretion potentiation). The 143 healthy, nondiabetic men and women, aged 18-55 years, had no diagnosed sleep, psychiatric or cardiometabolic conditions. Habitual sleep function was assessed using actigraphy for 1 week. Insulin sensitivity was derived using a euglycemic hyperinsulinemic clamp. Postprandial metabolic indices were derived using a 2-day in-patient evaluation, wherein serial blood sampling was performed before and during 4 mixed-meal tests/day. Meals had identical fat and protein content, but carbohydrate content was manipulated. Hence, in randomized order, meals included standard carbohydrate load (300 kcal) on one day, and double carbohydrate load (600 kcal) on the other day. Metabolic indices were derived using quantitative decomposition modeling. Regression analyses assessed carbohydrate loading separately, examining the prediction of total daily postprandial insulinemia by sleep duration (SDur), insulin sensitivity (IS), and the interaction of these factors (SDur x IS). For the 300 kcal/meal day, the analysis indicated a significant SDur x IS interaction ($\beta=0.149$, $p=.031$) and a significant main effect for IS ($\beta=-0.394$, $p < .001$). For the 600 kcal/meal day, both the SDur x IS interaction ($\beta=0.161$, $p=.034$) and main effect for IS ($\beta=-0.486$, $p < .001$) remained significant. In sum, these findings show that the association of shorter sleep duration with more elevated postprandial insulinemia is linked with poorer insulin sensitivity in otherwise healthy persons, independent of age, sex, traditional cardiovascular risk factors and other metabolic measures. Thus, preclinical diabetic risk, when poorer insulin sensitivity emerges, may not only include a

compensatory adaptation of postprandial insulin regulation, but also a decrease in sleep duration.

USING THE TRANSTHEORETICAL MODEL TO PROMOTE BEHAVIORAL CHANGE WITH DIABETES SELF MANAGEMENT

Kerry Littlewood, Ph.D., MSW[1], Robert Sherman, na[2], Frances Russell, RN[2], Kerry Littlewood, Ph.D., MSW[3], Abhishek Pandey, MD[4]

[1]AAJ Reseaarch & Evaluation, Inc., Seminole, FL; [2]St. Anthony's Hospital, St. Petersburg, FL; [3]AAJ Research and Evaluation, Seminole, FL; [4]University of Arizona, Seminole, FL

Background: Success in chronic disease self management education programs require lifestyle change and not all participants may find themselves ready or willing to modify their behavior. Few studies have examined the relationship between insufficient sleep and motivation for change in behavior for persons with type 2 diabetes mellitus.

Purpose: This study uses data from a Diabetes Self-Management Education Program to explore the relationship between insufficient sleep and the participant’s stage of behavioral change as identified by the transtheoretical model. This study will use descriptive and anova analysis to examine these relationships.

Results: One hundred and one persons with T2DM (mean HbA1c = 8.79 ± 2.42) participating in a DSME Program at a southern urban community non profit hospital enrolled in this study. The majority of these patients were obese (mean BMI=38.56±8.20) . Only 11% reported normal sleep, with 41% reporting short sleep (< 6 hours). Pre-contemplative stages of change were related to more insufficient sleep (69%) [x^2(3, N=97=8.67, p < .05].

Conclusions: Participants in a DSME program were more likely to be motivated to change their behavior when they reported adequate sleep. Future studies should more closely examine sleep quality and quantity to more discriminately articulate this relationship as it relates to people desiring to better control their diabetes. Future interventions could integrate healthy sleep hygiene education into existing DSME programs to improve participant’s motivation. This could potentially improve the successful uptake of life style modifications for persons with T2DM.

MERITORIOUS AWARD WINNER

A “DEFAULT OPTION” TO ENHANCE DIETARY QUALITY IN PARTICIPANTS IN THE SUPPLEMENTAL NUTRITION ASSISTANCE PROGRAM

Jaime Coffino, M.P.H., Julia M. Hormes, Ph.D.

University at Albany, SUNY, Albany, NY

Introduction: Diets consumed by participants in the Supplemental Nutrition Assistance Program (SNAP) are of relatively lower quality, compared to eligible non-participants, leaving them at increased risk for adverse health outcomes such as type II diabetes. The effectiveness of psychoeducation or use of monetary incentivizes to enhance diets in SNAP participants remains limited and cost can be prohibitive. In behavioral economics, the “default option” refers to the option a consumer selects if s/he does not make an active choice (e.g., opting out vs. opting in to organ donation programs). We sought to assess if use of a default option would result in healthier food purchases within the constraints imposed by SNAP, compared to monetary incentives and psychoeducation. **Methods:** Female undergraduates (*n*=53, mean BMI=24.26, *SD*=5.12, age 20.24, SD=5.49) filled out a baseline questionnaire and were then given a budget of $48.50 and instructed to purchase “nutritious, affordable, and tasty food for a week” using the online shopping service of a local grocery store (T1). Before completing the task again (T2) they were then randomized to: (1) receive a $10 “incentive” if they selected groceries that met recommended nutritional guidelines, (2) read an “educational” brochure adapted from materials currently utilized by SNAP, and (3) be presented with a “default” pre-filled online shopping cart containing a nutritionally balanced selection of groceries and told they could make changes as they wished. **Results:** There was a significant difference among the 3 groups in average daily calorie consumption (*F* (2, 49 = 3.76, *p* = .03). Average daily caloric consumption decreased in all three groups, but the default group had the largest decrease and was significantly different from the education group. There was a significant difference among the three groups in average daily sodium intake (*F* (2, 49) = 3.43, *p* = .04), and average daily cholesterol intake (*F* (2, 49) = 3.92, *p* = .03). The default group showed significantly greater decreases in calories and sodium compared to the education group and a significantly greater decrease in cholesterol compared to the reinforcement group. **Discussion:** Although the initial focus of SNAP was on providing sufficient quantities of food to program participants, the importance of the quality of the food made accessible to benefit recipients is thus becoming increasingly clear. SNAP currently uses education to promote healthy eating even though it appears that education may not be very effective. This data shows that research regarding default menus is necessary as it is the least costly intervention

option. Preliminary data suggests this option may be the most effective intervention strategy in reducing unhealthy decisions surrounding food choices.

A COMPARISON OF DIET-RELATED RISK FACTORS FOR CHRONIC DISEASE BETWEEN BLACK AND WHITE MEN: FINDINGS FROM NHANES, 2007 - 2012

Terry Thompson, DHA, Chelesea Singleton, PhD, Sparkle Springfield, PhD, Angela Odomsyoung, PhD

University of Illinois @ Chicago, Chicago, IL

Compared to men of different racial/ethnic backgrounds, African American men experience higher rates of chronic disease such as cardiovascular disease and type 2 diabetes. Diet quality has been shown to be a key risk factor for chronic disease. While gender differences in dietary quality are well documented, the research literature is limited on evidence-based results targeting dietary quality in men. Furthermore, literature on the diet quality of specifically African American men is sparse. Using cross-sectional data from the National Health and Nutrition Examination Survey (NHANES) years 2007-2012, this study aimed to examine difference in diet quality, nutrient intake, and household food security status between African American and White men. Data on 5,050 male participants (31.3% African American; 68.7% White) over 20 years old were extracted and analyzed. Information on demographics and household food security was self-reported by study participants. Information on dietary intake was collected via 24-hour recall. Healthy Eating Index (HEI) 2010 total and component scores were calculated for each participant. Multivariable adjusted linear regression models were used to determine if African American race was associated with HEI-2010 total score. Compared to White men, a higher percentage of African American men were obese according to their body mass index (37.8% vs. 34.0%; $p < 0.0001$. A lower percentage of African American men were food secure (67.1% vs. 80.6%; $p < 0.0001$. Mean dietary fiber intake (18.6g ve. 14.7g; $p < 0.0001$) and sodium intake (4,126.3mg vs. 3,725.9mg; $p < 0.0001$) for White men was significantly higher than African American men. Mean HEI-2010 total score was significantly lower among African American men compared to White men (46.4 vs. 48.9; $p = 0.0003$). After adjusting for demographics (e.g. age, education level, marital status) and body mass index, African American race was found to not be associated with HEI-2010 total score ($\beta = 0.35$; $SE = 0.60$; $p = 0.57$). In conclusion, while household food security may significantly differ between Africian American and White men, diet quality was similar after accounting for factors such as education level. Future research on this subject will highlight the importance of developing interventions that target nutrition education among African American men.

"WEIGHING" THE OPTIONS: ENHANCED SELF-AWARENESS OF BODY WEIGHT IMPACTS FOOD CHOICE

Katie Hodgin, MPH, MS, Dan J. Graham, PhD

Colorado State University, Fort Collins, CO

Though enhanced self-awareness has been shown to reduce transgressive behaviors like cheating, few studies have examined how self-awareness of a health indicator, body weight, impacts food selection. The present study investigated how short-term self-awareness enhancement of body weight influences the nutritional content of foods chosen and hypothesized that those who weighed themselves prior to (vs. after) food selection would choose foods lower in calories, saturated fat, and sugar. Two hundred and twenty students participated in the study at a laboratory featuring a mock grocery aisle with a range of slow-to-perish food items including fruit juice, cereals, chips, and pasta. Participants were randomly assigned to weigh themselves on a calibrated scale either before or after making a selection of four food items that they could have had the opportunity to take home with them by winning a raffle drawing. After selecting their four food items, all participants completed an electronic questionnaire assessing their demographic information and some basic information about the food items chosen. *T*-tests revealed that participants chose foods approximately 9% lower in calories ($t(217) = -2.50$, $p = 0.013$) and 18% lower in saturated fat ($t(217) = -2.61$, $p = 0.010$) when they were asked to weigh themselves before rather than after selecting their food items from the mock grocery aisle. Further results indicated that average sugar content in the food items chosen did not significantly differ as a function of when participants weighed themselves. Such findings are consistent with self-awareness theory, and hold important intervention implications by suggesting that consumers who are reminded of their body weight before a food choice is made may make more healthful decisions related to that choice.

APPLYING PROSPECT THEORY TO EATING: ENDOWED FOOD IS WORTH MORE

David Ede, Jr., BS[1], Misty AW Hawkins, Ph.D.[2], John Gunstad, PhD[3], Joel W. Hughes, PhD[3]

[1]Kent State University, RAVENNA, OH; [2]Oklahoma State University, Stillwater, OK; [3]Kent State University, Kent, OH

Applying Prospect Theory to Eating: Endowed Food is Worth More

David Ede, BS[1], Misty A.W. Hawkins, PhD[2],John Gunstad, PhD[1], Joel W. Hughes, PhD[1]

[1]Department of Psychological Sciences, Kent State University, Kent, OH

[2]Department of Psychology, Oklahoma State University, Stillwater, OK

Introduction

Dual process theories of decision making, such as Prospect Theory, have rarely been used to study eating behaviors. The “endowment effect” from Prospect Theory is evidenced when people place a higher value on something if they own it compared to if they do not own it, reflecting loss-aversion. The endowment effect has been demonstrated with non-food objects like mugs and pens, but it has not been applied to food items. Risk-sensitive Foraging Theory suggests that foods with greater energy density are preferred to foods with lower energy density. Deriving from Prospect Theory and Risk-sensitive Foraging Theory, we hypothesized that participants would rate owned / endowed snacks as higher in value, and that this effect would be stronger for energy dense foods.

Method

The present study comprised four conditions based on two factors: whether the presented food was endowed to the participant or not (ownership), and whether the food had high energy density (candy) or low energy density (vegetables). A total of 59 undergraduates (age=19.5; 72% women) were randomized to evaluate either a pint of candy or vegetables in a clear container, which were of equal retail cost. They were told they either “get to keep” or “don’t get to keep” the snack when they were done with the evaluation. Participants rated how much they believed the food to be worth and how much they would personally pay for their food item. ANOVA was used to examine the main effects and interaction of endowment and energy density on perceived food value, using body mass index as a covariate.

Results

Endowed items were valued more highly than non-endowed items, *F*(1,54)=4.188, *p*=.046. Participants ranked the vegetables as more valuable than the candy, *F*(1,54)=5.668, *p*=.021. Endowment and food type did not interact, *F*(1,54)=.027, *p*=.870.

Discussion

Our results are consistent with the endowment effect, such that participants placed a greater value on endowed food items. In contrast to our hypothesis, vegetables were consistently rated as more valuable than candy. Dual process theories such as prospect theory can be applied to eating behaviors, which may yield insights relevant to the obesity epidemic.

ATTENTIONAL MECHANISMS UNDERLYING LEARNING TO READ NUTRITION LABELS

Lisa S. Miller, PhD[1], Tanja N. Gibson, MS[1], Kara DeSouza, PhD[2]

[1]University of California, Davis, Davis, CA; [2]UC Davis, American River College, Sacramento, CA

Individuals who use nutrition labels tend to eat healthier diets (Ollberding et al., 2010), still, many individuals avoid using labels because they are too difficult or time consuming to read (Guthrie et al., 2015). Eye tracking methodology has been used to shed light on the attentional mechanisms underlying nutrition label comprehension (e.g., Bialkova et al., 2014; Miller et al., 2015), however, relatively less work has focused on eye movements while learning to read nutrition labels. In the present study, we examined changes in attention as individuals completed a nutrition label reading training tool.

40 college students (75% female) participated in the study. The training began with a 7-minute slide presentation on general nutrition information, followed by a label reading task requiring participants to select the more healthful product using two nutrition labels, presented side-by-side on a computer screen. Participants used a mouse to select their choice, and were told if their choice was correct or incorrect before moving on to the next comparison. There were 24 comparisons in each of 3 blocks of practice. Eye movements were monitored using a video-based eye tracker to determine if training is accompanied by a reduced number of sweeps between choices prior to making a decision, reflecting greater efficiency. Participants provided usability ratings on the training tool at the end of the session.

Individuals improved their accuracy across practice blocks, $t(35)=7.1$, $p < .001$, with the greatest improvement from block 1 to 2, $t(35)=5.8$, $p < .001$, but significant improvement also evidence from block 2 to 3, $t(35)=2.2$, $p < .05$. Importantly, eye tracking data showed significant decreases across the 3 blocks in the number of sweeps between the labels for both the to-be-limited nutrients (e.g., saturated fat), $t(35)=3.4$, $p < .01$, and the non-limited nutrients (e.g., protein), $t(35)=4.5$, $p < .001$. Usability ratings indicated that participants generally agreed that the tool was very easy or easy to use (76%), very useful or useful (77%), and was fun (72%). Participants also indicated that it was very likely or likely (88%) that they would continue to improve their skills if they continued practicing. In general, label training can increase accuracy and reduce attentional demands associated with label reading. Additional research is needed to determine whether increased efficiency can translate into sustained, healthier food choices.

DEVELOPMENT OF LA VIDA INC, A MOBILE-ENABLED INTERACTIVE COMIC TO PROMOTE HEALTHY EATING AMONG LOW-INCOME HISPANIC YOUTH

Katrina F. Mateo, MPH[1], Jennifer R. Furman, MS[2], Olivia Barata-Cavalcanti, MPH, MIA [3], May May Leung, PhD, RD[4]

[1]City University of New York, Graduate School of Public Health and Health Policy, New York, NY; [2]City University of New York, Hunter College Nutrition Program, Brooklyn, NY; [3]City University of New York, Graduate School of Public Health and Health Policy, Brooklyn, NY; [4]City University of New York, Hunter College Nutrition Program, New York, NY

Background: Childhood obesity continues to be a serious clinical and public health issue in the US, with increased prevalence particularly among low-income Hispanics. Effective, yet innovative interventions are needed to capture the attention of children in a technology and media-dense environment. Digital health interventions have potential to reach and engage with culturally diverse and hard-to-reach communities. We aimed to: 1) identify factors influencing child dietary behaviors, 2) assess technology use, and 3) identify preferred character profiles based on popular youth media.

Methods: Hispanic parent-child dyads were recruited using convenience sampling in East Harlem, New York City. Participants completed a survey and participated in a semi-structured interview. Question domains included: knowledge, attitudes and practices around eating/health and technology, popular media/storylines, preferred character profiles, and possible intervention components. Audio-recordings were transcribed and translated, and analyzed by two coders using Dedoose software.

Results: Thirteen dyad and two triad interviews were conducted (parent: n=15, mean age 37.4 ±5.1; child: n=17, mean age 10.4 ±1.3). Most child participants were female, self-identified Mexican and bilingual; all were US-born. All reported their mother being primarily responsible for food shopping and preparation. Family food-related practices, culture, and food taste/texture strongly impacted child eating behaviors and food preferences. Nearly all children and parents identified eating fruits/vegetables and drinking water as the most important habits/behaviors for being healthy. All children used mobile apps regularly mainly for homework, games, and watching videos. Children preferred characters who evolve over time to develop traits or powers to help others, fight evil, or solve problems. Children expressed willingness to receive information to help make healthy choices and understand the benefits of different foods through interactive gameplay. They preferred built-in

motivation (e.g. unlocking game elements) as opposed to external/monetary incentives to encourage continual health tool use.

Conclusions: Findings will inform the design of a mobile-enabled interactive nutrition comic prototype that will be used in a 2-group pilot randomized study targeting behaviors to reduce childhood obesity risk. Our user-centered approach will help develop culturally-tailored material and may increase potential intervention adoption, engagement, and sustained use.

DIETARY INADEQUACY AMONG SMOKELESS TOBACCO USER HOUSEHOLDS IN BANGLADESH

Mandeep Virk-Baker, PhD, MPH, MSc, RDN[1], Muhammad J. Husain, PhD[2], Mark Parascandola, PhD, MPH[3]

[1]NCI/NIH, Clovis, CA; [2]CDC, Atlanta, GA; [3]NCI/NIH, Rockville, MD

Tobacco users on average have less adequate diet as compared to non-users. While the majority of the studies are from developed countries, less is known about the influence of tobacco on dietary composition in developing countries where malnutrition is a major public health challenge. Additionally, the effect of smokeless-tobacco use on dietary composition are unknown. We present a household-level analyses that compares diet using the nationally representative Household Income Expenditure Survey (HIES-2010) from Bangladesh. Overall, 71% of the households reported expenditure on tobacco (smoking and/or smokeless), and were considered tobacco users. Out of 12240 households, 2061 used smoking tobacco only (16.8%), 3284 used smokeless tobacco only (26.8%), and 3348 were dual-users (27.4%). After controlling for household expenditure, household size, place of residence, and education, smokeless-tobacco user households consumed significantly lower mean per capita daily total calories ($\beta = -342.88$; $p < 0.0001$) as compared to non-users. Dietary analyses revealed smokeless-tobacco users consumed significantly lower daily mean per capita of vegetables ($\beta = -19.65$ g/day; $p < 0.0001$), milk and dairy ($\beta = -9.81$ g/day; $p < 0.0001$), fish ($\beta = -9.84$ g/day; $p < 0.0001$), meat ($\beta = -10.9360$ g/day; $p < 0.0001$), legumes ($\beta = -3.23$ g/day; $p < 0.0001$), eggs ($\beta = -1.60$ g/day; $p < 0.0001$) as compared to non-users. However, mean per capita daily intakes of cereal products ($\beta = 39.26$ g/day; $p < 0.0001$) was significantly higher among smokeless-tobacco users as compared to non-users. Corresponding to these profound dietary differences, the intake of total dietary protein ($\beta = -10.01$ g/day; $p < 0.0001$), dietary fat ($\beta = -27.55$ g/day; $p < 0.0001$) were significantly lower, and dietary carbohydrate ($\beta = 94.32$ g/day; $p < 0.0001$) was significantly higher among smokeless-tobacco users as compared to non-users. The study provides evidence to inform policy for addressing dietary inadequacy and malnutrition burden among smokeless-tobacco user households in Bangladesh.

EATING FREQUENCY AND CHRONIC DISEASE RISK AMONG POSTMENOPAUSAL WOMEN

Cynthia Thomson, PhD, RD[1], Betsy Wertheim, MS; [1], Melanie D. Hingle, PhD, MPH, RD[1], Tracy Crane, BS: MS; PhD[1], Marian Neuhouser, BS; PhD[2]

[1]University of Arizona, Tucson, AZ; [2]Fred Hutchinson Cancer Research Center, Seattle, WA

Background/ Objective: Eating frequency, defined as eating events at least 30 minutes apart, has been associated with risk for chronic disease including obesity, CVD, and cancer. However, the findings are sparse and inconsistent. Efforts to expand on these results in order to develop guidance in regard to this modifiable behavior are warranted.

Methods: 24-hour dietary recall data collected at year 3 of study from a sub-sample of postmenopausal women (age 50-80 y) enrolled in the Women's Health Initiative Diet Modification Trial (n=2460) provided the eating frequency exposure data for this analysis. Adjudicated disease outcomes included incident cardiovascular disease (stroke and coronary heart disease combined), myocardial infarction, and cancer; self-reported diabetes was also evaluated. Risk for disease was assessed using Cox proportional hazards regression models, adjusted for potential confounders.

Results: Most women reported 3 (31%), 4 (33%), or 5 (20%) eating events over a 24-hour period. Higher eating frequency was reported in younger women, those with higher neighborhood socioeconomic status, non-Hispanic whites, and women with lower body mass index. Eating frequency was not associated with a higher risk for cardiovascular disease, myocardial infarction, or cancer. A significant association between eating frequency and diabetes was demonstrated such that women reporting eating 4 times per day showed 36% greater risk for developing diabetes than women reporting eating 1–3 times per day (HR, 1.36; 95% CI, 1.04–1.79); however, there was no difference in risk between women eating 1–3 versus ≥ 5 times per day.

Conclusion: An inverse U-shaped association between eating frequency and diabetes was demonstrated in this cohort of postmenopausal women; relationships between eating frequency and other obesity-related chronic diseases of aging were not found.

EFFECTS OF HEALTHY-EATER SELF-SCHEMA AND NUTRITION LITERACY ON HEALTHY-EATING BEHAVIORS

Chia-Kuei Lee, PhD[1], Li-Ling Liao, PhD[2]

[1]University of Rochester, Rochester, NY; [2]I-Shou University, Taiwan, Kaohsiung City, N/A, Taiwan (Republic of China)

Unhealthy-eating behaviors contribute to obesity and chronic illness. Researchers have increasingly recognized the role of healthy-eater self-schema (reflects the healthy-eating as an important aspect of the self) and nutrition literacy (reflects the competence of healthy-eating) in healthy-eating behaviors. However, the relative contribution of healthy-eater self-schema and nutrition literacy is unknown. This study aimed to determine the unique effects of healthy-eater self-schema and nutrition literacy on healthy-eating behaviors in undergraduate students

Participants were 1,216 students from three national and three private universities in Taiwan. Healthy-eating behaviors were measured with a 13-item frequency rating scale. Healthy-eater self-schema was measured by rating three key phrases – healthy eater, someone who eats in a nutritious manner, and someone who is careful about what I eat – according to self-descriptiveness (1-11) and importance (1-11). Ratings of at least two of the three descriptors as both very descriptive (8−11) and very important (8−11) were considered evidence of a healthy-eater self-schema. Nutrition literacy was measured with an 8-item scale. Known determinants of eating behaviors (nutrition-related information, health status, nutrition knowledge needs, gender, and residence) were covariates. Hierarchical multiple regression was conducted.

Results showed that healthy-eater self-schema ($\beta = 0.27$, $p < .001$) and nutrition literacy ($\beta = 0.37$, $p < .001$) were significant predictors of healthy-eating behaviors. A healthy-eater self-schema explained 9% of the variance in healthy-eating behaviors and nutrition literacy explained additional 12% of the variance in healthy-eating behaviors.

Findings suggest that a healthy-eater self-schema and nutrition literacy have additive effects on healthy-eating behaviors. Nutrition literacy has relatively stronger effect on healthy-eating behaviors than a healthy-eater self-schema. Intervention to improve healthy-eating behaviors may be more effective if they incorporate the enhancement of both personal value of healthy eating and nutrition literacy at the same time.

EMPOWERING INDIVIDUALS TO MAKE HEALTHY FOOD CHOICES THROUGH NUTRITION LABEL READING SKILLS

Lisa S. Miller, PhD[1], Jacqueline Bergman, PhD[2], Tanja N. Gibson, MS[1], Kara DeSouza, PhD[3]

[1]University of California, Davis, Davis, CA; [2]Nutrition Department at University of California, Davis, Davis, CA; [3]UC Davis, American River College, Sacramento, CA

Nutrition labels are an important tool for navigating healthful food choices. However, labels tend to be underutilized, partly because they are difficult to interpret (Cowburn & Stockley, 2005). Research has shown that label reading skills can be improved (Jay et al., 2009), however, it is unclear whether skill improvement is accompanied by changes in attitudes toward healthy food choices (Dukeshire et al., 2014). That is, do consumers feel more empowered to make healthy food choices after nutrition label training? We examined changes in self-perceptions and motivation before and after using a web-based nutrition label reading training tool.

Participants were 44 young adults (ages 18-29, 59% female, with an average of 18 years of education). The training tool included a 20-minute nutrition overview followed by 3 blocks of intense self-paced label reading practice with feedback. For the practice task, participants compared two nutrition labels, presented side-by-side on a computer screen, to determine which was more healthful. Feedback was provided after each comparison, as well as at the end of each of the 3 blocks of comparisons (24 in each block). Attitudes toward healthy food choices were assessed using the following 4 items: My ability/willingness to select healthful foods when I'm offered many, many choices (large grocery store, online shopping, restaurant) is ___: and "My ability/willingness to interpret nutrition information on food labels in order to select healthful foods is ___:" Participants used a slider bar to select a value between 0 (very low) and 100 (very high).

Results showed significant increases in objectively assessed label reading skills from the first to last practice block, $t(43)=2.4$, $p < .05$, Moreover, we found improvements in self-perceptions of both ability and willingness to use food labels and to select healthy foods, from pre- to post- training, $p < .05$, for all four t-tests. These data are consistent with the notion that label reading skills empower individuals to make healthy food choices. Future work in this area is needed to determine if label reading skills and feelings of empowerment can be sustained with additional training and can translate into more healthful food choices in the long run.

HEALTHY DIETS IN THE AFRICAN AMERICAN COMMUNITY: APPLYING THE THEORY OF PLANNED BEHAVIOR IN FAITH-BASED SETTINGS

Alexandria G. Booker, M.A.[1], Jannette Berkley-Patton, PhD[2], Kymberley K. Bennett, Ph.D.[3], Delwyn Catley, Ph.D.[4], Carole Bowe Thompson, BS[5], Sheila Lister, B.S.[3], Kelsey N. Christensen, M.A. [6]

[1]University of Missouri-Kansas City, Raytown, MO; [2]University of Missouri-Kansas City, Kansas City, MS; [3]University of Missouri-Kansas City, Kansas City, MO; [4]Children's Mercy Hospital & University of Missouri-Kansas City, Kansas City, MO; [5]Community Health Ressearch Group/School of Medicine/University of Missouri-Kansas City, Kansas City, MO; [6]University of Missouri - Kansas City, Kansas City, MO

Diabetes and heart disease are two major health concerns for African Americans, who tend to have worse nutritional intake than Whites. Black churches, which serve primarily African Americans, are influential institutions in the African American community that can assist with promotion of healthy eating behaviors. Although church involvement has been associated with healthier dietary beliefs and behaviors, church settings can also impede healthy eating due to social pressure to consume unhealthy foods. To contribute to better design of church-based dietary intervention studies, there is a need to understand psychosocial influences, particularly beliefs and intentions to eat a healthy diet. Yet, there is a gap in the literature on studies that have examined this key predictor of dietary behaviors among church-affiliated African American populations. The Theory of Planned Behavior (TPB) is an established theory that has been demonstrated to explain the relationships between behavioral beliefs, normative beliefs, control beliefs, intentions to perform a health behavior and the behavior itself. The purpose of the current study is to examine intentions to eat a healthy diet and dietary behaviors (i.e., F/V and fat intake) in a sample of African-American church and affiliated community members using the TBP. Participants (N = 352) were recruited from six Black churches in the Kansas City metropolitan area and completed surveys exploring TPB constructs and health behaviors. Participants were primarily female (68%), with an average age of 54 years. Results showed that path models testing fat intake and F/V intake had good overall fit (RMSEA = .058, PCLOSE = .334; and RMSEA = < .001, PCLOSE = .963, respectively). Findings indicated behavioral (β = .240, p < .001) and normative beliefs (β = .171, p < .05) predicted intentions to eat a healthy diet, even when controlling for covariates (i.e., age, sex, BMI, religiosity, baseline fat or F/V intake). Control beliefs predicted fat intake (β = -.011, p < .05). Intentions predicted fat (β = -.217, p < .05) and F/V intake (β = .313, p < .001). These

findings provide support for the use of the TPB in examining dietary behaviors among church-affiliated African Americans and suggest church-based healthy diet interventions should emphasize promotion of behavioral and normative beliefs. This study represents an opportunity to understand dietary beliefs and behaviors in the African-American faith community, with potential to inform dietary interventions in key African American faith-based settings.

IMPACT OF FRONT OF PACKAGE NUTRITION LABEL TYPE AND EXPLANATION ON PERCEPTION OF PRODUCT HEALTHINESS AND FOOD CHOICE

Pamela Lundeberg, M.A., Dan J. Graham, PhD

Colorado State University, Fort Collins, CO

Background: Front-of-package (FOP) nutrition labels are increasingly used to present nutritional information to consumers. A variety of FOP nutrition schemes exist, each of which presents condensed nutritional profiles in a different manner. The present study was designed to directly compare two policy-relevant symbolic FOP labeling systems –traffic light and star-based labeling schemes – with specific regard to healthiness perception and purchase intention for a variety of food products. Additionally, we sought to determine which method of message framing (gain, loss, gain+loss) would best enable customers to effectively utilize the FOP labeling schemes.

Method: Participants (n = 306) viewed food packages featuring either the star or traffic light FOP labels and rated both the healthiness of each product and their likelihood of purchasing the product. Within each label type, participants were presented with differing instructions regarding how to make use of the labels (i.e., differently-framed instructions).

Results: Participants who viewed the star labels rated products with the lowest healthiness as significantly less healthy and rated products with the highest healthiness as significantly healthier compared to participants who viewed those same products with traffic light labels. Purchase intention did not differ by label type. Additionally, including any type of framing (gain, loss, or gain+loss) of the labeling systems assisted consumers in differentiating between foods with mid-range nutritional value and foods with little nutritional value.

Conclusions: In our study, the star-based labeling system led to healthy foods being seen as even healthier and to unhealthy foods being seen as even less healthy compared to the same foods with traffic light labels. Additionally, our results indicate a benefit of including framing information for FOP nutrition label use instructions, however our study did not provide clear support for a particular method of framing. While ratings of product healthiness were influenced by the framing and the label type, purchase intention was not impacted by either of these factors.

IMPULSIVITY AND ITS ASSOCIATION WITH FOOD PURCHASING BEHAVIORS AND THE HOME FOOD ENVIRONMENT IN SOUTHEAST ALABAMA

Kimberly Garza, PharmD, MBA, PhD[1], Christiana Datubo Brown, MS[2], Philippe Gaillard, PhD[3], Ruth Jeminiwa, BPharm[1]

[1]Auburn University Harrison School of Pharmacy, Auburn, AL; [2]Abuurn University Human Development and Family Studies, Auburn, AL; [3]Auburn University Mathematics and Statistics, Auburn, AL

Background: Food purchasing behaviors such as the emphasis on certain food characteristics and the use of food labels while grocery shopping have been associated with purchasing decisions. Home food environment has also been shown to influence dietary behaviors, which in turn is associated with level of impulsivity. However, little is known about the relationship between impulsivity, food purchasing behaviors, and healthfulness of the home food environment.

Objective: To determine the relationships between impulsivity, food purchasing behaviors, and home food environment among employed adults.

Methods: A cross-sectional, online survey of employees of a southeastern university was conducted with participants recruited through mass electronic mailing. Main Measures: Impulsivity, consideration of food quality (nutrition, taste) and grocery characteristics (price, ease of preparation, shelf life) while shopping (5 items), use of food labels (2 items), and home food environment (4 items). Impulsivity is assessed by the area under the delay discounting curve (AUC), which is estimated using a binary choice delay discounting task incorporating hypothetical monetary rewards. Greater AUC reflects lower impulsivity. Structural equation modeling (SEM) was used to allow impulsivity to simultaneously predict purchasing behaviors and home food environment. SEM were conducted using Mplus.

Results: A total of 477 participants completed the online survey. The sample population were mostly female (n = 329), married (n = 332), and held at least an associate's degree (n = 407). More than half (55%) of participants reported a household income of $70,000 or more a year. AUC was positively associated with food label use and emphasis on nutrition and taste when grocery shopping ($p < 0.001$), meaning that individuals who were less impulsive were more likely to use food labels and placed greater emphasis on these factors. In the final model, AUC was shown to be positively associated with healthful foods in the home and emphasis on food quality and grocery characteristics when purchasing foods. About 33% of the variance in consideration of food characteristics, 5% of the variance in food label use, 7% of the variance in availability of healthful foods, and 4% of the variance in the availability of unhealthful foods

was explained by impulsivity.

Conclusions: Individuals with low impulsivity appear to be more thoughtful in making food purchasing decisions and perhaps as a result, have healthful foods available in the home more frequently compared to individuals with higher levels of impulsivity.

SNACK IT UP FOR PARENTS: A PILOT TRIAL TO IMPROVE CHILDREN’S SNACKS

Sara Folta, PhD[1], Namibia Lebron-Torres, MNSP[2], Stephanie Anzman-Frasca, PhD[3], Megan Halmo, MPH, MSW[4], Heather Angstrom, MS[4], Alyssa Koomas, MPH, MS, RD[4], Sarah Johnson, MS[2], Nicole Smith, MS[2], Shenjia Shi, BS[2], Delphine Van Roosebeke, MS[2], Sean Cash, PhD[2]

[1]Tufts University, Boston, MA; [2]Friedman School of Nutrition Science and Policy, Tufts University, Boston, MA; [3]University at Buffalo, Buffalo, NY; [4]ChildObesity180, Friedman School of Nutrition Science and Policy, Tufts University, Boston, MA

Purpose. Nearly one-quarter of children’s daily energy intake comes from snacks, typically energy-dense and nutrient-poor sweet and salty foods. The objective of the Snack It Up for Parents study was to test the feasibility and preliminary effectiveness of a parent intervention to improve snacks for children. Intervention strategies were designed to address the frequently-cited barriers of time and cost.

Methods. In this quasi-experimental, 7-week pilot study, a 3-arm intervention design was used. Four parent-child dyads received a $5 per week per child incentive for a local grocery store; seven received a brief nutrition education video (viewable on any device), with accompanying tip sheets with information on providing palatable snacks at low-cost and with minimal time; and five received both. Parents of children ages 8-12 were included in the study and were recruited based on enrollment of their child in the American SCORES Soccer for Success program for under-resourced youth. Outcomes included psychosocial factors (measured by survey) and snack quality (measured using web-based 24-hour recalls, ASA24). Key informant interviews with parents were also conducted to assess perceptions of change in children’s snacking habits, parents’ shopping habits, and experiences with the intervention activities.

Results. Across study arms, there was no increase in vegetable snacks from pre to post. Consumption of fruit as a snack increased in the video and incentive arms ($p < 0.05$). Only the video arm showed improvement in self-efficacy for providing healthier snacks ($p=0.003$). In key informant interviews, parents described an increase in the variety of snacks provided. Other themes were that the intervention activities provided an opportunity to evaluate household eating habits, consider healthier options, and experiment with new ideas for snacks. However, some parents identified on-going barriers to providing healthy snacks including limited income, food waste, food prices, and time constraints.

Discussion. Results suggest promise of these low-burden intervention strategies to reach parents to improve snacking in children, although barriers of time and cost remained an issue for some parents.

THE EFFECT OF ADHERENCE TO DIETARY TRACKING ON WEIGHT LOSS: USING HLM TO MODEL WEIGHT LOSS OVER TIME

J. Spencer Ingels, M.A., Jay Stewart, M.A., Samantha Shawley, MS, Brandon Lucke-Wold, MS, Ranjita Misra, PhD

West Virginia University, Morgantown, WV

The role of dietary tracking in weight loss has received little research attention despite being part of multiple diabetes and weight management programs. The Diabetes Prevention and Management (DPM) program was a 22-session, yearlong program that asked participants to track what they ate for the whole program. Participants were provided booklets to record food and beverage intake, and a Calorie King book was given to look up fat, carbohydrate, and fat content. A participant was considered to have tracked if they wrote down at least one food or beverage item for the day. This minimal requirement for dietary tracking provided data to explore the impact of a bare minimum effort to track dietary intake. A scatterplot of days tracked versus total weight loss revealed a non-linear relationship, to fit this relationship the total number of possible days to track was divided by 3, creating the following 3-groups: rare trackers (< 114 total days tracked), inconsistent trackers (114-228 total days tracked) and consistent trackers (>228 total days tracked). The tracking groups were split and dummy coded with the rare tracking group as the reference group. Multiple models were built to first best fit the weight loss data and then to determine the best controls control variables. A cubic model provided the best fit for weight loss change over time at level-1. At level-2, a model with initial BMI and A1c, gender, and week-1 weight loss was the best fit for the data, explaining 5.29% of within person variance and 6.26% of between person variance in total weight loss. Adding tracking further improved the model, explaining an additional 2.15% of within person variance and 15.31% of between person variance in total weight loss. After controlling for initial BMI, initial diabetes status, week-1 weight loss, and gender only the group that consistently tracked lost a statistically significant amount of weight (-10.58 pounds), the weight change for rare (-2.99 pounds) and inconsistent trackers (1.98 pounds) did not statistically differ from zero. None of the control variables were significant predictors of total weight loss. In addition, the weight loss trend for the rare and inconsistent trackers followed a non-linear path, with the holidays slowing weight loss and the onset of summer increasing weight loss. However, the consistent trackers weight loss trend more closely followed a linear relationship, with consistent loss throughout the year. These results show the importance of dietary tracking in long-term weight loss success. The implications and limitations of these results will be discussed.

EXAMINING MOBILE IMAGING, PERVASIVE SENSING, SOCIAL MEDIA AND LOCATION TRACKING (MISST) RESEARCH USING NIH REPORTER DATABASE

Sarah Dunseath, B.S.[1], Camille Nebeker, Ph.D.[2]

[1]UC San Diego School of Medicine, Coronado, CA; [2]University of California - San Diego, La Jolla, CA

Background: Researchers are using Mobile Imaging, pervasive Sensing, Social-media and location Tracking (MISST)technologies to intervene with and/or observe personal health behaviors. Studies using MISST methods/tools raise new challenges for Institutional Review Boards (IRBs) charged with protecting research participants. This study explores the MISST landscape by identifying the nature and scope of studies supported by the National Institutes of Health (NIH).

Objectives: Due to the novelty of MISST use in research, we sought to: 1- examine the extent to which the NIH is supporting this research and, 2- identify how these tools are being used in currently funded research. A high level aim is to conduct a systematic evaluation of how IRBs carry out their obligations to protect participants and facilitate high quality scientific research.

Methods: MISST research supported by the NIH and its agencies and centers were identified through a search of the NIH Research Portfolio Online Reporting Tools (RePORTER) database using 43 key words and phrases during 2005, 2010 and 2015. Relevant abstracts were coded by the technology used, theme of the research, funding institute/center, amount of funding, and funding recipient.

Results: Results reveal MISST use in research is relatively novel as funded projects using these devices accounted for only approximately 1% of the total NIH budget in 2015. However, the number of awards allocated to MISST research increased 384% from 2005 to 2015. Additionally, the types of MISST devices used in research has shifted from geographic information systems (GIS) being the most widely used tool in 2005 to mobile devices/application being the most widely used tools in 2015. The number of institutes, agencies, and centers supporting MISST research has also increased by roughly 50% and the scope of MISST research has widened, with its increasing use in diverse fields ranging from tracking disease transmission via analysis of social media content to personalizing medicine through mobile health applications.

Conclusions: Evolving research practices and methods enabled by technological advances are rapidly changing how research is conducted. This study sheds light on studies using MISSTE technologies and the institutes supporting this research.

ANALYSIS OF A MOBILE HEALTH APPLICATION TO INCREASE WILLINGNESS TO ASK FOR A LIVING KIDNEY DONATION IN BLACK RENAL PATIENTS

John C. Sieverdes, PhD[1], Lynne S. Nemeth, PhD, RN, FAAN[1], Frank A. Treiber, PhD[2], Brenda M. Brunner-Jackson, MPH[1], Sachin K. Patel, MSc[1], Shawntel M. Parker, BS[1], Prabhakar K. Baliga, MD, FACS[1]

[1]Medical University of South Carolina, Charleston, SC; [2]Medical Univ of South Carolina, charleston, SC

Rates of living donor kidney transplantation (LDKT) are greater in White renal patients while the burden of renal disease disproportionately affects the Black population. The Living Organ Video Educated Donors program (LOVED) was designed to address this disparity using a distanced-based education platform delivered on 10” tablet computers to aid Black renal patients who had difficulty approaching others to ask for a living kidney donation (LKD). The 8-week culturally tailored mobile health (mHealth) education program consists of short weekly video education modules and online video chat sessions led by a Black former patient “navigator” who has had a LDKT. A parallel convergent mixed method approach was used to triangulate quantitative data from pre-post surveys and qualitative data from end of trial focus group transcriptions. Four LOVED groups (n=25, 11 men; mean age = 48.6 years (SD14.6)) using 2 navigators were conducted between 2014 and 2016. Analysis showed an increase in LDKT knowledge ($p=0.02$), lower LDKT concerns ($p=0.03$), and higher self-efficacy/willingness to speak with others about LDKT ($p < 0.001$). Thematic analysis of qualitative data using NVivo 10 (QSR International Ltd.) showed that social support and self-efficacy were two key constructs. Results showed: 1) Video chat sessions were viewed positively as an opportunity to develop social support, LDKT knowledge, and behavior skills to seek a potential LKD. The co-learning that occurred through shared conversations with other participants increased a sense of self-efficacy, which converged in agreement with the survey results. 2) The positive opportunities for interaction outweighed the barriers of connectivity and adaptation to video chat as a mechanism for communication. However, some individuals needed technical support or stronger cellular or network signals to achieve consistently good connectivity to outweigh live group interactions. 3) Participants viewed the content of the video modules as informative, helpful, and conducive to generate requests for a kidney donation. This increase in knowledge lessened barriers to ask others for a LDKT 4) A sense of increased empowerment resulted from the interactions between group members through mentoring activities and practicing asking others for a LDKT. Overall, the video education modules and video chat sessions were inherently interdependent with the results and findings

were positive. Refinement of content and presentation material was made and LOVED is undergoing a small scale efficacy RCT. Further study would be needed to determine if self-efficacy can be maintained without the video chat sessions to support asking for a LDKT.

COLLEGE STUDENTS’ USE OF MOBILE APPLICATIONS FOR WEIGHT LOSS

Matthew C. Whited, PhD, Licensed Psychologist[1], Jordan Ellis, MA[1], Ansley Taylor Corson, M.A.[1], John T. Freeman, B.A.[1], Emily P. Midgette, Psychology, BA (Expected May 2017)[2], Sherry Pagoto, PhD[3], Molly E. Waring, PhD[3], Christine May, PhD[4], Kristin Schneider, Ph.D.[5], Andrew Busch, PhD[6], Brad Appelhans, PhD[7], Eliza Varju, BS (Expected May, 2019)[1], Laura K. Nye, BA in Psychology, May 2017[1]

[1]East Carolina University, Greenville, NC; [2]East Carolina University, Vanceboro, NC; [3]University of Massachusetts Medical School, Worcester, MA; [4]University of Massachusetts Medical School, Fiskdale, MA; [5]Rosalind Franklin University of Medicine & Science, North Chicago, IL; [6]The Miriam Hospital, Rumford, RI; [7]Rush University Medical Center, Chicago, IL

Understanding college students’ use of and preferences for health-related mobile applications is needed to inform the development of mhealth interventions for this population.

As part of an annual survey of college student health, students were asked: “have you ever used a mobile application (“app”) for weight loss?” Users, those who reported using an app for weight loss (WL) reported on their most and least liked feature of the WL app they used the most; Non-users, who never used a WL app, reported on desired features for a WL app. Responses to these open-ended questions were categorized by 3 coders (percent agreement 78-88%).

Of all participants (n=1906; 67% women; 30% overweight/obese), almost one-third (31%) were users. Among overweight/obese students 44% were WL app users compared to 26% of normal weight students (p

Of the users (n=586), 43% reported using a WL app for both exercise and diet, 23% for exercise only, and 32% for diet only. Three in 10 (29%) reported using the app for 1-2 months; 39% for less than one month; 16% for 3-4 months; and 15% for 5 months or longer. Most users (57%) reported daily use. Users reported that tracking/self-monitoring (64%) and tutorials/instructions (9%) were their most liked features. Least-liked features included tracking/self-monitoring (38%) and financial/time cost (6%). Non-users (n=1320) reported needing features related to tracking/self-monitoring (18%) and tutorial/instruction (12%). Users and non-users infrequently reported preferences for other features such as goal setting, motivational features, social networking.

For the two most liked features among users, more men liked tutorial features (26% of men) than women (10% of women; p=.002). Most liked feature did not differ based on weight status. No differences for gender or weight status were observed for least liked or needed features.

Almost one third of college students have used an app for WL, although most have used them for less than 2 months. Tracking is important to this population, and satisfaction with tracking appears important to attract and maintain users. Other features that are part of empirically-supported weight loss treatment were reported infrequently and may not feature prominently into users’ experiences (i.e., goal setting and motivational features to maintain engagement). College men are underrepresented among app users.

FEASIBILITY AND ACCEPTABILITY OF A SMARTPHONE APPLICATION FOR MEASURING TIME USE (LIFE IN A DAY) IN BREAST CANCER SURVIVORS

Matthew C. Ainsworth, MPH[1], Dori Pekmezi, PhD[1], Heather R. Bowles, PhD[2], Edward McAuley, PhD[3], Kerry S. Courneya, PhD[4], Laura Q. Rogers, MD, MPH[1], Diane K. Ehlers, PhD[5]

[1]University of Alabama at Birmingham, Birmingham, AL; [2]National Cancer Institute, Rockville, MD; [3]University of Illinois at Urbana Champaign, Urbana, IL; [4]University of Alberta, Edmonton, AB, Canada; [5]University of Illinois at Urbana-Champaign, Urbana, IL

Background: Advancements in mobile technology allow innovative data collection techniques such as measuring time use (i.e., how individuals structure their time) for the purpose of improving health behavior change interventions. To advance technology-based measurement of time use, the current study examined the acceptability of a five-day trial of the Life In A Day (LIAD) smartphone app measuring time use in breast cancer survivors. **Methods:** Feasibility and acceptability data were collected from participants (N=40; 100% response rate) using a self-administered survey after 5 days of LIAD use. **Results:** Overall, participants had a mean age of 55 years (SD=7.96) and completed 16 years of school (SD=2.08). Participants generally agreed that learning to use LIAD was easy (82.5%, N=33) and preferred to log activities using LIAD over paper and pencil diary (72.5%, N=29). Most felt that completing LIAD for 5 consecutive days was not too much (60%, N=24) or overly time consuming (67.5%, N=27). LIAD was rated as easy to read (87.5%, N=35)) and navigate (70%, N=32). Participants also agreed that it was easy to log activities using the activity timer at the start and end of an activity (89.7%, N=35). Only 12.5% (N=5) downloaded the app on their personal phone while 63.3% of the remaining 35 would have preferred to use their personal phone. Overall, participants felt that the LIAD app was “good” or “very good” (76.9%, N=30). Those who agreed it was easy to edit activities were significantly more likely to be younger when compared with those who disagreed (M=53 vs 58 years, $p < .05$). Similarly, those who agreed that it was easy to remember to log activities were more likely to be younger (M=52 vs 60 years, $p < .05$). Qualitative coding of two open-ended survey items yielded three common themes for LIAD improvement (i.e., convenience, user interface, and reminders). **Conclusion:** A smartphone app is a feasible and acceptable time use measurement modality. Improving convenience, user interface, and memory prompts while addressing the needs of older participants are needed to enhance app utility.

MFIT (MOTIVATING FAMILIES WITH INTERACTIVE TECHNOLOGY) STUDY: A RANDOMIZED PILOT TO PROMOTE PHYSICAL ACTIVITY & HEALTHY EATING

Danielle E. Jake-Schoffman, PhD[1], Brie Turner-McGrievy, PhD, MS, RD[2], Sara Wilcox, PhD[2], James Hussey, PhD[2], Justin B. Moore, PhD, MS, FACSM[3], Andrew Kaczynski, PhD[4]

[1]University of Massachusetts Medical School, Worcest, MA; [2]University of South Carolina, Columbia, SC; [3]Wake Forest School of Medicine, Winston-Salem, NC; [4]University of South Carolina, Colubmia, SC

BACKGROUND: The purpose of the Motivating Families with Interactive Technology (mFIT) study was to test the feasibility, acceptability, and effectiveness of two remotely-delivered family-based health promotion programs for improving physical activity (PA) and healthy eating (HE).

METHODS: Thirty-three parent-child (child age 9-12 years) dyads were randomized to one of two 12-week mobile interventions to increase PA and HE, which included weekly email newsletters and the use of pedometers. The programs differed in focus of content (individual vs. family) and method of tracking (paper vs. mobile website). At baseline and 12 weeks height and weight were measured, and participants completed questionnaires about dietary intake (BRFSS and YRBSS), and feedback on and engagement in the mFIT program. Descriptive statistics and linear mixed effects models were used to analyze program data; all analyses were conducted in SAS 9.4.

RESULTS: Of the 33 randomized dyads (parents: 43+6 years, 88% female, 70% white, BMI 31.1+8.3 kg/m^2; children: 11+1 years, 64% female, 67% white, BMI 77.6+27.8 percentile), 31 (94%) had follow-up data. There were no between-group differences for PA or HE, but there was an overall significant increase in average daily steps and servings of fruit during the intervention and excellent adherence to self-monitoring protocols. Most parents (97%) and children (86%) would recommend the program to a friend.

CONCLUSION: The mFIT program showed excellent feasibility and acceptability as a low-cost, remotely-delivered family intervention for PA and HE promotion, and could serve as a disseminable model for public health interventions.

MYLIFE: USING DIGITAL HEALTH TECHNOLOGY TO ENCOURAGE HEALTHY BEHAVIORS IN PATIENTS AT RISK FOR LIFESTYLE-RELATED DISEASES

Daniel M. Croymans, M.D., M.B.A., M.S.[1], Paul Bixenstine, M.D.[2], Ian Hurst, High School Diploma[3], Carlos Casillas, B.S.[4], Lisa Gantz, M.D.[2], Sung Hyun Kim, M.P.H.[4], Sally Elliott, B.S.[4], Sarah Tan, High School Diploma[3], Alice Kuo, M.D., Ph.D.[2]

[1]Internal Medicine, UCLA Health, Los Angeles, CA; [2]Internal Medicine and Pediatrics, UCLA Health, Los Angeles, CA; [3]UCLA, Los Angeles, CA; [4]UCLA David Geffen School of Medicine, Los Angeles, CA

Background:
Many patients at risk for lifestyle-related chronic disease struggle to adopt and maintain healthy behaviors despite health education and lifestyle recommendations from their physicians. Digital health technology could improve patient-provider communication and patient health outcomes if integrated into the health delivery workflow. MyLife is a 16-week digital health program that uses wearable activity trackers, mobile messaging, and data analytics to encourage healthy behaviors in patients at risk for lifestyle-related chronic diseases.

Methods:
UCLA primary care providers (PCPs) referred patients for enrollment. Upon intake, study personnel gave patients a Jawbone UP3 tracker and instructions for using the mobile application. Patients set exercise goals, identified barriers and discussed solutions. Patients received follow-up calls every 2 weeks and 4-6 text messages per week for 16 weeks. PCPs were given periodic reports on patient progress and helped promote patient engagement. PDSA cycles were used to evaluate and refine the MyLife program based on changes in patient bodyweight, physical activity (PA), motivation and feedback. The Behaviour Change Wheel and Behavior Change Techniques (BCT) Taxonomy were consulted to guide iterative improvements.

Results:
Participant baseline characteristics (cycle 1, n=12; cycle 2, n=10) included mean age 42 ± 11 years, 50% female, mean BMI 35.4 ± 7.5, mean PA 34.5±38 min/wk, and mean patient activation measure 42 ± 5 (raw score, stage 3 of 4). Patients who completed the 16-week program increased their baseline PA by more than 200% and lost an average of 5% of their bodyweight. Based on results and patient feedback from the first cycle, which focused on

increasing PA, the second cycle will also address patient dietary choices and patients will have a designated health coach. In total over 100 unique, branching logic messages that leverage several key BCTs including Goal Setting + Behavioral Contract, Problem Solving + Graded Tasks, Action Planning, and Review Behavior Goals were developed.

Conclusions:

Our pilot digital health intervention demonstrated significant improvement in PA and weight among participants after 16 weeks. Digital health technology may be a powerful tool to prevent lifestyle-related chronic diseases when integrated into the health system. In the future, we hope to improve our program by using more interactive messaging and real-time analytics to leverage proven behavior change techniques.

REGIONAL CHALLENGES OF USING DATING APPS AMONG MSM IN RURAL AREAS

Anne Marie Schipani-McLaughlin, MPH[1], Danielle N. Lambert, MPH, CHES[2], Natalia Truszczynski, MPH[1], Carolyn Lauckner, PhD[1], Nathan Hansen, PhD[1]

[1]University of Georgia, Athens, GA; [2]University of Georgia, Atlanta, GA

Background: Little is known about the challenges of using dating apps to meet potential partners among MSM residing in different geographical locations of the United States. This study explored MSM's experiences of using dating/hookup apps to meet potential sexual and romantic partners within different US regions and areas of varying population density.

Methods: Semi-structured qualitative interviews were conducted with 20 MSM between the ages of 18-60 years currently residing in rural areas. Eligibility criteria included identifying as a man who dates or has sexual relations with other men, being at least 18 years of age, and residing in a non-metropolitan area of the United States. Interviews were transcribed verbatim and analyzed in NVivo 11 by a diverse coding using grounded theory approaches.

Results: Results reveal a number of challenges MSM face when using dating/hookup apps to meet partners in rural areas, specifically regarding regional characteristics, comfort being "out," and population size. Population density and sprawling regional characteristics limit the number of openly identifying MSM who use dating/hookup apps in rural areas. This leads to a limited number of partner matches on the apps and respondents therefore cycle through multiple dating/hookup apps to increase their dating pool. Rural areas with populations predominantly comprised of university staff or students ("college towns") also present issues for finding potential matches online. Respondents indicated that they did not feel comfortable being "out" within the context of their rural community, which deterred them from meeting partners in that area. This was not perceived to be an issue in large urban areas where respondents had more anonymity and many preferred to use dating/hookup apps when they were visiting metropolitan cities with larger communities of MSM.

Conclusion: These findings reveal that the regional environment plays a key role in the success of using dating and hookup apps to meet potential partners among MSM. The regional environment also impacts MSM's comfort openly identifying as gay within their community and seeking partners in rural areas. Health professionals should therefore consider regional characteristics and partner-seeking behavior using dating/hookup apps when designing interventions for MSM in rural areas.

SELF-EFFICACY FOR EXERCISE-SPECIFIC MEMORY AND PROSPECTIVE MOBILE HEALTH APPLICATION USE

Daniel Palac, MA[1], Sean P. Mullen, PhD[2]

[1]University of Illinois at Urbana-Champaign, Champaign, IL; [2]University of Illinois at Urbana-Champaign, Urbana, IL

As smart phone devices become more prevalent in today's society, so do mobile health (mHealth) applications (apps). Tens of thousands of mHealth apps are commercially available that target health and fitness, yet minimal research has identified antecedents associated with continued use. Research has consistently associated self-efficacy and memory with physical activity behavior. Exercise-specific memory is a construct that has received little attention, yet there is reason to believe high levels of self-efficacy for exercise-specific memory (SEFESM, i.e., confidence in one's ability to remember public health recommendations, modifications, and how to evaluate progress with respect to aerobic, strength, and flexibility training) might contribute to the frequency and continued use of exercise-related mHealth apps. To test this hypothesis, a survey was administered on two occasions: baseline (126 initiated; n=94 completed; M_{age}=38 years; 64% female) and one-month follow-up (n=76). Path modeling with robust maximum likelihood estimation was conducted using MPlus (version 7.4) to assess theorized direct and indirect effects of SEFESM on weekly app use ("...to assist me with my exercise program;" assessed via an 8-point ordinal scale ranging from 0 to 30+ times) at baseline and at one-month follow-up, while statistically adjusting for age, gender, education, access to technology (e.g., "Do you own a smartphone/tablet/wrist device?"), and self-reported moderate-to-vigorous physical activity levels (derived from the Godin Leisure-Time Exercise Questionnaire). The overall model fit the data (χ^2=20.908 (19), p=.34, RMSEA=.03, CFI=.99, SRMR=.07). Results indicated that SEFESM and access to technology had significant ($p < .05$) direct effects on app use at baseline (β=.235 and β=.177, respectively). App use at baseline also had a direct effect at one-month follow-up (β=.667); also found was a marginal indirect effect of SEFESM on weekly app use at follow-up via app use at baseline (β=.157, p=.06). These results support our hypothesis that self-efficacy for exercise-specific memory contributes to an individual's use of exercise-related apps and should be an important consideration when designing mobile interventions.

THE EHEALTH ACTIVITY ASSESSMENT: PRELIMINARY FINDINGS AND IMPLICATIONS FOR CANCER SURVIVORSHIP AND USER-CENTERED DESIGN

Hayley S. Thompson, Ph.D.[1], Nicole Senft, PhD[2], Anne Katz, PhD[3], Tara Eaton, PhD[4], Deborah H. Charbonneau, PhD[5], Charity A. Barnes, B.S.[5], Jennifer L. Beebe-Dimmer, Ph.D., M.P.H.[6], Ke Zhang, PhD[5], Judith Abrams, PhD[7], Elisabeth Heath, MD[8]

[1]Karmanos Cancer Institute - Wayne State University, Detroit, MI; [2]Karmanos Cancer Institute/Wayne State University, Ann Arbor, MI; [3]Wayne State University/Karmanos Cancer Institute, Detroit, MI; [4]Levine Cancer Institute, Charlotte, NC; [5]Wayne State University, Detroit, MI; [6]Wayne State University School of Medicine/Karmanos Cancer Institute, Detroit, MI; [7]Wayne State university/Karmanos Cancer Institute, Detroit, MI; [8]Karmanos Cancer Institute, Detroit, MI

There are an increasing number of eHealth interventions targeting cancer survivors but little is known about eHealth preferences and experiences in this group, areas that are central to user-centered digital design. The current study presents early data from an ongoing, population-based study of eHealth activity among African American (AfAm) and white cancer survivors that will establish “survivor-centered” design principles to be translated in the development of a survivor resource app. Investigators created the eHealth Activity Assessment (eAA), a mixed methods interview examining 17 eHealth activities across 5 domains: informational, communal, self-care, expert care, and transactional. Dimensions of activity examined included direct versus surrogate engagement, frequency, the extent to which an activity served a cancer-related need, and future interest. Participants were 96 survivors (mean age= 61 years; 64% AfAm; 78% breast cancer) enrolled through the Metropolitan Detroit Cancer Surveillance System - SEER. Quantitative findings are presented here. In this sample of internet users and non-users, 89% reported at least one eHealth activity but only 6% reported any surrogate engagement (i.e., others conducted activity on their behalf). The median number of activities was 6 (min=1; max=14). The most common activities were online search for health information related to symptoms, treatments, or procedures (81%), online search for healthy lifestyle information (62%), and use of technology to reduce stress (60%). In terms of frequency, a substantial proportion of those who used technology to manage medications (100%), reduce stress (54%), and track weight, diet, or exercise (50%) did so on a daily basis. On average, 16% of reported activities addressed cancer-related needs post-treatment. Across the sample, future interest was highest in online search for ways to reduce healthcare costs (37%) and looking at medical records or test

results online (31%). T-test results showed that, compared to white survivors, AfAm survivors engaged in fewer eHealth activities (4 vs. 8, p < .0001). Fisher's exact tests showed that a significantly lower proportion of AfAms engaged in 9 of the 17 eHealth activities, most notably in the communal and informational domains. AfAms also reported fewer activities related to cancer needs post-treatment (11% vs. 22%, p < .0003). Finally, a significantly greater proportion of AfAms indicated strong interest in connecting with similar others online (p < .001) and using technology to reduce stress (p < .04) if they had never done so. Findings suggest that in-depth assessment of eHealth activity may reveal trends that can inform and enhance the user-centeredness of new and existing digital interventions for cancer survivors, especially among specific subgroups, thereby increasing the likelihood of adoption and meaningful impact.

USABILITY TESTING OF AN MHEALTH INTERVENTION TO IMPROVE ADOLESCENTS' HEADACHE SELF-MANAGEMENT

Kelly A. Manser, B.A.[1], Lisa Sawyer, BFA[2], Kimberlee J. Trudeau, Ph.D.[1]

[1]Inflexxion, Inc., Waltham, MA; [2]QuickBase, Cambridge, MA

Adolescents who experience recurring headaches report lower quality of life as headaches become more frequent and severe (Donovan et al., 2011; Sillanpaa, 1983). Self-management skills training has been shown to increase self-efficacy for healthful behaviors as part of multidisciplinary care for chronic health conditions (Burckhardt, 2005). To facilitate adolescents' self-management of recurring headaches, we developed the Headzup App for the iPhone. Features of Headzup include a daily headache tracker, evidence-based self-management strategies that were developed with clinician and end-user input, and a "stats" view showing recent tracking trends (e.g., pain level, suspected headache etiology).

Nine adolescents who experience >4 "bothersome" headaches per month (mean age = 14.33 years) were recruited via online resources. They were asked to use Headzup daily for 14 days, then participate in a one-hour interview about their use of the app. At the end of the interview participants were asked to complete the 10-item System Usability Scale (Brooke, 1996). The SUS is a standard measure to assess ease of use with new programs/products. Participants were paid $50 for participating in the interview.

All participants completed the headache tracker on > 11 days (M = 14.33; range from 11 to 21 days). SUS scores >68 indicate above-average usability; the mean SUS score for the Headzup App was 88.6 on a 100-point scale. All but one of the participants reported that using Headzup helped them to cope with headache pain. When asked which specific feature was most worth keeping, 6 teens (66.7%) advocated for the tracker. While 7 participants did not notice the stats feature until they were directed to it during the interviews, all said it was "helpful" and "really interesting." Common "wish list" items included the ability to provide free-text answers to a tracker question about suspected headache cause and stats reports that display a longer (>7 days) tracking period.

The present study suggests that the Headzup app has good usability and includes features that teens find useful for headache self-management. Developers of future mHealth interventions for adolescents should consider including highly visible features that provide data that helps users identify patterns in the co-occurrence of certain health behaviors and chronic disease symptoms. The relationship between longer-term use of Headzup and adolescents' headache frequency, coping, and self-efficacy is currently being evaluated in a clinical trial (Clinical Trials # NCT02475005).

AN ASSESSMENT OF PARTICIPANTS' EXPERIENCES WITH TWO EHEALTH INTERVENTIONS

Marie A. Sillice, Ph.D.[1], Patricia J. Morokoff, Ph.D[2], Ginette Ferstz, Ph.D.[3], Timothy Bickmore, Ph.D.[4], Beth C. Bock, PhD[5], Wayne F. Velicer, Ph.D.[6]

[1]Department of Psychiatry and Human Behavior, the Miriam Hospital and Alpert School of Medicine at Brown University, Providence, RI; [2]University of Rhode Island, Kingston, RI; [3]College of Nursing, University of Rhode Island, Kingston, RI; [4]College of Computer and Information Science Northeastern University, Boston, MA; [5]Brown Medical School, Providence, RI; [6]Cancer Prevention Research Center Behavioral Science, University of Rhode Island, Kingston, RI

Objective: During the last 30 years, computer-based intervention for changing health behaviors have been developed and demonstrated to be effective in clinical trials. However, the effect sizes have been small due to a lack of engagement by a significant proportion of the population. Relational Agents (RAs) represent one of the recent innovative eHealth approaches to increasing engagement. RAs are computational figures designed to engage participants in the change process. A recent study tested the effectiveness of RAs, combined with existing computer-based interventions, to increase regular exercise and sun protection behaviors. The study demonstrated that these interventions can be effective but need further development. This study focuses on examining the participant's experiences of using the RA, using mixed methods approaches.

Method: Thirty-four participants completed a standardized semi-structured open-ended interview. A 25-question interview guide assessed different components of participants' experiences with the intervention, including motivation, engagement, satisfaction/ dissatisfaction, quality of their interaction with the RA, and behavior change. Quantitative assessment of satisfaction was based on a scale of 1 to 10, with 1 representing *least satisfied* and 10 representing most *satisfied.* A summative analytic approach was used to assess individuals' qualitative responses. An ANOVA examined levels of satisfaction by gender.

Results: The results showed individuals were motivated by and satisfied with the intervention, viewed the RA as *supportive*, *informative*, and *caring*, and reported positive behavior change in both exercise and sun protection. Some participants felt that the RA was less judgmental and less "overbearing" compared to a human counselor, others said that the interaction was sometimes repetitive or overly general. The majority of participants viewed the RA as an important contributor to their behavior change for exercise, sun protection, or both. Levels of

satisfaction ranged between 7 and 10. Gender differences were not noted for levels of satisfaction.

Conclusion: RAs provide an innovative and attractive platform to increase exercise and sun protection behaviors. This component can serve as an effective medium to increase other health behaviors. Nevertheless, improvement of this component to include a broader database of tailored messages to decrease receptiveness of information will further increase its appeal.

AN UPSTREAM APPROACH TO ADDRESS ALCOHOL & SUBSTANCE USE: INTEGRATING SBIRT IN HEALTH PROFESSIONAL TRAINING PROGRAMS

Diane King, PhD, Alexandra Edwards, MA, Bridget Hanson, PhD, Jodi Barnett, MA, Amanda Zold, M.S.

University of Alaska Anchorage, Anchorage, AK

Misuse of alcohol and drugs is the third leading cause of preventable death in the United States. Despite strong research evidence that standardized screening, brief intervention and referral to treatment (SBIRT) changes behavior and improves patient outcomes in diverse practice settings, its adoption lags best practice recommendations. The Substance Abuse and Mental Health Services Administration (SAMHSA) has identified a need to move SBIRT implementation approaches further upstream, including the integration of SBIRT within medical residency and multi-disciplinary health professional training programs. We studied the implementation of SBIRT training into psychology, social work, nursing and family medicine residency programs at a state University. A standardized SBIRT curriculum was adapted to allow implementation within core and elective courses, in conjunction with opportunities to practice skills with standardized patients through the University's Simulation Center. Over eight academic terms, 704 students and 30 residents received the course curriculum. Student surveys administered before and after receiving the SBIRT curriculum, indicated significant increases in curriculum knowledge, confidence to apply SBIRT skills with patients related to alcohol and drug use, and perceived level of responsibility to use SBIRT skills with patients related to alcohol and drug use ($p < .001$ for all). Effect sizes were $\eta^2 = .00$ for responsibility to use SBIRT, $\eta^2 = .04$ for confidence, and $\eta^2 = .25$ for knowledge. Recommendation from students included more hands-on opportunities to practice SBIRT skills, which may also improve the effectiveness of the training in increasing student confidence to apply SBIRT with patients. Recommendations from faculty included more discipline-specific SBIRT skills demonstration videos for students, and resources, such as articles and discussion materials, that would help instructors fit the SBIRT curriculum content into courses already constrained by limited classroom time—a key implementation challenge. While use of videos and readings was reported to improve implementation feasibility, maintaining SBIRT within program curricula may require changes to professional accreditation and credentialing standards, as well as dissemination of SBIRT within practice settings, to ensure upstream training of healthcare professionals is necessitated by its midstream use in clinical practice as a standard of integrated evidence-based care.

THE GROW! PARENTING PROGRAM: A HYBRID TYPE III DESIGN STUDY

Jennifer M. DiNallo, Ph.D.[1], Melina T. Czymoniewicz-Klippel, Ph.D.[2], Ryan P. Chesnut, Ph.D.[2], Daniel F. Perkins, Ph.D.[2]

[1]Pennsylvania State University, Boalsburg, PA; [2]Pennsylvania State University, State College, PA

Background: The development and dissemination of evidence-based parenting programs is a major focus of researchers and practitioners in the social and behavioral sciences. Traditionally, these programs have focused on enhancing specific parenting skills, such as assertive discipline and labeled praise, in an attempt to improve parent and child mental health outcomes. The *Grow!* parenting program (*Grow!*), for parents of five-to-eight year olds, emphasizes these same parenting skills, but is unique in that it also underscores evidence--informed stress management and health promotion skills (e.g., child feeding, physical activity, and screen time behaviors) in an effort to impact parent and child health holistically.

Methods: In 2015, a Hybrid Type III design study was conducted in two Pennsylvanian communities. Implementation data were collected from facilitators and participants throughout program delivery and at program completion. Treatment data were collected from participants at pretest, posttest, three-month, and six-month follow-up using measures assessing positive parenting practices, stress management, and health promotion. Responses from 15 participants who completed measures at all four time points were analyzed using Friedman's ANOVAs and appropriate follow-up tests.

Findings: Overall, participants and facilitators were satisfied with the program. Participants were engaged during the sessions and indicated the material was useful. Facilitators also delivered the program with a high degree of fidelity (i.e., adherence rating = 94%). Repeated measures analyses showed statistically significant ($p < .05$) improvements on several stress management and health promotion measures with some parenting measures approaching significance ($p < .10$). Effect sizes (i.e., r) for significant outcomes ranged from .29 to .48.

Implications for D&I Research: Dissemination and implementation research seeks to translate knowledge into practice. This study contributes to that mission by expanding the focus of parent programming to include evidence-informed stress management and health promotion strategies. The findings demonstrate that implementing *Grow!* with fidelity in community populations is feasible and well received. In addition, the results indicate *Grow!* has the

potential to produce changes in stress management and health promotion outcomes. These findings will help to stimulate greater thinking about how best to develop, disseminate, and evaluate parenting programs that influence all aspects of children's health.

ONLINE EDUCATION TO ENHANCE DISCUSSION ABOUT COMPLEMENTARY THERAPIES BETWEEN HEALTH CARE PROVIDERS AND CANCER PATIENTS

Kirsti Toivonen, HBA[1], Greg Levin, PhD[1], Aven Sidhu, BSc[2], Erin Zelinski, PhD[1], Michelle J. Flynn, BA Hons, Psychology[1], Jennifer White, PhD[3], Lynda Balneaves, PhD[4], Linda Carlson, PhD[1]

[1]University of Calgary, Calgary, AB, Canada; [2]Alberta Health Services, Calgary, AB, Canada; [3]Hunter Medical Research Institute, New South Whales, N/A, Australia; [4]University of Manitoba, Winnipeg, MB, Canada

Background: Nearly 50% of cancer patients report using complementary therapies (CTs) since diagnosis and evidence supports the use of CTs in conjunction with usual cancer treatment. However, both patients and health care practitioners (HCPs) report a lack of knowledge about the benefits and potential adverse effects of CTs, and research indicates there is little discussion between HCPs and cancer survivors about CT use. The present study examines whether an online CT education program delivered to HCPs can improve attitudes toward CTs as well as increase discussion about CTs between patients and providers.

Methods: All HCPs affiliated with the Tom Baker Cancer Centre in Calgary, Canada (approx. 300) were invited to enroll in a 3-module online course, which included information about patient CT use, how to talk to patients about CTs, and a summary of evidence for CTs. Attitudes towards CTs and CT-specific clinical practice behaviours with patients over the past 30 days were assessed at baseline and two months later following completion of online modules. HCPs were assessed at follow-up regardless of whether they completed all modules. Quantitative and qualitative data were examined.

Results: Of the HCPs who were invited, 105 expressed interest, 83 enrolled in the study, 73 completed all assessments and 61 completed all three modules. Both those who completed all modules and those who did not reported an increase (80% and 10%, respectively) in asking their patients about CT use. However, only completers provided more information about CTs (+11.5% vs -16.7%), made more recommendations for CTs (+14.7% vs 0%), and discussed the evidence supporting CTs (+18.1% vs -8.3%). While HCPs saw the value in knowing about CTs to help counsel interested patients, they felt that they did not have sufficient depth of knowledge and expressed interest in having a support staff with specialized CT knowledge.

Conclusions: The online education course appeared to increase the frequency of HCPs asking their patients about CT use, but only those who completed the course were able to engage in more meaningful discussions about CTs. Interested HCPs may benefit from more advanced seminars about CTs. Further, a designated position for a CT practitioner in a Cancer Centre may be valuable given the great patient interest in CT use.

A MIXED METHODS APPROACH TO DESIGNING A SOCIAL MEDIA INTERVENTION FOR MOTHERS OF ADOLESCENT GIRLS IN TENNESSEE

Katie Baker, DrPH, MPH[1], Sherry Pagoto, PhD[2], David Buller, PhD[3], Barbara Walkosz, PhD[4], Joel Hillhouse, PhD[1], Julia Griffith, Master of Social Work[5], Oluwatosin Ariyo, MPH[1]

[1]East Tennessee State University, Johnson City, TN; [2]University of Massachusetts Medical School, Worcester, MA; [3]Klein Buendel, Inc., Golden, CO; [4]Klein Büendel, Inc., Wheat Ridge, CO; [5]Klein Buendel Inc, Golden, CO

Reducing indoor tanning (IT) is critical to preventing melanoma among young women. Mothers strongly influence whether daughters engage in IT, and teen girls often initiate IT with their mothers. Furthermore, girls who first experience IT with their mothers begin at an earlier age, become more habitual tanners, and are more resistant to change. Thus, mothers of teen girls are a significant target for IT interventions. Currently, 27 states, including Tennessee (TN), require parental permission for minors to IT. To ensure these laws have maximum prevention benefits, we developed a social media health intervention aimed at motivating mothers in TN to withhold IT permission. Because mothers who use IT might not be motivated to join a program designed to change their attitudes about tanning, we designed an approach in which tanning messages are embedded in an intervention about health topics of high interest to moms. To identify high interest topics, trained facilitators conducted key informant interviews with TN coordinated school health (CSH) personnel and focus groups with mothers of teen girls. Interviews and focus groups were recorded and transcribed and content analyzed. CSH interviews (n=19, representing 40 high schools) indicated that mental health (stress, bullying), substance abuse (tobacco, alcohol, prescription drugs), and obesity (physical activity, nutrition) were the topics of greatest interest. Results were confirmed in the focus groups with mothers (n=10), who also cited body image and healthy peer relationships. Intervention content was then designed using theory-driven messages to address IT plus these other health topics to maintain mothers' interest throughout the social media campaign. An initial prototype of a Facebook group was used by mothers (n=8) for 1 week, who then attended a focus group to provide feedback. Mothers reacted positively to the intervention, appreciating the diversity of topics delivered over a popular platform, felt more aware of important teen health issues, and used the posts as a 'checklist' that often prompted mother-daughter communication. Using 5-point Likert-type agreement scales, participants rated the IT posts on interest (avg. rating = 3.99), clarity (avg. rating = 4.70), credibility (avg. rating = 3.81), and appropriateness for social media (avg. rating = 4.43). Results were used to refine the intervention, which was launched in fall 2016.

“IT’S NOT JUST SKIN CANCER”: UNDERSTANDING THEIR CANCER EXPERIENCE FROM MELANOMA SURVIVOR STORIES SHARED ONLINE

Smita Banerjee, Ph.D.[1], Thomas A. D'Agostino, PhD[1], Mallorie Gordon, MA[2], Jennifer L. Hay, Ph.D.[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]The New School for Social Research, New York, NY

Cancer survivors narrate their stories in unique ways, articulating different aspects of cancer experience. The purpose of this study was to analyze the content of cancer stories that melanoma survivors share online in order to present the ways that survivors narrate their cancer experience, to identify survivors’ motivations for sharing, and to better understand the ways in which survivors are impacted by and cope with the diagnosis and treatment of cancer. In order to accomplish the objective, we conducted a qualitative analysis of melanoma survivor stories shared online. The sample consisted of 95 unique melanoma survivor stories, accessed from the Melanoma Research Foundation in November 2015, that were inductively and deductively coded for key themes and sub-themes. Emergent themes described different aspects of the melanoma experience from pre-diagnosis (identification of self-phenotype, putative behavioral causes of melanoma, suspicious findings, delay in diagnosis), diagnosis (communication of diagnosis, emotional responses), transition from diagnosis to beginning treatment (second opinion), treatment (positive reframing of attitude, proactive cancer management, side effects), and post-treatment phases (social support, vigilance behaviors post-treatment). Two themes that cut across all phases of the cancer journey were recognizing and dealing with uncertainty and survivors’ motive for sharing stories. The time period between undergoing a diagnostic test and receiving results is rife with uncertainty and anxiety, and the stories described uncertainty across three time periods: between diagnostic test and receiving results, while undergoing treatment (uncertainty about efficacy of a new drug used/clinical trial), and the period after finishing treatment and getting the next PET scan to assess the effectiveness of the treatment in shrinking tumor/eliminating cancer. In addition, survivors expressed interest in sharing their stories for a variety of reasons, frequently related to lessons they had learned through the trajectory of their illness and a desire to pass on their knowledge. Many survivors additionally expressed a strong desire to improve public awareness of melanoma and draw attention to the difficulty, and often deadliness, of the disease. These findings have implications for understanding how melanoma survivors may benefit personally from sharing their cancer experience online as well as the potential for survivor narratives to motivate behavior change and facilitate coping among

readers. Finally, this study presents immense potential to inform melanoma prevention health communication campaigns and interventions, and to help inform supportive models of care for other melanoma survivors

DO US HOSPITAL HOMEPAGES PROVIDE ACCESSIBLE CONTACT MODES FOR PEOPLE WITH HEARING LOSSES? A NATIONALLY REPRESENTATIVE STUDY

Liza S. Rovniak, PhD, MPH[1], Laura Penny, BS[1], Sean Nutting, BS[1], Christina Li, BS[1], Jessica Dick, BS[1], Khaled Iskandarani, MS[1], Allen R. Kunselman, MA[1], Melbourne F. Hovell, PhD, MPH[2], Jennifer L. Kraschnewski, MD, MPH[1], Christopher N. Sciamanna, MD, MPH[1]

[1]Penn State College of Medicine, Hershey, PA; [2]San Diego State University, San Diego, CA

Background: A hospital's homepage is like a virtual "front door" that can function to either welcome diverse patients or discourage entry. Patients with hearing losses are a medically underserved priority population who may use hospital homepages to identify non-hearing dependent contact modes for accessing medical or mental health services. No prior study, to our knowledge, has assessed the extent to which a nationally representative sample of US hospital homepages provide accessible contact modes for patients with hearing losses.

Methods: From an initial database of 3,484 US hospitals that accepted Medicare in 2015 (www.medicare.gov), we used stratified cluster random sampling (stratified by hospital type and clustered by US state) to obtain a representative sample of 526 hospitals. The homepages and immediate relevant linking pages (e.g., contact information pages) of these hospitals were coded for the presence vs. absence of five contact modes: telephone, email (address or online email form), text message, TDD/TTY, and sign language services. Coding was done by two independent raters who were trained to use a scripted search strategy that simulated how a typical patient might search for contact modes. Discrepancies between the initial two raters were resolved by a third independent rater.

Results: Cohen's kappa across all five patient contact modes averaged 0.82, with a range of 0.73 to 0.91, p's < .0001, indicating good to excellent inter-rater agreement. Of the 526 hospitals, 4 had no website and 4 were closing. Of the remaining 518 hospitals, almost all (99.4%) provided a phone number on their homepages. Among contact modes accessible to both deaf and hard-of-hearing populations, 74.9% of hospitals provided email contact information (62.7% had an online email form, and 18.5% had an email address), while just 0.4% provided text messaging information. Among contact modes typically used by deaf populations, only 9.1% of hospital homepages provided a TDD/TTY number, and just 0.6% described the availability of sign language services. One in five (20.3%) of the hospital homepages failed to provide any non-hearing dependent contact mode that would be accessible to deaf or hard-of-hearing populations.

Conclusions: Many hospital homepages provide limited contact information for people with hearing losses. The limited diversity of contact modes suggests a need to update existing website design guidelines in the Americans with Disabilities Act and related policies. Some of the contact modes studied, such as email and text messaging, could also offer collateral benefits to those with language barriers or those with limited availability during working hours. As hospital homepages provide an initial access point to healthcare for many patients, providing more diverse contact modes could help reduce public health disparities.

EXPLORING IDENTITY RECONSTRUCTION IN PEOPLE LIVING WITH MULTIPLE SCLEROSIS

Rebecca Floyd, Ph.D.[1], Shirin Khazvand, B.A.[2], Rebecca Howell, B.A.[1], Lara Stepleman, Ph.D.[1]

[1]Medical College of Georgia at Augusta University, Augusta, GA; [2]N/A, Augusta, GA

A person's identity shapes one's perspective of life's possibilities and aspirations for the future. Quality of life can be adversely impacted by changes in indentity that lead to downshifts in beliefs about future possibilities and in engagement in participatory roles in life. Understanding how a person's identity is reshaped by experience of chronic disease is therefore important to exploring attitudes that may impact treatment interventions and restrict rehabilitation outcomes.

Ninety people living with Multiple Sclerosis (MS) and receiving services from a clinic in the southeastern United States responded to the query of “how, if at all, has MS changed the way you think about yourself?” Responses were analyzed using grounded theory and a number of themes emerged. People indicated that their identity had been impacted by loss of focus on the present, including lack of continuity between one’s present self and one’s past or future selves. Additionally, sense of self was affected by changes in social relationships and threats to one’s integrity. Being forced to slow down, even when core components of self were preserved, was enough to disturb one’s identity, forcing identity reconstruction. These effects may be moderated by the role of faith, spirituality, or religiosity in influencing the person’s perspective on the valence of altering one’s identity. The salience of these themes was also compared across demographic groups such as age and race/ethnicity and these findings will be discussed.

Findings suggest that people may have difficulty focusing on the present due to a narrowing of perspective that either overemphasizes past abilities or riddles a person with anxiety about the future. Being unable to concentrate on the present or to perceive continuity between present and past, or present and future, may likely stymy the rehabilitation objective of meeting people where they are to move them forward.

Additionally, people living with MS appear to view being forced to slow down or being interdependent as steps backward in their treatment trajectory, escalating the perception of lost identity. While engagement of important others in one's care is often a vital source of support, it is important then for the clinician or provider to recognize that involvement of others may exacerbate a person's sense of identity disturbance rather than facilitating identity sustainment or reconstruction. Realizing how people with MS communicate barriers to identity reconstruction, in addition to disease management, will likely provide an interdisciplinary rehabilitation team with better understanding of obstacles to psychosocial functioning and overall quality of life.

HEALTH INFORMATION SEEKING AMONG SEXUAL MINORITY PEOPLE IN THE HEALTH INFORMATION NATIONAL TRENDS SURVEY (HINTS)

Jennifer M. Jabson, PhD, MPH[1], Joanne G. Patterson, MSW, MPH[1], Charles Kamen, PhD, MPH[2]

[1]University of Tennessee, Knoxville, TN; [2]University of Rochester Medical Center, Rochester, NY

Background. Seeking health information about health outcomes is associated with a reduction in health risk behaviors, more informed healthcare decision making, and better health outcomes. The general population increasingly uses the internet as a source for health and cancer-related information. However, all subgroups within the population may not use the internet at the same rate. Sexual minority people (SMP; i.e., lesbian, gay, and bisexual people) are considered "early adopters" of technology and therefore may be more likely to use the internet as a source of health and cancer-related information. However, there is no published evidence concerning health information seeking behaviors among sexual minority people as compared to heterosexual people (HP). The current project addresses this gap.

Methods. Data from the 2015 Health Information National Trends Survey (HINTS) FDA Cycle were used to describe and summarize health and cancer-related information seeking among SMP (n=103) and HP (n=1443). Differences in health and cancer-related information seeking were tested using chi-squared tests.

Results. More SMP in this sample reported having access to the internet (92.4%) than HP (79.4%; *p*=.001). SMP people were equally as likely as HP (59% vs 58%) to report unintentional exposure to health information while online (*p*=.21). SMP used the internet for a broad range of health information seeking activities. SMP used the internet most often to seek health information for themselves (88.1%) and least often to participate in online support groups (4.2%). The only statistically significant difference between SMP and HP was the use of health related videos on YouTube; SMP (37.2%) were more likely than HP (22.5%) to watch health-related videos on YouTube (*p*=.001). Multi-variable logistic regression did not reveal differences by sexual orientation in information seeking.

Conclusion. SMP are a difficult-to-reach population that experience significant health disparities. Our findings confirm that SMP access the internet at high rates and seek out health information online. This provides empirical evidence that online interventions could be a valuable way to address and reduce health disparities that affect SMP.

HOW ARE NON-NUMERICAL PROGNOSTIC STATEMENTS INTERPRETED AND ARE THEY SUBJECT TO POSITIVE BIAS?

Samantha Siess, MA[1], Anne Moyer, Ph.D.[1], Sumeet Bhinder, BS[2]

[1]Stony Brook University, Stony Brook, NY; [2]Stony Brook University, Hopewell Junction, NY

Background: Frank, clear communication with surrogate decision makers for terminally-ill or incapacitated patients has important implications for satisfaction with care and sound decision making. Negative numerical prognostic statements have been found to be interpreted in a positively-biased manner. Less precise non-numerical statements, particularly those using threatening terms, may be even more subject to such biases.

Objective: This study examined whether there is an optimistic bias in the interpretation of non-numerical prognostic statements and the extent to which this might vary by the severity of the prognosis portrayed and the language used to convey them.

Methods: 200 participants interpreted 14 non-numerical prognostic statements about a hypothetical patient with varying levels of risk framed in terms of dying or surviving. They indicated what they believed the likelihood of survival to be, on a scale from a 0% to a 100%.

Results: The most negative prognostic statement, “They will definitely not survive,” was interpreted significantly more optimistically (18.82%), in that it was significantly further from its reference point of 0% survival, than the most positive prognostic statement, “They will definitely survive,” (92.77%) was from its reference point of 100% survival, $t(199) = 6.59$, $p < .001$. A 2 x 2 within-group ANOVA was used to examine the main effects of framing and prognostic outcome in response to the statements “It is very likely that they will die,” “It is very unlikely that they will die,” “It is very likely that they will survive,” and “It is very unlikely that they will survive.” There was no main effect of framing, $F(1, 199) = .119$, $p = .731$, and no interaction of framing and prognostic outcome, $F(1, 199) = .66$, $p < .001$. However, there was a main effect of outcome, again suggesting that statements that conveyed a poorer prognosis were more likely to be interpreted in a positively biased manner, $F(1, 199) = 61.01$, $p < .001$.

Conclusions: In addition to using suggested strategies, such as inquiring about how much individuals wish to know about prognoses, practitioners should be aware of the ways in which commonly-used non-numeric language will be understood in numeric terms during prognostic discussions, and check recipients' understanding for potential positive bias.

ILLUSTRATING CANCER RISK: DEVELOPMENT OF BREAST CANCER RISK COMMUNICATION MATERIALS FOR A NOVEL BRCA1/2 GENETIC MODIFIER TEST

Margaux C. Genoff, B.S.[1], Joy S. Westerman, B.A.[1], Elyse Shuk, M.A.[1], Jennifer L. Hay, Ph.D.[1], Kenneth Offit, M.D. , M.P.H.[1], Mark E. Robson, M.D.[2], Jada G. Hamilton, Ph.D., M.P.H.[1]

[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York City, NY

Background: Breast cancer risk estimates by age 70 range from 31-78% for *BRCA1/2* carriers. Recent research has identified a set of genetic variants that modify breast cancer risks among female *BRCA1/2* carriers. These variants will be used as part of a clinical genetic modifier test (GMT) to help healthcare providers more accurately predict *BRCA1/2* carriers' breast cancer risk. To prepare for the future availability of GMT, It is critical to develop effective strategies for communicating this risk information to *BRCA1/2* carriers.

Method: We conducted in-person interviews with 30 female *BRCA1/2* carriers about their perceptions and preferences regarding sample GMT risk communication materials. Participants (aged 25-80 years; 87% Caucasian; numeracy M=4.8 on a scale ranging from 1-6) were randomized to receive one of three sample GMT results (indicating low, moderate, or high breast cancer risk). Participants were shown results in four different formats (panel of genes, social comparison icon array, verbal risk estimate, and graphical risk estimate) and asked how likely they would be to get breast cancer in their lifetime (rated from 1=*very unlikely* to 5=*very likely)* in response to each format.

Results: The preferred format across the three breast cancer risk levels was the graphical estimate, alone or in combination (often with the verbal estimate). Participants described positive, neutral, and negative emotional responses to the formats; however, the icon array evoked only negative emotions. The perceived lifetime risk of developing breast cancer significantly differed among participants in the three groups in response to the verbal risk estimate (Low M=3.06*;* Moderate M=3.75*;* High M=4.65; $p < .001$) and graphical risk estimate formats (Low M=2.85; Moderate M=3.55; High M=4.33; p=.002*);* no differences across risk groups were observed in response to the panel of genes or icon array formats. Overall, interest in obtaining GMT was high, and the majority of participants reported that GMT results would make their cancer risk management decisions easier.

Conclusion: The minimal amount of necessary information to include in GMT test results

appears to be graphical and verbal estimates of risk. Information presented in these formats is acceptable to patients, influences their breast cancer risk perceptions, and may assist in decision making about risk management. These findings will inform future efforts to translate GMT into care consistent with patients' preferences.

OVERCOMING BARRIERS TO A SCHOOL BMI SCREENING PROGRAM

Bryce Abbey, PhD, Kate Heelan, PhD, Todd Bartee, PhD

University of Nebraska at Kearney, Kearney, NE

Body Mass Index (BMI) screening in schools has been scrutinized due to privacy issues and costs associated with communicating BMI screening results to parents. To overcome these barriers a web application was developed to decrease the burden of staff training, easily generate BMI Report Cards (BMI RC) and send them electronically to parents via email. The current research compared parental satisfaction of BMI screening in schools and utilization of BMI RC. Methods: In 2011, paper copies of BMI RC were sent via a sealed envelope addressed to the parents of 2557 elementary school children. In 2015, emails were sent to parents of 2718 elementary school children that included their child’s BMI RC. Parents responded to a survey that was sent approximately ten days after delivery of the BMI RC. In 2011, 971 parents completed either a paper or email survey. In 2015, the survey was administered only via email with 503 parents responding. The survey consisted of thirteen closed-ended questions regarding BMI RC content, parent perceived importance of BMI screening in school, and parent intention for behavior change. Results: The response rate in 2011 was 38.0% and 18.5% in 2015. Nearly all respondents (95%) reported they read all or most of the BMI RC in both 2011 and 2015. More than three-quarters (76.4%) of respondents reported it was somewhat or very important to include height and weight measurement as part of their child’s yearly health screening in 2015, compared to 88.4% in 2011. In 2011 and 2015, respectively, parents with children equal to the 85th percentile or above reported that after they had received the BMI RC that they had already or intended to create a better eating plan at home (41.7%, 64.7%), decrease TV/video time (59.9%, 56.9%), and increase exercise or physical activity (33.8%, 72.5%). The electronic calculation of BMI percentile decreased staff time and electronic generation and distribution of BMI RC decreased printing costs by $0.15 per student. Discussion: Using email to send BMI RC allowed schools to address concerns through protecting children and peers from seeing the BMI RC. In both survey years, parents reportedly read all or most of the BMI RC, which included nonjudgmental language about student BMI percentiles and their use as a screening tool, importance of lifestyle changes for better health, suggested actions for parents, as well as, local and national resources on healthy lifestyles. Parents also continued to respond that it is somewhat or very important to include height and weight as part of yearly health screenings. These findings are consistent with past research suggesting when schools communicate BMI screening results with parents they are more likely to support healthy lifestyle changes for their children. Schools who utilize a BMI RC as part of their BMI Screening program should consider safeguards and cost saving methods such as email-based communication.

PATIENT REPORTS ABOUT COMMUNICATION WITH THEIR PHYSICIAN AND ASSOCIATIONS WITH PATIENT ACTIVATION

Jorie Butler, PhD[1], Bryan Gibson, PhD[2], Man Hung, PhD[2], Marjorie Carter, MSPH[1], Candace Haroldsen, MS[3], Matthew Samore, MD[2]

[1]University of Utah, SALT LAKE CITY, UT; [2]University of Utah, Salt Lake City, UT; [3]University of Utah, Salt Lake Çity, UT

Patient activation involves 4 developmental stages 1) patient recognition of the importance of their vital role in health management 2) patient development of confidence and acquisition of information necessary to be an active participant in health management 3) actively participating in health actions, and 4) maintenance of active health management despite challenges, such as stress. The relationship and communication between physicians and patients may play an important role in supporting patients in the process of becoming activated: patients with positive interactions with their providers may be more likely to develop the necessary skills and tenacity to maintain active involvement in health maintenance. Understanding patient-provider communication factors that contribute to activation is important to support patients in developing greater activation. A survey of 810 patient participants receiving care in primary care clinics in rural communities was conducted to understand patient experience in primary care clinics. Patients with at least one chronic illness were more heavily recruited to ensure that participants had a need for regular follow-up care and interaction with their provider. The participants were likely to report a chronic illness (79%) and were largely female (61%, 39% male) with 42% over age 65 and mean education level above high school graduation. In a telephone survey, participants were asked to relate their experiences with their primary care physician over the preceding twelve months. Participants reported on two communication areas - how often their physician listened carefully to them and whether their physician was helpful when talking with the patient about problems or concerns. Participants also completed the 13-item Patient Activation Measure (PAM). A regression model examining patient reports of activation demonstrated that age, and two items about communication with their provider were related to patient activation whereas patient gender was not. Patient reports that the doctor really listened ($\beta = .10$; p .05) was not (F (4, 600) = 13.10; $p < .01$). Results suggest that sensitive communication style from a primary care physician may be an important contributor to patient activation. Implications include interventions to support providers in developing communication skills to foster patient activation particularly for older patients.

THE PROVIDER-PATIENT RELATIONSHIP AND SATISFACTION WITH CARE AMONG HIGH AND LOW ACCULTURATED LATINA BREAST CANCER SURVIVORS

Dara H. Sorkin, PhD[1], Senxi Du, Undergraduate Student[2], Kelly Biegler, PhD[3], Yunan Chen, PhD[3], Alfred Kobsa, PhD[3], Alice Police, MD[3], Mienah Sharif, PhD[3], Dana B. Mukamel, PhD[3], Sadeeka Al-Majid, PhD[4]

[1]University of California Irvine, Irvine, CA; [2]University of Chicago, Irvine, CA; [3]UC Irvine, Irvine, CA; [4]California State University, Fullerton, Fullerton, CA

Due to advances in breast cancer detection and treatment, the average 5 year survival rate is 89%. Thus, efforts to improve health outcomes during survivorship are a high priority. Converging evidence suggests that the quality of the provider-patient relationship is not only associated with satisfaction with care, but also associated with improved health outcomes and better quality of life.

Important factors in the provider-patient relationship have been shown to include participatory decision making (PDM), trust in the physician, and being treated as an equal partner. Several recent studies have identified disparities in PDM with Latina patients exhibiting the lowest rates of PDM and poorest physician-patient communication; however, this group generally has the highest ratings of satisfaction with care. This paradoxical finding may be attributed to the fact that prior studies have not considered acculturation factors, including English language proficiency, which are likely to impact physician-patient communication and patients' confidence in initiating participation in treatment decision making.

Objective: This study aimed to address this gap in the literature by examining: 1) Associations among three factors important to the provider-patient relationship: PDM, trust in physician, and being an equal partner, 2) Associations between these qualities and satisfaction with care, and 3) Whether acculturation differences moderate the association between these qualities of the provider-patient relationship and satisfaction with care.

Method: Data were derived from 70 surveys completed by Latina breast cancer survivors.

Results: PDM scores were positively correlated with trust ($r = 0.48$, $p < 0.001$) and satisfaction with care ($r = 0.39$, $p < 0.001$), irrespective of acculturation status. In higher acculturated women, lower trust ratings were associated with lower satisfaction with care; however, associations between trust and satisfaction with care were not observed in women with lower acculturation status (F (1,66) = 5.43, p=0.02). Being treated as an equal partner was not significantly associated with ratings of satisfaction with care in either of the acculturation groups of our sample.

Discussion: High-acculturated patients may have greater familiarity with the healthcare system, and thus have adapted expectations that are in-line with those of non-white Hispanic women. Low-acculturated patients, in contrast, may not have the same expectations of trust for contributing to their ratings of care. Implications for providing high-quality care for diverse women will be discussed.

THE RELATIONSHIP BETWEEN FORGIVENESS, WELL-BEING AND HEALTH-INFORMATION SEEKING BEHAVIOR IN A SAMPLE OF LGBTQ INDIVIDUALS

Victoriya Vakhotina, M.S[1], Asani H. Seawell, PhD[2]

[1]Pacific University Oregon, West Hollywood, CA; [2]Pacific University, Hillsboro, OR

Forgiveness has been found to be beneficial to human health in previous research, suggesting that this construct may be protective of health. Well-being also appears to promote health as those who are lower on life satisfaction tend to have poor to fair general health and that life satisfaction was related to positive health outcomes. Forgiveness and well-being both tap into the health-information seeking behavior (HISB) construct as part of the overall health construct. Previous studies regarding HISB have mostly looked at the general population; therefore, the purpose of this study was to see if a relationship exists between forgiveness, well-being and HISB in a minority (LGBTQ) population.

Participants (N = 136) for the study were recruited through social media and the Q Center – a safe space for Portland's LGBTQ community - and asked to take an online survey through Qualtrics, a survey-building website. The survey consisted of a consent form, demographic information, Heartland Forgiveness Scale, Flourishing Scale, Krantz Health Opinion Survey and a thank you note. Participants were asked to complete the survey in one sitting to ensure privacy and anonymity and took less than 30 minutes to complete.

Multiple regression analysis found marginal significance between well-being and behavioral HISB (b = .044, SE = .023, p = .059) with higher well-being scores indicating less behavioral involvment in healthcare needs. Situational forgiveness and informational HISB was significant (b = .135, SE = .059, p < .05) as situational forgiveness increased, information seeking declined. Finally, well-being and informational HISB was significant (b = -.086, SE = .20, p < .01) indicating that LGBTQ individuals who scored higher on well-being were more likely to be actively involved in seeking out information regarding their healthcare needs.

These findings reveal that a relationship exists between forgiveness, well-being and HISB in this sample; therefore, it would be prudent to utilize this connection in future studies as tools

to better combat health disparities in the LGBTQ population, as previous studies denote that this community does not seek out health information and treatment on par with the general population due to prejudice and discrimation.

TOBACCO INFORMATION SEEKING AND SOURCES OF HEALTH INFORMATION AMONG RACIAL/ETHNIC GROUPS

Anh Nguyen, PhD, MPH[1], Joelle Robinson, MPH[2], Erin Keely. O'Brien, Ph.D.[3], Xiaoquan Zhao, Ph.D.[4]

[1]Center for Tobacco Products/ FDA, Silver Spring, MD; [2]U.S. Food and Drug Administration Center for Tobacco Products, Silver Spring, MD; [3]Center for Tobacco Products, U.S. Food and Drug Administration, Silver Spring, MD; [4]George Mason University, Fairfax, VA

Introduction

Racial/ethnic differences in tobacco use may be explained by different levels of access and use of tobacco-related health information. The objectives of the study are to describe the different sources of health information and the different types of tobacco-specific information that are sought after among specific racial/ethnic groups.

Methods

We analyzed cross-sectional data from HINTS-FDA 2015, a nationally representative survey of non-institutionalized U.S adults. Weighted bivariate analyses assessed differences in first sources of health information and types of tobacco information sought among racial/ethnic groups. Racial/ethnic groups examined included non-Hispanic (NH) White, NH-Black, Hispanics, NH-Asian and Pacific Islander, and NH-Other.

Results

A significantly higher proportion of NH-Whites (13%) compared to NH-Asians and Pacific Islanders (4%) reported ever searching for information related to cost/coupons for tobacco products.

Among NH-Other, a higher proportion of respondents who sought health information from print media and traditional sources (59%) or the Internet (34%) reported searching for information related to the health effects of tobacco compared to those who sought information from interpersonal health sources (< 1%).

Among NH-Blacks, respondents who sought health information from print media and traditional sources had a significantly lower proportion of those who ever searched for

information related to quitting (1%) compared to those who sought information from the Internet (12%) or the interpersonal health sources (30%). A similar same pattern was found among Hispanics with regard to information related to cost/coupons: print media and traditional sources (< 1%), Internet (7%), and interpersonal health sources (26%).

Among NH-Blacks, non-current tobacco users had a significantly higher proportion of those who sought health information from the Internet (70%) compared to those who sought information from print media or traditional sources (12%) or interpersonal health sources (18%).

Conclusions

Information seeking behavior varies by information type and source of the information across racial/ethnic groups. The current research suggests that different strategies, such as culturally tailoring messaging and leveraging the use of preferred information channels, could more effectively reach specific racial/ethnic groups.

PENNSYLVANIA POLICYMAKERS’ ATTITUDES & KNOWLEDGE REGARDING WATERPIPE TOBACCO SMOKING & ELECTRONIC NICOTINE DELIVERY SYSTEMS

Beth L. Hoffman, BSc[1], Megan C. Tulikangas, MPP[2], Ariel Shensa, MA[1], A. Everette James, JD, MBA[1], Jason B. Colditz, MEd[1], Brian A. Primack, MD, PhD[1]

[1]University of Pittsburgh, Pittsburgh, PA; [2]Allegheny County Health Department, Pittsburgh, PA

Introduction. While youth smoking of traditional cigarettes is decreasing, waterpipe tobacco smoking (WTS, also known as hookah smoking) and use of electronic nicotine delivery systems (ENDS, such as e-cigarettes) are rapidly increasing. However, most current nicotine and tobacco regulations, do not apply to WTS and ENDS. Furthermore, legislatures have been slow to update policy measures related to them. Therefore, we sought to assess knowledge of and attitudes toward WTS and ENDS among members of the Pennsylvania legislature.

Methods. We approached all standing members of the key health and welfare committees for both the Pennsylvania House and Senate. Recognizing that this is a notoriously difficult population to assess, we developed a complex protocol that allowed completion via mail, email, or fax. To assess knowledge, we asked participants to self-report familiarity with these products using a visual analogue scale. We also asked 14 factual items related to WTS and ENDS; items were based upon recent data reports including the 2014 National Youth Tobacco Survey. To assess attitudes, we included 5 items based upon current pending legislation concerning substance regulation. Additionally, participants ranked different substances of abuse from highest to lowest legislative priority. We also included four open-ended items, and three independently working researchers analyzed responses to these items using thematic analysis.

Results. We received responses from 13 of 25 eligible individuals (52%). On a scale from 0 (not at all familiar) to 100 (very familiar), participants ranked their familiarity with WTS and ENDS as 28 (SD=15) and 50 (SD=13), respectively. Participants answered a mean of 27% (SD=20) of knowledge items correctly. With regard to legislative priority of substance abuse, WTS ranked eighth (least urgent) and ENDS ranked fifth. Thematic analysis revealed that the most

common sentiment was that policy makers were eager for additional information and guidance around these substances.

Conclusion. Despite the fact that tobacco use remains a leading cause of preventable death worldwide, lawmakers exhibit a lack of knowledge concerning newer forms of tobacco and nicotine and consider them to be relatively low legislative priorities. However, respondents did express a desire for more information about these substances, suggesting the potential for public health entities to promote effective policy development via improved dissemination of information.

DEVELOPING A BIOBEHAVIORAL HIV INTERVENTION FOR HIGH-RISK DRUG USERS: TAKING INTO ACCOUNT IMPACT OF NEUROCOGNITIVE IMPAIRMENT

Roman Shrestha, MPH[1], Pramila Karki, RN[2], Frederick Altice, PhD[3], Michael Copenhaver, PhD[2]

[1]University of Connecticut Health Center, Willimantic, CT; [2]University of Connecticut, Storrs, CT; [3]Yale University, New Haven, CT

Introduction: There is an urgent need for innovative approaches to the prevention of HIV transmission. Innovative 'combination' approaches can be comprised of both evidence-based biomedical and behavioral interventions while incorporating strategies to accommodate a wide range of neurocognitive deficits (NCI) for many people who use drugs (PWUDs). We therefore conducted formative research aimed at systematically adapting and combining evidence-based interventions that integrates HIV risk reduction, strategies to accommodate cognitive deficits, and encourage uptake and adherence to pre-exposure prophylaxis (PrEP) to implement among drug users in treatment.

Methods: Between May and June 2016, we conducted structured focus group sessions with treatment providers (n=10) and members of the target population (n=20) who were enrolled in a community-based methadone maintenance program in New Haven, Connecticut. Data analysis followed a thematic analysis approach utilizing several qualitative data analysis techniques, including inductive analysis and cross-case analysis.

Results: Given the parameters that were suggested, it seemed appropriate to refine the CHRP intervention – an evidence-based behavioral intervention that has demonstrated efficacy in reducing drug- and sex-related HIV risk behaviors – by focusing primarily on a range of relevant topics pertaining to reducing sex- and drug-related HIV risk behaviors. We also concluded that greater emphasis would be given to certain strategies to accommodate participants with NCI in order to help them to better concentrate, learn, and remember details. Additionally, it was noted that the revised intervention should cover content specific to PrEP, including basics about PrEP, potential motivation driving PrEP use (e.g., pros and cons of achieving high levels of adherence to PrEP), problem solving (e.g., improving strategies for identifying and overcoming obstacles to adherence), facilitators to PrEP adherence (e.g., learning memory aids for improving adherence), enhancing decision-making related to PrEP, and overcoming stigma related to being on PrEP.

Conclusion: The current study details the formative research process in preparation to adapt and to enhance an EBI – taking into account both published empirical evidence and input from target population and treatment providers – for use with high risk PWUDs and are in drug treatment. The resulting bio-behavioral intervention, the CHRP-NCI, is designed to address the HIV-related risk behaviors and PrEP uptake and adherence as experienced by many the drug users in treatment. We hope that the process and outcome of this formative research will help to inform similar work in the future as a growing number of EBIs have become widely available, but may not yet be in optimal form for implementation among individuals with neurocognitive issues.

FOOD INSECURITY, DEPRESSION, AND ALCOHOL USE IN PERSON'S LIVING WITH HIV

Dominica Hernandez, PhD[1], Seth Kalichman, PhD[2]

[1]University of Connecticut, Storrs, CT; [2]University of Connecticut, Institute for Collaboration on Health, Intervention, and Policy (InCHIP), Storrs, CT

Background: Food insecure persons living with HIV/AIDS (PLWHA) suffer desperate economic circumstances and are at a higher risk for poorer mental health outcomes, which in turn may lead to maladaptive coping behaviors, such as alcohol use. Due to a compromised immune system and the need to be on anti-HIV medication in order to suppress HIV replication, the use of any alcohol places PLWHA at greater health risks. Furthermore, the association of food insecurity and Alcohol use may be co-facilitated by depression.

Aims: The aim of this study was to assess the impact of depression on alcohol use in food insecure PLWHA.

Methods: Analyses were carried out on a 171 PLWHA in Atlanta, Georgia. Participants were recruited as part of an intervention trial aimed at decreasing alcohol use in PLWHA. Baseline data was collected at enrollment where participants were consented and asked to complete an anonymous survey that included the Center for Epidemiologic Studies Short Depression Scale (CESD-10) and the Alcohol Use Disorders Identification Test (AUDIT) as well as a measure of food security.

Results: Our sample was primarily Black (94%), 64% were male and 36% female, mean age was 47.2 years, SD = 9.3. A mediation model was constructed to assess the affects of depression on food insecurity and alcohol use, with AUDIT score as the continuous outcome variable, CESD-10 score as the continuous mediator variable, and food insecurity as a dichotomous predictor. The model displayed a statistically significant indirect effect as expressed by a 95% confidence interval that is above zero (CI = .352 – 1.82). The indirect effect showed that relative to participants that were food secure, participants with food insecurity scored, on average, .97 units higher on the AUDIT as a result of the effect of food insecurity on depression, which, in turn, affected their alcohol use. The direct effect was not statistically significant, which suggests that when accounting for depression there was no effect on food security in their AUDIT score.

Conclusion: Our findings suggest depression mediates the use of alcohol in food insecure PLWHA; however, results may not be generalizable to other PLWHA. Even so, these results

suggest important findings that should be further explored and considered in future intervention development for PLWHA living in poverty.

PATIENT REPORT VS “OBJECTIVE MEASURES” IN PREDICTING EVERYDAY FUNCTIONING OUTCOMES IN HIV+ ADULTS

Anne Heaton, N/A[1], Raeanne C. Moore, PhD[2], Emily Paolillo, B.S.[3], Alexandra Rooney, B.A.[4], Dilip J. Jeste, MD[5], David J. Moore, Ph.D.[6]

[1]UCSD HIV Neurobehavioral Research Program, Del Mar, CA; [2]University of California, San Diego, San Diego, CA; [3]SDSU/UCSD Joint Doctoral Program in Clinical Psychology, San Diego, CA; [4]University of California San Diego, San Diego, CA; [5]UCSD Stein Institute for Research on Aging, La Jolla, CA; [6]UCSD HIV Neurobehavioral Research Program, San Diego, CA

Functional disability is a common and growing problem in older HIV+ adults. Due to the new generation of antiretrovirals, HIV+ individuals are living longer, producing an emerging need for researchers to identify and treat real-world functioning problems. This study assesses ways to predict such problems in older HIV+ adults by evaluating functional capacity and cognitive complaint constructs as they relate to everyday functioning. One hundred HIV+ adults (Mean age=50 years; range: 35-65 years) completed a comprehensive neuropsychological and neuromedical battery, including a measure of functional status (IADL Dependence vs. IADL Independence), an objective measure of functional capacity (UCSD Performance-Based Skills Assessment-Brief [UPSA-B]) and a self-report measure of cognitive complaints (Profile of Mood States [POMS]-Confusion/Bewilderment subscale). Higher UPSA-B scores were related to better global neuropsychological ability, but unrelated to functional independence ($p>0.05$). Conversely, while POMS scores were unrelated to global neuropsychological ability or the UPSA-B, lower POMS scores were significantly associated with functional independence (*p*p < 0.001) than the area of no information (AUC of 0.50). A cutoff score of 7.5 best discriminated between functional dependence vs. functional independence, with a sensitivity of 73.1% and specificity of 71.3%. This study found that the POMS demonstrates good support as a brief screening tool for functional dependence among adults living with HIV. Functional disability among adults HIV+ is still not well understood and is likely multifactorial in nature. Self-appraisals of cognitive status may be just as important (or perhaps even more so) than actual cognitive or functional ability in understanding real-world problems in everyday functioning.

PERCEIVED RISK OF HIV TRANSMISSION APPRAISAL AMONG MSM WHO ARE PREP AWARE VERSUS PREP UNAWARE

Redd Driver, BA[1], Devon Price, MS[1], Stephanie D. Finneran, MA[2], Seth Kalichman, PhD[1]

[1]University of Connecticut, Storrs, CT; [2]University of Connecticut, Vernon, CT

New diagnoses of HIV in Men who have sex with men (MSM) are 44 times that of men who do not have sex with men (CDC, 2015). Current HIV treatments, daily-dosed antiretroviral therapy (ART), reduce the amount of HIV in the body preserving immune functions. Additionally, ART serves as a prevention strategy, treatment as prevention (TasP), preventing transmission to others (CDC, 2015). Although TasP is efficacious in preventing transmission, it remains unclear how MSM perceive the relative risks of condomless receptive anal sex with a partner who is using TasP. Moreover, the perceived risk of sex with an HIV positive partner using TasP may be associated with awareness of using ART as pre-exposure prophylaxis (PrEP). PrEP is the use of a daily dose of ART in HIV negative individuals to prevent infection if exposed to HIV. Previous research has indicated that a central predictor of attending to health information and engaging in health behavior is perceived risk (Gerard et al., 1996). Therefore, perceptions of sexual risks with a partner using Tasp may be related to knowledge of PrEP. The present study examined whether perceptions of risk associated with engaging in condomless anal sex with a TasP-using partner generalizes across MSM who are aware of PrEP and those who have no prior knowledge of PrEP.

Participants (267 MSM) were surveyed during the 2015 Atlanta Pride Festival. Surveys assessed demographics, sexual behaviors, and health care experiences. Risk perceptions were assessed through four 5-point measures under two condition; (1) condomless anal with an HIV positive partner using TasP, and (2) condomless anal sex with an HIV positive partner not receiving treatment. For each condition participants rated risks for both receptive and insertive anal sex.

Results demonstrated that MSM who were aware of PrEP reported significant differences in receiving health care in the past year, and being open about their sexual orientation Additionally, PrEP aware MSM did not report a significant difference in engaging in condomless receptive anal sex compared to PrEP unaware MSM, p =.96. Regarding perceived risk of engaging in condomless anal sex, PreP aware MSM reported significantly greater risk perceptions of engaging in the highest risk behavior, condomless receptive anal sex with an HIV positive partner not receiving treatment, than those who were not aware of PrEP p = .02. However, risk perceptions of engaging in lower risk behavior, condomless insertive anal sex

with an HIV positive partner using TasP, were not significantly different for PrEP aware MSM compared to PrEP unaware MSM p = .09. These findings suggest that PrEP awareness is associated with HIV TasP risk perceptions reflecting a realistic view of risks, whereas unawareness of PrEP may be related to misperceptions of risk related to TasP. These results have implications for educating MSM more generally about HIV prevention treatments to increase PrEP uptake.

SELF-EFFICACY MEDIATES THE ASSOCIATION OF DEPRESSION TO ANTIRETROVIRAL MEDICATION ADHERENCE AMONG HIV-POSITIVE OUTPATIENTS

Jacklyn Babowitch, B.S.[1], Peter A. Vanable, PhD[1], Shannon M. Sweeney, PhD[2]

[1]Syracuse University, Syracuse, NY; [2]Le Moyne College, Kirkville, NY

Adherence to prescribed antiretroviral therapy (ART) is a central feature in the clinical management of HIV. Although several studies have documented the negative effects of depression on ART adherence, little is known about the mechanisms underlying this association. In this study, we test the hypothesis that medication-taking self-efficacy will mediate the relationship of depression to medication adherence utilizing a sample of HIV-positive outpatients recruited during routine care (*N* = 206). Participants (*M* age = 46.5; 62% male) completed the Center for Epidemiological Studies – Depression Scale (CES-D), as well as self-report measures of ART adherence for the previous week. Across the sample, 62% endorsed clinically significant depressive symptomatology on the CES-D. Nevertheless, participants reported missing few antiretroviral doses in the past week (*M* = 0.10, *SD* = .26). Mediation analyses confirmed that depressive symptoms were negatively associated with medication-taking self-efficacy (*b* = -1.20, *SE* = .29, *p* < .001), and there was a significant correlation of medication-taking self-efficacy with the number of missed antiretroviral doses for the past week (*b* = -.06, *SE* = .01, *p* < .001). Although depressive symptoms were not directly associated with ART adherence (*b* = -.03, *SE* = .04, *p* = .38), a test of the indirect effect of depressive symptoms on ART adherence via medication-taking self-efficacy was significant (*b* = .07; bootstrap 95% CI: .03, .14). Thus, findings support the hypothesis that medication-taking self-efficacy mediates the association between depressive symptoms and ART adherence assessed for the previous week. Behavioral interventions to enhance self-efficacy may benefit from the inclusion of content focusing on alleviating depressed mood as a means of enhancing ART adherence.

VARIATION IN THE FORMS AND SOURCES OF SOCIAL SUPPORT FOR CARE-SEEKING ACROSS THE HIV CARE CONTINUUM IN THE RURAL SOUTH

Miranda Iverson Hill, MPH[1], Amber Huff, PhD[2], Neale Chumbler, PhD[3]

[1]University of Georgia, Athens, GA; [2]Institute of Development Studies, University of Sussex, Brighton, East Sussex, England, United Kingdom; [3]Western Kentucky University, Bowling Green, KY

In spite of progress towards understanding the importance of social support for improved health outcomes in Persons Living with HIV (PLWH), more remains to be known about which sources and forms of support are most beneficial at each stage of HIV treatment. In this study, we use a qualitative analytic approach to investigate the mechanisms of social support that have been deemed most integral to the HIV diagnosis, care linkage, engagement, and retention behaviors of a diverse sample of rural PLWH (N=18). The in-depth interviews used for this study were collected during the qualitative phase of a larger mixed methods needs assessment for the Northeast Georgia health district. A deductive-inductive analysis of participant narratives revealed variation in the perceived importance of particular forms and sources of social support during the initial versus advanced stages of HIV care. Participants identified the emotional, informational, and appraisal support provided by family as critical for emotional stability, coping, and care linkage during the initial stages of diagnosis and treatment. Once in care, participants emphasized informational and instrumental forms of support from care providers and appraisal support from peers as key influences in care engagement and retention. Increased understanding of how social support contributes to the HIV treatment behaviors of PLWH can fill important knowledge gaps in research and inform the efforts of health care providers seeking to leverage HIV patients' social networks towards improving treatment and health.

BEHAVIORAL HEALTH NEEDS ASSESSMENT OF AN UNDERSERVED URBAN FAMILY MEDICINE CLINIC

Zach Radcliff, M.S.[1], Allison Baylor, B.A.[1], Sarah Braun, MS[1], Mark Ryan, MD[2], Bruce Rybarczyk, PhD[1]

[1]Virginia Commonwealth University, Richmond, VA; [2]Department of Family Medicine and Population Health, Virginia Commonwealth University School of Medicine, Richmond, VA

Title: Behavioral Health Needs Assessment of an Underserved Urban Family Medicine Clinic

Objective: Family medicine clinics are a common access point for mental health care for underserved populations. These patient groups often have limited access and other barriers to receiving adequate mental health services, which can place the burden on physicians to provide extensive behavioral healthcare. In 2015, integrated behavioral healthcare (IBHC) services were added to a safety net family medicine clinic to address these needs. Currently, psychology doctoral students provide pro-bono, IBHC sessions at this clinic. The present study describes this population and delineates behavioral health needs of this vulnerable population.

Methods: As part of regular patient monitoring, English or Spanish versions of the Patient Health Questionnaire-9 (PHQ-9), the Generalized Anxiety Disorder-7 (GAD-7), and Pediatric Symptom Checklist-17 (PSC-17) are administered to screen for depression and anxiety in adults and externalizing/internalizing behaviors in children, respectively. Presenting problems and session length/type are also documented daily.

Results: The family medicine clinic provided services to more than 3,500 unique patients resulting in 10,000 medical visits annually. The population was 58.3% African American, 24.2% Caucasian, 22.9% Hispanic/Latino, and 17.5% other race/ethnicity. Further, 28.8% of patients were

In the initial year of IBHC clinic, 687 unique patients (19.4% of the clinic population) were provided IBHC services for 1560 sessions. The PHQ-9 and GAD-7 for an initial sample of 105 patients (64% African American, 22% Caucasian, 7% Hispanic/Latino, 7% other) indicated that those who are referred to the IBHC team have moderately severe levels of depression (*m*=15.2) and moderate levels of anxiety (*m*=13.1). Descriptive statistics for presenting problems, length of sessions, and session interventions will be provided.

Conclusion: This sample provides a unique view of the needs of a largely minority urban population with limited access to mental healthcare. Early indications show that patients referred to the IBHC team have significant behavioral healthcare needs that were likely unmet prior to initiation of these critical services.

PATIENT RETENTION: THE KEY TO SUCCESSFUL SHARED MEDICAL APPOINTMENTS.

Ruth Nutting, MA

Via Christi, Wichita, KS

Shared medical appointments (SMA’s) optimize patient and provider time through a team based, interprofessional approach. SMA’s have been shown to reduce hemoglobin HbA1C, blood pressure, and LDL cholesterol; boost adherence to ADA standards of care; and decrease hospitalization rates. Although research has demonstrated that SMA’s improve health related outcomes, literature also indicates that poor retention rates of patients have affected health related outcomes. We undertook a mixed-methods study to explore why our SMA program had a high rate of retention and achieved success.

This study took place at a Joint Commission certified Primary Care Medical Home. Patients with poorly controlled Type 2 diabetes, determined as HbA1C greater than 8.0% were invited to participate in the project. A total of 21 patients chose to participate. Four SMA group cohorts were formed—participants joined whichever meeting time was convenient for them. Ultimately, group sizes ranged from 4-6 participants. In order to maintain cohesion, new patients were added to these groups once per year.

At the end of year one, 18 of the 21 participants (86%) who attended the first SMA continued to participate. At this time, we performed a quantitative pre/post study of clinical outcomes and survey responses. Quantitative tools included the Patient Health Questionnaire-9, the Diabetes Lifestyle Survey, and the Full Circle Diabetes Program. A1C and other biometric screenings were analyzed. Qualitative investigation included four semi-structured interviews that assessed: barriers patients faced before joining SMAs; how patients increased control over diabetes; changes in mood; patients’ overall experiences of SMAs; perceptions of the value of SMAs; and patients’ confidence in sustaining learned coping behaviors. These interviews were held at the conclusion of the year two.

Quantitative and qualitative findings depicted patients experiencing increased psychosocial wellbeing and improved adherence to treatment regimens. Qualitative findings highlighted that SMAs reduced barriers to self-management, through the accessibility of resources provided by the inter-professional team.

First, the presenter will highlight the implications of SMA’s. Second, the presenter will discuss the findings of this study. Third, the presenter will highlight the importance of retention in SMAs and how to achieve this.

PROVIDER PRACTICES AND PATIENT PERSPECTIVES REGARDING THE MANAGEMENT OF MULTIMORBIDITY AMONG OVERWEIGHT AND OBESE VETERANS

Laura J. Buchholz, Ph.D.[1], Jennifer S. Funderburk, PhD[2]

[1]VA Center for Integrated Healthcare, Buffalo, NY; [2]VA Center for Integrated Healthcare, Syracuse, NY

Roughly 77% of veterans are overweight or obese (Kahwati, Lance, Jones, & Kinsinger, 2011). Among primary care patients, overweight and obesity is associated with a greater likelihood of multimorbidity (Booth, Prevost, & Guilford, 2014), defined as the prevalence of one or more conditions (Valderas et al., 2009). Because multimorbidity is associated with increased cost of healthcare expenses, increased mortality, and greater healthcare utilization (Wolff, Starfield, & Anderson, 2002), it is imperative for research to identify facilitators and barriers to reduce the prevalence and consequences associated with multimorbidity. To date, existing research has not examined primary care provider practices in the management of multimorbidity among patients who are overweight and obese, in conjunction with patients' perspectives regarding these practices. The purpose of this study is to examine primary care provider referral practices for multimorbidity among a sample of overweight and obese veterans. A secondary goal of this study is to examine patients' perspectives regarding the management of multimorbidity. We examined chart data and performed telephone-based interviews for overweight and obese primary care patients (*N* = 45) who screened positive for four annual behavioral health screens (i.e., at-risk drinking, tobacco use, depression, and PTSD). On average, veterans had 3.6 (*SD* = 1.34) comorbid conditions, and were prescribed 3.4 (*SD* = 2.77) medications. Results indicated primary care providers were more likely to place behavioral treatment referrals for smoking cessation (60%), depression (44.4%), weight management (44.4%), and PTSD (26.7%), as compared to alcohol use (15.6%) and sleep (8.9%). Meanwhile, veterans were more likely to attend referrals for PTSD (50%), depression (45.0%), alcohol use (28.6%), and sleep (25.0%), as compared to weight management (10.0%), and smoking cessation (3.7%). These findings highlight the need for using a multidisciplinary treatment approach amongst members of the primary care team in the management and treatment of patients with multimorbidity. Limitations and future directions will be discussed.

SELF-MANAGEMENT STRATEGIES FOR STRESS AND ANXIETY USED BY NON-TREATMENT SEEKING PRIMARY CARE PATIENTS

Robyn L. Shepardson, PhD, Jennie Tapio, MA, Jennifer S. Funderburk, PhD

VA Center for Integrated Healthcare, Syracuse, NY

The majority of individuals with anxiety disorders and subthreshold symptoms do not seek or receive formal mental health treatment. One of the most common reasons for this is a preference to manage emotional concerns on one's own. Self-management refers to the strategies or techniques that individuals use on their own (i.e., without professional guidance) to manage their symptoms. If promoted as the first step in a stepped care model of primary care treatment for subthreshold and mild anxiety symptoms, self-management holds great potential for prevention and early intervention. However, little research has examined self-management for anxiety. Therefore, the objectives of this study were to describe patients' anxiety self-management strategies, identify which types of strategies were perceived to be effective, and explore potential correlates. Participants were 182 non-treatment seeking Veteran primary care patients (*M* age=58.3 years, *SD*=14.9) who reported current anxiety symptoms (≥8 on the Generalized Anxiety Disorder-7, *M*=14.2, *SD*=3.7). Self-management strategies were assessed via telephone and coded by two independent raters into one of 7 categories (kappa=.85) and 23 subcategories (*M* kappa=.82). Participants reported nearly universal (98%) use of self-management, with an average of 2.96 (*SD*=1.2) strategies used in the past three months, and 91% of all strategies perceived as effective. Self-care (37.0%), cognitive (15.8%), and avoidance (15.1%) strategies were reported most commonly; more specifically, the most prevalent strategies were exercise (11.0% of all strategies), redirecting thoughts (9.1%), and family/friends (8.1%). Sex, age, and depression screen status were associated with self-management strategy use. This study demonstrates the ubiquity and high perceived effectiveness of self-management for anxiety among primary care patients. Further research should explore the utility of promoting evidence-informed self-management for anxiety in primary care, given its potential as a wide-reaching initial step in a population-based approach to stepped care. Primary care providers and integrated behavioral health providers can encourage patients to use healthy, effective self-management strategies to cope with anxiety symptoms.

THE ELEPHANT IN THE EXAM ROOM: MEDICAL PROVIDER PERCEPTIONS OF AND COMFORT IN DISCUSSING WOMEN'S BEHAVIORAL HEALTH NEEDS

Kerri Garruba, PsyD, Laura Maphis, PhD, Julie Hergenrather, PhD, ABPP

Geisinger Health System, Danville, PA

Primary care has become the defacto mental health system in the country, with 70-90% of all visits entailing a psychosocial or behavioral component. Similarly, OB/GYN practices address women’s health needs across the lifespan. Research is limited on behavioral health integration into specialty care clinics, like OB/GYN. This grant funded study aimed to 1) ascertain women’s health specialty provider perceptions of patient behavioral health needs and 2) understand attitudes and perceived barriers to referral to and collaboration with behavioral health.

Methods: Two distinct, 90-minute focus groups were conducted and recorded by an independent moderator trained in focus group facilitation. Focus group discussions centered on participant awareness of the mental and behavioral health needs of patients, barriers to behavioral health referral and access, and strategies for remediating problems. The groups consisted of 1) physicians and advanced practitioners and 2) nursing staff and medical assistants. A trained research assistant transcribed the recordings, and the research team coded the transcript for themes.

Results: Analysis revealed three main themes: Patient needs, barriers to access and solutions. Within the main themes, subthemes were evident. Patient needs were identified according to life transition (ante- and post-natal periods, menopause, infertility, sexual health, cancer diagnosis), health behaviors (smoking, obesity, pain management), traditional mental health and substance abuse, and domestic violence and relationship conflicts. Barriers to access included: provider experience with and knowledge about behavioral health integration; issues around patient access (cost, transportation, time commitment, stigma/reluctance to consult); provider access to behavioral health during the office day (lack of warm hand offs and same day appointments, limited presence in clinic, uncertainty about outcome of referrals). Solutions included improving workflow (referral process, office space, billing, creating opportunities for warm hand offs and same day appointments), use of telemedicine to increase patient access and increase the presence of behavioral health in the clinic.

Discussion: Results suggest that focus group participants are aware of patients’ psychological distress and problematic health behaviors yet lack knowledge of the role of behavioral health in integrated care settings. At the same time, participants enthusiastically welcomed the

integration of behavioral health into the specialty women's setting. While barriers to access were identified, participants also generated several possible solutions to enhance integration efforts. Future research will focus on how provider education impacts patient acceptance of behavioral health referrals, and whether services improve overall patient health and wellbeing.

THE IMPACT OF URGENT VISITS ON DELIVERING HOME-BASED PRIMARY CARE TO HOMEBOUND SENIORS

Gregory Norman, PhD[1], Kristann Orton, BA[1], Julie Beecher, BA[2]

[1]West Health Institute, La Jolla, CA; [2]Medstar Washington Hospital Center, Washington DC, DC

Background: Home-based primary care (HBPC) is a multidisciplinary care delivery model that provides comprehensive longitudinal care to medically complex seniors in the home. Recent studies demonstrate HBPC can result in better quality of care at a lower cost for homebound older adults. The over four million homebound seniors in the US represent a significant proportion of the most costly Medicare beneficiaries. These seniors are typically frail with multiple chronic conditions, behavioral health conditions, and functional disabilities. Without easy access to primary care, homebound seniors resort to the emergency department and hospitalizations when they experience exacerbations of their chronic conditions. In fee-for-service Medicare, the number of patients visited per day by the provider can impact the sustainability of the practice.

Methods: A clinical practice quality improvement project was undertaken at one mid-Atlantic HBPC practice to determine potential efficiency solutions. The nature and impact of urgent visits on nurse practitioners' (NPs) daily workflows was examined to determine ways to improve how the practice managed these unscheduled appointments. GPS software on mobile tablets tracked patient visits of 5 NPs from September 29th to December 24th in 2015.

Results: During the data collection period NP's visited 416 of the 589 patients in the practice (71%) at least once. A total of 711 visits were tracked and matched out of 1448 visits (49%) logged in the practice's arrival database. The majority of house call visits were scheduled regular visits (79%), 6% were follow-up visits after hospitalization, and 15% were urgent visits. Patients with a greater number of visits had a greater proportion of urgent visits ($X^2_{(5)} = 32.7$, p $2_{(4)} = 30$, $p < .001$), but urgent visits did not vary by time of day. Travel time and visit-duration at patients' homes did not vary by visit type. The top three most frequently used ICD-9 codes, regardless of visit type, were for hypertension, constipation, and immunization. When ICD-9 codes were used for billing a home visit, 70% of urinary tract infection, 53% of insomnia, and 50% of Type 2 diabetes with peripheral angiopathy codes were used for urgent visits.

Conclusions: Although NPs reported they reserve time in their schedules in anticipation of urgent visits, these visits only occurred 15% of all house call visits. In many respects, urgent visits did not differ in nature from routine house call visits. The commonly used ICD-9 codes across all visit types suggest some urgent appointments might not need a same-day visit. Changing the work flow and management of urgent visits across NPs in the practice might allow for an increase in the volume of house call visits/day without decreasing quality of care delivery.

WILLINGNESS TO ENGAGE IN TOBACCO AND ALCOHOL INTERVENTIONS DEPENDS ON FOCUS BUT NOT FORMAT OF THE INTERVENTION

Jennifer M. Wray, PhD[1], Jennifer S. Funderburk, PhD[2], Julie C. Gass, PhD[3]

[1]Ralph H. Johnson VA Medical Center, Buffalo, NY; [2]VA Center for Integrated Healthcare, Syracuse, NY; [3]VA Center for Integrated Healthcare, Buffalo, NY

Background. Integrated primary care is an optimal setting for the delivery of interventions for tobacco use and at-risk drinking, but rates of implementation are low. Patient perspectives on the focus and format of interventions they would be willing to engage in may help to improve the rates at which these types of interventions are received. *Objective.* We examined the extent to which willingness to engage in an intervention was influenced by the described (1) focus and (2) format of the intervention. *Design.* This was a one-time telephone survey. *Participants.* Patients who had recently attended a primary care appointment and who screened positive for tobacco use and at-risk drinking were eligible to participate. Data from patients who used cigarettes and met criteria for at-risk drinking in the last 30 days (N=53) were included in analyses. *Main Measures.* Participants rated a number of scenarios based on their willingness to engage in different services in primary care on a scale from 1 (“highly unlikely”) to 5 (“highly likely”). *Key Results.* Participants reported that they would be more willing to engage in services focused on helping them reduce their risk of medical problems than in services focused on discussing cigarette or alcohol use. They did not indicate a preference related to whether the intervention was delivered by a behavioral health provider during a primary care appointment, immediately following a primary care appointment, or as a scheduled follow up. *Conclusions*. Framing services for tobacco use and at-risk drinking as a way to reduce patients’ risk of medical problems may increase willingness to attend these interventions. Patients reported being equally receptive to receiving brief interventions in several different formats available in integrated primary care settings.

WOMEN’S PELVIC EXAM EXPERIENCE: A PATIENT-CENTERED VIEW

Lisa R. Rubin, PhD[1], Christina Shenko, MD[2], Saskia Schuman, MHS[2], Margaux C. Genoff, B.S.[1], Katrina S. Hacker, BA[1], Lara Dhingra, PhD[3]

[1]New School for Social Research, New York, NY; [2]Institute for Family Health, New York, NY; [3]MJHS Institute for Innovation in Palliative Care, New York, NY

Background: Women commonly describe the pelvic exam (PE) as a negative experience. Yet it is also a routinely conducted and important examination. Given these factors, researchers in medicine, psychology, and public health have explored factors that influence women’s pelvic exam experiences to inform patient-centered best practices for this routine procedure. However, little of this research is focused on urban low-income and ethnically diverse groups within the United States.

Methods: In depth interviews were conducted with 11 cisgender women, recruited from a federally-qualified community based health center network providing integrative care in NYC. Participants reflected the center’s diversity (46% African-American/Black; 55% Latina; 64% heterosexual). Forty-six percent reported at least some college or post secondary vocational training). Interviews explored participants understanding of the purpose of the PE; early and recent experiences of the PE; descriptions of PE’s that went well and PE’s that went poorly; and recommendations for improving the PE. Interviews were transcribed verbatim, and transcripts were evaluated using a thematic content analysis approach consisting of coding and interpretation of the data by team consensus.

Results: Among participants, first-time PE’s often were experienced in the context of a stressful medical/reproductive circumstance. The PE remained (to varying degrees) a stressful experience, but for some participants, it was also described as a “self-care” activity that allowed them to exercise agency in relation to their body/health. Study findings highlight emotional (e.g., anticipatory anxiety) and behavioral (e.g., avoidance) responses to the PE, and participants’ PE coping strategies. Strategies for improving the PE suggested by participants include improved communication/explanation and acknowledging the patient experience. Several participants expressed a preference for a female provider. Findings are contextualized in relation to participants’ self-reported trauma history.

Conclusions: Although many women view the PE as a stressful medical experience, these findings highlight both negative *and* positive dimensions of the PE among study participants.

Further, these results highlight strategies for improving practitioner training, and support the approach of trauma-informed care.

A SYSTEMATIC REVIEW OF MENTAL HEALTH AND WELLNESS INTERVENTIONS FOR MEDICAL STUDENTS

Breanne Dixon, Current student[1], Andrea T. Kozak, PhD[2]

[1]Oakland University, Lake Orion, MI; [2]Oakland University, Rochester, MI

Background: Medical students have some of the highest rates of depression, anxiety diagnoses, suicide, stress, and burnout. Programs developed to prevent or treat these issues are being conducted and evaluated. Methods: A systematic review of programs/interventions was conducted. PsychInfo, Pubmed, SCOPUS, and EMBASE were searched for articles from Jan 1990 to June 2016 based upon predetermined inclusion criteria. The search yielded a total of 1743 titles/abstracts. Thirty-eight articles were coded after reviewing the titles/abstracts and removing duplicates. Results: Of the 38 articles coded, 27 were intervention studies (9 were randomized controlled trials [RCTs]) and 11 were focused on the medical school curriculum. Most of the programs involved first year students only or students from all four years of medical school. The types of programs were categorized as course/curriculum modification (e.g., new course or program change), psychological intervention (e.g., mindfulness), wellness program, mental health referral program, and other. The majority of the programs were psychological interventions (n=15), followed by course/curriculum modification (n=11). The duration of the program was highly dependent on the type of intervention provided to the students, such that curriculum changes were over a semester or ongoing, whereas RCTs ranged from 4 to 8 weeks. The number of participants ranged from 5-1,008. Fourteen psychological intervention studies (n=7 RCTs) provided results; twelve of the fourteen demonstrated significant improvement on measures of stress, anxiety, depression, and/or mindfulness. For the course/curriculum modification studies, all but one study had significant findings which showed a positive change in stress, anxiety, and/or depression. Conclusion: This systematic review suggests that psychological interventions and course/curriculum modifications benefit medical students on important mental health outcomes. However, many of the studies did not include a comparison group, which limits one’s confidence that the intervention lead to the improved mental health outcomes. The long-term impact of these interventions/programs is not well documented given the minimal amount of follow-up evaluations. Further research should be conducted to address these limitations.

ACTIVE DUTY: THE ROLE OF INCOME, DEPRESSION, AND STRESS ON HEALTH BEHAVIORS AMONG MILITARY SPOUSES

Aaron Swank, B.S. Human Nutrition; B.S. Kinesiology

Kansas State University, Manhattan, KS

Active Duty: The role of income, depression, and stress on health behaviors among military spouses

Aaron Swank, Emily Mailey, Brandon Irwin

Kansas State University

Introduction

Military spouses report high levels of stress and depression and low participation in health behaviors. Barriers such as frequent moves, isolation from family and friends, uncertainty of the spouse’s well-being, inability to find work, and sole caregiving responsibilities contribute to poor health in this population. Interventions to improve health in military spouses are needed and could focus on reducing financial burdens or improving access to mental health services. The purpose of this investigation was to enhance our understanding of factors related to health behaviors among military spouses by examining the relationships between income, stress and depression and physical activity (PA) and nutrition behaviors.

Methods

Military spouses (N=300) completed questionnaires online. Surveys included the PA and nutrition subscales of the Health Promoting Lifestyle Profile, the Perceived Stress Scale, and the Hospital Anxiety and Depression Scale. Participants also reported their annual household income. A series of multiple linear regression analyses were conducted with PA and nutrition as the dependent variables. Each analysis included income and one mental health outcome (i.e., perceived stress or depression) as an independent variable.

Results

Income was significantly assoicated with PA (B=.122, p=.03), but the relationship was no longer signifcant when depression (B=-.300, p < .001) was added to the model (B=.092, p=.11). Similarly, perceived stress was more strongly associated with PA (B= -.266, p < .001) than

income (B=.080, p=.16). Income remained significantly associated with nutrition when depression (B= -.404, p < .001) and perceived stress (B=-.315, p < .001) were added to the models.

Discussion

Both income and mental health status are significantly associated with health behaviors such as PA and nutrition, however mental health variables (e.g., depression and perceived stress) are more strongly associated with PA than income. Interventions to improve health among military spouses should address individual, social, and environmental barriers to PA and healthy eating, and should explicitly include strategies for actively managing stress and depression. These results support the position that investing in the mental health of military service members and their families should be a higher priority in military populations.

ACUTE STRESS DISORDER SYMPTOMS AFTER EVALUATION FOR ACUTE CORONARY SYNDROME PREDICT 30-DAY READMISSION

Jennifer A. Sumner, PhD[1], Ian Kronish, MD, MPH[1], Bernard Chang, MD, PhD[2], Ying Wei, PhD[3], Donald Edmondson, PhD, MPH[2]

[1]Columbia University Medical Center, Center for Behavioral Cardiovascular Health, New York, NY; [2]Columbia University Medical Center, New York, NY; [3]Columbia University Mailman School of Public Health, New York, NY

Introduction: Both costly and common, 30-day readmissions are a major concern for U.S. hospitals. Numerous readmission risk prediction models have been developed, but their performance has been modest, and few predictors are modifiable. Potentially life-threatening medical events that prompt patients' index hospitalizations, along with experiences during hospitalization, can trigger psychological stress, including posttraumatic stress reactions. Stress may increase risk of adverse post-hospitalization outcomes. We examined whether posttraumatic stress days after evaluation for acute coronary syndrome (ACS)—termed acute stress disorder (ASD) symptoms—was associated with 30-day all-cause emergency department (ED) and hospital readmission.

Methods: The REactions to Acute Care and Hospitalization (REACH) study is an observational cohort study that enrolls patients during ED evaluation for ACS. During inpatient stay or by phone after discharge (median 3 days after enrollment), participants reported their ASD symptoms with respect to the event that brought them to the ED using 14 items from the Acute Stress Disorder Scale (range=14-70). Scores ≥28 suggest probable ASD. ED and hospital readmissions in the month after discharge were identified by contacting patients and reviewing electronic health records. Readmissions were confirmed by research nurse record review. Participants were excluded if they were readmitted before ASD symptom assessment or died within 30 days of discharge, resulting in an analytic sample of 974 adults (mean age=60.9±13.2 years; 45.7% female; 55.7% Hispanic; 20.7% black). Logistic regression was used to determine the association between ASD symptoms and 30-day ED/hospital readmission with and without adjustment for demographics, clinical characteristics, ACS discharge diagnosis, and depression.

Results: There were 123 ED/hospital readmissions in the 30 days after discharge. A 10-point ASD symptom increase was significantly associated with increased 30-day readmission risk in the unadjusted model, odds ratio (OR)=1.32 (95% CI, 1.12-1.56), *P*=.001, and adjusted model,

OR=1.24 (95% CI, 1.02-1.51), *P*=.03. Results were consistent when using a dichotomous probable ASD variable based on the 28+ cutoff score: unadjusted OR=1.92 (95% CI, 1.29-2.87), *P*=.001; adjusted OR=1.65 (95% CI, 1.04-2.63), *P*=.04.

Conclusions: The psychological stress that often follows ACS evaluation was associated with greater odds of 30-day ED/hospital readmission, independent of demographics, clinical characteristics, and ACS discharge diagnosis. Research is needed to examine if preventing or treating ASD symptoms may reduce readmission risk.

ASSOCIATIONS BETWEEN NEUROPSYCHIATRIC SYMPTOMS, COGNITIVE FUNCTION, AND DAILY FUNCTIONING IN ELDERLY WITH EARLY DEMENTIA

Rainbow T. H. Ho, PhD[1], Ted C. T. Fong, MPhil[1], Tiffany Hon, BSc(Psy)[2], Bing-yu Li, M.Ed.[2], Wai Chi Chan, MRCPsych (UK)[3], Joseph SK. Kwan, MPhil MD FRCP FHKCP FHKAM[2], Patrick K. C. Chiu, MBBS[4], Linda C. W. Lam, MD[5]

[1]Centre on Behavioral Health, Hong Kong, N/A, Hong Kong; [2]The University of Hong Kong, Hong Kong, N/A, Hong Kong; [3]The University of Hong Kong, Pokfulam, N/A, Hong Kong; [4]Queen Mary Hospital, Hong Kong, N/A, Hong Kong; [5]The Chinese University of Hong Kong, Hong Kong, N/A, Hong Kong

Background: Elderly with early dementia suffer from progressive deteriorations in cognitive functioning such as memory, spatial navigation, movement and language, leading to interferences in daily functioning. The present study aims to examine the associations between neuropsychiatric symptoms, psychosocial well-being, cognitive functioning, and daily functioning in elderly with early dementia.

Methods: The study sample was 86 elderly who were diagnosed with early dementia via a clinical dementia rating rating of 0.5 to 1. The mean age of the sample was 81.1 years old and the majority of them were female (83%), widowed (58.8%), and had at most primary education (75%). Data on neuropsychiatric symptoms, psychosocial well-being, cognitive functioning, and daily functioning were collected from the participants via cognitive tests (Digit Span Test, Fuld Object Memory Evaluation and Trail Making Test) and self-reported scales (Geriatric Depression Scale, Neuropsychiatric Inventory, Loneliness Scale, and Instrumental Activities of Daily Living).

Results: Male participants showed greater neuropsychiatric symptoms and older participants showed worse digit spans, memory storage and recall, and daily functioning. Controlling for gender and age, neuropsychiatric symptoms were negatively correlated with backward digit span, memory storage and recall. Loneliness was positively associated with depression but not with any other variables. Digit spans, particularly backward digit span, were correlated with memory storage, memory recall, trail making time and daily functioning. Higher memory storage and recall and shorter trail making time were associated with better daily functioning among the participants.

Discussions: The study findings suggest that better episodic memory, executive functioning,

and visuospatial construction are linked to fewer neuropsychiatric symptoms and better functioning in daily lives. Further studies could explore the effects of non-pharmacological interventions on ameliorating cognitive impairments and improving prognosis of dementia.

Depressive Symptoms in Patients with COPD Participating in a Pragmatic Trial of a Physical Activity Coaching Intervention

Ellen Rippberger, MPH, Erika L. Estrada, BS, Janet Lee, MS, Mayra Macias, MS, Leah Maddock, MPH, Huong Q. Nguyen, PhD, RN

Kaiser Permanente Southern California, Department of Research and Evaluation Pasadena, CA, USA.

Background: Depression is common in chronic obstructive pulmonary disease (COPD) with prevalence rates ranging from 20-50%.

Aim: We aimed to compare depressive symptoms between patients randomly assigned to standard care (SC) vs. a 12-month physical activity coaching intervention (Walk On!).

Methods: Walk On! is a pragmatic individual-level randomized trial testing the effectiveness of a 12-month physical activity coaching intervention compared to SC on the primary composite outcome of hospitalizations, emergency department visits, observational stays and death.

Patients assigned to Walk On! were contacted to participate in study activities, whereas SC patients were contacted to complete only the surveys without knowledge of the intervention. Participants completed an assessment of depressive symptoms using the modified Patient Health Questionnaire (PHQ-8) either during a baseline visit (Walk On!) or via postal mail/telephone (SC).

Results: A total of 235 patients completed the PHQ-8 (Walk On!=158, SC=77). Mean age of the sample is 72 (10) with 56% females and 25% non-Caucasian. Mean PHQ-8 scores were higher for SC 7.3 (6.4) compared to Walk On! 5.7 (5.0) (p=.05). The overall prevalence of PHQ-8 scores >10 was 33% vs. 15% in SC and Walk On! When patients were grouped into severity of

depressive symptoms (19=severe), more SC patients were severely depressed compared to Walk On! (8% vs. 3%, p

Conclusions: Standard care patients reported higher depressive symptoms compared to Walk On! patients. Patients who consent to participate in a 12-month physical activity coaching program are likely more activated and have better psychological well-being than patients who are responding to a mailed survey that does not ask for a high level of engagement.

DISPARITIES IN HEALTHCARE UTILIZATION AND FUNCTIONAL LIMITATIONS IN U.S. ADULTS WITH SERIOUS PSYCHOLOGICAL DISTRESS

Judith D. Weissman, PhD, JD

NYU, New York, NY

Objective: The study’s purpose was to compare healthcare utilization in adults age 18 years and over with and without serious psychological distress. Approximately 3.4% of U.S. adults have serious psychological distress, defined as having mental health problems causing moderate to serious impairment in social, occupational, or school functioning, requiring treatment. Serious Psychological Distress is associated with substantial comorbidity and up to 30 years premature mortality compared to the general population, representing the greatest U.S. health disparity. Methods: The 2006-2014 National Health Interview Survey was used to compare nine indicators of healthcare and functional impairments: no healthcare coverage, delays in healthcare, insufficient money for healthcare, change in usual place of healthcare, change in usual place of healthcare due to insurance, more than 10 doctor visits in 12 months, insufficient money to buy prescription medications, having seen a mental health provider, insufficient money for mental healthcare, limitations in ability to work and activities of daily living. Results: Compared to adults without serious psychological distress, adults with serious psychological had diminished healthcare utilization and functioning after controlling for other health conditions and sociodemographic characteristics. From 2006-2014, we observed an increasing trend in the proportion of adults with serious psychological distress who lacked healthcare coverage, experienced delays in healthcare, lacked mental healthcare and/or money to buy prescription medications. Conclusions: Our study suggests a need for greater attention to factors underlying healthcare utilization in the mentally ill, and to identify mechanisms for improving access to care.

EFFECT OF INDIVIDUAL DIFFERENCES ON RELATIONSHIP BETWEEN SUBJECTIVE DISTRESS AND HEART RATE DURING 7.5% CO2 CHALLENGE

Rachel Wallace, B.S. Psychology[1], Charles Calderwood, Ph. D.[2], Roxann Roberson-Nay, Ph. D.[3], Scott Vrana, Ph. D.[4]

[1]Clinical Psychology/Department of Psychology/Virginia Commonwealth University, Richmond, VA; [2]Department of Social Psychology Virginia Commonwealth University, Richmond, VA; [3]Department of Psychiatry Virginia Commonwealth University, Richmond, VA; [4]Virginia Commonwealth University Departments of Psychology and Psychiatry, Richmond, VA

Literature suggests that an individual's self-reported experience during psychological distress is associated with their psychophysiological response. However, studies examining synchrony and concordance in these measures have found inconsistent results. Individual differences have been found that affect the relationship between physiological response and self-report. This study examines the effects of individual differences in Anxiety Sensitivity (AS) and baseline heart rate variability (HRV) on the relationship between heart rate (HR) and Subjective Units of Distress (SUDS) ratings within an undergraduate sample (n=179, M_{age}=20.1, 55.3% female, 27.4% African-American) during CO2 challenge. The CO2 challenge reliably elicits changes in physiological responding and self-reported distress. Participants breathed a steady state of 7.5% CO2 gas mixture for 8 minutes, preceded and followed by 5-minutes of breathing room air. Average HR and SUDS were collected every 2 minutes. A series of multilevel models were employed to assess whether SUDS, AS, and baseline resting HRV (a physiological measure of emotion regulation) predicted HR. An unconditional model revealed that 76% of the criterion variance in heart rate was at the between-participants level. Entry of SUDS, AS, and HRV in the model led to an improvement in model fit, *difference of -2 log likelihood = 141.48, p < .05*. The coefficient relating SUDS to HR was positive and statistically significant (γ = 0.12, p < .001), indicating that higher heart rate covaried with higher SUDS ratings. The coefficient relating AS to HR (γ = 0.05, p = 0.58) was positive but not statistically significant and HRV to HR (γ = -5.03, p < .001) was negative and statistically significant, indicating that HR during C02 challenge was lower for people with higher baseline HRV. The addition of a random slope term in the next step led to an improvement in model fit, *difference of -2 log likelihood = 16.76, p < .05*. However, a cross-level moderator analysis found no evidence to suggest that this slope variability was explained by AS (p = 0.57) or HRV (p = 0.09). Thus, while individual differences in HRV, but not AS, predicted HR during a CO2

challenge, neither variable significantly predicted synchrony between HR and self-reported distress.

FORGIVENESS AND PSYCHOLOGICAL WELL-BEING OF ADULT MALE SURVIVORS OF CHILDHOOD SEXUAL ABUSE BY CATHOLIC PRIESTS.

charlene Niemi, RN, PHN, MSN, PhD

California State University Channel Island, Newbury Park, CA

Forgiveness and psychological well-being of adult male survivors of childhood sexual abuse by Catholic priests.

Purpose: The purpose of this study was to (a) explore the mediating effects of forgiveness with the psychological well-being of adult male survivors of childhood sexual abuse by Catholic priests and (b) elucidating relationships may enhance interventions. Characteristics of abuse include age of first occurrence, frequency, length of time abuse continued, and types of abuse.

Methods: A non-experimental, cross sectional design was used to examine the relationship between forgiveness and psychological well-being among adult male survivors of childhood sexual abuse by Catholic priests. This quantitative, descriptive, correlational study employed self-administered questionnaires that were distributed through the Internet to obtain information from the 67 participants. Descriptive statistics were used to summarize data. Additionally, t test and analysis of variance was used to compare men's abuse characteristics across forgiveness and psychological well-being. Pearson's correlation was conducted between forgiveness and psychological well-being. Simultaneous multiple regression was performed to ascertain the effects of the various characteristics of abuse and forgiveness on prediction of psychological well-being.

Results: The results found the highest number of men were first abused between 11 and 14 years of age; the abuse continued over a period of few years; frequency was three to 10 times; and a total of 355 types of abuse noted, for an average of 5 to 6 types of abuse per participant. The only t-test results that were statistically significant were forgiveness (absence of negative) and age of first occurrence, with the second category (11 to 17 years) having higher forgiveness (absence of negative). Pearson's correlation showed moderate to high significance. The multiple regression revealed forgiveness had the highest variance in predicting psychological well-being.

Conclusion: While this study identified facilitation of forgiveness as a possible intervention to improve psychological well-being in male survivors of child sexual abuse by Catholic priests,

the small size limited the possibility of discovering the role the other factors of abuse may have in well-being. Of importance is that while the characteristics of abuse cannot be altered, forgiveness was the only variable that can be modified.

HIGHER PERCEIVED THREAT UNDERLIES GREATER POSTTRAUMATIC STRESS SYMPTOMS IN YOUNGER ADULTS WITH ACUTE CORONARY SYNDROME

Laura Meli, M.S.[1], Melinda Chang, M.S.[1], Faith Parsons, B.S.[1], Donald Edmondson, PhD, MPH[2], Jennifer A. Sumner, PhD[3]

[1]Center for Behavioral Cardiovascular Health, Columbia University Medical Center, New York, NY; [2]Columbia University Medical Center, New York, NY; [3]Columbia University Medical Center, Center for Behavioral Cardiovascular Health, New York, NY

Introduction

Acute coronary syndrome (ACS) is a traumatic event that can trigger posttraumatic stress symptoms (PSS). Younger age is linked to elevated risk for PSS after ACS. Younger individuals may perceive an ACS event as particularly threatening as it may be their first life-threatening illness, and thus may be more vulnerable to develop post-ACS PSS. We examined associations between age and PSS in the acute aftermath of evaluation for ACS in the emergency department (ED) and whether perceived threat in the ED mediated this association. We hypothesized that younger age would be associated with greater ED perceived threat and PSS and that perceived threat would mediate, in part, the age-PSS relation.

Methods

The Reactions to Acute Care and Hospitalization (REACH) study is an observational cohort of patients presenting to the ED with suspected ACS. Demographics and perceived threat were assessed in the ED. PSS were measured upon hospital admission. The analytic sample comprised 871 participants (mean age=60.9±12.9 years; 45.8% women; 56.6% Hispanic; 19.7% black). Regression analysis was used to test if perceived threat mediated the association between age and PSS; bootstrapping with percentile-based confidence intervals (CIs) was used to test the indirect effect.

Results

Each year of age was associated with lower PSS (*b*=-0.12, *p* < .001), adjusting for demographic and medical covariates. Older age was also associated with lower perceived threat (*b*=-0.05, *p* < .001). Greater perceived threat predicted greater PSS (*b*=0.94, *p* < .0001). The indirect effect was negative (-0.04) and statistically different from zero (95% CI, -0.07, -0.02).

Conclusions

Compared to older individuals, younger individuals were at risk for greater PSS after ED evaluation for ACS, and elevated perceived threat in the ED partially mediated this association. These findings begin to explain why younger age predicts PSS after ACS. Understanding age differences and the potential impact of age on threat perceptions may help inform treatment in the ED.

HOW DEPRESSED PATIENTS AND THEIR CAREGIVERS INTERACT AROUND SELF-CARE

Rashmi Risbud, MA[1], Cindie Slightam, MPH[2], James E. Aikens, Ph.D.[3], Tim Guetterman, PhD[3], Erin D. Bouldin, MPH, PhD[4], Ranak B. Trivedi, PhD[5]

[1]VA Palo Alto Health Care System, Menlo park, CA; [2]VA Palo Alto Healthcare System, Menlo Park, CA; [3]University of Michigan, Ann Arbor, MI; [4]Appalachian State University, Boone, NC; [5]Stanford University/VA Palo Alto, Menlo park, CA

Objective: To characterize enhanced collaboration between depressed patients and their caregivers.

Methods: Patients were recruited after receiving a yearlong research intervention involving interactive voice response (IVR) system for depression self-care. Each patient participated with an in-home caregiver and a non-cohabitating caregiver (“CarePartner”). All participants underwent individual semi-structured interviews. Interviews were professionally transcribed, coded using Atlas.ti, and analyzed via rapid analyses techniques using grounded theory.

Results: We interviewed 10patients (mean age 39.6±16.2 years; 60% female), 8 CarePartners (56.3±12.1 years; 100% female), and 6 in-home caregivers (46.8±15.7 years; 33.3% female). Emergent themes were: (1) Communication, (2) Roles, and (3) Barriers to self-care. Patients collaborated with both caregivers, yet the caregivers seldom collaborated with each other. Both types of caregivers provided emotional and instrumental support, but differences were noted in their roles. For instance, CarePartners often encouraged outside activities, socializing, and engaging in hobbies, whereas in-home caregivers were more involved with daily management such as household chores, medication and appointment reminders, and monitoring symptoms. All respondents noted at least one barrier to depression self-care. Patients’ barriers tended to be logistical, motivational, or mood related. Caregivers were concerned about violating the patients’ privacy and noted that this was a barrier to initiating and maintaining discussions about depression care. Participating in the intervention program gave caregivers explicit permission to discuss patient’s depression more openly with the patient. For all participant types, intervention appeared to increase open communication, leading to increased mutual awareness of the patient’s mood status.

Conclusions: Patients and caregivers often play unique roles in depression self-care.Assigning a role to a close family member or friend improves communication with the patient about their depression. Given the lack of communication between the two types of caregivers, the

patient’s role remains central to depression self-care.

Impact: In depression, the role of an outside caregiver may be critical in ensuring optimal self-care. Specific aspects of social interaction among the patient and caregivers can be bolstered to better impact patient health outcomes.

INDIRECT EFFECTS FROM NEUROLOGICAL SIGNS TO FUNCTIONAL OUTCOMES VIA PSYCHIATRIC SYMPTOMS IN CHINESE SCHIZOPHRENIA PATIENTS

Ted C. T. Fong, MPhil, Rainbow T. H. Ho, PhD, Adrian H.Y. Wan, MSW

Centre on Behavioral Health, Hong Kong, N/A, Hong Kong

Background: Neurological soft signs (NSS) in motor coordination and sequencing of complex motor acts occur in the majority of schizophrenia patients and are an intrinsic sign of the underlying neural dysfunctions of schizophrenia. The present study explored the longitudinal relationships among NSS, psychiatric symptoms, and functional outcomes in patients with chronic schizophrenia.

Methods: The present study recruited a sample of 151 Chinese patients with chronic schizophrenia from a residential care hostel in Hong Kong. The participants completed the Neurological Evaluation Scale for NSS at Time 1, Positive and Negative Syndrome Scale for psychiatric symptoms at Time 1 and Time 2 (3-month follow-up), Activities of Daily Living (ADL) index and Instrumental Activities of Daily Living (IADL) scale for daily functioning at Time 3 (6-month follow-up). Direct and indirect effects of NSS on functional outcomes via psychiatric symptoms were evaluated using path analysis in Mplus 7.2 under bootstrapping.

Results: The path model showed an adequate model fit to the data ($\chi^2(38) = 45.11$, $p = 0.20$, CFI = 0.99, TLI = 0.96, RMSEA = 0.04, SRMR = 0.05). Time 1 motor coordination and motor sequencing NSS did not have any significant direct effects on Time 3 functional outcomes in the path model. However, motor coordination NSS exerted significant and negative indirect effects on ADL via positive and disorganized symptoms and on IADL via negative and disorganized symptoms.

Discussions: The current results contribute to a better understanding of the determinants of functional outcomes by demonstrating significant indirect pathways from motor coordination NSS to functional outcomes via psychiatric symptoms. The finding that motor sequencing NSS did not affect functional outcomes either directly or indirectly may be explained by their trait marking features.

PSYCHOLOGICAL FUNCTIONING IN LUNG TRANSPLANT CANDIDATES

Lauren Z. Rynar, M.S.[1], Mekhala Samsi, Ph.D.[2]

[1]Rosalind Franklin University of Medicine and Science, Chicago, IL; [2]Loyola University Medical Center, Maywood, IL

Background: Lung transplant candidates are in a highly critical state of physical health and experience a marked reduction in their vitality and quality of life. Existing literature suggests that up to one-fourth of patients with end-stage pulmonary disease awaiting lung transplantation meet diagnostic criteria for a mood or anxiety disorder. Understanding the interrelationships between depressive symptoms and other biopsychosocial variables relevant to lung transplant candidacy may help to identify patients who are high-risk from a psychological standpoint.

Methods: 81 patients with end-stage lung diseae completed a packet of clinical questionnaires prior to their pre-transplant psychosocial evaluation. Scores on the PHQ-9, a multipurpose depression screening tool, were summed and categorized into depression severity. One-way ANOVA was used to examine differences across categories.

Results: 56.8% of the sample (N=46) did not endorse depression, 29.6% (N=24) endorsed mild depression, and 9.9% (N=8) endorsed moderate depression. Patients with moderate depression exhibited higher anxiety (p=.003), higher use of denial (p=.050) and substance use (p=.003) as coping strategies, more family dissatisfaction (p=.034) and poorer medication adherence (p < .001) than patients with no depression. Endorsing mild or moderate depression was associated with higher stress (p < .001), worse shortness of breath (p=.009), more fatigue (p < .001), worse quality of life (p=.006), and higher use of disengagement (p=.037) and blaming (p=.004) styles of coping when compared to patients with no depression.

Conclusions: Depression predicts reduced quality of life, poor medication adherence, and maladaptive coping among a sample of patients with ESLD, each of which has been shown to predict poor outcomes pre- and post-lung transplantation. This finding highlights the importance of referring depressed candidates for behavioral health treatment as early as possible in the pre-transplant period. The PHQ-9 is a user-friendly depression screening tool that can be used in multiple clinical settings to identify patients endorsing depressive symptoms, enabling transplant teams to intervene proactively to improve patients' physical

and psychological well-being, engagement in health behaviors, and overall candidacy for transplantation.

PSYCHOLOGICAL OUTCOMES OF HEALTH ANXIETY IN CHRONIC ILLNESSES: A SYSTEMATIC REVIEW OF THE LITERATURE

Georden Jones, B.A. , Viviane Ta, Christina Tomei, M.A. , Caroline Séguin-Leclair, B.Sc., Danielle Petricone-Westwood, B.A. , Brittany Mutsaers, B.Sc., Sophie Lebel, Ph.C., C.Psych

University of Ottawa, Ottawa, ON, Canada

Purpose. Health anxiety (HA) is a prevalent, highly preoccupying belief that is apparent in individuals living with chronic medical conditions, such as diabetes, cancer, cardiac disease, and multiple sclerosis. Despite its debilitating effects on chronically ill patients, HA remains a vastly understudied topic. This study was part of a larger systematic review conducted to comprehensively examine the literature on HA in individuals living with a chronic illness, with a specific focus on psychological correlates of HA. **Methods.** A systematic review of the literature was undertaken on HA in individuals living with a chronic illness. Relevant studies were identified via PsycINFO, PubMED, CINAHL, Web of Science, and SCOPUS, from January 1996 to October 2014. A total of 244 articles and abstracts were retained for data extraction. A standardized data spreadsheet was designed and utilized to extract and summarize data. **Results.** The most prevalent illnesses included cancer (n = 95), Parkinson's disease (n=47), diabetes (n=43), and cardiac illnesses (n=27). Results indicated strong evidence of a relationship between HA and depression (r=0.21 to 0.67), general anxiety (r=0.29 to 0.71), trait anxiety (r=0.25 to 0.58), state anxiety (r=0.22 to 0.56), mental health (r = -0.25 to -0.67) and quality of life (r= -0.25 to -0.74). Moderate evidence was found in relation to HA and mood, and limited evidence was found in stress, and post-traumatic stress disorder symptoms. A moderate relationship between HA and avoidance strategies was found (r=0.17 to 0.60). Mixed and limited results were found in other coping strategies and HA. **Conclusions.** These results suggest that HA is associated to negative psychological functioning including symptoms of depression, general anxiety, state and trait anxiety, lower mental health and lower quality of life across diverse chronic illnesses. It also appears that avoidance may be a coping strategy utilized by this population. This emphasizes the importance of screening for and addressing HA in patients living with chronic illnesses to promote psychological wellbeing.

SOCIAL MEDIA USE DURING CRISIS: THE UTILIZATION OF FACEBOOK IN RESPONSE TO CAMPUS VIOLENCE

Holly Rus, B.A. , Jitske Tiemensma, PhD

University of California, Merced, Merced, CA

Social media has become an important resource during and after crises. Platform affordances such as real-time information sharing and broad network reach have the potential to facilitate previously unprecedented communication among victims, witnesses, and their associated social network members. However, little is known about how social media is used in response to trauma, and how it may influence (long-term) well-being. Given the reliance on virtual communication during crises, as well as the importance of social support and emotional expression in promoting recovery after trauma, the current study assessed Facebook use for the purposes of seeking information, seeking social support, and expressing emotions in response to the acts of violence carried out at the University of California, Merced in November of 2015. Students (*n* = 552) reported their uses of Facebook on the day of the attacks and their current depressive and post-traumatic stress disorder (PTSD) symptoms five months after the attacks. Results showed that many students were experiencing psychological distress even after five months. The majority of students reported using Facebook more, and in different ways than normal in response to the events, with most reporting using it to seek information. Although students reported short-term affective change, using the site to seek information, seek social support, or express emotions was not significantly associated with depressive or PTSD symptoms five months later. Findings highlight the lasting impact of campus violence on psychological well-being as well as the function and impact of social media use during crisis.

THE IMPACT OF A MIND-BODY PROGRAM ON MULTIPLE DIMENSIONS OF RESILIENCE AMONG PATIENTS WITH NEUROFIBROMATOSIS

Catherine Pierre-Louis, BA[1], Emily Zale, MS[2], Eric Riklin, BS[3], Eric A. Macklin, PhD[4], Jessica N. Coleman, BA[5], Ana-Maria Vranceanu, PhD[2]

[1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts General Hospital/Harvard Medical School, Boston, MA; [3]Fordham University, Boston, MA; [4]Massachusetts General Hospital & Harvard Medical School, Boston, MA; [5]Massachusetts General Hospital, Cambridge, MA

Introduction: The neurofibromatoses (NF) comprise of a group of genetic disorders (NF1, NF2, and schwannomatosis) that predispose patients to develop nerve sheath tumors, which often cause: significant morbidity, including disfiguring cutaneous tumors (NF1); complete hearing loss, facial weakness, and poor gait (NF2); and chronic disabling pain (schwannomatosis). There is currently no cure for NF, treatments are primarily focused on symptom management (e.g., via surgery and palliative measures), and patients with NF have been found to report psychological distress and impaired quality of life. Resiliency –the ability to bounce back when faced with chronic stressors – is a multidimensional construct that may be particularly relevant to patients with NF, who have to adjust to leaving with a chronic incurable condition. A recent randomized controlled trial (Vranceanu et al., 2016) demonstrated that the 8 session live video Relaxation Response Resiliency Program adapted for patients with NF (3RP-NF) produced sustained increases in both physical and psychological quality of life, relative to an attention placebo control The purpose of this secondary analysis is to further examine the effects of the 3RP-NF versus control on multiple dimensions of resilience.

Method: Sixty-three patients (46 female, 56 White) were randomized to 3RP-NF (*N* = 32, *M*age = 43) or control (*N* = 31, *M*age = 40), and completed pre- and post-intervention measures. Of these, 52 completed a 6-month follow-up assessment. The multidimensional assessment of resilience included measures of coping, social support, gratitude, optimism, spirituality, and mindfulness.

Results: Repeated measures ANOVA with linear contrasts indicated that the 3RP-NF produced sustained increase in multiple measures of resilience. Participants randomized to 3RP-NF

demonstrated greater improvements from pre- to post-intervention in coping (6.68; 95% CI: 1.78–11.58; *p* = .008), social support (9.16; 95% CI: 0.82-17.50; *p* = .032), and mindfulness (2.23; 95% CI: 0.16–4.29; *p* = .035), relative to control, and these improvements were maintained at 6-month follow-up. Although, on average, participants in 3RP-NF showed improvements at in optimism and spirituality, they were similar to those in HEP-NF.

Conclusion: The 3RP-NF improved multiple dimensions of resilience, and produced increases in coping, social support, and mindfulness that were over and above those observed in the control condition. Improvements were sustained at six-month follow-up. Results suggest that psychosocial intervention can promote resilience among patients with NF and that 3RP-NF may be efficacious in targeting multiple dimensions of resilience.

THE PREVALENCE OF PSEUDOBULBAR AFFECT IN A MENTAL HEALTH CLINIC

Kishen Bera, Undergraduate, Bachelor of Science

University of California, Riverside, Irvine, CA

Objective: Pseudobulbar Affect (PBA) is a neurological condition affecting the brain, characterized by frequent uncontrollable laughing/crying episodes often unrelated to mood or social context. Our main objective was to determine if the Center for Neurologic Study-Liability Scale (CNS-LS), the only scrrening tool for PBA, could be a valuable primary tool for clinicians to use in an outpatient mental health clinic to screen for PBA.

Methods: We administered the CNS-LS scale to 223 outpatients who came in for their regularly scheduled outpatient mental health appointment. A score of 13 or higher on the scale is felt to coordinate with a high likelihood that PBA may exist.

Results: It was found that 44.39% of the patients had a score of 13 or greater, indicating that further questioning for possible PBA was warranted.

Conclusion: To my knowledge this is the first screening for PBA utilizing the CNS-LS Scale in an outpatient psychiatric clinic. The high prevalence of positive screening that was found suggests that PBA may be more common than previously recognized in the psychiatric setting. With newly approved pharmacologic treatments now avaialble for PBA, regular assessments for PBA in the mental health clinic may lead to improved outcomes for patients.

USING THE TRANSTHEORETICAL MODEL TO PREDICT PHYSICAL ACTIVITY AMONG OVERWEIGHT ADULTS WITH SERIOUS MENTAL ILLNESS

Ahmed Jerome Romain, PhD, Amal Abdel-Baki, MD, Msc, FRCPC

University of Montreal Hospital Research Centre, Montreal, PQ, Canada

Introduction: While physical activity (PA) is widely recommended among adults with serious mental illness (SMI), most of them are inactive or insufficiently active. In this context, the transtheoretical model (TTM) could provide a theoretical framework to understand the motivational factors associated with PA practice. However, the TTM has been rarely used among adults with SMI.

Objectives: Analyze whether TTM components are related to PA practice among overweight adults with SMI

Methods: Cross-sectional study. Participants completed questionnaires assessing TTM components: stages of change (SOC), decisional balance (pros and cons), self-efficacy and processes of change (POC; experiential and behavioural). PA was evaluated using the GPAQ questionnaire.

Results: 43 participants with SMI (27 males; mean age of 29.0 ± 6.64; mean body mass index: 31.91 ± 5.10 kg/m^2; 30% (n = 13) with schizophrenia, 23% with bipolar disorder) were included. Among them, 44% (n = 19) were physically inactive and 81% (n = 35) reported no vigorous PA at all. PA was positively correlated to SOC ($p = 0.008$), experiential POC ($p = 0.01$), behavioural POC ($p = 0.002$) and perceived Pros ($p = 0.01$). SOC, behavioural POC and age explained 47% of PA variance. Physically active participants had higher score in behavioural POC ($p = 0.04$) and perceived Pros ($p = 0.0001$).

Discussion: Our results confirm the validity and interest of taking into account the TTM in PA promotion planning. Future studies should create PA plans using behavioural POC (e.g., social support, counter-conditioning) and perceived Pros (enlist advantages to exercise).

“I DON’T KNOW MY RISK”: ADDITIONAL EVIDENCE THAT DON’T KNOW RESPONDING TO RISK PERCEPTION QUESTIONS IS DUE TO KNOWLEDGE DEFICITS

Heather Orom, PhD[1], Jennifer L. Hay, Ph.D.[2], Caitlin Biddle, MA, MS[1], Marc T. Kiviniemi, BA, PhD[1], Erika A. Waters, PhD, MPH[3], Yuelin Li, PhD.[2]

[1]University at Buffalo, Buffalo, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Washington University in St. Louis, St. Louis, MO

Purpose: There are competing explanations for why survey takers respond “don’t know” to survey questions. Correspondingly, there is debate over whether don’t know options should be included in surveys and how these responses should be treated in analyses. The purpose of this study is to test whether people respond “don’t know” to perceived risk questions because they lack knowledge about risk factors or because such a response is less time consuming and effortful, i.e., satisficing.

Methods: Participants were 280 MTURK workers (median education = some college; 80% White; mean age = 34 (SD = 9)) who completed a one-time on-line survey. We used logistic regression to test whether actual knowledge (number of correct responses to risk knowledge questions) or perceived knowledge about risk was associated with lower don’t know responding (DKR) for both absolute risk and comparative risk for diabetes and colorectal cancer. We controlled for satisficing (time to complete the survey), race/ethnicity (white vs. minority), level of education, income and age in all four models.

Results: Participants’ perceived knowledge (mean=2.8 vs. 2.2), and actual knowledge (mean=4.1 vs. 3.8) about risk factors were higher for diabetes than colorectal cancer ($ps < .002$). They were more likely to indicate that they did not know their risk for colorectal cancer (31.8% for absolute and 18.2% for comparative risk) than for diabetes (14.3% for absolute risk and 5.4% for comparative risk). The hypothesized association between lower risk factor knowledge and higher DKR was confirmed for both colorectal cancer models ($ps \leq .01$). Only lower actual knowledge was associated with higher odds of DKR for comparative risk for diabetes ($p=.03$) and lower perceived knowledge of risk factors was associated with higher DKR for absolute diabetes risk ($p>.12$).

Discussion: Evidence is mounting that knowledge deficits result in uncertainty about personal risk and DKR to perceived risk questions. These responses appear to be meaningful and should be assessed and analyzed. Furthermore, despite decades of risk messaging about both

diseases, the public has persistent uncertainty and incorrect beliefs about risk factors for common diseases, even among relatively well-educated individuals. Novel approaches to risk communication are warranted.

DEVELOPING AND VALIDATING AN INSTRUMENT MEASURING THEORY-BASED DETERMINANTS OF SUGARY DRINK CONSUMPTION OF OVERWEIGHT ADULTS

Maria Collado-Rivera, MS, CHES, Paul Branscum, PhD, RD

The University of Oklahoma, Norman, OK

Interventions directed towards obesity prevention and treatment are greatly needed, and planning for such interventions should include community participation. The purpose of this study was to develop and validate a new theory-based instrument with overweight and obese adults to assess theory-based determinants of the behavior “To stop drinking regular soda and other sugary drinks for the next 6 months”. The theoretical underpinnings of this study were housed within the Integrative Model of Behavioral Prediction (IMB). According to the IMB, individual behavior is predicated upon having sufficient intentions to behave in certain ways, barring any deficiency in skills and abilities to perform the behavior, and environmental constraints. Behavioral intentions are further influenced by three factors: attitudes towards a behavior, perceived norms (PN), for which there are two types (injunctive and descriptive norms) and perceived behavioral control (PBC). The IMB is a Value Expectancy Theory, and as such, each construct of the model is measured via direct methods (i.e. asking respondents to evaluate whether engaging in a behavior is Good/Bad or Pleasant/Unpleasant), and indirect methods (i.e. asking respondents to judge the likelihood an outcome of a behavior (behavioral beliefs) and value associated with each value (outcome evaluation). In order to operationalize all of the direct and indirect measures of the IMB, this study was conducted over 2 phases. During Phase 1, an elicitation of behavioral, injunctive normative, descriptive normative and control beliefs was accomplished, using a brief survey with open-ended items to a sample of overweight and obese adults attending a weight loss clinic (n=30) in a Southwestern city. Results were then thematically analyzed into codes, and the top codes were used for instrument development and validation in Phase 2. For Phase 2, the newly developed 65-item instrument was first tested for face and content validity by a panel of 6 experts, and pilot tested with a small sample within the target population (n=10). Next, the survey was administered to 410 patients. Psychometric properties next tested the instrument for construct validity (confirmatory factor analysis(CFA)), and internal consistency reliability (Cronbach’s alpha). Initial results from CFA models suggested some scales required respecification by removing weak items. After model respecification, all scales appeared to be valid and reliable. Results from this study can be used to facilitate other researchers in survey development when using behavioral prediction models.

ETHNIC DIFFERENCES IN SOCIAL NETWORKS AND SUPPORT: MEASUREMENT CONSIDERATIONS, AND IMPLICATIONS FOR DISPARITIES RESEARCH

Melissa Flores, MS[1], John M. Ruiz, Ph.D.[2], Christian R. R. Goans, M.S.[3], Emily Butler, Ph.D.[2], Michiyo Hirai, Ph.D.[4], Timothy Smith, PhD[5]

[1]The University of Arizona, Tucson, AZ; [2]University of Arizona, Tucson, AZ; [3]University of North Texas, Lewisville, TX; [4]University of Texas Rio Grande Valley, Edinburg, TX; [5]University of Utah, Park City, UT

Social relationships, and the quality of these relationships are associated with health. Racial/ethnic, and cultural differences in valuing social relationships are increasingly hypothesized as important moderators of these effects. However, there is little published research documenting the size and quality of social networks across different ethnic groups. The aims of this study were to 1) test whether Hispanics and non-Hispanics (NH) respond similarly to classic measures of social networks and support, and 2) examine whether there are significant between group differences on these measures.

A sample of 3,283 undergraduate participants (37.3% Hispanic) from 3 population bases (Texas, Utah, Georgia) completed the Social Network Index (SNI; Cohen, et.al., 1997), Social Provisions Scale (SPS; Russell, et.al., 1984), and the Interpersonal Support Evaluation List (ISEL; Merz et al., 2014) as part of a larger online survey study.

To assess whether groups responded similarly to the measures, a confirmatory factor analytic model was used to test for the invariance of factor covariance and mean structures in three latent constructs: SNI, SPS, and ISEL. Configural, weak factorial, and strong factorial invariance was found using the change in comparative fit index < .01, and model fit indices (Little, 1997). These findings indicate that Hispanics and NHs respond in similar ways to the measures and that a reasonable between groups comparison can be pursued.

To test for ethnic differences in network size and support, a multiple indicator, multiple causes (MIMIC) model was used to determine mean differences in these latent constructs. Model fit indices indicated adequate overall model fit, $\chi 2(60, N = 3283) = 1208.63$, $p < .001$; RMSEA = .076 (90% CI: .073, .080); CFI = .96; SRMR = .04. Contrary to expectations about Hispanics and high support, we found that NHs reported larger social networks ($p < .001$), and greater social provisions ($p < .01$).

Results are limited to the specific measures employed here and other measures emphasizing a particular source of support (e.g., family) may yield different findings. This study represents an important first step to understanding how size and quality of social networks and social support vary across ethnicity with implications for studying racial/ethnic health disparities.

FACTORIAL INVARIANCE OF DECISIONAL BALANCE AND SELF-EFFICACY MEASURES FOR BLOOD DONATION INTENTIONS AMONG BLACK ADULTS

Alexandra N. Murray, MA[1], Mark Robbins, PhD[2]

[1]University of Rhode Island, New London, CT; [2]Cancer Prevention Research Center, University of Rhode Island, Kingston, RI

Black adults in the United States donate blood at lower rates than non-Hispanic Whites despite significant need for antigen-matched blood to treat medical conditions that disproportionately affect Blacks (e.g., sickle cell disease). Measures and tailored interventions were previously developed, guided by the Transtheoretical Model (TTM) of behavior change with all Black samples to increase blood donation. This study aimed to establish factorial invariance of these measures to support their generalizability and the validity of the items as measuring the same underlying constructs across population subgroups. Participants were 716 Black adults recruited from the northeastern U.S. in two studies conducted to develop and pilot TTM measures for decisional balance (DB) and self-efficacy (SE) to donate blood. Measurement invariance was conducted using three sequentially more restrictive models: configural (unrestricted), metric/weak (factor loadings restricted), and strong (factor loadings and error variances restricted). Invariance of measures was evaluated across gender (male/female) and age groups (18-25; 26-39; 40-54; 55-75). For DB, strong factorial invariance was achieved for gender with good model fit [CFI = .960, RMSEA = .063 (90% CI = .053-.072)]. Metric invariance was not achieved for DB across age groups as this model did not provide better fit than the unrestricted model [ΔCFI = .018]; though the DB measure did show adequate model fit across all age groups [CFI = .964, RMSEA = .07 (90% CI = .06-.08)]. Invariance of SE measures was not achieved across gender or age groups, and configural invariance showed poor model fit for gender [CFI = .886, RMSEA = .17 (90% CI = .16-.19)] and age [CFI = .875, RMSEA = .18 (90% CI = .17-.20)]. The existing measure of blood donation DB was found to have strong invariance across gender groups and weak invariance across age groups. Results of this study indicate that potential differences between gender and age groups may exist for confidence to donate blood that are not captured by this scale. Future efforts aimed at exploring blood donation SE across subgroups and multicultural populations could ensure that measures reflect meaningful behavior change. This study will inform future TTM interventions aimed at examining DB and SE for blood donation in minority groups.

INTERACTIVE GROUP-BASED ORIENTATION SESSIONS TO IMPROVE ADHERENCE AND DATA COMPLETION IN PRAGMATIC CLINICAL TRIALS

Allison Bonifay, MA, LPC[1], Meghan Mayhew, MPH[1], Lynn DeBar, PhD, MPH[2], Michaela Kiernan, PhD[3]

[1]Kaiser Permanente Center for Health Research, Portland, OR; [2]Kaiser Permanente, Center for Health Research, Portland Oregon, Portland, OR; [3]Stanford University School of Medicine, Stanford, CA

Recruitment and retention are challenging for intensive behavior change intervention trials requiring high patient engagement. Specifically, pragmatic clinical trials typically do not use incentives and rely on patient-reported outcomes, underscoring the need for successful recruitment and retention strategies. Guided by methods employed with success in behavioral weight-loss (Goldberg & Kiernan, 1995) and chronic disease self-management studies, we developed an interactive group-based orientation session to improve participant understanding of our chronic pain intervention, address ambivalence about behavior change, and emphasize the importance of assessing patient-reported outcomes for pragmatic trials in general. During the orientation session attendees learn about the intervention components, randomization process, and methodological impact of not completing assessments. They engage in a small group motivational enhancement-based activity, identifying pros and cons of being or not being in the study. The facilitator uses reflective listening and remains neutral regarding study participation.

The Pain Program for Active Coping and Training (PPACT) is a pragmatic trial conducted in Kaiser Permanente Northwest (NW), Georgia, and Hawaii that evaluates the integration of a primary care-based intervention versus usual care among chronic pain patients. The intervention, delivered by an interdisciplinary team, includes comprehensive intake and end-of-treatment evaluations, 12 weekly cognitive behavioral therapy skills training group sessions, individualized coaching calls, and physician consult. The primary outcome assesses patient-reported pain-related severity and functioning using the 4-item Brief Pain Inventory-short form (BPI) collected quarterly over a 1-year period. Given initial trial adherence, we conducted interviews with non-adherent participants (attended ≤6 sessions) that revealed confusion about intervention and trial requirements. Thus, we began requiring orientation session attendance prior to enrollment.

Before orientation session implementation (3/2014-12/2015), 234 patients enrolled in NW. 88% completed the3-month BPI assessment and 86% the 6-month; completion varied greatly between intervention and usual care groups. 115 NW patients were randomized to the intervention, 30% attended 0 sessions and 34% attended 9-12 sessions. After orientation session implementation (1/2016), 110 enrolled; 97% completed the 3-month BPI and 98% the 6-month with no difference between study groups. 47 were randomized to intervention, 12% attended 0 sessions whereas 56% attended 9-12 sessions. The interactive orientation sessions show promise as a method to improve adherence and data completion for pragmatic trials.

PREDICTING POST-TRAUMATIC STRESS DISORDER: A MACHINE LEARNING APPROACH

Dejan Magoc, Ph.D.[1], Tanja Magoc, Ph.D.[2], Joe Tomaka, Ph.D.[3], Stormy Monks, Ph.D.[4]

[1]Stetson University, DeLand, FL; [2]Jacksonville University, Jacksonville, FL; [3]New Mexico State University, Las Cruces, NM; [4]Texas Tech University Health Sciences Center El Paso, El Paso, TX

Introduction: Post-Traumatic Stress Disorder (PTSD) is an anxiety disorder that involves a specific set of symptoms which develop after experiencing, witnessing, or confronting stressful and traumatic events. With repeated exposure to such traumatic events, firefighters are at great risk for developing post-traumatic-stress (PTS) symptoms and related problems such as alcohol misuse, especially if they use alcohol as means of coping with stress. The purpose of our study was to build an automated predictor of PTSD in municipal firefighters, using three machine learning algorithms.

Methods: 740 municipal firefighters completed assessments of PTS symptoms, alcohol consumption, alcohol problems, drinking motives, and coping with stress as part of a larger study. We used data on PTS symptoms and alcohol related outcomes to train and test the machine learning algorithms, including Neural Network (NN), Naïve Bayes Method, and Decision Tree, to build and validate the automated predictor of PTSD in municipal firefighters.

Results: The results of this study indicated that the automatic predictors can successfully predict PTSD with the accuracy of 88.65% using Naïve Bayes and 91.76% using both NN and Decision Tree.

Conclusions: Even though the results are not 100% perfect, they are highly promising and show a great potential for quick and early identification of firefighters susceptible to PTSD and potentially alcohol related problems, which could help focus on less intense interventions among firefighters, such as education and simple advice rather than counseling, diagnostic evaluation, and treatment in more severe cases when firefighters with health related problems are identified in later stages.

PROMIS MEASURES FOR PATIENT CENTERED CARE

Jerry Bounsanga, BS[1], Andrew R. Tyser, MD[2], Tom Greene, PhD[3], Yushan Gu, BS[4], Maren Wright. Voss, MS[4], Charles L. Saltzman, MD[2], Wendy C. Birmingham, PhD[5], Man Hung, PhD[4]

[1]University of Utah Orthopaedics Department, Salt Lake City, UT; [2]Universtiy of Utah Orthopaedic Surgery Operations, Salt Lake City, UT; [3]Universtiy of Utah Study Design and Biostatistics Center, Salt Lake City, UT; [4]University of Utah, Salt Lake City, UT; [5]Brigham Young University, Provo, UT

INTRODUCTION:

Measuring treatment response is an indicator of not just an objective treatment outcome but also the patient-perceived value of treatment. The responsiveness of patient-reported outcome (PRO) instruments, their ability to detect change over time, is particularly meaningful when linked to the patient's report of meaningful change. This study evaluated the responsiveness of several Patient-Reported Outcome Measurement Information System (PROMIS) instruments pre to post treatment in patients with hand and upper extremity disorders and provided comparisons with the legacy qDASH instrument.

METHODS:

Patients presenting at an orthopaedic hand clinic completed the PROMIS and qDASH PROsprior to the doctor visit. The responsiveness of the PROMIS Upper Extremity (UE) v1.2, the PROMIS Physical Function (PF) v1.2, the PROMIS Pain Interference (PI) v1.1, and the qDASH was assessed. Changes in functional outcomes from baseline visit to follow-up were evaluated by paired-sample t-test, effect size, and standardized response mean (SRM) at four different follow-up periods (3-6 months or more) after initial assessment. Institutional Review Board approval was obtained prior to study commencement.

RESULTS:

The study sample consisted of 255 patients (131 females and 124 males) with an average age 50.75 years (SD = 15.84). Effect sizes for all measures were large and ranged from 0.80-1.48

across the four different follow-up time-points. Responsiveness was high, with SRMs ranging from 1.05 to 1.63. Changes in patient scores were significant for all instruments (*p* p=0.253).

DISCUSSION:

The three PROMIS instruments and the qDASH demonstrated the ability to detect patient-reported health changes at various follow-up time points. This high level of responsiveness in an orthopaedic hand population provides the necessary information to assess treatment outcomes in clinical and research settings. Having instruments that can effectively measure a patient's response to treatment is critical for informing clinical care. When treatment response is adequately measured and studied it becomes a valuable aspect of patient-centered care, allowing doctors to help patients set expectations for treatment outcomes.

PSYCHOMETRIC PROPERTIES OF A SELF-EFFICACY SCALE AMONG VETERANS WITH HYPERTENSION

Maria Antonia Rodriguez, PhD, Matthew Zhao, N/A, Binhuan Wang, PhD, Sundar Natarajan, MD

Department of Veterans Affairs, NY, NY

Background: Hypertension in adults remains a major risk factor for cardiovascular disease, the leading cause of death in the United States. We conducted a 6-month RCT that followed 533 adult veterans with uncontrolled hypertension, which demonstrated that a tailored stage-matched intervention was more effective at improving blood pressure control than non-tailored health education intervention and the usual care. The aim of the current study is to examine the psychometric properties of the self-efficacy scale utilized in the original study.

Methods: This self-efficacy instrument is comprised of three subscales that assess diet self-efficacy (DSE), exercise self-efficacy (ESE), and medication adherence self-efficacy (MSE). We examined the psychometric properties of this self-efficacy instrument in order to determine its validity and reliability. Cronbach's α coefficients were calculated in order to determine internal consistency. Spearman's Rho correlation coefficients were used in the determination of convergent and divergent validity, test-retest reliability, as well as exploratory factor analysis.

Results: The self-efficacy instrument demonstrated strong internal consistency with relatively high values for Cronbach's alpha: DSE (α=.81), ESE (α=.82), and MSE (α=.74). Between baseline and 6-month follow up, the instrument showed only some test-retest reliability. Analysis showed that the instrument possesses both convergent and discriminant validity. Factor analysis and the Skree plot demonstrated three distinct factors, which correspond to the three subscales in our self-efficacy instrument.

Conclusion: The results of this investigation have demonstrated that the self-efficacy instrument utilized in our parent hypertension study for adult male veterans in the United States suffering from uncontrolled hypertension is a valid and reliable instrument.

REDUCING "DON'T KNOW" RESPONSES AND MISSING SURVEY DATA: IMPLICATIONS FOR MEASUREMENT

Deanna Denman, MA[1], Austin S. Baldwin, PhD[1], Emily G. Marks, MS[2], Amy McQueen, PhD[3], Jasmin A. Tiro, PhD[2]

[1]Southern Methodist University, Dallas, TX; [2]University of Texas Southwestern Medical Center, Dallas, TX; [3]Washington University, St Louis, MO

“Don’t know” (DK) responses are common in health behavior research among underserved populations (Hay et al., 2015; Waters et al., 2013). These responses are typically treated as missing data which can limit interpretation of a study’s findings (Waters et al., 2013). Effects of methodologic approaches to minimize DK responses are not well understood.

Methods: As part of a larger study, parental responses to psychosocial variables about adolescent HPV vaccination (intentions, perceived susceptibility, perceived benefits) were collected through a telephone survey with DK responses coded as missing data. After one year, to reduce the large number DK responses, survey procedures were changed and research assistants were instructed to remind participants of survey response options and encourage use of the Likert scale (i.e., “We just want to know your opinion. Does your opinion match with any of the following choices…?”)

Analyses: To assess methodologic effects, survey data were compared before and after procedural changes in three ways: (1) number of participants providing DK responses; (2) magnitude of correlations between psychosocial variables; and (3) invariance of the factor loadings for these latent constructs.

Findings: The percentage of participants responding DK 1 or more times declined from 66.5% pre- to 22.5% post-procedure change. Mean number of total DK responses per survey was 3.6 vs. 1.3, respectively, out of 41 possible responses. The magnitude of correlations between scales consistently increased post-change (e.g., for intentions and benefits the correlation increased from .404 to .589). Confirmatory factor analyses comparing participants pre- and post-change showed invariance in the factor loadings for all factors ($\Delta \chi^2 = 14.88$, $p = .317$) and Cronbach's alpha >.70.

Implications: Reminding participants of survey response options appears to be a useful approach to reduce "don't know" (missing) responses. Although the measurement properties of latent variables were consistent over time, having less missing data increased observed correlations between variables. Our findings suggest that simple reminders of survey response options can reduce missing data, improve measurement reliability and concurrent validity, and thus reduce Type II errors.

RESPONSIVENESS OF THE PROMIS INSTRUMENTS FOR PAIN AND FUNCTION

Maren Wright. Voss, MS[1], Charles L. Saltzman, MD[2], Yushan Gu, BS[1], Jerry Bounsanga, BS[3], Tom Greene, PhD[4], Wendy C. Birmingham, PhD[5], Man Hung, PhD[1]

[1]University of Utah, Salt Lake City, UT; [2]Universtiy of Utah Orthopaedic Surgery Operations, Salt Lake City, UT; [3]University of Utah Orthopaedics Department, Salt Lake City, UT; [4]Universtiy of Utah Study Design and Biostatistics Center, Salt Lake City, UT; [5]Brigham Young University, Provo, UT

INTRODUCTION:

Healthcare is increasingly concerned with providing treatment that meets the patient's expectations and needs. Patient reported outcomes (PRO)s are a way to measure treatment outcomes from the patient perspective. A PRO that can measure the level of response to treatment must be sensitive enough to detect change over time. This study reported the responsiveness to change of two Patient-Reported Outcomes Measurement Information System (PROMIS) instruments – PROMIS Physical Function (PF) v1.2 and PROMIS Pain Interferences (PI) v1.1, in an orthopedic sample with foot and ankle ailments pre- and post-treatment.

METHODS:

Patients aged 18 and older presenting to an orthopaedic foot and ankle clinic between the years 2014 and 2016 responded to the PROMIS PF and PROMIS PI while in the clinic waiting area at the initial clinic visit as well at follow-up visits at 3-6 months and beyond. Analysis of responsiveness to changes in functional and pain outcomes were analyzed by paired sample t-test, effect size, and standardized response mean. In order to assess change levels that were considered meaningful from the patient perspective, analyses were anchored by patient responses to the question: "How much relief and/or improvement do you feel you have experienced as a result of your treatment?" Institutional Review Board approval was obtained for this study.

RESULTS:

A total of 1,715 patients completed follow-up measures either at three months and/or six months (1,010 females and 704 males). Their average age was 52.01 years (SD = 16.54). Effect sizes for the PROMIS PF ranged from 0.92 and 1.14 and for the PROMIS PI ranged from 0.89 and 1.02. PROMIS PF and PI's standardized response means had a narrow range across time points of 1.04-1.28. Paired sample t-tests indicated these changes from pre to post treatment were significant ($p < 0.05$) for the PROMIS PF and PI at all four different follow-up periods.

DISCUSSION:

As the use of the PROMIS instruments becomes more widespread in health outcomes research, it is important that these instruments are responsive to medical treatment. The PROMIS PF and the PROMIS PI were sensitive to patient-reported health changes in this lower extremity orthopaedic population. Clinical access to information about treatment response levels made available by research conducted with responsive instruments will assist clinicians in setting expectations with patients about likely treatment outcomes.

Gulf War Illness is characterized by multiple medically unexplained symptoms. Current guidelines for Gulf War Illness focus on improving quality of life through behavioral treatments (e.g., Cognitive Behavioral Therapy, Graded Exercise). There is a need to better tailor behavioral treatments for Gulf War Veterans to improve adherence and outcomes. Life and treatment goals impact motivation for treatment. Identifying Gulf War Veterans' goals for their life and treatment is important as they could be used to tailor treatments.

Methods: We recruited 117 Gulf War Veterans with Gulf War Illness for a randomized controlled trial comparing Problem-Solving Therapy to Health Education. At baseline, Veterans were asked their goals for life and their goals for treatment. We developed codes based on Veterans' responses.

Results: The most prevalent life goals were to improve their quality of life (interpersonal relationships (21%), career (13%), a good life (13%), live longer (9%) and spirituality (6%)) and to improve heath (both physical (20%) and emotional (14%)). The most common treatment goals were to improve health (both physical (31%) and emotional (20%)), improve quality of life (15%), to engage in treatment (10%), and understand health (10%).

Conclusions: Current treatment recommendations for Veterans with Gulf War Illness are primarily to improve quality of life. This is consistent with Gulf War Veterans' own primary life goals (to improve quality of life (47%)). Gulf War Veterans' goals for treatment are more focused on improving (51%) and understanding (10%) their health. Current treatment recommendations for Gulf War Illness are more consistent with Veterans' goals for their life than their goals for treatment. Behavioral treatments should focus on explicitly connecting treatments to Veterans' goals for their life, and addressing inconsistencies between Veterans' goals for treatment and what behavioral treatments can be expected to achieve.

POST-TRAUMATIC STRESS DISORDER AND DEPRESSION ARE ASSOCIATED WITH TINNITUS HANDICAP IN A SAMPLE OF MILITARY VETERANS

Matthew Valente, B.S.[1], Michelle Sisson, M.A.[1], Sumner Sydeman, Ph.D.[1], Samantha Russell, M.A.[2], O'neil Guthrie, Ph.D.[1]

[1]Northern Arizona University, Flagstaff, AZ; [2]University of Montana, Missoula, MT

Tinnitus is the most common disabling condition among veterans, with an estimated two billion dollars spent annually by the U.S. government in disability compensation. Psychological distress is frequently co-morbid with tinnitus, however, few studies have examined tinnitus, PTSD, and depression in veterans. Thus, the purpose of the current project was to explore the relationship of PTSD and depression with tinnitus handicap among United States veterans with tinnitus. Data were retrospectively extracted from patient medical records at a tinnitus clinic for ninety-five veterans ranging from 31-84 years of age (*M* = 62.00) at a veteran's administration hospital and included audiometric information, data on tinnitus, and measures on PTSD and depression. PTSD was considered present if the veteran had an ICD-9 code of Post-Traumatic Stress Disorder in their medical records. Furthermore, depressive symptomatology was measured using the Hospital Anxiety and Depression scale depression scale (HADS-D). Tinnitus was assessed using the Tinnitus Handicap Inventory (THI) total score. On average, veterans with tinnitus and PTSD reported significantly higher levels of tinnitus handicap (*M* = 59.75, *SD* = 22.12) than those with tinnitus alone (*M* = 39.86, *SD* = 26.78), *t*(93) = −3.01, *p* = .003, 95% CI [-33.02, -6.76], *d* = 0.74. A simple linear regression analysis regressing tinnitus handicap on depression found that a significant proportion of the total variation in tinnitus handicap was predicted by the HADS-D, $R^2 = .319$, *F*(1, 93) = 43.50, *p* < .001, 95% CI [2.04, 3.79]. Lastly, a multiple linear regression identified that a significant amount of the variance in THI scores was accounted for by the combination of PTSD and depression; $R^2_{adj} = .321$, *F* (2, 92) = 23.24, *p* < .001, 95% CI [13.90, 36.91] with depression (b = .52, p < .001), but not PTSD (b = .14, *p* = .129) being a significant predictor. Findings suggest that both PTSD and depression are associated with tinnitus handicap among military veterans. Future research needs to explore effective strategies (e.g. SSRIs, CBT, sound therapies, etc.) to reduce the risk of tinnitus severity among veterans experiencing psychological distress.

THE ROLES OF PAIN AND INJURY IN THE CURRENT STRESS-PTSD RELATIONSHIP AMONG OEF/OIF/OND VETERANS

Sharon Y. Lee, MS, MA[1], Crystal L. Park, PhD[2], Rani Hoff, MPH, PhD[3]

[1]University of Connecticut, Vernon, CT; [2]University of Connecticut, Storrs, CT; [3]Yale School of Medicine, West Haven, CT

Pain and PTSD co-occur at prevalence rates as high as 16.5% among OEF/OIF/OND veterans. To explain the high comorbidity, Sharp and Harvey (2001) proposed the mutual maintenance model of pain and PTSD, in which properties of one condition feed into the escalation of symptoms for the other. The relationship is maintained, in part, because pain triggers reminders of the trauma, which may be particularly salient for veterans injured during combat. Psychological states also alter pain perceptions, such that current stress increases pain perceptions. However, the mediating role of pain in the current stress-PTSD relationship has yet to be tested. The present study tested a moderated mediation model to examine if sustaining a combat-related injury moderates the pain-PTSD relationship, and if the strength of the indirect effect of current stress on PTSD is conditional on whether an injury is sustained. The current study is limited to the 729 veterans from the Survey of the Experiences of Returning Veterans study who completed phone surveys at baseline, 3-months, and 6-months. Consistent with our hypotheses, pain partially mediates the effect of current stress on PTSD. Further, greater pain predicted greater PTSD ($B=4.07$, $p < .001$), particularly for veterans with a combat-related injury ($B=.92$, $p < .001$). Overall, the moderated mediation model explains more of the effect of current stress on PTSD ($B=2.85$, $p < .001$) than did the direct effect of current stress on PTSD ($B=2.64$, $p < .001$). Our study shows that pain is a mechanism by which current stress affects PTSD, which may be particularly important for veterans with combat-related injuries. Our findings about the pain-PTSD relationship support and build upon the mutual maintenance model by demonstrating that the relationship can unfold over several months. Given that many veterans perceive mental health care as stigmatized in military culture, veterans may be more amenable to targeting pain as an indirect way of treating PTSD. Treatments targeting pain may provide a less stigmatized and more comprehensive approach to improving well-being.

ACCULTURATION AND WEIGHT CHANGE IN ASIAN-AMERICAN CHILDREN: EVIDENCE FROM THE ECLS-K:2011

Cassandra S. Diep, PhD[1], Tom Baranowski, PhD[2], Rachel T. Kimbro, PhD[3]

[1]The University of Texas MD Anderson Cancer Center, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]Rice University, Houston, TX

Background: Despite relatively low rates of overweight and obesity among Asian-American children, disparities exist based on acculturation, socioeconomic status, and Asian ethnicity.
Purpose: The purpose of this study was to examine the association between acculturation and weight change in Asian-American children. Secondary aims were to compare changes by Asian ethnic group and acculturation x socioeconomic status.
Methods: Participants included 1,200 Asian-American children from the Early Childhood Longitudinal Study, Kindergarten Class of 2010-11, a longitudinal study of U.S. children attending kindergarten in 2010-2011. Multinomial logistic regressions were conducted to predict weight change, which was categorized based on body mass indices in kindergarten (spring 2011) and second grade (spring 2013): consistently healthy weight, consistently overweight/obese, healthy weight change, and unhealthy weight change. Models included demographic, household, socioeconomic status, and acculturation measures, specifically mother's English proficiency and percentage of life spent in the U.S.
Results: Overall, 72.3% of children were at healthy weights in kindergarten and in second grade. Filipino children, when compared to Chinese children, had higher odds of being in the "consistently overweight/obese" category than "consistently healthy weight" (OR: 2.26, $p < .05$). In addition, mother's English proficiency significantly predicted unhealthy weight change (OR: 0.83, $p < .001$) and healthy weight change (OR: 0.75, $p < .001$), relative to "consistently healthy weight." English proficiency also predicted being consistently overweight/obese but only for children with less educated mothers.
Conclusion: Findings enhance our understanding of obesity disparities within Asian Americans and highlight the need to disaggregate the population. Specifically, obesity interventions are needed for Filipino children and families with low socioeconomic status but high English proficiency.

ADOLESCENT DEPRESSION MEDIATES LONG-TERM IMPACT OF CUMULATIVE MATERNAL DEPRESSION EXPOSURE ON ADOLESCENT'S BODY MASS INDEX

Amber Cordola Hsu, MPH[1], Zhongzheng Niu, MS, MD[2], Emily Kiresich, MS, RD[3], Bin Xie, PhD[2]

[1]Claremont Graduate University, Marina del Rey, CA; [2]Claremont Graduate University, Claremont, CA; [3]Claremont Graduate University, Lakewood, CA

Introduction

Prior research shows that maternal depressive symptoms may influence child's risks of both depression and obesity. However, the potential mediating role of child's depression in the linkage of maternal depression to adolescent's obesity remain unclear in the literature. In this study, we use existing data from the Eunice Kennedy Shriver National Institute of Child Health and Human Development Study of Early Child Care and Youth Development (SECCYD) to evaluate the mediation effects of adolescent's depression on the pathway from cumulative maternal depression exposure to adolescent's BMI at age 15.

Method

The analysis sample size includes 844 children and their families from child's age 1 month to 15 years old. Weight and height measured at age 15 years were used to calculate BMI and define overweight/obesity status. Maternal depression reported by mother of the study child as repeated assessed from child's age 1 month to grade 6 by the Center for Epidemiological Studies Depression Scale (CES-D). Cumulative measures of exposure to maternal depression were developed to capture the dynamic variation across time and were used to prospectively link to adolescent's BMI and overweight/obesity status. Children's Depression Inventory (CDI) at age 15 years was used as the mediator in the analysis. Multivariate linear regressions were employed and mediational effects were estimated with bias-corrected bootstrapping resampling approach to obtain 95% confidence intervals for indirect effects. Covariates included child's gender, mother's delivery age, mother's minority status (dichotomous), mother's educational level (years), and income-to-need ratio at grade 5 were also included in the analysis.

Results

Prospective analysis linking cumulative exposure to maternal depression by grade 6 of the study child to child's BMI percentile at age 15 revealed a statistically significant positive relationship (total effect = 0.35, p = 0.03, 95% CI: 0.02, 0.67). The child's depression at age 15 was included as a mediator and a statistically significant mediation effect was observed (indirect effect = 0.06, 95% CI: 0.01, 0.12). The direct effect of cumulative maternal depression by grade 6 on child's BMI percentile at age 15 was not statistically significant (direct effect = 0.29, 95% CI: -0.03, 0.61).

Conclusion

Our findings revealed a prospective positive effect of cumulative exposure to maternal depression from age 1 month to grade 6 on adolescent's BMI percentile at age 15, which was fully mediated by adolescent's depression. The observed significant pathway from maternal mental health to child's mental health status, which in turn has impact on child's obesity risk. Our findings highlight the needs to incorporate mental health efforts in pediatric obesity prevention.

AN EXAMINATION OF DIETARY COMPOSITION PRECEDING LAPSES FROM A WEIGHT CONTROL DIET

Cara Dochat, B.A.[1], Stephanie Goldstein, M.S.[1], Brittney Evans, BA[1], Evan M. Forman, PhD[1], Alexis Wojtanowski, N/A[2], Gary Foster, Ph.D.[3]

[1]Drexel University, Philadelphia, PA; [2]Weight Watchers Intl, New York, NY; [3]Weight Watchers, New York, NY

Traditional behavioral weight loss programs instruct participants to consume less than a target number of daily calories as the primary mode of weight loss. Though programs typically recommend a low-fat, high-fiber diet, they rarely address absolute and relative intake of macronutrients, sugar, and fiber. In these programs, frequency of lapsing from one's diet plan (e.g., eating a "forbidden food," eating when one had not planned, or eating more than planned) predicts less weight loss. Preliminary evidence suggests that feelings of hunger, cravings, and deprivation increase likelihood of lapsing, yet little is known about whether and how the quality of one's diet predicts lapsing independently, which is examined in the current study for overweight individuals following a self-directed Weight Watchers® (WW) plan. Adults (n=12) completed six weeks of dietary self-monitoring using the WW mobile phone app, and responded 6 times per day to EMA prompts from another app regarding whether a lapse had occurred since the last prompt (90.9% of prompts completed). Separate generalized estimating equations were used to examine whether dietary intake at one time of day (morning or afternoon) prospectively predicted lapse occurrence at the following time of day (afternoon or evening). Reported here are results from study Phase I; Phase II ($n=30$) will also be reported for presentation. Results indicated that WW PointsPlus (β=-.04, p=.04) and fiber (β=.032, p=.07)—but not calories, fat, carbohydrate, protein or sugar (βs < .01, ps>.05)—negatively predicted lapsing at the following meal time, such that greater points consumption (but lower fiber consumption) predicted lower likelihood of lapsing. Because WW points are a composite score (reflecting macronutrient composition) which represent the balance of calories and macronutrients in a meal, meals with relatively higher WW points may be more satiating, thus decreasing likelihood of future lapse. An alternative explanation for our findings is that participants lapsed less frequently because they were simply less hungry; however, null findings for the predictive validity of calorie intake alone suggest that lapsing is not necessarily a result of hunger or low energy, and that higher energy intake alone is not protective against lapsing. Future work in this domain may help weight loss programs construct dietary plans that best facilitate adherence and weight loss.

BEHAVIORAL PHENOTYPES IN OVERWEIGHT AND OBESE ADULTS: PATHWAYS TO THE ONSET AND MAINTENANCE OF OBESITY

Daniel Flack, M.A.[1], Stephanie M. Manasse, MS[1], Brittney Evans, BA[1], Ross D. Crosby, PhD[2], Meghan L. Butryn, PhD[1], Evan M. Forman, PhD[1]

[1]Drexel University, Philadelphia, PA; [2]Neuropsychiatric Research Institute, Fargo, ND

Even our best behavioral weight loss treatments produce sub-par outcomes in a large proportion of those receiving them. Better understanding the heterogeneity within obese populations, especially in the differential pathways to obesity, could inform enhancements to standard behavioral treatments. Identification of distinct pathways comprised of potentially malleable psychological factors associated with obesity (such as food reward sensitivity, susceptibility to internal and external cues, depressive symptoms, and impulsivity) would be especially relevant for treatment development. As such, the current study utilized latent profile analysis to identify obesity phenotypes within a treatment-seeking sample of overweight and obese individuals (n=190).

Indicator variables included self-report measures of susceptibility to external cues, emotional eating, depression, food reward sensitivity, and a behavioral measure of impulsivity. A five-class solution emerged from latent profile analysis (LPA), comprised of (1) an “unknown vulnerability” class (low food and emotional responsivity, low impulsivity, low hedonic hunger); (2) an “impulsive” class (high impulsivity, but otherwise better than average across other measures); (3) an “impulsive plus” class (high impulsivity, elevated other measures relative to the “impulsive” class); (4) a “cue reactive” class (high food and emotion responsivity, low general impulsivity); and (5) a “disinhibited-hedonic” class (high food and emotion responsivity, poor impulsivity, high hedonic hunger). Additionally*, post-hoc* analyses revealed that classes differed on both baseline physical activity levels and weight loss following a behavioral weight loss intervention.

To our knowledge, this was the first study to utilize LPA to identify phenotypes of obesity within a treatment-seeking sample of obese adults. The findings that these behavioral phenotypes may effectively discriminate between both baseline and post-treatment measures of weight-related behaviors strongly support the hypothesis that combinations of reward sensitivity, susceptibility to cues, depression, and impulsivity do relate to the

maintenance and etiology of obesity. Future research should incorporate these ideas when attempting to create and refine refine obesity treatment and prevention programs.

CONSCIENTIOUSNESS AND BODY MASS INDEX: MEDIATION BY EATING BEHAVIORS

Natalie Keirns, B.S., Misty AW Hawkins, Ph.D.

Oklahoma State University, Stillwater, OK

Background: Over 30% of American adults are obese. This high prevalence combined with the adverse consequences of excess adiposity support the need for continued identification of risk factors in obesity development and progression. Such research is essential given that obesity is resistant to treatment in the long term. Personality factors are now being examined in relation to health outcomes, and conscientiousness has emerged as the most robust personality predictor of obesity. Relatedly, conscientiousness may also predict food choices. It is less clear which facets of conscientiousness are related to obesity and whether disordered eating accounts for observed relationships. **Objective:** Thus, the objective of our study was to discover which facets of conscientiousness predict body mass index (BMI), and if any observed relationships are mediated by eating behaviors. **Methods**: Participants were 523 young adults (age: 19.9 ± 1.8 years, female: 400 (76.5%), non-white: 113 (21.6%), BMI: 25.0 ± 5.8 kg/m^2) who completed online self-report questionnaires assessing personality and eating-related variables. Conscientiousness (CN) was assessed with the M5-120. Excess adiposity was estimated continuously using BMI. Eating behaviors were measured with the Three Factor Eating Questionnaire (TFEQ) and its subscales of Cognitive Restraint, Disinhibition, and Perceived Hunger. Data were analyzed using PROCESS regression-based mediation macros in SPSS. Covariates included age, gender, race, parents' education, parents' occupation, and English as primary language. **Results**: Linear regression results indicated that total domain score of CN did not significantly predict BMI (*b* =-.07, *p*=.096). When the facets were examined Orderliness and Achievement Striving did predict BMI (*b* =-.15, *p* < .001; *b*=.13, *p*=.037). Mediation analysis of the Orderliness facet revealed that Disinhibition (*b* =-.08, *CI*[-.13, -.04], *p* < .001) mediated the relationship. The relationship between Achievement Striving and BMI was not mediated by eating behaviors. **Conclusions**: Results indicate that orderliness and achievement striving predict BMI in young adults. For orderliness, this relationship was mediated by disinhibited eating. As personality is an enduring, lifelong trait, it may be beneficial to provide tailored obesity prevention and intervention programs for individuals low in orderliness. Further research into the relationship between achievement striving and BMI is needed.

DIETARY OUTCOMES WITHIN THE STUDY OF NOVEL APPROACHES TO WEIGHT GAIN PREVENTION (SNAP) RANDOMIZED CONTROLLED TRIAL

Jessica G. LaRose, PhD[1], E. Whitney Evans, PhD, RD[2], Rebecca Neiberg, MS[3], Letitia Perdue, MS[3], Karen Hatley, MPH[4], Deborah F. Tate, PhD[5], Mark Espeland, PhD[3], Amy A. Gorin, Ph.D.[6], Cora E. Lewis, MD[7], Erica Robichaud, MSW, RD[8], Rena R. Wing, PhD[2]

[1]Virginia Commonwealth University School of Medicine, Richmond, VA; [2]The Miriam Hospital / Brown Medical School, Providence, RI; [3]Wake Forest University School of Medicine, Winston-Salem, NC; [4]UNC Chapel Hill / Lineberger Cancer Center, Chapel Hill, NC; [5]University of North Carolina at Chapel Hill, Chapel Hill, NC; [6]University of Connecticut; Institution for Collaboration on Health, Intervention, and Policy, Storrs, CT; [7]University of Alabama at Birmingham, Birmingham, AL; [8]The Miriam Hospital, Providence, RI

Background: Young adulthood has been identified as a high-risk period for unhealthy dietary behaviors, as well as significant weight gain. Previously we reported that two innovative self-regulation approaches were effective in reducing this weight gain over 2 years. Here we examine changes in key dietary behaviors and their association with weight change.

Methods: Participants were 599 young adults, age 18-35 years with BMI of 21.0 to 30.0 kg/m^2 (27.4±4.4 years; 25.4±2.6 kg/m^2; 22% men; 73% non-Hispanic White), who were randomized to self-regulation with Small Changes (SC), self-regulation with Large Changes (LC) or Control (C). Both SC and LC emphasized frequent self-weighing to cue behavior changes. SC promoted daily small decreases in intake and increases in physical activity to produce a 200 kcal/day change. LC focused on making larger changes to produce initial weight losses of 2.3-4.5 kg to buffer against anticipated weight gains. Both approaches directly targeted high-risk dietary behaviors associated with weight gain in young adulthood, including fat, fast food, sugared beverages, alcohol, and breakfast consumption. Dietary behaviors were assessed at baseline, 4 months (i.e., post initial intervention) and 2 years using the Block Food Frequency Questionnaire and another questionnaire on dietary patterns. Weight was assessed objectively at baseline, 4 months, 1 and 2 years.

Results: Although the 3 groups all differed in weight gain over time (C>SC>LC), there were no significant differences between groups for changes in fast food or other meals away from home, or overall dietary quality as measured by the HEI-2010. However, compared to Control, both LC and SC trended toward greater decreases in alcohol intake (p=.08) and more frequent

breakfast consumption (p=.07) at 4 months. Moreover, the relationships of weight change at 4 months with improvements in breakfast consumption (p=.02), alcohol intake (p=.05) and overall dietary quality (p=.005) differed across the 3 groups, with significant associations with weight change in LC relative to C.

Conclusions: This study suggests that decreased alcohol intake, increased breakfast consumption, and improved dietary quality might be important dietary targets within weight gain prevention programs for high-risk young adults.

GRIT'S EFFECT ON WEIGHT LOSS THROUGH INCREASED TREATMENT ADHERENCE: A PILOT STUDY

Caitlin Smith, B.S., Misty AW Hawkins, Ph.D.

Oklahoma State University, Stillwater, OK

Background: Obesity is a public health crisis affecting 37% of U.S. adults. Although existing interventions have proven successful in the short-term, long-term weight loss is rare – highlighting the need to identify factors that foster long-term success. One such factor is grit, defined as the perseverance/persistence for long-term goals. Lower levels of grit are associated with higher body mass index, suggesting grit may be linked to weight regulation efforts. Given that grit has been associated with greater adherence in the academic literature, higher levels of grit may also predict adherence and success to weight loss treatment.

Objective: To examine the predictive ability of grit on treatment adherence and percentage weight loss (%WL) among overweight/obese persons in a larger, ongoing NIH-funded behavioral weight-loss intervention. We hypothesized that grit would have a positive effect on %WL through increased treatment adherence.

Method: The pilot sample was 26 adults (BMI≥27 kg/m^2) enrolled in a randomized controlled trial for behavioral weight-loss (aged 41.81±11.13 years; 81% female). Baseline grit was tested using the 12-item GRIT scale, and treatment adherence was indexed by the percentage of treatment sessions attended. %WL was calculated as follows: (baseline weight – post treatment weight/baseline weight)*100. The hypothesized indirect effect was tested using 1,000 bootstrapped resamples.

Results: Results indicated a non-significant direct effect for grit (B=.3919, SE=2.6415, 95% BC [-5.2085, 5.9922]) on %WL. A significant indirect effect was found for grit on greater %WL through increased treatment adherence (B=2.6513, SE=1.5122, 95% BC [0.2014, 6.1875]. Participants with higher levels of grit had nearly 10% points higher adherence to treatment when compared to participants with lower levels of grit (79% vs. 70% adherence, respectively). Additionally, participants who attended 80% or more treatment sessions had a mean %WL of 8.91, while participants who did not had a mean %WL of 5.31.

Conclusions: Grit predicted a person’s ability to adhere to weight-loss treatment or not, which in turn predicted weight loss success or not. Though replication is clearly needed, grit may be a promising target for screening at-risk clients and improving outcomes. If the findings are

replicated (data collection is on-going), the next steps include determining whether enhancing grit is possible in an effort to foster greater weight loss success and maintenance.

HOW ACCURATE ARE RECALLS OF SELF-WEIGHING FREQUENCY? DATA FROM A 24-MONTH RANDOMIZED TRIAL

Melissa M. Crane, PhD, Jennifer A. Linde, PhD

University of Minnesota, Minneapolis, MN

Background: Recommendations for frequency of self-weighing during weight loss have not been determined but are needed. In order to properly assess the behaviors needed to create recommendations, methods of measuring self-weighing need to be compared and validated. The purpose of this analysis is to compare self-reported self-weighing frequency to objective self-weighing recorded via wireless scales.

Methods: Data come from the 24-month Tracking Study. All participants in the study received 12 months of a group-delivered behavioral weight loss program and were randomly assigned to receive 1 of 3 different self-weighing recommendations: 1) do not weigh at home, 2) weigh weekly at home (WEEKLY), or 3) weigh daily at home (DAILY). Those in the WEEKLY and DAILY conditions received Wi-Fi enabled scales that automatically recorded weights to a web-based platform. Participants were asked on a seven-point scale how frequently they weighed themselves (1=never, 7=more than once a day) during assessment visits every 6 months. Data from the WEEKLY and DAILY conditions at baseline, 12-month, and 24-month assessments are included here.

Results: Participants (N=223; age 46.6±10.2 years; BMI 33.0±3.6; 85% white; 66% female) were assigned to the DAILY or WEEKLY groups. At baseline, 57% of participants reported weighing themselves less than once per week while 9% reported weighing daily. At 12 and 24 months, 87% and 43% of DAILY participants reported weighing themselves daily while 91% and 62% of WEEKLY participants reported weighing themselves weekly (p’s < 0.001). During the intervention (from baseline to 12 months), DAILY participants weighed themselves an average of 4.8±1.8 times per week while WEEKLY participants weighed themselves 0.9±0.3 times per week ($p < 0.001$). Post-intervention (from 12 to 24 months), DAILY participants weighed themselves an average of 1.7±1.9 times per week compared to 0.6±0.8 in the WEEKLY condition ($p < 0.001$). At the 12 month assessment, regardless of assigned frequency, those who reported weighing themselves daily had weighed themselves an average of 5.3±1.6 times per week over the first year vs. 1.2±0.8 times for those who reported weekly self-weighing ($p < 0.001$). At 24 months, individuals who self-reported daily weighing weighed themselves 2.7±2.3 times per week between the 12 and 24 month assessments compared to 0.9±1.0 times per week in individuals who reported weekly weighing ($p < 0.001$).

Conclusions: Self-reported weighing frequency is able to correctly order frequency of self-weighing but may overestimate daily self-weighing. This overestimation was greater during the follow-up period without continued intervention contact. Future studies should assess the concordance of self-reported and objective weighing in the absence of specific self-weighing recommendations.

HOW DO DIETARY LAPSES IMPACT WEIGHT LOSS? EXAMINATION OF LAPSES AND ENERGY INTAKE

Brittney Evans, BA[1], Stephanie P Goldstein, M.S.[2], Cara Dochat, B.A.[1], Evan M. Forman, PhD[1], Alexis Wojtanowski, N/A[3], Gary Foster, Ph.D.[4]

[1]Drexel University, Philadelphia, PA; [2]Drexel University, Philadelphi, NJ; [3]Weight Watchers Intl, New York, NY; [4]Weight Watchers, New York, NY

Failure to successfully adhere to a weight loss diet can be attributed to discrete instances in which an individual violates a dietary recommendation, i.e., dietary lapses. Research on the characteristics of lapses and the magnitude of their contribution to excess caloric intake is still in its infancy. To better understand if and how to target lapses in the context of a behavioral weight loss program, it is important to clarify the nature of lapses (e.g., frequency, size, macronutrient content) and investigate whether lapse frequency relates to broader weight loss failures. Participants (*n*=12) tracked dietary intake through Weight Watchers® mobile app for six weeks and used another app that repeatedly assessed lapses from the program's dietary prescription. Lapse frequency, nutritional content of lapse vs. non-lapse eating occasions, and the associations between lapse frequency, daily caloric intake, and dietary goals were examined. On average, participants lapsed 3.47 times per week (*SD*=2.41) and the number of daily lapses ranged from 0-2. Lapse frequency decreased over time spent in the program ($p < .01$). As expected, caloric intake at eating occasions when a lapse was reported (M=742.49, *SD*=536.26) was greater than occasions when a lapse was not reported (*M*=579.61, *SD*=551.20), indicating that lapse reports represented substantially higher caloric intake (p < .001). Converting macronutrient grams to calories, lapse eating occasions were higher in fat (mean difference=81.18, $p < .01$), protein (mean difference=22.77, $p < .01$), and sugar (mean difference=2.93, $p < .01$) than non-lapse occasions. Frequency of lapses was correlated with the degree to which participants exceeded their daily dietary goals (r=.26, $p <$ .001) and total number of daily calories consumed (r=.14, p< .001). Overall, results confirmed expected findings that lapses are related to excess caloric intake. Findings underscore the importance of interventions to reduce frequency of lapses in order to promote success in weight loss programs.

IMPACT OF ADVERSE CHILDHOOD EXPERIENCES ON RISK FOR FOOD ADDICTION AND SUBSTANCE USE IN OBESITY TREATMENT SEEKING INDIVIDUALS

Allison Holgerson, Ph.D.[1], Matthew Clark, Ph.D.[1], Gretchen Ames, Ph.D.[2], Maria Collazo-Clavell, M.D.[1], Todd Kellogg, M.D.[1], Karen Graszer, M.A.[1], Sarah Kalsy, M.A.[1], Karen Grothe, Ph.D.[1]

[1]Mayo Clinic, Rochester, MN; [2]Mayo Clinic, Jacksonville, FL

Personal history of adverse childhood experiences (ACE) is a known risk factor for psychopathology (Caslini et al., 2015; Clark et al., 2007) and substance misuse (Dube et al., 2003). In addition, there is a strong association between ACE and disordered eating (Moulton et al., 2015), and lifetime risk for developing obesity (Danese & Tan, 2014; Grilo et al., 2005). This is an important area of study as some survivors of ACE will also experience psychiatric symptoms after weight loss surgery (Clark et al., 2007). Food addiction has also been shown to have a positive relationship with ACE (Imperatori et al., 2016; Mason et al., 2013). The present study evaluated the risk for food addiction, alcohol abuse, and tobacco and drug use associated with a history of ACE. Participants were 1,609 individuals seeking obesity treatment (73.6% female) with (m_{age}= 48.48, SD = 13.07) and ($m_{BMI =}$ 45.57, SD = 9.17). Analyses included binary logistic regressions of three types of ACE (abuse, neglect, and family dysfunction) as well as total number of ACE and the risk for food addiction, alcohol abuse, and tobacco and drug use. Results indicated no significantly increased risk for alcohol abuse yet found an increased risk for tobacco and drug use with exposure to ACE, with odds ratio (OR) of Exp(B) = 1.25 (95% CI = 1.12-1.39), *p* = .000. Moreover, all types of ACE corresponded to increased risk for tobacco and drug use: abuse (Exp(B) = 1.43 (CI = 1.10-1.87), *p* = .008), neglect (Exp(B) = 1.79 (CI = 1.21-2.67), *p* = .004), and family dysfunction (Exp(B) = 1.57 (CI = 1.27-1.93), *p* = .000). There was also an increased risk for food addiction associated with ACE, with OR of Exp(B) = 1.14 (CI = 1.05-1.24), *p* = .002, and for all types of ACE: abuse (Exp(B) = 1.32 (CI = 1.09-1.60), *p* = .005), neglect (Exp(B) = 1.54 (CI = 1.14-2.08), *p* = .005), and family dysfunction (Exp(B) = 1.19 (CI = 1.02-1.40), *p* = .031). The present study demonstrated that a history of ACE, in general, as well as specific types corresponds to increased risk for tobacco and drug use and food addiction. Of note, those who endorsed neglect in childhood had the greatest risk for both tobacco and drug use and food addiction. Individuals seeking treatment for obesity should be carefully evaluated for history of ACE. For some patients, it might be important to provide evidence-based treatment for the impact of childhood trauma prior to or during with weight management intervention to enhance obesity treatment outcomes.

INVESTIGATING THE RELATIONSHIP BETWEEN PERCEIVED STRESS AND COPING SKILLS ON ADIPOSITY IN PRE-TEEN GIRLS

Biagina-Carla Farnesi, MSc[1], Nicola J. Paine, PhD[2], Kim L. Lavoie, PhD[3], Simon L. Bacon, PhD[4]

[1]Concordia University & Hôpital du Sacré-Cour de Montreal, Brossard, PQ, Canada; [2]Concordia University & Hôpital du Sacré-Cœur de Montreal, Montreal, PQ, Canada; [3]University du Quebec a Montreal, Montreal, PQ, Canada; [4]Concordia University, Montreal, PQ, Canada

Background: Elevated levels of acute and chronic stress have been hypothesized to be a risk factor for the development of childhood obesity. However, it remains unclear whether children who have better coping skills can mitigate these risks. The purpose of this research was to examine the relationship between perceived stress and coping skills on adiposity in girls.
Methods: Baseline data from the NIH's National Growth and Health Study (NGHS), an American longitudinal study, was used for these cross-sectional analyses. Measures of acute stress were taken from the Perceived Stress Scale, while coping was represented using the total score from the Coping Strategies Inventory. Measures of adiposity were: body mass index (BMI), BMI z-score, minimum and maximum below waist circumference, and % fat by skinfolds. GLM-like linear regressions examined the main and interaction effects of coping and stress on adiposity. Analyses were adjusted for age, race, maximum parental education, and household income.
Results: A total of 2287 girls were included in the study (mean age = 11.0 ± 0.57 yrs; white = 48%). Increased stress was found to be significantly related to higher BMI (β=0.03 ± 0.01, F=4.59, p=.033), minimum waist circumference (β=0.07 ± 0.03, F=5.89, p=.015) and maximum below waist circumference (β=0.06 ± 0.03, F=4.71, p=.030). When both stress and coping total score were entered into the models, only stress was significant for BMI (β=0.03 ± 0.01, F=4.24, p=.040), minimum waist circumference (β=0.07 ± 0.02, F=5.64, p=.018), and maximum below waist circumference (β=0.06 ± 0.03, F=4.40, p=.036). There were no relationships between coping and any measures of adiposity, with no evidence of a stress by coping interaction on adiposity.
Conclusion: Though more longitudinal and intervention work needs to be done, our findings indicate the potential importance of focusing on perceived stress when considering ways to prevent or manage obesity in girls.

IS SOCIAL MEDIA HARMFUL FOR THE BODY IMAGE OF YOUNG ADULTS WITH OVERWEIGHT/OBESITY? EXAMINING THE ROLE OF APPEARANCE COMPARISON

Dean Lim, M.A.[1], Amanda F. Suplee, PhD[2], Sylvia Herbozo, Ph.D.[3]

[1]Department of Psychology, Loma Linda University, Rancho Cucamonga, CA; [2]Children's Hospital Colorado, Riverside, CA; [3]Loma Linda University, Loma Linda, CA

Previous research has established that social media usage has increased significantly over the past decade. Approximately 10% of young adults reported using social media in 2005 and 90% of young adults reported using social media in 2015. Research has also shown that the relationship between social media use and body dissatisfaction is mediated by appearance comparison. However, this research has primarily focused on average weight young adult women, despite the prevalence of overweight/obesity in young adult women and men. The current study investigated appearance comparisons as a mediator between social media use and body dissatisfaction in young adults with overweight/obesity. Participants were 385 young adults (63.50% female) aged 18 to 29 (M = 19.40, SD = 1.67) with a body mass index (BMI) of 25 or greater (M = 30.03, SD = 5.89). They completed the Physical Appearance Scale, Eating Disorder Inventory-Body Dissatisfaction, and a social media questionnaire. Results indicate that approximately 23.9%, 18.8%, 22.6%, and 13.7% of young adults use Facebook, Twitter, Instagram, and other forms of social media for about one hour per day, respectively. Appearance comparisons was found to significantly mediate the relationship between the amount of time spent on social media (i.e., Facebook, Instagram, Twitter, or other) and body dissatisfaction (ab = .40, 95%CI [.26, .60], $p < .05$). As the amount of time spent on social media sites increases, body dissatisfaction increases via the effect of appearance comparisons. Findings suggest that individuals with overweight/obesity who spend greater amounts of time on social media websites may experience greater body dissatisfaction if they engage in more appearance comparisons. Further research examining the effects of social media on body image is needed, especially as social media usage has increased among young adults in recent years.

PRIOR BEHAVIORAL WEIGHT LOSS TREATMENT EXPERIENCE IS ASSOCIATED WITH BETTER OUTCOMES

Stephanie Kerrigan, MS, Evan M. Forman, PhD, Meghan L. Butryn, PhD

Drexel University, Philadelphia, PA

Introduction: Repeated attempts at behavioral weight loss (BWL) may be common given that, at the end of treatment, many individuals remain overweight and weight regain is typical. Prior BWL experience may be advantageous, as individuals may be more familiar with lifestyle changes required of treatment or may have greater self-efficacy for change given earlier success. Alternatively, repeated BWL efforts may be a marker of inability or low motivation to make or sustain adequate lifestyle change for weight control. No prior research has evaluated differences pre-treatment in psychological processes often associated with outcome (such as self-efficacy or motivation for behavior change) or treatment outcome between these groups.

Methods: Participants (n=281) entering a BWL program completed measures assessing self-efficacy for weight control, motivation, and prior weight loss experiences at baseline. Participants wore an accelerometer for seven days and were weighed at baseline, mid-treatment (6 months), and post-treatment (12 months).

Results: At baseline, individuals with prior BWL experience (60.8% of sample) had lower self-efficacy for weight loss when confronted with negative emotions (p=.02) and physical discomfort (p<.01). Additionally, individuals with prior BWL experience had greater weight losses at 6 (9.79% vs. 7.47%; p < .01) and 12 (10.75% vs. 8.09%; p < .01) months. Although at 6 months, groups had similar levels of physical activity (102.47 minutes vs. 90.66 minutes; p=.42), only those with prior BWL sustained this level (102.19 minutes vs. 65.96 minutes; p=.01) at 12 months.

Discussion: Individuals with prior BWL experience, as opposed to those without, had lower self-efficacy in several domains, but higher autonomous motivation. Additionally, they had better weight losses and higher physical activity than those without BWL experience.

Individuals with prior BWL may better anticipate and have higher motivation for behavioral changes required of treatment, and thus make greater behavioral commitment throughout treatment. Thus, experience with BWL may confer advantages for individuals entering new BWL attempts. Repeated exposure to BWL techniques and messages may be necessary for individuals to make sufficient lifestyle modifications to induce and sustain behavior change.

RACE, PLACE AND OBESITY IN NEW YORK CITY

Stephanie A. Grilo, N/A[1], Shayna Cunningham, PhD[2], Carlos M. Grilo, PhD[3]

[1]Columbia University Mailman School of Public Health, New York, CT; [2]Yale School of Public Health, New Haven, CT; [3]Yale University School of Medicine, New Haven, CT

Race, Place and Obesity In New York City

Objectives: This study examined the relationships among race and ethnicity, neighborhood factors (“place”), and selected behavioral factors (nutrition and physical activity) associated with energy regulation in relation to obesity.

Methods: This study utilized data from 8,665 participants living in 34 neighborhoods who participated in the 2010 New York City Community Health Survey. Chi-square and ANOVAs were used to test univariate categorical and continuous variables. Linear and logistic regression models were used to examine the independent and joint effects of neighborhood, neighborhood factors (distance to fresh produce, neighborhood safety), and individual factors relevant to weight regulation (overall diet quality, meeting physical activity guidelines) on body mass index (BMI) and obesity (BMI > 30 kg/m2).

Results: Chi-square analyses revealed that the 34 neighborhoods considered in the NYC Community Health Survey differed significantly in rates of obesity (c2 (33) = 303.83, p < .0001). Obesity rates ranged from a low of 8.1% (Upper East Side) to a high of 38.2% (East Harlem).ANOVAs revealed significant differences in BMI across ethnic/racial groups (F (3, 8131) = 140.72, p < .0001) as did chi-square analyses (p < .001) indicating higher rates of obesity in black and Hispanic groups relative to white and Asian groups. Nominal logistic regressions using neighborhood to predict obesity while controlling for race and also using race/ethnicity to predict obesity while controlling for neighborhood demonstrated that both were significant in predicting obesity. Linear regression analyses revealed neighborhood factors (distance to produce, neighborhood safety), individual factors (overall diet quality, meeting physical activity guidelines), neighborhood, and demographic (race, income) variables were significant predictors of BMI, together accounting for 9.8% of the variance.

Conclusions: There exist striking disparities regarding obesity in NYC. Rates of obesity in NYC vary markedly by race and place, with significantly higher rates occurring in persons of color and in certain neighborhoods. The two neighborhoods with the lowest and highest rates of

obesity respectively were directly adjacent to each other. Moreover, both race/ethnicity and "place" were significant independent predictors of obesity.

SELF-MONITORING BEHAVIORAL CHARACTERISTICS AS PREDICTORS OF PHYSICAL ACTIVITY AND WEIGHT LOSS MAINTENANCE

Kara L. Gavin, MPH, Jennifer A. Linde, PhD

University of Minnesota, Minneapolis, MN

Despite moderately positive weight outcomes from behavioral weight loss interventions, behavior change maintenance resulting in sustained weight loss continues to be a challenge. Although high rates of physical activity (PA) are associated with better weight loss maintenance, strategies to improve PA continuation, and to identify individuals who show signs of behavioral disengagement are still lacking. In order to improve intervention efficacy and identify individuals in need of supplemental intervention support, interventionists may be able to use information from behavior tracking logs. This analysis aims to define and examine the effect of PA self-monitoring gaps during an active weight loss intervention on PA maintenance and weight loss maintained at 24-month follow-up.

Data were collected from 339 adults participating in a weight loss intervention study in Minneapolis, MN between July 2012 and August 2013. Participants were instructed to track diet and PA behaviors for the 12-month active weight loss intervention using electronic or paper logs. Tracking gaps were defined from these logs as ≥1 week of no activity logging. Short gaps were defined as gaps lasting 1-3 weeks, medium gaps were defined as 4-7 weeks, and long gaps were defined at 8-12 weeks of no behavior tracking. PA was self-reported at baseline, 6, 12, 18, and 24 months via the Paffenbarger Physical Activity Questionnaire. Weight was measured at the same time points by trained staff. The association between gaps in tracking and PA level and weight outcomes at 24 months was examined. All models were adjusted for gender, race, marital status, education level, age, baseline self-efficacy, and treatment arm.

Increases in total number of gaps in PA tracking (RR: 0.95 $p < 0.01$), average length of gaps in PA tracking (RR: 0.99 $p = 0.01$), and medium length gaps in PA self-monitoring (RR: 0.89 $p = 0.02$) were associated with lower PA level at 24 months. Late onset of PA tracking (RD: 6.31 $p < 0.01$), increased total gaps in PA tracking (RD: 0.77 $p < 0.01$) and increased gaps in dietary tracking (RD: 0.90 $p < 0.01$) were associated with higher weight at 24 months. Finally higher numbers in short gaps in both PA self-monitoring (RD: 0.58 p 0.04) and dietary self-monitoring (RD: 0.80 $p=0.02$) were associated with higher weight at 24 months. This analysis offers information about self-monitoring behavior during active weight loss interventions that may be utilized to improve intervention outcomes.

THE IMPACT OF HEDONIC CAPACITY ON FOOD INTAKE AND NEGATIVE MOOD

Laura Aylward, B.S.[1], Kristin Schneider, Ph.D.[2], Sherry Pagoto, PhD[3]

[1]Rosalind Franklin University of Medicine & Science, Chicago, IL; [2]Rosalind Franklin University of Medicine & Science, North Chicago, IL; [3]University of Massachusetts Medical School, Worcester, MA

Background: Low hedonic capacity, a reduced ability to experience pleasure from things that are typically rewarding, could increase the risk of emotional eating. Low hedonic capacity is associated with increased substance use and similar reward mechanisms may influence food intake. We hypothesized that low hedonic capacity would predict greater food intake following negative mood induction relative to neutral mood condition and more rapid mood recovery following food consumption during negative mood states.

Methods: In study 1, participants (n=61; 74% female, 39% obese) underwent neutral, anxiety, and anger mood inductions and received 2400 kcal of palatable food. In study 2, participants (n=54; 67% female, 41% obese) underwent anxiety and anger mood inductions; after each they consumed a fixed amount of palatable food (1/5 of their total energy requirement). They completed the Profile of Mood States questionnaire at post-mood induction, post food consumption, and 15 and 30 minutes post food consumption. Hedonic capacity was assessed using the Fawcett Clark Pleasure Capacity Scale.

Results: For study 1, the interaction between mood condition and hedonic capacity did not predict food intake. Hedonic capacity predicted food intake, F(1, 177)=6.149, p=.014, such that participants with lower hedonic capacity consumed more calories. For study 2, a significant time by hedonic capacity interaction was observed for the anxiety condition [F(3, 192)=5.122, p=.002] and the anger condition [F(3, 191)=21.622, p < .001]. Simple slopes analyses showed that the lower the participant's hedonic capacity, the slower the recovery of negative mood.

Discussion: Those with lower hedonic capacity consumed more calories than those with higher hedonic capacity, regardless of mood, but negative mood recovered more slowly for them after consuming palatable foods. Future research should examine if low hedonic capacity is a risk factor for obesity.

THE NEIGHBORHOOD ENVIRONMENT IN THE CONTEXT OF A CHILDHOOD OBESITY INTERVENTION.

Fabiana Brito, BSN, MSPH, PhD[1], Jennie L. Hill, PhD[2], Korine Kolivras, Ph.D.[3], Jamie Zoellner, PhD, RD[3], Wen You, Ph.D.[4], Paul A. Estabrooks, PhD[2]

[1]University of Nebraska Medical Center, La Vista, NE; [2]University of Nebraska Medical Center, Omaha, NE; [3]Virginia Tech, Blacksburg, VA; [4]Virginia TEch, Blacksburg, VA

This study examined potential relationships between neighborhood environmental factors and the reach and effectiveness of a family-based childhood obesity intervention. In this mixed method study reach and individual level data were collected as part of the intervention assessments and census data and maps were used to create a geodatabase for the region. Families' addresses were georeferenced and a 400 and 1600-meter buffer was used to determine existing food and physical activity resources (i.e. NEMS and PARA audits). Family participant demographic characteristics were compared with census data by block group. Spatial distribution was evaluated by location, distance, proximity and multiple ring buffer analyses. Multiple regression analysis was used to investigate environmental factors related to change in child outcomes. **Results.** Enrolled families (n=99) were representative based on census data with 36% from low income categories, with the exception of African American families who were over represented in the sample (74% vs 48% census). The majority of enrolled families (81%) were located 10 miles from the intervention location and a high proportion of those that declined participation (77%) were from more than 10-miles away. Physical activity resources were not within 400m of home for 70% of families and one third had no resources within 1600m. PA resources that were available were rated as having poor features (0.43±.14) and limited amenities (1.11±0.27). Families traveled an average 3.7 miles for their grocery shopping. Similar to PA resources, 74% of families did not have any type of food outlet within 400m of home and over half did not have any grocery store within 1600m. Further, grocery stores that were closer to participant homes were rated significant lower in availability of healthy items (27.05±6.46) when compared to those where families reported actually shopping (34.69±4.43). None of the investigated food and PA environmental factors were associated with changes in child outcomes. **Conclusions.** Spatial analysis indicated that distance from intervention site may be an important factor for reach and recruitment of families in this rural region. Enrolled families did not shop at the closest grocery store—but rather shopped at stores that were further away but had higher quality options. This is an important finding considering food access is most often conceptualized as distance in the food

environment literature. Expanding conceptual definitions of food access beyond distances an important next step.

USING TELEHEALTH TO ENHANCE FAMILY-CENTERED CARE IN A CHILDHOOD OBESITY INTERVENTION

Sarah Price, MPH, Christine Horan, MPH, Lauren Fiechtner, MD, MPH, Monica Gerber, MPH, Caitlin Perry, MS, Gabriella Puente, B.S., Elsie M. Taveras, MD, MPH

MassGeneral Hospital for Children, Boston, MA

Background: Family-centered interventions to address childhood obesity have been found to be effective. Incorporating digital technologies to provide parents with tailored behavior change support outside the primary care visit could increase family engagement in interventions.

Objective: To describe the use of telehealth to enhance engagement in a family-centered, randomized trial to improve weight-related outcomes in 2-12 year olds with a BMI ≥85th percentile.

Methods: Health coaches provided tailored behavior change support to families in the intervention arm of *Connect for Health*, a two-arm RCT. Coaching tools considered family preferences, needs, and residential location to improve their experience and study outcomes. Telehealth modalities used included: interactive text messaging to assess behavioral goals and provide counseling; video calls as an alternative option to in-person visits or phone calls with health coaches; and a GIS-mapping tool to identify neighborhood resources that support healthy living (i.e. healthy eating, physical activity).

Results: Between July 2014-March 2015, 360 children were randomized to the intervention arm of *Connect for Health*. From that group, 336 (93%) parents were sent text messages, with 99% responding to at least 1 text message question and 61% responding to more than half of the 46 text questions over a 1-year period. Among parents who completed the 1 year follow-up survey, 72% (226/314) were very satisfied and 23% (72/314) were satisfied with the text message content. Health coaches used a GIS-mapping tool to identify neighborhood resources for families at their first visit and 314 (87%) completed this visit; 95 (30%) parents completed at least one visit by video call, and at follow-up 96% (93/95) of them indicated they would recommend video calls for health coach visits, with 66% citing time saved on travel, 54% the face-to-face interaction, and 38% the money saved on babysitter/parking/travel as reasons to use this modality.

Conclusions: Telehealth enhanced engagement in a family-centered intervention to address childhood obesity. Follow-up analyses will assess how levels of engagement impacted study outcomes.

WEIGHT STIGMA AND WEIGHT CHANGE OVER THE FRESHMAN YEAR

Irene van Woerden, MS[1], Marc A. Adams, PhD, MPH[2], Alexandra Brewis, PhD[3], Stephanie Brennhofer, MS, RDN[2], Meg Bruening, PhD, MPH, RD[2]

[1]ASU, Tempe, AZ; [2]Arizona State University, Phoenix, AZ; [3]Arizona State University, Tempe, AZ

OBJECTIVE

The purpose of this study was to assess how weight stigma predicted changes in BMI over the course of the academic year among college freshmen in the SPARC (**S**ocial impact of **P**hysical **A**ctivity and nut**R**ition in **C**ollege) study.

METHODS

Freshman students (n=527; 72% female; 49% white), residing on campus at a southwestern university had height and weight measured by trained research assistants at the start, and up to three additional times during, the 2015-2016 academic year. Participants completed surveys measuring weight stigma by 1) hesitating to have a romantic relationship with a person who is obese 2) being too embarrassed to participate in physical activity in public places because of your weight 3) rating who is most responsible when someone is obese. Response options for 1 and 2 were a four point likert scale and dichotomized to agree/disagree. Response options for 3 were 'The individual' and 'Other factors'. Growth curve models examined the relation between levels of weight stigmaand level of BMI change over the year, after adjusting for gender, race/ethnicity, Pell grant status, initial weight status, and clustering of students within dormitories.

RESULTS

On average, participants’ BMI at time one was 24.1 kg/m^2 and increased by 0.7 kg/m^2 over the academic year. The majority of BMI change occurred in the first semester. A significant non-linear effect of BMI change was observed (p2,95% CI: 0.58 to 2.13, p=0.001). Among those who were embarrassed, BMI change over the academic year was 0.32 kg/m^2 less than their counterparts (95% CI: -0.65 to 0.01, p=0.061). Participants who stated the individual was the most responsible for being obese had a BMI change of 0.37 kg/m^2 less than their counterparts over the year (95% CI: -0.62 to -0.11, p=0.005). Hesitating to have a romantic relationship was not related to BMI change.

CONCLUSIONS

Participants embarrassed about their weight status and who believed they were responsible for their own weight had significantly smaller changes in their BMI over the academic year. This suggests that freshman's attitudes towards obesity is related to weight gain, however, this finding needs to be interpreted with extreme caution. Future research should address potential mechanisms behind these changes.

AN EXAMINATION OF FACTORS THAT ACCOUNT FOR RACE-RELATED DIFFERENCES IN PAIN INTENSITY AMONG INNER-CITY WOMEN

Teresa A. Lillis, PhD[1], John Burns, PhD[1], Frances Aranda, PhD, MPH[1], Yanina A. Purim-Shem-Tov, MD[2], Helen Burgess, Ph.D.[1], Stevan E. Hobfoll, PhD[2]

[1]Rush University Medical Center, Chicago, IL; [2]Rush University, Chicago, IL

Objective: Painful conditions disproportionately affect minority populations as compared to Non-Hispanic/Whites. However, little is known about the mechanisms underlying these race-related differences. The current study investigated 3 potential mediators of the relationship between Race and pain intensity from a diverse sample of women presenting to an inner-city Emergency Department (ED) for treatment of an acute pain complaint.

Methods: As part of an ongoing, longitudinal study examining the relationship between pain and trauma among inner-city women presenting to the ED, baseline ratings of pain catastrophizing [Pain Catastrophizing Scale; (PCS)], posttraumatic stress symptoms [PTSD CheckList; (PCL)], subjective sleep quality [PROMIS-Short Form; (SQ)] and pain intensity were collected from 177 women (M Age = 28.91 years; 65% Black, 20% Latina, 15% White). Three series of bootstrapped mediation models with contrast coding of racial status were conducted to examine whether PCS, PCL and SQ scores mediated links between Race and pain intensity

Results: Across all races, PSC, PCL, SQ and pain intensity scores were significantly correlated (all p's < .05). Significant relative indirect effects were observed for PCL on pain intensity for Black participants relative to Non-Black participants [Latina and Whites combined; (a_1b=0.233)] and Black participants relative to White participants (a_2b=.326). No significant relative indirect effects were observed for PCS or SQ for any race-related comparison on pain intensity.

Conclusion: Results suggest that Black participants reported higher pain intensity as compared to Non-Black and White participants, respecitvely. These effects may be partly accounted for by Black participants having the tendency to report greater PTSD symptoms. Significant race-related differences in pain intensity were not accounted for by race-related differences in Pain Catastrophizing or Sleep Quality. Instead, results imply that greater pain intensity among Black participants when reporting to an ED for acute pain may be due in large measure to their disproportionately greater exposure to traumatic events.

ARE PHYSICAL ACTIVITY RECOMMENDATIONS PROVIDED TOO LATE IN THOSE WITH ARTHRITIS AND OBESITY?

Madelyn Ruggieri, B.A.[1], Taylor L. Stallings, B.S.[2], E. Amy Janke, PhD[2]

[1]Center for Weight and Eating Disorders, University of Pennsylvania, Kennett Square, PA;
[2]University of the Sciences, Philadelphia, PA

Background: Physical activity is a key component of evidence-based guidelines to manage many forms of arthritis-related pain. However, implementation of guideline recommendations is suboptimal. Patient characteristics that may influence guideline implementation are not well examined.

Objective: To evaluate patient factors associated with receiving a health professional's recommendation for physical activity to help manage arthritis symptoms in a nationally-representative sample.

Method: Data from the CDC Behavioral Risk Factor Surveillance System 2011 were used. Binary logistic regression models examined the impact of weight status, symptom severity, sociodemographic factors, and health risk behaviors on likelihood of receiving a physician or health professional's recommendation to engage in physical activity to aid symptom management in overweight or obese individuals with arthritis (n=15,004).

Results: Among those with arthritis and BMI ≥ 25, 59.6% (n= 6,555) reported receiving a recommendation for physical activity. Individuals who met criteria for obesity were 1.5 times more likely to receive a recommendation compared to overweight peers (95% CI=1.4, 1.6). Pain and symptom severity were also associated with a recommendation for physical activity. Those reporting increased joint limitation (OR=1.2, 95%CI=1.1, 1.4), negative impact of pain on social function (OR=1.5, 95%CI=1.3, 1.8), and mild (OR=1.8, 95% CI=1.5, 2.1) to maximum pain (OR=1.6, 95%CI=1.3, 2.0) were all more likely to receive a recommendation. Several sociodemographic variables increased likelihood of receiving a recommendation for physical activity including female sex, Black race, and inability to work (p's ≤ .05)

Conclusions: Recommendations for physical activity in those with arthritis were associated with higher BMIs and more severe symptom presentations, and only occur in about half of those who may benefit from physical activity. Given barriers to physical activity for those with more persistent pain and the potential for even small amounts of physical activity to positively

impact arthritis outcomes across time, it is possible recommendations are being given too late in the disease course for maximal benefit.

COMORBIDITY OF CHRONIC PROSTATITIS AND FUNCTIONAL DISORDERS, A TWIN STUDY.

Marianna Gasperi, Ph.D.[1], John N. Krieger, M.D.[2], Christopher W. Forsberg, MS[3], Jack Goldberg, PhD[4], Dedra Buchwald, N/A[5], Niloofar Afari, PhD[6]

[1]UC San Diego, La Jolla, CA; [2]University of Washington, Seattle, WA; [3]VA Puget Sound HCS, Portland, OR; [4]Vietnam Era Twin Registry, Seattle VA ERIC, Carlsborg, WA; [5]Washington State University, Seattle, WA; [6]University of CA, San Diego & VA San Diego Healthcare System, La Jolla, CA

Chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS) is characterized by pelvic and perineal pains of unclear etiology. CP/CPPS frequently occurs with non-urological associated chronic somatic syndromes (NUAS) of unknown etiology. As part of the MAPP Research Network, we conducted a discordant twin study with men to investigate whether the comorbidity between CP/CPPS and NUAS may reflect a shared familial liability. Data from 1,947 male monozygotic and dizygotic twin pairs participating in the Vietnam Era Twin Registry were used. The twins were middle aged adults (mean age = 61.1 years; SD = 3.1) and self-reported lifetime physician diagnoses of chronic prostatitis (CP of which approximately 90% is CP/CPPS), fibromyalgia, chronic fatigue syndrome, irritable bowel syndrome, and temporomandibular disorder. The overall association of CP with NUAS was examined with a series of mixed effects logistic regression models controlling for twin status and age, resulting in ORs. To test for familial liability, prevalence rates in the non-CP member of discordant pairs were compared to rates in the non-CP control twins and ORs were calculated. A total of 59 twin pairs were discordant for CP and 1,886 pairs were classified as non-CP control pairs. Twins with CP were significantly more likely to also report all of the examined NUAS, confirming the comorbidity of these conditions. With the exception of the association with temporomandibular disorder (OR = 4.73; 95% CI = 1.93-11.58), none of the associations remained significant in analyses examining familial liability, possibly as a result of limited statistical power. There is substantial comorbidity between CP and a number of NUAS in men, but the comorbidity may reflect limited shared familial liability. Larger studies are needed to elucidate familial and environmental factors underlying the association of CP/CPPS with NUAS, especially with temporomandibular disorder.

COPING PROFILES AND HEALTH OUTCOMES AMONG INDIVIDUALS WITH SYSTEMIC SCLEROSIS: A LATENT PROFILE ANALYSIS APPROACH

Shelley Condon, MA[1], Scott Roesch, Ph.D[2], Michael H. Weisman, MD[3], Suzanne Kafaja, MD[4], Philip J. Clements, MD[4], Daniel E. Furst, MD[4], Vanessa L. Malcarne, Ph.D.[2]

[1]San Diego State University, Tuscaloosa, AL; [2]San Diego State University, San Diego, CA; [3]Cedars-Sinai Medical Center, Los Angeles, CA; [4]UCLA School of Medicine, Los Angeles, CA

Systemic sclerosis (SSc) is a severe, chronic, and progressive rheumatic disease with an extensive impact on quality of life. Although coping has been identified as a mechanism by which individuals can exercise control over serious health challenges and adapt more successfully, to date most studies of coping with illness have examined the relationship of individual coping strategies to adjustment, rather than examining profiles of coping. Latent profile analysis (LPA) allows the identification of coping profiles that incorporate multiple strategies, and that can be used to distinguish subgroups of patients. The primary aims of this study were to (1) identify patient groups with distinct coping profiles using LPA, and (2) compare identified coping profile groups on physical and mental health outcomes.

Participants (*N* = 94) filled out psychological measures including the revised Ways of Coping Checklist (WCCL-R), Health Assessment Questionnaire (HAQ), Psychological Adjustment to Illness Scale (PAIS), and Modified Rodnan Skin Score (mRSS). Two LPAs were done to create profiles derived from participants' raw and relative scores on the eight coping subscales from the WCCL-R including problem-focused (PF), wishful thinking (WT), seeking social support (SS), avoidance (AV), self-blame (SB), blaming others (BO), counting one's blessings (CYB) and religiosity (RG).

A three-profile solution was supported using participants' raw scores. *Low Copers* (*n* = 7) exhibited below-average coping across all subscales; *High Copers* (*n* = 23) exhibited above-average coping across all subscales, and *Mixed Copers* (*n* = 64) exhibited relatively infrequent use of SB, WT, AV, and BO strategies versus frequent use of the PF, WT, CYB, and RG strategies. Two ANCOVAs examined group differences in physical health (HAQ) controlling for age and disease severity, and psychological health (PAIS) controlling for age. Significant differences were found on the PAIS, with *High Copers* exhibiting greater levels of psychological distress when compared with the other two groups.

A two-profile solution was supported using participants' relative scores. *Adaptive Copers* (*n* = 62) emphasized PF, SS, WT, and RG while *Maladaptive Copers* (*n* = 32) emphasized SB AV, CYB,

and BO. The ANCOVA comparing the groups on psychological health revealed that *Adaptive Copers* were significantly less distressed than *Maladaptive* Copers. The findings suggest that patient groups with profiles for coping with illness can be identified. These profiles can further impact patients' mental and physical adjustment to the disease, thus underscoring the importance of examining coping in a multidimensional way.

EVALUATION OF PAIN DISABILITY AMONG VETERANS: A TALE OF TWO MEASURES

Jane A. Skoyen, PhD[1], Anya V. Kogan, PhD[2], Sarah A. Palyo, PhD[3], Timothy P. Carmody, PhD[4]

[1]None, Broadmoor, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA; [3]San Francisco VA Health Care System, San Francisco, CA; [4]San Francisco VA Medical Center, San Francisco, CA

Purpose

A large proportion of Veterans experience chronic pain; however, studies assessing performance of different chronic pain measures in this population are lacking. The present study evaluates psychometric properties and responsiveness of two frequently used measures of functioning with chronic pain, the Oswestry Disability Inventory (ODI) and Pain Disability Questionnaire (PDQ), including both the Functional Status Component (FSC) and Psychosocial Component (PC).

Methods

In Study I, 1988 Veterans with chronic pain who were enrolled in a VA facility and seeking pain management services (10.5% female, *mean age* = 57.5, *SD* = 14.0) reported on locations of pain sites and typical pain levels over the past week, and also completed the ODI and PDQ. Correlations were examined between the ODI, PDQ, and the Veterans' typical pain levels.

In Study II, a subsample of these Veterans (n = 71; 22.5% female, *mean age* = 55.3, *SD* = 9.5) reported on the above measures before and after completing a 12-week Intensive Pain Rehabilitation Program, which included psychological, physical, and medical treatment modalities. A series of t-tests were completed to evaluate these measures' responsiveness to change among Veterans in treatment for chronic pain.

Results

Study I. The ODI demonstrated good internal consistency ($\alpha = .85$). PDQ and its component scales demonstrated good to excellent internal consistency ($\alpha = .92$ for total PDQ, $\alpha = .91$ for FSC, $\alpha = .82$ for PC). The ODI, PDQ-total, PDQ-FSC, PDQ-PC, and typical pain were all significantly, positively correlated (e.g., $r = .74$ for ODI and PDQ, $r = .41$ for ODI and typical pain, and $r = .42$ for PDQ and typical pain, all $p's < .001$).

Study II. Paired-samples t-tests comparing pre- and post-treatment scores revealed significant change in the ODI ($t = 3.1$, $p = .003$), PDQ-total ($t = 5.4$, $p < .001$) and both its subscales ($t =$

5.0, $p < .001$ for FSC, $t = 4.4$, $p < .001$ for PC), as well as typical pain ($t = 3.7$, $p < .001$) for Veterans who completed pain treatment.

Conclusions

Results suggest that both ODI and PDQ measures are useful in measuring pain-related disability among US Veterans with chronic pain. Both measures demonstrated good to excellent internal consistency, and were highly positively correlated with each other and moderately positively correlated with typical pain. Both scales detected change over a 12-week pain rehabilitation program. Future research is needed to better understand the differences in how these measures perform in samples with specific pain conditions.

EXERCISE IS ASSOCIATED WITH RESILIENCE TO PAIN IN PEOPLE WITH SPINAL CORD INJURY

Kristen E. Riley, Ph.D. [1], Michelle M. Rodriguez Diaz, B.A., Doctoral Candidate[2], Kim Anderson, PhF[3], Eva Widerstrom-Noga, DDS, PhD[4]

[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]University of North Carolina at Charlotte, Miami, FL; [3]University of Miami, Davie, FL; [4]Miller School of Medicine, University of Miami, Miami, FL

Severe chronic pain is common among people with spinal cord injury (SCI), and interferes with medical treatment, quality of life, and adjustment after injury. Exercise has been broadly shown to help manage chronic pain. However, only a few studies have been conducted about exercise and coping with pain in the context of SCI, and these have focused on the efficacy of pain management programs. No studies using a mixed methods approach have examined personal perspectives regarding the association between exercise and resilience to chronic pain in people with SCI. The primary purpose of the present study was to examine the association between utilizing exercise to relieve pain and resilience to chronic pain.

Method

This mixed method study focused on positive (facilitators) and negative (barriers) contributors to individual experiences of living with chronic pain after SCI. The study consisted of 2 parts: (1) individual open-ended qualitative interviews (n=35) to identify common perspectives/themes, and convert them into statements; and (2) online survey (n=491) to quantify the agreement with each statement using Numerical Rating Scales (NRS). The present study utilized part of the data obtained from the survey, specifically regarding pain characteristics and associated psychosocial factors, resilience to pain, and utilizing exercise to relieve pain.

Results and Discussion

Participants (56.0%) reported severe pain (NRS > 6) in the past week. We performed two sets of stepwise regression analyses controlling for age, time since injury, gender, and average pain level. Utilizing exercise was shown to be positively and significantly related to resilience to pain ($\beta = .182$). Gender ($\beta = -.122$), perceived control over one's life ($\beta = .191$), and preferring treatment other than medication ($\beta = .155$) predicted utilizing exercise. Men reported engaging in exercise to relieve pain more than women ($\beta = .201$).

Overall, individuals with SCI who reported utilizing exercise to relieve pain also had higher agreement ratings on resilience to chronic pain. Utilizing exercise was predicted by gender, having greater life control, and preferring alternative treatments to pain medication. Clinical implications include encouraging women with SCI to utilize exercise to relieve their pain, offering additional non-pharmacological treatments, including psychotherapy focused on increasing perceived life control, and increasing physical activity. Study limitations include limited demographic and geographic variability, which may not be generalizable.

PAIN CATASTROPHIZING IN VETERANS: A PILOT STUDY INVESTIGATING PREVALENCE, CLINICAL CORRELATES, AND TREATMENT OUTCOMES

Nidhi Anamkath, B.A., Sarah A. Palyo, PhD, Irina Strigo, Ph.D

San Francisco VA Health Care System, San Francisco, CA

Pain catastrophizing (PC) is a psychological construct comprised of three dimensions (rumination, magnification, helplessness) that is known to heighten chronic pain intensity and severity; however, research on this topic has been mostly limited to Civilian populations. To date, Veteran-specific investigations of PC have found that higher levels of catastrophizing are linked to increases in negative clinical outcomes (depression, pain severity) and that decreases in catastrophizing via Cognitive-Behavioral Therapy (CBT) explains decreases in these very outcomes. However, ongoing evaluation of this construct in the Veteran population is critical as results may better inform pain treatments. The current pilot study aims to fill a gap in the literature by examining 1) the prevalence and 2) the relationship of PC to clinical outcomes in Veterans with chronic pain in an intensive pain rehabilitation program (IPRP) (n=35; 71.4% male; age (36-68, M=56.2); pain duration in years (0.5-46.0, M=18.7)). Unlike prior Veteran studies, the IPRP is an integrated program which includes CBT but also contains Acceptance and Commitment Therapy and physical therapy. A retrospective study design evaluated pre- and post- treatment assessments of PC (using the 13-item Pain Catastrophizing Scale) in relation to pain intensity, depressive symptoms, pain disability, and kinesiophobia. Results indicated the prevalence of PC was similar to previous Veteran samples, and on average catastrophizing was not clinically significant (M =23.8, SD = 12.2). Pre-treatment Spearman's correlations indicated greater overall PC was related to greater depressive symptoms ($r = 0.57$, $p < .01$), fear of movement ($r = 0.56$, $p < .01$), and pain disability ($r = 0.46$, $p < .01$). In addition, Wilcoxon signed-rank tests comparing pre- and post-treatment measures indicated significant decreases in depression ($z = -3.61$, $p < .001$), pain disability ($z = -3.69$, $p < .001$), and participants' subjective "acceptable" level of pain ($z = -3.80$, $p < .001$), but not significant changes in current pain intensity ($z = -1.59$, $p > .05$). This suggests the administered treatment affected cognitions and emotions associated with chronic pain and subjects' perceived disability level, but had minimal effects on self-reported pain levels. These findings warrant further clarification on the role of PC in the experience and treatment of chronic pain in Veterans, as well as an investigation into mechanisms of change during treatment.

PAIN IN CHILDBIRTH

Lana Kinney, BSc, Anne Howarth, PhD, Nicola Swain, PhD

University of Otago, Dunedin, Otago, New Zealand

Pain in childbirth receives little research attention. Although it may be seen as a biological imperative, pain experienced in childbirth is a predictable acute pain episode that has the potential to be well managed. Just like initial reluctance to use anesthesia in surgery, there seems some opinion that childbirth pain should be tolerated rather than treated. Previous research suggests anxiety is the strongest predictor of childbirth pain. A sample of 137 first time mothers were recruited nationwide in New Zealand. Data from 3 questionnaires is included in this analysis: 24 weeks gestation, pre-birth and post-birth. Caesarian and complicated births were excluded from analysis. A general linear model analysis of covariance was constructed to predict labour pain from both dichotomous and continuous variables. Socio-economic status, the use of hot/warm water, walking, and movement as pain management techniques, antenatal yoga for pregnancy, Plunket antenatal classes, how painful the woman expected her labour to be at 32 weeks, and a woman’s birth expectations at 32 weeks were found to significantly predict experienced labour pain. This data has implications for both birth preparation and managment and may be helpful for various practitioners involved in childbirth. Childbirth is both an emotional and painful experience and much is to be learned from examining the intersection of the various contributions to the pain experience.

RANDOMIZED CONTROLLED TRIAL OF A NURSING-DELIVERED CBT VERSUS SUPPORTIVE CARE TELEPHONE INTERVENTION FOR CHRONIC BACK PAIN

Thomas Rutledge, PhD[1], Rachael Holloway, PsyD[2]

[1]VA San Diego, San Diego, CA; [2]VA San Diego Healthcare System, San Diego, CA

Objective: To evaluate the efficacy of a nursing-delivered, telephone-based intervention of cognitive behavioral therapy versus supportive care for chronic low back pain.

Methods: Participants (N=57) were patients with chronic back pain (experiencing pain “on a daily basis” ≥ 6 months at a minimum intensity ≥4/10 on a 10-point scale) randomized to either an 8-week, 8-session, Cognitive-Behavioral Self-Management Skills Training (CBSST) or to a Supportive Care condition (SC) matched for contact frequency, format, and time, with each treatment delivered by a trained nurse. Primary outcomes included changes in Roland Morris Disability Questionnaire (RMDQ) and changes in pain and function as self-rated on the Patient Global Impressions Scale (CGI).

Results: Participants in the CBSST condition (n=29) showed significant improvements on the RMDQ (mean=11.3[5.6] at baseline versus mean=8.2[6.1] at post-treatment, $p < .05$) and on the CGI (83.6% reporting improvement). SC participants (n=28) also showed improvement on the RMDQ (mean=11.1[5.5] at baseline versus mean=9.0[5.3] at post-treatment, $p < .05$), with 48.1% reporting improvement on the CGI. Between groups comparisons showed no differences in changes on the RMDQ but significantly better outcomes for CBSST participants on the CGI ($p < .05$).

Conclusions: Results from this clinical trial suggest that telephone-based, nurse-delivered CBSST and SC treatments for patients with chronic back pain each offer potential benefits and may warrant further research for applications to hospital settings.

SELF-REPORTED RATINGS OF PAIN: DIFFERENCES AT HOME AND AT THE HOSPITAL

Julie Kangas, PhD[1], Peter Link, MA[2], Colin Depp, PhD[3]

[1]UC San Diego & San Diego VA Healthcare System, Oak Leaf, TX; [2]Veterans Affairs San Diego Healthcare System, San Diego, CA; [3]University of California San Diego, La Jolla, CA

Background. Little work has been done to monitor how social-contextual environment influences subjective pain rating. In other vital signs, such as blood pressure, hospital-based recordings are often exacerbated compared to home-based assessments. We conducted an analysis comparing pain scores collected via home telehealth device to pain scores that were collected at the hospital by a medical provider.

Methods. Data was obtained for a two-year period from a home telehealth device designed to help Veterans with chronic illness monitor and manage their health on a daily basis. Veterans had an opportunity to rate their pain daily on the standard 0-to-10 pain scale. We also retrieved pain scores from each Veteran’s electronic medical record that were collected at outpatient hospital appointments during the same timespan. Veterans (N = 33) each completed an average of 94 pain ratings (range = 2-546) at home through the home telehealth system, without a provider present (n = 3102 total ratings). They rated their pain to a medical provider at an average of 7.88 outpatient medical appointments (range = 2-32) during the same timespan (n = 260 total ratings). Patient-averaged scores for pain were calculated and paired T-tests were conducted, and a discrepancy scores (home minus hospital pain scores) were associated with selected clinical characteristics.

Results. We found that pain ratings at home were significantly higher than those taken at the hospital, $t(32) = 4.16$, $p < .001$, with average at-home pain being rated as 5.42 (SD = 2.15) and average at-hospital pain being 3.79 (SD = 2.33), $d = .73$. We also found that discrepancy scores were associated with hospitalizations, such that higher pain at home than at the hospital was related to a lower likelihood of medical hospitalization, $r = -.38$, $p=.03$; note, 13 of the 33 Veterans were hospitalized. Discrepancy scores were also associated with suicide behaviors, such that higher at-home pain than at-hospital pain was related to a higher likelihood of suicide behaviors, $r = .40$, $p=.02$; note, 4 of the 33 Veterans had suicide behaviors during the two-year period.

Implications. In contrast to what might be expected from other home- versus hospital- based vital sign comparisons, results indicate that pain ratings are reported as being lower when taken at the hospital than at home. The findings suggest that there may be important

environmental cues and psychological processes that impact either actual perceptions of pain or willingness to disclose true pain that may differ according to environmental context. Systems for home-based telemonitoring of pain may need to consider these potential discrepancies in designing clinical response alerts. Future research directions regarding the associations of pain score reporting with hospitalizations and suicide behaviors will also be discussed.

THE PAIN RELATED SELF-EFFICACY SCALE: A SHORT FORM

Dagmar Amtmann, PhD, Fraser D. Bocell, PhD, Kendra Liljenquist, PhD, Mark Jensen, PhD, Dennis Turk, PhD

University of Washington, Seattle, WA

Introduction: Pain-Related Self-Efficacy (PRSE) is a person's confidence that she or he can engage in activities despite chronic pain (CP). Self-reported PRSE is an important therapeutic target because it is more predictive of disability than measures of biomedical domains. Interventions that target and increase PRSE have been found to improve pain, mental health, and quality of life of people with CP. Brief, flexible, and psychometrically sound measures of PRSE facilitate development of effective strategies for managing CP. This study developed a short form (SF) for measuring PRSE.

Methods: The full PRSE item bank contains 35 items calibrated to Item Response Theory (IRT). Development followed rigorous psychometric methodology. CP experts and people with CP provided feedback. All items were administered to a sample of people with CP (n=583) including those with low back pain, multiple sclerosis, osteoarthritis, spinal cord injury, amputations, and diabetic neuropathy. Items for the SF were selected from the full item bank using the IRT parameters and representation of the subdomains. Validity of the IRT-based t-score based on the SF was examined by correlations with related constructs. Test-retest reliability was tested 40 to 80 hours after the first administration.

Results: A correlation between the 5-item SF and the full item bank score (r=.95) and the test-retest reliability (ICC=.90) were both excellent. The correlations of the SF score with related constructs were all in the expected direction and magnitude. The SF five items ask about a person's confidence in, despite having pain, maintaining personal hygiene, ability to do things she/he wants and enjoys doing, ability to cope with pain, and socialize with friends. The SF can be administered on the computer or by paper and pencil questionnaires. A lookup table that converts a simple summary score to an IRT-based t-score was developed.

Conclusions: A 5-item SF measures well across the PRSE continuum and covers important subdomains of PRSE. The results support the validity and reliability of the 5 item PRSE SF. The SF score is on the same metric and directly comparable to the t-score based on the whole item bank. Because the SF is brief it lends itself well for inclusion in clinical practice and research. The SF and the full item bank are publicly available to researchers and clinicians.

VIEWING A DOCUMENTARY ON BEHAVIORAL MEDICINE APPROACHES TO PAIN REDUCTION INCREASES EMPATHY AMONG FUTURE HEALTH PROFESSIONALS

Luciana Lagana, Ph.D.[1], Larisa Gavrilova, David Grewe, Alberto Zacarias, Melissa Martinez, N/A[2], Abigail Pajulas, none[3]

[1]CSUN, Chatsworth, CA; [2]California State University Northridge, Canyon Country, CA; [3]California State University Northridge, Glendale, CA

In this experimental study, we tested whether viewing an original documentary created by the first author could reduce ageism and increased empathy among future health professionals such as psychology students. The film's duration is one and a half hours; it features several interviews with pain experts who are members of the American Pain Society and who discuss in simple terms: the findings of their behavioral medicine research in areas such as breast cancer-related pain; health disparity topics, including why pain medications may not work well for patients from ethnic minority backgrounds; as well as pain prevention and treatment strategies, emphasizing the difficulties concerning achieving effective pain management for older patients. Moreover, the movie contains accounts of living in chronic pain by several people age 50 and older. To our knowledge, no published literature is available on the effects of viewing a documentary covering prevention and treatment issues related to pain in older age on young people's empathy and ageism scores. We hypothesized that only those research participants who viewed our documentary would have reported lower ageism and higher empathy scores, not the control group participants, who watched a neutral/nature and park documentary of the same duration. Eighty psychology students (age 18 to 29) were randomized via tossing a coin to either the experimental or the control condition, with 40 people per group. Measures included a demographic list, the 17-item Jefferson Scale Empathy–Health Profession Students' version, and the 20-item Prescriptive Intergenerational-Tension Ageism Scale. An independent samples t-test approach was used to compare pre-test and post-test scores between the control and the experimental conditions. For empathy before viewing a film, scores of the control (M=87.44, SD=12.22) and the experimental (M=89.5, SD=13.84) groups were not statistically different, $t(75) = -.069$, $p>.05$. For post-viewing empathy, there was a significant difference in scores between the control (M=88.46, SD=13.43) and the experimental (M=95.66, SD=9.72) groups, $t(75) = -2.69$, $p < .05$, suggesting that viewing the experimental documentary influenced empathy scores. Ageism scores, contrary to our predictions, were not influenced by viewing our film, as we achieved non-significant findings on this variable. The study's limitations and clinical implications are discussed.

IMPACT OF PROLONGED CLASSROOM SITTING TIME ON STUDENT PERCEPTIONS OF PHYSICAL DISCOMFORT AND ALERTNESS. HOW MUCH IS TOO MUCH?

Katie Hosteng, M.S., Roberto Benzo, M.S., Alison Phillips, Ph.D., Lucas Carr, Ph.D.

University of Iowa, Iowa City, IA

Background: Prolonged sitting has been shown to increase fatigue and risk of low back pain and injury in sedentary office workers. Conversely, regularly breaking up workplace sitting with standing bouts every 30 minutes has been shown to improve fatigue and musculoskeletal discomfort in office workers. It is not known whether prolonged classroom sitting similarly impacts fatigue and discomfort in college students and/or how much sitting is too much.

Objective: To explore the impact of prolonged bouts of classroom sitting on student's perceived physical discomfort and alertness. To determine the minimum duration of classroom sitting time needed to induce meaningful impairments in student's perceived physical discomfort and alertness. We hypothesize a positive association between sitting time and perceived discomfort, and a negative association between sitting time and alertness.

Methods: We recruited 58 undergraduate college students enrolled in a single 2.5-hour lecture. Students were asked to remain seated the entire lecture. Students completed the Stanford Sleepiness Scale (SSS; 1=feeling active, vital, alert, wide awake; 8=asleep) to measure altertness and the Shackel General Comfort Scale (SGCS; 0 = I feel completely relaxed; 10 = I feel unbearable pain) to measure physical discomfort every 15 minutes throughout the lecture. Pearson correlations were used to determine relations between sitting time, alertness, and comfort. Regression analysis was used to determine the time it took for student's to report a 4 (I feel uncomfortable) on the SGCS and a 3 (Awake, but relaxed; responsive but not fully alert) on the SSS as these values represent critical thresholds for discomfort and alertness.

Results: A positive association was observed between sitting time and perceived discomfort ($r = 0.31$, $P < 0.01$) while a negative association was observed between sitting time and alertness ($r = 0.47$, $p < 0.01$). Regression analyses indicate student's reported a 4.0 on the SGCS after 88.4 minutes and a 3.0 on the SSS after 26.8 minutes.

Conclusion: These findings suggest student's alertness and discomfort deteriorated over the duration of the seated class period. These findings also suggest students may also benefit from brief activity breaks every 30 minutes during class to minimize impairments in alertness. Future sedentary classroom interventions are needed to confirm these findings.

ACCELEROMETER-ASSESSED PHYSICAL ACTIVITY AND SEDENTARY TIME IN LUNG CANCER SURVIVORS: ASSOCIATIONS WITH QUALITY OF LIFE

Adrijana D'Silva, BSc[1], Gwyn Bebb, MD, PhD[2], Terry Boyle, PhD[3], Steve Johnson, PhD[4], Jeff Vallance, PhD[4]

[1]Athabasca University, Calgary, AB, Canada; [2]University of Calgary, Calgary, AB, Canada; [3]Curtin University, Perth, Western Australia, Australia; [4]Athabasca University, Athabasca, AB, Canada

Background: Few studies have examined physical activity and sedentary time among lung cancer survivors. These studies self-reported these behaviors, which may lead to biased results and incorrect conclusions. This study set out to determine associations of accelerometer-assessed moderate to vigorous intensity physical activity (MVPA) and sedentary time with health-related quality of life (HRQoL) and fatigue among lung cancer survivors. **Methods**: Lung cancer survivors in Southern Alberta (N=527) were invited to complete a mailed survey that assessed HRQoL (FACT-L: Functional Assessment of Cancer Therapy-Lung) and fatigue (FS: Fatigue Scale). Consenting participants wore an Actigraph® GT3X+ accelerometer on their hip for seven days. Average daily MVPA and sedentary time were derived from the accelerometer data, processed using 60-second epochs, and examined as quartiles. To examine associations between accelerometer outcomes and HRQoL, we used linear regression adjusting for wear time, demographic, and clinical variables. **Results:** A total of 127 lung cancer survivors participated (Mean age=71 years; Mean time since diagnosis=75 months) for a 24% response rate. MVPA was significantly associated with FACT-L (B=3.35, 95% CI, 0.37 to 6.32, p=.028) and FS (B=1.83, 95% CI, 0.17 to 3.5, p=.031). Total sedentary time was associated with FACT-L (B=-5.03, 95% CI, -8.45 to -1.61, p=.004) and FS (B=-2.63, 95% CI, -0.46 to -0.72, p=.007). Sedentary time accrued in 30-minute bouts was associated with FACT-L (B=-4.03, 95% CI, -6.97 to -1.09, p=.008). **Conclusion:** Objectively measured MVPA was positively associated with HRQoL and fatigue, while sedentary time was negatively associated with HRQoL and fatigue in lung cancer survivors. Differences in HRQoL and fatigue met thresholds for determining clinically meaningful differences. This is the first study to examine associations of accelerometer-assessed physical activity and sedentary time with HRQoL and fatigue in lung cancer survivors.

BODY IMAGE AND SELF-EFFICACY AS PREDICTORS OF ACHIEVING PHYSICAL ACTIVITY GUIDELINES IN UNIVERSITY STUDENTS

Jamie Faro, MS[1], Jessica Whiteley, PhD[2], Laura L. Hayman, PhD, RN, FAAN, FAHA[3], Samuel J. Simmens, PhD[4], Melissa Napolitano, PhD[5]

[1]University of Massachusetts Boston, Newton, MA; [2]UMass Boston, Boston, MA; [3]University of Massachusetts Boston, Boston, MA; [4]George Washington University, Washington, DC; [5]The George Washington University, Washington DC, DC

Declines in moderate-to-vigorous physical activity (MVPA) have been observed during developmental transitions particularly in young adults entering college. Negative body image, which also tends to become more negative in young adults, has been associated with lower levels of exercise self-efficacy and physical activity (PA). **PURPOSE:** To examine the role of body image and other predictor variables on meeting MVPA guidelines among university students at 2 campuses. **METHODS:** N=128 college students (28 males and 84 females, mean±sd: age, 21.6±3.1 yrs; BMI 31.6±3.7 $kg{\cdot}m^{-2}$) completed demographic questions (age, gender, race, BMI), the International Physical Activity Questionnaire (IPAQ), the Body Image Quality of Life Inventory Scale (BQLI) and physical activity self-efficacy (PA-SE). MVPA was calculated for each participant based on the days and minutes of self-reported activity, with meeting guidelines defined as 150 minutes/week of combined MVPA. **RESULTS:** When entered separately into logistic regression models, higher levels of PA-SE (*p*ppCONCLUSION: Among young adults with excess weight, physical activity self-efficacy was an important factor in predicting MVPA. While body image might play a role in the initiation of PA, further work should be conducted to determine the importance of the confidence young adults have to continue PA despite barriers (including negative body image).

DOES TIME MATTER? ASSOCIATIONS BETWEEN REPORTED PARENT-CHILD TIME TOGETHER AND OBJECTIVELY MEASURED CHILD PHYSICAL ACTIVITY

Helena H. Laroche, MD[1], Brad R. Julius, MD[2], Amy O'Shea, PhD [1], Shelby L. Francis, M.A.[1], Kathleen F. Janz, EdD[1]

[1]University of Iowa, Iowa City, IA; [2]University of Iowa Hospitals & Clinics, North Liberty, IA

Background: Active parents tend to have active children but how much of this is due to encouragement and facilitation of activity compared with actual time spent being active with their children?US guidelines note that there is little research to fully substantiate how and how much parents influence child physical activity (PA).

Methods: We examined the effects of 1) daily waking parent-child time together (parent reported average over past month) and 2) parent-child time doing PA (parent-reported over the past week) on both moderate-vigorous intensity physical activity (MVPA) and sedentary time (min/d) of children in the following week. All variables were separated by weekend days (WE) and weekdays (WD). A low-income parent with obesity and her child aged 6-12 years wore accelerometers simultaneously for a week (minimum of 3 WD and 1 WE day). Linear regression was used to determine the effect of self-reported parent-child time together on objectively measured child PA adjusting for child age, child sex, parent BMI, child BMI %, and parent education.

Results: The initial 47 parent-child dyads with complete data from an ongoing study of 240 families were included. 96% of adult and 51% of children were female. On average, children performed MVPA for 17.6 (SD =10.9) and 17.7 (SD = 11.3) min/d for WD and WE days. Parents averaged 1.4 (SD = 1.44) hours total time participating in PA with their children on weekends (2 days) and 2.63 hours (SD= 2.61) over 5 WD. Parent MVPA (accelerometry) during the same week showed a significant effect on child MVPA on both WD ($\beta = 0.246$, $p = 0.044$) and WE days ($\beta = 0.428$, $p = 0.005$). However self-reported average daily waking time spent with children had no effect on sedentary time (WD β= 1.821, p=0.46; WE β=0.111, p=0.98) or MVPA (WD β= 0.158, p=0.63; WE β=0.255, p=0.60) in children. Neither did time spent in PA with children in the week prior affect sedentary time (WD β= -5.626, p=0.27; WE β= -0.784, p=0.95) or MVPA (WD β= 0.658, p=0.30; WE β=1.209, p=0.36).

Conclusions: Measurement of MVPA simultaneously with accelerometers showed an association between parent and child MVPA. However parent reports of waking time spent

with children and time spent in PA with children did not affect objectively measured child MVPA or sedentary time. Self-reported measures of time children and parents spend together may not be sufficient. Technology tracking movement and proximity to another person may be needed to understand these effects.

ENHANCING INTERNAL VALIDITY IN WORK PERFORMANCE ASSESSMENTS WITH ACTIVE WORKSTATIONS: RECOMMENDATIONS FROM A CASE STUDY

Liza S. Rovniak, PhD, MPH[1], Jay Cho, BS[2], Mari Greecher, PhD[1], Erica Mellinger, BS[1], Jason Stanton, Student[2], Thomas Hartmann, Student[2], Melissa Bopp, PhD[3], Christopher N. Sciamanna, MD, MPH[1], Andris Freivalds, PhD, CPE[2]

[1]Penn State College of Medicine, Hershey, PA; [2]Pennsylvania State University, State College, PA; [3]Pennsylvania State University, University Park, PA

Background: As lack of time is a common barrier to exercise, many studies are investigating if adults can concurrently use active workstations (e.g., pedaling or treadmill desks) while accomplishing productive office work. Experimental studies that assess if concurrent physical activity affects work performance should be set up with high internal validity. However, there is a lack of established protocols to maximize internal validity in studies assessing the effects of active workstations on work performance.

Methods and Results: We present a case study of efforts to maximize internal validity in an ongoing lab-based experiment with approximately 90 sedentary adults that is comparing the effects of using a compact under-the-desk pedaling device at 17 and 25 watts vs. a standard seated condition on office-based work performance. First, to ensure a consistent pedaling speed at each wattage level, we designed a pedaling speed monitor that uses Hall effect sensors with a microcontroller to transmit participants' pedaling data to a computer in real-time. Participants substantively deviating from the targeted speed during our experiment have received real-time visual and auditory prompts, yielding typical adherence rates of over 85% to the pedaling speed protocol. Furthermore, on four separate trials, the 60 observed pedaling rotations corresponded 100% to the actual-measured pedaling rotations recorded by the speed monitor, indicating reliable and valid measurement. Second, to facilitate valid assessment of work performance at different pedaling speeds, we selected typing, reading, and phone/logic tasks with non-significant learning curves/improvement after performing two initial practice trials, and we developed scripted task instructions. Third, based on pilot-testing, to control confounding ergonomic/environmental factors we used an adjustable-height desk, a non-swivel and non-wheeled adjustable-height chair, non-slip equipment mats, and 30 second to 5 minute rest/hydration breaks between randomly-sequenced experimental tasks.

Conclusions: Assessing the effects of active workstations on work performance requires controlling measurement errors related to physical activity, work performance, and extraneous ergonomic and environmental factors. Grant proposals should budget funds for developmental work to maximize internal validity and journal editors should require describing this work, so that efforts to integrate active workstations into workplaces are based on valid and reproducible science.

EXERCISE-RELATED ATTITUDINAL CHANGES AFTER 20 HOURS OF COGNITIVE TRAINING

Tiffany Bullard, B.S. [1], Amanda L. Reber, MS, PhD[2], Jason D. Cohen, B.S.[1], Daniel Palac, MA[3], Aaron L. Wichman, Ph.D.[4], Edward McAuley, PhD[5], Sean P. Mullen, PhD[1]

[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]Central Queensland University, Rockhampton, Queensland, Australia; [3]University of Illinois at Urbana-Champaign, Champaign, IL; [4]Western Kentucky University, Bowling Green, KY; [5]University of Illinois at Urbana Champaign, Urbana, IL

Explicit and implicit attitudes can influence motivation for engagement and maintenance of physical activity (PA) behavior. To date, no randomized controlled trial has been designed to change PA-related attitudes through cognitive training (CT). The aim of the NHLBI-funded Cognitive Regulation and Exercise (CORTEX) trial was to test the efficacy of a 20-hour CT program to increase exercise adherence for middle-aged adults by enhancing exercise self-efficacy and self-regulatory strategy-use. The CT intervention emphasized dual task training and self-as-exerciser priming while the control group watched health education videos. All participants were then enrolled in a 4-mo exercise program. In a secondary data analysis, path modeling was used to test mechanisms of exercise-specific cognitive change. Explicit attitude was assessed via a composite score from the *Exercise Self-Schema Questionnaire*. Implicit attitude was assessed via a PA-specific *Single-Category Implicit Association Task* (S-CIAT). Pre-post CT change scores were computed for both mediators. The total number of electronically-recorded fitness facility visits was the dependent PA behavioral outcome. The model (χ^2 (5)=10.93, p=.053, CFI=0.93, SRMR=0.03) adjusted for age, gender, education, race, baseline PA, injury, and pre-exercise dropout, fit the data with group having a significant direct effect on total visits (β=0.30, p= < 0.05), favoring the CT group. The results show significant (p= < 0.05) direct effects of group on changes in self-schema (β=-0.45), which had a direct effect on total visits (β=0.13) and a marginally significant indirect effect of group on total visits via exercise self-schema (β=-0.13, p=0.08). Group and total visits were not predicted by implict attitudes. In a simple regression model, baseline Implicit Assoication Task (S-CIAT) did predict lifestyle PA (β=0.22, p= < 0.05) assessed via Fitbit steps at program end. These findings are consistent with prior research, indicating that explicit self-schema influences goal-directed behavior and lifestyle PA may be more sensitive to effects from implicit attitudes. Changing explicit and implicit attitudes towards PA can increase adherence to exercise programs.

FEASIBILITY AND EFFICACY OF A PHYSICAL ACTIVITY INTERVENTION FOR THE PREVENTION OF POSTPARTUM DEPRESSION: A RANDOMIZED TRIAL

Beth Lewis, PhD, Katie Schuver, PhD, Dwenda Gjerdingen, MD, MS, Carrie Terrell, MD, FACOG, Melissa Avery, PhD, CNM

University of Minnesota, Minneapolis, MN

Approximately 10-13% of women experience postpartum depression. Furthermore, one-third of women who have a history of depression report depression following childbirth. Therefore, it is important to examine the efficacy of low cost, innovative interventions designed to prevent postpartum depression among women at risk. Research indicates that physical activity interventions prevent depression among the general population; however, few studies have examined the efficacy of these interventions for postpartum women. The purpose of this study was to examine the efficacy of a six-month physical activity intervention on the prevention of postpartum depression. Specifically, 450 sedentary postpartum women (participants were less than eight weeks postpartum) who had a history of depression prior to pregnancy and were not taking an antidepressant were randomized to one of three groups: (1) Telephone-based exercise intervention (based on social cognitive theory and self-determination theory); (2) telephone-based wellness/support intervention (topics such as sleep, stress, and healthy eating); or (3) usual care. Participants were recruited via online, email, and print advertisements. Participants were mostly married (72%), a majority had a college education (68%), and several were employed (65%). Forty-one percent of the participants identified as a racial or ethnic minority. Depression was assessed using the Structured Clinical Interview for DSM-IV Axis I Disorders (SCID-I) and the Edinburgh Postnatal Depression Scale (EPDS). Physical activity was assessed using the 7-Day Physical Activity Recall Interview and the ActiGraph. Of the 423 participants due for their six-month assessments, 91% have completed this assessment. The assessments are currently ongoing and the six-month assessments will be available at the time of the conference presentation. Based on a 3-item questionnaire administered at 9 months, preliminary data indicate that 91% of the participants reported enjoying the program and found it useful. Our study indicated that a physical activity intervention is feasible and acceptable among postpartum women at risk for depression.

FEASIBILITY OF A CLIMATE-BASED AFTER SCHOOL PHYSICAL ACTIVITY INTERVENTION FOR MIDDLE SCHOOL YOUTH; CONNECT THROUGH PLAY

Nicole Zarrett, PhD[1], Dawn K. Wilson, Ph.D., FSBM[1], Bethany A. Bell, PhD, MPH[1], Brittany S. Cook, M.A[2], Michelle Abraczinskas, M.A.[1], Stephen Taylor, B.S.[1], Alex Roberts, B.A.[1]

[1]University of South Carolina, Columbia, SC; [2]University of south Carolina, West Columbia, SC

The proposed study tested the feasibility of the ‘Connect through Positive Leisure Activities for Youth (‘Connect’) afterschool physical activity (PA) program, a climate-based intervention that expands on the social-motivational constructs highlighted by Self-Determination Theoryand Achievement Goal Theory, to increase the PA of underserved (i.e., low income, minority status) middle school youth within afterschool programs (ASPs). The Connect intervention aims to improve the PA social motivational climate of pre-existing ASPs by emphasizing social benefits of PA (i.e., developing friendships, peer connectedness, staff-youth connections, and group belonging), as the primary goal, purpose and achievement of PA. The two primary components of the program involved “Get to know you” small group sessions aimed at providing youth guided social opportunities that facilitate peer acceptance, cooperation, and friendship, and a novel socially-oriented PA curriculum infused within ASPs free play sessions. For the current study, intervention feasible was evaluated by examining: 1) youth’s greater perceived connectedness and affiliation goal orientation toward PA from baseline to post-intervention (e.g., The Need for Relatedness Scale; Social Motivational Orientations Scale for Sport) using youth survey; 2) changes in targeted social climate components from baseline to post-intervention as measured by systematic observations (SOCARP and MCOT supplement) and youth surveys (e.g., Perceived Teacher Support Scale; Peer Motivational Climate in Youth Sport Questionnaire), and; 3) whether youth in the social climate program (vs. comparison) demonstrate greater increases in positive PA affect, and cognitions (e.g., The Intrinsic Interest Scale), and moderate-to-vigorous PA (accelerometer and SOCARP) from baseline to post-intervention. Comparison of ASPs receiving the “Connect” intervention (N=3 ASPs) with ASPs providing the typical curriculum serving as the control (N=3 ASPs) yield preliminary data on the effectiveness of social mediators for improving PA among at-risk youth that can inform future intervention design and youth programming policy. For example, preliminary analyses indicated changes in critical social climate components (e.g., positive peer interactions [$t(59)=3.60$, $p=.000$]; peer PA social support [$t(47)=2.46$, $p=.001$]), youth PA motivations (e.g., PA regulatory motives [$t(47)=2.12$, $p=.05$]; PA engagement [$t(59)=6.73$, $p=.000$]) and youth PA ([$t(59)=4.65$, $p=.000$]).

HOW LONG DOES THE POSITIVE AFFECTIVE RESPONSE TO EXERCISE LAST? AN EMA STUDY.

Lauren Connell, Ph.D.[1], Shira Dunsiger, PhD[2], Jessica Emerson, MS[3], Courtney J. Stevens, MA[4], David Williams, Ph.D.[5]

[1]The Miriam Hospital and Alpert School of Medicine at Brown University, Providence, RI; [2]The Miriam Hospital and Brown University, Portsmouth, RI; [3]Brown University, East Providence, RI; [4]Alpert Medical School of Brown University, Providence, RI; [5]Brown University School of Public Health, Providence, RI

Background/Aim: Prior research has shown that many people experience a positive shift in affective valence from pre- to post-exercise. This study aims to describe the duration of this positive affective response in a natural setting.

Methods: Participants included 59 overweight or obese insufficiently active adults enrolled in a 6-month field-based exercise (i.e., walking) promotion intervention. Participants were asked to self-report via ecological momentary assessment (EMA) the beginning and end of each exercise session, and were then prompted to report their affective valence on the 11-point Feeling Scale (FS; from -5 [very bad] to +5 [very good] with zero as neutral) immediately prior to exercise, immediately following exercise, and 15 minutes after the end of exercise. Participants were also prompted to respond to the FS at random intervals throughout the day. The responses to the FS were used to characterize how long it took for the positive shift in affective valence from immediate pre- to immediate post-exercise to return to pre-exercise levels among those who experienced a positive shift from pre- to post-exercise.

Results: The data set included 2788 sessions of exercise of at least 10 minutes over the 6-month period from the 59 participants. Of these, 1169 (42%) displayed a positive shift in affective valence from pre- to post-exercise, 1135 (41%) showed no change, and 480 (17%) showed a negative shift. For 17% of the exercise sessions for which there was a positive shift in affective valence, participants' affect returned to pre-exercise levels within 15 minutes after exercise. Affective valence returned to pre-exercise levels in 25%, 31%, 41%, 47% and 51% of sessions by 1 hour, 2 hours, 3 hours, 4 hours, and 5 hours post-exercise, respectively, representing a significant dissipation of affective valence over time (Z=4.02, $p < 0.001$).

Discussion: The commonly experienced positive shift in affective valence from pre- to post-exercise dissipated over time, but nonetheless persisted in nearly 50% of exercise sessions by 5 hours post-exercise, suggesting a lasting positive effect of acute exercise on affective

valence in a significant proportion of exercise sessions. In future research we plan to identify predictors of the persistence versus dissipation of the positive effect of exercise on affective valence.

IDENTIFYING UNIQUE PATTERNS OF DAILY ACTIVITY AMONG LATINAS ENROLLED IN A 12-MONTH PHYSICAL ACTIVITY INTERVENTION

Lucas Carr, Ph.D.[1], Shira Dunsiger, PhD[2], Bess H. Marcus, Ph.D.[3]

[1]University of Iowa, Iowa City, IA; [2]The Miriam Hospital and Brown University, Portsmouth, RI; [3]University of California, San Diego, La Jolla, CA

Background: Traditional randomized controlled trial physical activity interventions have relied on measuring physical activity during brief time points over the course of the intervention (baseline, 6 months, 12 months) to determine effectiveness. Adding a continuous measure of activity (pedometer) would allow interventionists to better understand the impact of intervention exposures on patterns of physical activity through the use of latent class analyses.

Objective: The purpose of the current study is to use a latent class model (LCM) to identify unique patterns of daily step counts over 12 months, among Latinas enrolled in a print-based physical activity intervention.

Methods: Participants were low-active females (N=122, mean age=41.1, SD=10.0) randomized to an individually tailored and linguistically adapted physical activity intervention. Objective daily steps were recorded using Omron HJ720ITC pedometers which were given to participants as part of the intervention. Steps were recorded daily for 12 months. Self-reported physical activity (as collected via the 7-day PAR) was the primary study outcome, and was collected at baseline, 6 and 12 months.

Results: Results suggested a 5-class model was best supported by the data. Based on the observed patterns, classes were labeled as “non-engaged” (26%), “steady adopters” (29%), “early attempters” (18%), “late attempters” (12%), and “unstable engagers” (15%). Analyses suggested a significant association between class and mean min/week of self-reported moderate to vigorous physical activity (MVPA), $p < .01$, such that "steady adopters" reported significantly more MVPA at 6 and 12 months compared to all other classes. Furthermore, "late attempters" reported significantly more MVPA at 12 months compared to "non-engaged", "early attempters", and "unstable engagers", $p < .05$. In addition, between-class differences were found in baseline demographics (BMI, household make-up), and changes in psychosocial constructs (self-efficacy, enjoyment, process variables) over time.

Conclusions: These findings identified five unique patterns of activity uptake among participants of a 12 month intervention. This information could be used to further enhance future interventions by identifying participants who are at risk of failing the intervention (e.g., “non-engaged”, “unstable engagers”) early in the process and providing those individuals with enhanced or additional treatment.

LONGITUDINAL RELATIONSHIPS BETWEEN SELF-CONCEPT AND NEIGHBORHOOD SOCIAL LIFE AS PREDICTORS OF PHYSICAL ACTIVITY

Allison Sweeney, PhD[1], Dawn K. Wilson, Ph.D., FSBM[1], M Lee Van Horn, PhD[2]

[1]University of South Carolina, Columbia, SC; [2]U of new mexico, Abq, NM

People are more likely to engage in physical activity (PA) when PA engagement is seen as a central to their self-concept (SC). Self-Determination Theory and Social-Cognitive Theory propose that volition (i.e., self-determined-motivation; SDM) and competency (i.e., self-efficacy; SE) are critical for PA, but these constructs may fluctuate across time as motivation and barriers change. SC, which is grounded more centrally in one's self-identity, should be a more stable predictor of PA. Little research has directly compared how SC, SE, and SDM predict longitudinal PA, with few studies testing these relationships among underserved groups. Furthermore, it remains unclear how well such individual-level factors predict PA when accounting for broader ecological factors including perceived neighborhood social life (SL) and neighborhood satisfaction (NS). We hypothesized that SC would be a stronger predictor of longitudinal PA (relative to SDM or SE) and that SL and NS would also predict PA. Data were collected from African Americans ($N = 417$, $M_{\text{age}} = 51.65$, 62% female, $M_{\text{income}} <= \$25,000$/yr) enrolled in the Positive Action to Today's Health randomized trial. PA was assessed using 7-day accelerometry-estimates and psychosocial data were collected at baseline, 12- and 24-months. Multilevel growth modeling was used to test for within- and between-person effects. Sex, age, time, BMI, income, and community were included as covariates (no community effects were observed). There were no significant within-person effects. At the between-person level, only average SC was significant, ($b = .58$, $SE = .24$, $p = .018$), which was not moderated by time. At baseline people with a higher average SC engaged in greater PA than those with a lower average SC, and the positive association between average SC and PA at baseline remained constant across time. A significant interaction between time and average SL ($b = .29$, $SE = .11$, $p = .010$) also showed that people with a higher average SL increased their PA over time compared to people with a lower SL. These results suggest that SC and SL are critical predictors of PA in African Americans, which should be considered in future interventions. These factors may be particularly relevant to long-term changes and maintenance of PA in underserved populations.

MORE THAN JUST A GAME? A RANDOMIZED CONTROLLED TRIAL OF POKéMON GO ON PHYSICAL ACTIVITY HABITS

Allene Gremaud, B.S., Jacob Simmering, PhD, Sarah Coe, B.S., Nicholas Evans, B.A., B.S., Linnea Polgreen, PhD, James Cremer, PhD, Alberto Segre, PhD, Philip Polgreen, M.D., Lucas Carr, Ph.D.

University of Iowa, Iowa City, IA

Background: With only 20% of Americans meeting the federal physical activity guidelines, there is a need for scalable and effective interventions. Pokémon Go is a free, augmented reality game that encourages users to explore/walk to real locations to complete the game's objectives. While extremely popular (100 million downloads, 20 million active users daily), the efficacy of Pokémon Go for increasing physical activity habits has not yet been tested.

Objective: The purpose of this study was to test the efficacy of Pokémon Go for increasing daily steps as compared to a control group that did not receive Pokémon Go over eight weeks.

Methods: We recruited 100adults who owned a smart phone and reported having never played Pokémon Go previously. Upon enrollment, all participants were provided a Fitbit Zip to wear daily throughout the intervention as an objective measure of physical activity. Participants were randomized (1:1 ratio) to either: 1) Fitbit only (FB; N=50; 80% female, 37.3 ± 14.0 years; BMI=29.1 ± 6.6 kg/m^2); or 2) Fitbit + Pokémon Go (FB+P; N=47; 70% female; 39.1 ± 16.0 years; BMI=28.7 ± 6.5 kg/m^2). Average daily steps and number of daily active minutes ($\geq$100 steps/minute) over the 8 week intervention were analyzed with linear mixed models.

Results: The FB+P arm walked more daily steps/day (+539 steps/day; SE=630, t = 0.86) and completed more active steps (+5.0; SE=3.56; t = 1.14) than FB participants on average over the entire eight-week intervention but neither effect was statistically significant. However, by the end of eight-weeks, the FB+P arm completed significantly more active minutes than the FB group.

Conclusions: Pokémon Go appears to have had a modest, but positive, impact on physical activity levels among these participants. Given its widespread adoption and use, this innovative game and others like it hold significant potential for improving physical activity levels on a large scale. Future collaborative relationships between public health researchers and game developers are encouraged.

OBESE ADULTS' FORECASTED AND ACTUAL EXPERIENCES DURING PHYSICAL ACTIVITY: IS THERE A DISCREPANCY?

Leah M. Schumacher, M.S., Margaret Clark, B.S., Alexandra Convertino, B.S., Evan M. Forman, PhD, Meghan L. Butryn, PhD

Drexel University, Philadelphia, PA

Affective experiences during physical activity (PA) are related to current and future PA behavior. Limited research has examined individuals' predictions of how they will feel during PA, despite the potential of such forecasts to affect PA decisions. The present study examined forecasted and actual affective (i.e., excitement, contentment) and physical (i.e., energy, strength, pain) experiences during PA, as well as the accuracy of forecasts based on current PA level, among 311 obese adults beginning weight loss treatment. Participants (M_{BMI}=35.6 kg/m^2, 78.5% female) completed a half-mile walk test on a treadmill in the laboratory. Prior to the task, participants forecasted how they would feel during the walk along five bipolar scales (bored-enthusiastic, irritable-content, exhausted-energetic, weak-strong, great pain-no pain). Negative ratings were anchored at 0; positive ratings were anchored at 100. Mid-walk, participants used the same scales to report on their actual experiences. After the walk, PA was measured for 7 days using accelerometers, and participants were classified as currently engaging in no PA (no bouted moderate-to-vigorous PA/week) or in some PA (≥10 min. of moderate-to-vigorous PA/week). Results revealed participants generally made favorable forecasts (*M*s = 64.3 to 82.8). Contrary to past research, participants' experienced enthusiasm (*M*=60.7) was *lower* than forecasted (*M*= 64.3; p=.01, partial eta squared=.02). However, there was a trend for experienced energy (*M*=70.7) being greater than forecasted (*M*=68.9, p=.07). Differences also were observed in forecasting accuracy for strength and pain based on 7-day PA level (no vs. some). While individuals engaging in some PA forecasted slightly greater strength and less pain than was experienced, individuals engaging in no PA forecasted lower energy and more pain than was experienced (*ps* < .03). Of note, however, all effect sizes and differences in forecasted and actual ratings were small. These findings suggest obese adults make generally favorable forecasts about PA experiences, though forecasts may not be completely accurate. Additionally, inactive individuals may make greater, more negative forecasting errors for some aspects of PA. As this is the first study to examine PA forecasting among obese individuals, additional research on this topic is needed. Future studies should examine whether forecasting errors impact PA decisions to help clarify the clinical significance of these findings.

PHYSICAL ACTIVITY AND MULTIPLE SCLEROSIS: AN UPDATED META-ANALYSIS

Dominique Kinnett-Hopkins, B.S. [1], Brynn Adamson, MS[1], Kate Rougeau, M.S.[1], Robert W. Motl, PhD[2]

[1]University of Illinois at Urbana-Champaign, Urbana, IL; [2]University of Alabama at Birmingham, Birmingham, AL

Introduction: Approximately 2.5 million people worldwide are living with multiple sclerosis (MS). Evidence suggests that persons with MS can manage the manifestations of the disease with physical activity. This meta-analysis examines physical activity levels in persons with MS compared with non-diseased and other clinical populations. Methods: We searched PUBMED, PsycINFO and Web of Science using the key words physical activity, exercise and physical fitness in conjunction with MS. Manual searches of bibliographies of the retrieved papers were included. We conducted a quantitative synthesis of the difference in physical activity levels among persons with MS compared with non-diseased and other clinical populations and then examined moderators that explain variation in the overall difference of physical activity using meta-analytic procedures. Results: Overall, 21 studies were included involving 5,303 persons with MS and yielded a mean effect size (ES) of -0.567 (95% CI= -0.763,-0.371). The weighted mean ES was heterogeneous ($Q=443.811$, $df=31$, $p < 0.001$). The magnitude of the ES increased when comparing non-diseased populations versus the MS population but decreased when comparing clinical populations with the MS population. Likewise, the ES was larger for objective measures of physical activity versus subjective measures of physical activity. Conclusion: The cumulative evidence suggests that persons with MS are less physically activity than non-diseased, but not clinical populations.

QUALITY PARTICIPATION AND DELIVERY STRATEGIES OF PHYSICAL ACTIVITY PROGRAMS FOR VETERANS WITH A PHYSICAL DISABILITY

Celina H. Shirazipour, PhD(cand), MHK, BA, Amy E. Latimer-Cheung, PhD

Queen's University, Kingston, ON, Canada

Introduction: The number of physical activity programs for veterans with a physical disability has increased due to improved knowledge of the physical and psychosocial benefits of physical activity participation for veterans post-injury. When developing physical activity programs for veterans post-injury, it is important that program developers and staff focus not only on whether their participants are showing up (i.e. the quantity of a veteran's participation) but whether they are providing a quality program that fosters quality physical activity experiences. A quality program or experience can be conceptualized as including the following elements: autonomy; belongingness; challenge; engagement; mastery; and meaning. While the elements of quality participation have been identified, an important research gap exists when building evidence for how to develop and deliver quality experiences for veterans, particularly the need to understand what program delivery strategies result in quality physical activity experiences. The purpose of the current study is to identify strategies used to deliver physical activity programs to veterans with a physical disability, and interpret these strategies in relation to their potential utility for fostering quality participation.

Methods: Semi-structured interviews were conducted with program staff from three veteran physical activity programs, and program documentation collected. Each program represented a different country, with programs for veterans from the United States of America, United Kingdom, and Canada represented. Interviews and documents were first analyzed using a thematic analysis to identify delivery strategies. Strategies were then interpreted in relation to their potential links to fostering quality elements of participation.

Results: Four themes were identified as program delivery strategies: (1) foster social connections; (2) challenge participants; (3) tailor programs and outcomes to match participant needs; and (4) include knowledgeable coaches/instructors. All strategies linked to elements of quality participation.

Discussion/Conclusion: This study provides a first look at physical activity program delivery for veterans with a physical disability. The findings, evidence of real-world strategies used to deliver programming to veterans, provide indications of how future programs may potentially create and deliver quality physical activity experiences.

SOCIO-DEMOGRAPHIC MODERATORS OF ENVIRONMENT-PHYSICAL ACTIVITY ASSOCIATIONS: THE INTERNATIONAL PREVALENCE STUDY RESULTS

Lilian Perez, MPH[1], Terry L. Conway, PhD[2], Adrian Bauman, PhD[3], Heather R. Bowles, PhD[4], James F. Sallis, PhD[2]

[1]UC San Diego/San Diego State University, San Diego, CA; [2]University of California, San Diego, San Diego, CA; [3]University of Sydney School of Public Health, Sydney, N/A, Australia; [4]National Cancer Institute, Rockville, MD

Background: Neighborhood environmental factors are related to physical activity (PA). Associations between environmental factors and PA may vary across socio-demographic factors, but evidence has been limited to single-country studies with little variability in geographic and population characteristics. We investigated socio-demographic moderators of associations between perceived environmental factors and self-reported PA using data from a multi-country study of adults' PA.
Methods: Questionnaires assessed socio-demographic factors, 7 perceived neighborhood environmental factors, and total physical activity as measured by the IPAQ short from 11,144 adults from 9 countries. Logistic models, weighted and adjusted for country site, examined associations of the perceived environment factors with meeting PA guidelines (PAG). To assess moderator effects, we tested interactions of age, sex, and education with each perceived environmental factor.
Results: 3 out of 21 interactions tested were significant ($p < .05$). Sex moderated associations of safety from crime and the presence of transit stops with meeting PAG. Perceived safety from crime was positively related to meeting PAG only among women (OR= 1.24, 95% CI: 1.07-1.45). Perceived presence of transit stops was positively related to meeting PAG only among men (OR=1.29; 95% CI: 1.03-1.62). Education moderated associations between perceived presence of transit stops and meeting PAG. Perceived presence of transit stops was positively related to meeting PAG among the high education group (OR=1.27; 95% CI: 1.04-1.56) but inversely related in the low education group (OR=0.71, 95% CI: 0.53-0.94).
Conclusions: For women, safety from crime was the most important perceived environmental factor for meeting PAG while for men it was the presence of transit stops. In the high education group, the presence of transit stops was important for meeting PAG. Among those with lower education, the presence transit stops may be a barrier to meeting PAG. Disparities in global PA levels may be partly explained by interactions between neighborhood environmental and socio-demographic factors.

SUNBURN AND SUN PROTECTIVE BEHAVIOR IN RELATIVELY ACTIVE AND INACTIVE TEENS

Frank Perna, EdD, PhD[1], Kasey Morris, PhD[2]

[1]National Cancer Institute, Rockville, MD; [2]National Cancer Institute, Bethesda, MD

Physical activity (PA) has been strongly related to melanoma in adults, ostensibly via increased sun exposure. Surveillance data also documents similarly strong positive associations between PA and sunburn, the best clinically relevant proximal intervention target for melanoma. However, we lack national data regarding these associations in teens. These data are vital since children typically have more outdoor time, are more physically active, and have greater sensitivity to ultraviolet radiation than adults. Using data from the National Cancer Institute's Family Life, Activity, Sun, Health, and Eating (FLASHE) national survey, our purpose was to compare incidence of sunburn and sun-safe behaviors among relatively physically active and inactive teens (N = 1661) aged 12 -18. More girls (47%) than boys (39%)reported sunburn in the last year (X^2 (1) = 8.03, p = .003). In logistic regressions stratified by gender and controlling for age and race, total PA was associated with slightly increased odds of sunburn (at least one in last 12 months) for girls (*OR* = 1.003, *p* = .009), but not for boys. However, out-of-school PA was associated with increased odds of sunburn (*OR* = 1.005, *p* = .005) for both boys and girls. In multiple regressions controlling for age, race, and gender, PA was positively associated with sunscreen and hat use (*b's* = .003 & .004, *ps* < .0001, respectively), but not use of other clothing or sun-safe practices. Unfortunately, frequent sunscreen use ("often" or "always on warm sunny days") was uncommon (34%) and positively associated with sunburn (*OR* = 1.14, *p* = .012), whereas clothing (except hat) use was unrelated to sunburn. These data are consistent with prior reports of high sunburn rate among teens, but extend knowledge by indicating that sunburn incidence may be heightened, albeit minimally, by PA participation, especially out-of-school PA. The association of PA with both sunburn and some sun-safe behaviors suggests several possibilities, including, reverse causation between sunburn and sun protection or the influence of a third unmeasured variable; less than optimal use of sunscreen or pairing of sunscreen with sun-protective clothing among physically active teens (given likely higher sun exposure accompanying PA); or possible strategic intent for sunscreen use gone awry among the physically active (i.e., to tan, but not burn). We discuss these prospects and implications for future research that may explore the extent to which motives for PA (e.g., appearance) impact sun-safe behavior, and intervention research opportunity with youth sports and recreation organizations who may leverage their infrastructure and rule making authority to infuse sun-safe policies and practices.

TRACKING PATTERNS OF FATIGUE AND THE SYMPTOM BURDEN IN ACUTE LEUKEMIA - PACE-AL RANDOMIZED CONTROLLED TRIAL

Mary Jarden, Ph.D. [1], Tom Møller, RN, MPH, Ph.D.[2], Lars Kjeldsen, MD, DMSc[3], Henrik Birgens, MD, DMSc[4], Lis Adamsen, Ph.D.[5]

[1]University Hospitals Center for Health Research, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Hovedstaden, Denmark; [2]Copenhagen University, Faculty of Health Sciences, Copenhagen O, Hovedstaden, Denmark; [3]Copenhagen University Hospital, Rigshospital, Copenhagen, Hovedstaden, Denmark; [4]Herlev Hospital and University of Copenhagen, Herlev, N/A, Denmark; [5]Universitets Hospitalernes Center for Sundhedsfaglig Forsksning, Rigshospitalet, Copenhagen, Hovedstaden, Denmark

Background: Exercise and counseling interventions, widely used as rehabilitation strategies in cancer patients to remedy disease and treatment-related sequel is novel in patients with acute leukemia due to the life threatening nature of the disease and its intensive treatment. In a two-center, randomized controlled trial (PACE-AL; clinicaltrials.gov identifier:01404520), we assessed whether a multimodal intervention could modulate treatment-related symptoms and physical and functional debilitation of patients with acute leukemia during outpatient consolidation chemotherapy.

Objective: To evaluate the effect of a multimodal intervention on the type, severity and pattern of commonly experienced treatment-related symptoms in patients with acute leukemia during consolidation chemotherapy.

Material and methods: Patients were randomized to usual care or a 12-week, 3 day/week supervised multimodal program: stationary cycle, resistance training, dynamic exercises, relaxation training, nutritional support and a goal-setting counseling intervention. 70 patients (mean 53.1 years) were randomly assigned to the intervention (n=32) or control group (n=34), and 62 completed study requirements (88.6%). All patients scored their symptoms weekly using the MD Anderson Symptom Inventory and Brief Fatigue Inventory during the 12 week study period.

Results and conclusion: Fatigue and symptom patterns were identified throughout the 12-week study period. The intervention group reported experiencing greater fatigue during the study period, however there was no difference in symptom interference in daily life. At end-of study, most symptoms were lessened in both groups, though there was a clear trend towards reduced fatigue intensity experienced in the intervention group. Understanding the patterns of fatigue and the symptom burden during consolidation chemotherapy treatment for patients with acute leukemia can assist in the development of important strategies in symptom management. The role of exercise and counseling integrated in the clinical setting has the potential of optimizing the management of acute leukemia and may facilitate resumption of everyday activities.

THE RELATIONSHIP BETWEEN CHRONOTYPE AND PHYSICAL QOL IN COLLEGE STUDENTS: THE MEDIATING EFFECT OF FATIGUE AND ACADEMIC BURNOUT

Hae lim Noh, MA, Donghee Jeong, BA, Hyeju Ha, BA, Jungmin Yoon, BA, Eun-Jung Shim, Ph.D

Pusan National University, Busan, N/A, Republic of Korea

Objective: Evening chronotype has been previously reported to be associated with decreased overall health of college students. According to the social jetlag theory, social time demands evening type students to accordingly adjust their daily rhythm, which potentially results in poor health outcomes. Given that regular schedule in college appears to be more workable for morning type students, evening type students might be more vulnerable to fatigue and burnout due to the inconsistency between their daily life and personal chronotype. The present study examined whether fatigue and academic burnout mediate the relationship between chronotype and physical quality of life (QOL).

Methods: The participants (*N*=500, mean age=21.3, 56.2% male) completed Composite Scale for Mornings, Chalder Fatigue Scale, Maslach Burnout Inventory-Student Survey, and World Health Organization Quality of Life Instrument-Short Version. PROCESS macro for SPSS (Hayes, 2013) was used to examine the mediating effects

Results: Chronotype, fatigue, and academic burnout accounted for 38.6% of variance in the physical QOL. The direct effect of chronotype on physical QOL was not significant (*b*=.007, *p*=.574). By contrast, the indirect effects of chronotype on physical QOL through fatigue (*b*=.014, [95% bias-corrected bootstrap CI .005, .026]) and academic burnout (*b*=.007, [.002, .014]) were significant. Furthermore, the dual mediating effect of fatigue and academic burnout between chronotype and physical QOL was also significant (*b*=.001, [.000, .003]).

Discussion: Our results suggest that the chronotype (evening type) negatively affects physical QOL through its impact on fatigue and academic burnout. Evening type students may benefit from interventions aiming at reducing fatigue and academic burnout in order to improve their physical QOL.

A QUALITATIVE STUDY OF PREPAREDNESS FOR END-OF-LIFE CARE AMONG FAMILY CAREGIVERS CONFRONTING ADVANCED CANCER

Allen C. Sherman, PhD, Stephanie Simonton-Atchley, PhD, E Anderson, MS, Cindy W. Mikeal, MS, Konstantinos Arnaoutakis, MD, Laura F. Hutchins, MD, Fade Mahmoud, MD, Natasha Milojkovic, MD, Sarah E. Harrington, MD, James Y. Suen, MD

Winthrop P. Rockefeller Cancer Institute, University of Arkansas for Medical Sciences, Little Rock, AR

End-of-life care presents families with myriad challenges; however, it remains unclear what family caregivers need to feel prepared to manage this phase of illness. Perceptions of preparedness may have considerable implications for caregiver burden and quality-of-life, as well as for the cancer patient's course of treatment and healthcare utilization. This study sought a deeper understanding of preparedness for end-of-life care, from the caregiver's perspective.

Family members caring for cancer patients with end-stage disease participated in individual open-ended interviews. (Independent interviews were conducted with patients as well and are reported separately.) Sixty-four percent of caregivers were spouses and 72.7% were white. A variety of malignancies were represented. Transcribed audiotapes were coded by 3 raters using thematic analysis, and data were organized using NVivo 11 software; recruitment continued through data saturation.

Findings were classified into 6 major themes that caregivers regarded as salient aspects of preparedness: (1) emotional well-being (e.g., managing caregiver stress, grief, resentment, etc.); (2) spiritual well-being (e.g., religious strain or reassurance); (3) financial well-being (e.g., coping with healthcare costs and estate planning); (4) relationships with healthcare providers (e.g., questions about prognosis, symptom management, and resources); (5) relationships with family/friends (e.g., obtaining support, managing conflict); and (6) end-of-life decisions (e.g., choices about intensity of care, utilization of hospice or palliative care, funeral plans).

Findings illuminate dimensions of "preparedness" that are important to family caregivers. Readiness to accommodate these particular demands was viewed as a central challenge of end-of-life care. Delineation of these core concerns provides a critical step toward construct definition, and helps pave the way toward creation of useful measures and relevant screening and intervention services.

AN IDIOGRAPHIC MEASURE OF MEANINGFUL ACTIVITY PARTICIPATION IS LONGITUDINALLY ASSOCIATED WITH GREATER WELL-BEING

Stephanie A. Hooker, M.S., M.P.H.[1], Kevin Masters, PhD[1], Jean A. Wood, MSW[2]

[1]University of Colorado Denver, Denver, CO; [2]University of Colorado, Arlington, VA

Background: Engagement in personally meaningful activities is associated with greater well-being. However, most studies use cross-sectional or recall methods, and the researchers pre-determine which activities are "meaningful." Yet, individuals differ in the extent to which they rate activities as meaningful; thus, personalized assessment of meaningfulness of activity may enhance measurement precision. This study examined an idiographic measure of meaningful activity participation in relation to well-being.

Methods: Participants (*N*=160; *M* age=43.3 years; 77% female) were recruited into a 4-week longitudinal study. At baseline, they rated the meaningfulness of 48 common daily activities. During the next 4 weeks (4 weekdays and 4 weekend days), participants received emailed surveys on 8 random days asking them to recall their activities for the last 24-hours. Participants also completed surveys at baseline and follow-up of life satisfaction, vitality, meaning, purpose, and depressive symptoms. Meaningful activity participation scores were calculated and entered into multilevel models and regression analyses to predict well-being at 4-weeks.

Results: Greater engagement in meaningful activities was positively related to thoughts of meaning, b=.28, $p < .0001$, and positive affect, b=.19, p=.005, on that same day. After controlling for relevant covariates, the average engagement in meaningful activities over eight days was positively associated with subjective vitality, b=.30, p=.0004, life satisfaction, b=.22, p=.0078, and purpose in life, b=.29, p=.0007, at 4-week follow-up. Engaging in personally meaningful activities was not significantly associated with global ratings of meaning in life, b=.15, p=.087.

Discussion: Results suggest that an idiographic measure of meaningful activity participation may be useful for furthering understanding of relationships between daily engagement in meaningful activity and greater well-being. Relationships between meaningful activity participation and well-being were stronger than in previous studies using nomographic ratings of meaningfulness. Future research should examine interventions targeting participation in activity that is personally meaningful as a way to enhance well-being.

DEVELOPMENT OF A BILINGUAL PEDIATRIC CRANIOFACIAL QUALITY OF LIFE OUTCOMES MEASURE

Julia Drizin, MA[1], Viridiana J. Tapia, MPH[2], Vanessa L. Malcarne, Ph.D.[3], Amanda Gosman, MD[4]

[1]San Diego State University, San Marcos, CA; [2]UCSD School of Medicine, Department of Surgery, Chula Vista, CA; [3]San Diego State University, San Diego, CA; [4]UCSD, san diego, CA

Craniofacial conditions (CFCs) can have a severe impact on health-related quality of life (HRQoL) for children. Yet, little is known about how diverse CFCs can differentially impact HRQoL, and there is limited research on HRQoL in less prevalent CFCs. Presently, there are no suitable instruments that measure HRQoL of patients with diverse CFCs from the perspective of children and parents. Current measures either have not been validated for use with the population of interest or focus on one specific CFC, precluding cross-group comparisons. Additionally, many HRQoL measures are self-report in format, a challenge for pediatric use as some children are too young to express themselves. Finally, most existing measures were developed for use in one culture and language, thus limiting their utility. The present study describes the development of a comprehensive, bicultural patient- and parent-reported CFC HRQoL outcomes measure. A literature review and expert opinion were used to develop in-depth interview questions. Interviews were conducted with 139 subjects: 89 parents of patients ages 0–18+ and 50 patients ages 7–18+. English and Spanish speakers were represented. CFCs included were cleft lip/palate, craniosynostosis, craniofacial microsomia, microtia, and dermatological conditions. Qualitative analysis of interviews revealed six domains that represent the conceptual framework of CFC-associated HRQoL. Themes that emerged within each domain were operationalized into items in English and Spanish that represent HRQoL issues for both patient and parent versions. Six bilingual, bicultural subscales were developed based on the following domains: (1) Social Impact; (2) Psychological Function; (3) Physical Function; (4) Family Impact; (5) Appearance; and (6) Finding Meaning. The new scales will now undergo reliability and validity testing at multiple sites in the United States and Mexico.

EXPLORING INDIVIDUAL DISEASE BURDEN IN PATIENTS WITH ALOPECIA, ATOPIC DERMATITIS AND PSORIASIS

Melissa M. Matos, Ph.D.

California School of Professional Psychology at Alliant International University, Artesia, CA

Exploring Individual Disease Burden in Patients with Alopecia, Atopic Dermatitis and Psoriasis

Melissa M. Matos, Ph.D., Peter Theodore, Ph.D., Ron Duran, Ph.D., and Erin O’Callaghan, Ph.D.

California School of Professional Psychology

at Alliant International University, Los Angeles

The concept of *individual disease burden* measures individual disability by encompassing psychological, physical, social and economic factors. The factors that contribute specifically to the individual burden of skin disease remain unclear. The present investigation examined a model in which emotional distress, body image change, social discomfort, perceived discrimination, social support stress, unpredictable disease course, and financial stress were expected to load onto individual skin disease burden (ISDB) as a latent construct. The relationships between threat appraisals, illness perceptions, and self-efficacy with ISDB were subsequently examined. A sample of 207 adults with alopecia, atopic dermatitis and/or psoriasis participated in this study (n=175 participated online; n=31 participated at a local dermatology office). The results supported emotional distress, social discomfort, and social support stress broken into two distinct factors—partner and parental-based support stress as components of ISDB. Body image change, perceived discrimination, unpredictable disease course, and financial stress were not included in the latent construct. In the final model, general self-efficacy was found to covary inversely with ISDB (r=-.471, pp2/df = 2.071, CFI=.91, RMSEA=.07, SRMR=.06). This study offers preliminary evidence for emotional distress, social discomfort, partner support stress, and parental support stress as important sources of individual skin disease burden. Higher levels of general self-efficacy beliefs may decrease the experience of individual skin disease burden. These findings serve to alert healthcare providers to the possible components of individual skin burden that may affect treatment planning, expectations, and barriers in patients with skin disease. Clinical implications also extend to mental health treatment approaches that promote self-efficacy, as well as

psychological flexibility and acceptance, which may serve to reduce the individual burden of skin disease.

PERCEIVED EPILEPSY STIGMA MEDIATES RELATIONSHIPS BETWEEN PERSONALITY AND SOCIAL WELL-BEING IN A DIVERSE EPILEPSY POPULATION

Seth Margolis, Ph.D.[1], Luba Nakhutina, Ph.D.[2], Sarah Schaffer, Ph.D.[3], Arthur Grant, M.D., Ph.D.[2], Jeffrey Gonzalez, Ph.D.[4]

[1]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, RI; [2]SUNY Downstate Medical Center, Brooklyn, NY; [3]Northwell Health, Formerly North Shore-LIJ Health System, Great Neck, NY; [4]Yeshiva University, Bronx, NY

Perceived epilepsy stigma and reduced social well-being are prevalent sources of distress in people with epilepsy. Yet, research on patient-level correlates of these difficulties is lacking, especially among underserved groups. Racially/ethnically diverse adults with intractable seizures (*N*=60, 62% female; 79% Black, 20% Hispanic/Latino, 8% White) were recruited and completed validated measures of personality (NEO Five Factor Inventory, NEO-FFI-3), perceived epilepsy stigma (Epilepsy Stigma Scale), and quality of life (Quality of Life Inventory in Epilepsy, QOLIE-89). Controlling for covariates, ordinary least-squares regression and path analysis evaluated the direct and indirect effects of NEO-FFI-3 neuroticism and extraversion scores on epilepsy-related social well-being (i.e., combination of QOLIE-89 Social Functioning and Social Isolation subscales, α=.87), mediated through perceived epilepsy stigma. In separate models, higher levels of neuroticism (N) and lower levels of extraversion (E) were significantly and independently associated with greater perceived stigma (N path a=.71, p=.005; E path a=-1.10, $p < .005$); stigma, in turn, was significantly and independently associated with poorer social well-being (N path b=.23, $p < .001$; E path b=-.23, $p < .001$). Bias-corrected bootstrap confidence intervals showed that neuroticism and extraversion were indirectly associated with social well-being through their respective associations with perceived stigma (N path ab=-.16, 95%*CI's* [-.347,-.044]; E path ab=.25, 95%*CI's* [.076,.493]). These relations are consistent with a conceptual model wherein elevated neuroticism and reduced extraversion may predispose patients with epilepsy towards feeling stigmatized, which in turn leads to reduced social well-being. Future research should examine these associations longitudinally. Intervention studies may benefit from promoting cognitive re-appraisal strategies to reduce perceived stigma.

PREDICTORS OF SUBJECTIVE HAPPINESS IN OLDER ADULTS

Katie E. Greenawalt, BS, Elizabeth M. Orsega-Smith, PhD, Steve Goodwin, PhD, Jennie L. Turner, BS, Erica Rathie, Student

University of Delaware, Newark, DE

Predictors of Subjective Happiness in Older Adults

K. Greenawalt, E. Orsega-Smith, S. Goodwin, J. Turner, E. Rathie

Department of Behavioral Health & Nutrition, University of Delaware

Introduction:

Research has shown that positive psychology interventions can enhance subjective wellbeing and reduce depression, however, efficacy on older adult populations has not been widely examined. Specifically, subjective wellbeing, life satisfaction, optimism, and positive emotions have been shown to improve health and longevity. The present study sought to develop and evaluate an intervention with the goals of enhancing happiness levels and overall mental wellbeing in the older adult population.

Methods:

The Art of Happiness is an 8-week intervention that was conducted at 3 senior centers in the state of Delaware. Each 90 minute class examined a different topic including; (1) defining happiness, (2) stress management, (3) reflecting on happiness, (4) compassion and human connection, (5) forgiveness, (6) transforming suffering, (7) mindfulness, and (8) humor. Pre and post questionnaires assessed participant subjective happiness, stress, gratitude, life satisfaction, depression, mindfulness, arousal states, and general demographic and health information.

Results:

The 32 participants who completed the course were mostly married (43.8%), female (87.5%) and Caucasian (90.6%), with an age range of 53-84 years of age (mean age= 70 years). Results revealed that the intervention significantly increased participant’s subjective happiness ($p < .0001$), with life satisfaction as the strongest predictor of happiness ($r=.84$, $p < .0001$). Subjective happiness scores were also significantly correlated with gratitude ($r=.69$, $p <$

.0001), stress (r=-.50, p < .003), depression (r=-.46, p < .005), mindfulness (r=.34, p < .045), and the arousal state of energy (r=.47, p < .006).

Conclusion:

These results suggest that older adults' subjective happiness can be influenced or predicted by variables such as life satisfaction, gratitude, stress levels, depression, mindfulness, and energy levels. Programs like "The Art of Happiness," which emphasize these topics may have the potential to buffer the older adult population against poor mental health by improving subjective happiness and overall mental well-being. This may lead to the development of incorporating these types of programs into senior centers as part of their healthy lifestyle curriculum.

QUALITY OF LIFE IN CHRONIC HEMODIALYSIS PATIENTS: RESULTS FROM THE PATIENT CENTERED MEDICAL HOME FOR KIDNEY DISEASE STUDY

Denise M. Hynes, MPH, PhD, RN[1], Anna Porter, MD[2], Michael Berbaum, PhD[3], Ifeanyi Chukwudozie, MPH[4], Linda Schiffer, MS, MPH[5], Michael Fischer, MD, MHS[2], Marian Fitzgibbon, PhD[6], Jose Arruda, MD[7]

[1]ACADEMIC INTERNAL MEDICINE/UNIVERSITY OF ILLINOIS & US DEPT OF VETERANS AFFAIRS, CHICAGO, IL; [2]Nephrology Division/Department of Medicine/University of Illinois, Chicago, IL; [3]Institute for Health Research and Policy, Chicago, IL; [4]Cancer Center/University of Illinois, Chicago, IL; [5]University of Illinois at Chicago, Chicago, IL; [6]Pediatrics/University of Illinois, Chicago, IL; [7]Nephrology/Department of Medicine/COllege of Medicine/University of Illinois, Chicago, IL

Background:

In the U.S., more than 400,000 individuals with end-stage renal disease require chronic hemodialysis (HD). Chronic HD patients experience a high burden of morbidity, mortality, healthcare use, and poor quality of life (QOL). Under current care models, chronic HD patients receive fragmented care from multiple providers. The Patient-Centered Medical Home (PCMH) is a team approach to provide coordinated care across the healthcare continuum. While the PCMH model demonstrated early benefits for complex chronic diseases such as diabetes, this study is among the first applied to chronic HD patients.

Methods:

Using a non-randomized quasi-experimental intervention trial design, we implemented a PCMH model for kidney disease patients (PCMH-KD), which extended the existing HD care team (comprising a nephrologist, nurse, social worker, and dietitian) by adding a general internist, pharmacist, nurse coordinator, and health promoter. The PCMH-KD was implemented over 18 months at two sites in Chicago: a non-profit, university-affiliated dialysis facility and an independent for-profit dialysis facility operated by a national corporation. The RE-AIM (Reach, Effectiveness, Adoption, Implementation, Maintenance) framework was our organizing model for process evaluation. Patients were recruited and consented on a rolling basis at each site beginning in January 2015; the intervention ended in August 2016. Sample size estimates were based on self-reported QOL using the Kidney Disease QOL (KDQOL). Additional patient and caregiver reported outcomes, clinical measures, healthcare use, and

staff perceptions were assessed every six months. We examined QOL as measured by the KDQOL and used a mixed model to adjust for covariates.

Results:

Of 248 eligible patients, 175 (71%) patients ultimately consented, completed baseline assessments and continued in the intervention. Components of the KDQOL related to mental health (MCS) and kidney disease effects (KDE) were significantly improved in the intervention group compared to usual care group over 18 months (MCS 48.9 to 51.7 (5.7%) respectively; p=0.02; KDE 72.5 to 76.2 (5.1%), respectively; p=0.04). Covariates accounted for included sociodemographics, dialysis vintage, site, self-reported diabetes, prior access to a primary care provider, and time varying covariates for biochemical parameters for dialysis adequacy and overall health. Other QOL components increased early in the observation period or varied throughout. Improvements in depression, knowledge about kidney disease, and satisfaction with primary care were also noted in the intervention group.

Conclusions:

Compared to the usual dialysis care team model, chronic HD patients in the PCMH-KD model experienced improved QOL in mental health and kidney disease effects domains. Additional factors that may affect QOL and other outcomes of the PCMH-KD warrant further exploration.

ROLES OF ADULT ATTACHMENT AND CAREGIVING STRESS IN DEPRESSION IN HISPANIC VS. NON-HISPANIC CANCER CAREGIVERS

Amanda Ting, BS[1], Hannah-Rose Mitchell, MPH[2], Melanie McKenna, N/a[2], Youngmee Kim, PhD[2]

[1]University of Miami, Miami, FL; [2]University of Miami, Coral Gables, FL

Cancer diagnosis is life-changing also for the family caregivers. Resulting caregiving stress can be manifested in depression outcomes. Lesser known is the extent to which self-reported stress and adult attachment relate to caregivers' depression around the time of the patients' diagnosis and treatment, and whether ethnicity moderates the associations. This study aimed to extend current knowledge by investigating them.

Caregivers of recently diagnosed colorectal cancer patients (Stage I to IV) participated in the study (N=102; 73% female; 49 years old; 55% Hispanic; 3 months post diagnosis). Self-reported Hispanic vs non-Hispanic ethnicity, caregiving stress (stress overload subscale of the Pearlin Stress Scale), depression (CES-D), as well as adult attachment orientations (MAQ: secure, avoidant, anxious-ambivalent worry, and anxious-ambivalent merger) were measured. Age and gender were covariates.

Results showed caregivers (40%) reported clinical levels of depression. Hierarchal regression analysis revealed that female caregivers, greater caregiving stress, lower attachment security, and higher attachment anxiety-merger related to greater depressive symptoms (βs>.40, $ps\beta=.54$, $p\beta=.13$, ns).

Findings provide evidence that gender, ethnicity, relationship quality, and perceived caregiving stress played a significant role in family caregivers' depression symptoms. These results suggest that sociocultural factors and relationship quality to the patient may play an influential role on the caregiver's depression during the period of initial caregiving stress with diagnosis and treatment. Findings warrant further investigation for specific factors – at an individual, dyadic, and cultural level – in close relationships relating to promoting adaptive outcomes of lower depression with caregiving stress.

THE PROTECTIVE ROLE OF SOCIAL SUPPORT IN CHRONIC LYMPHOCYTIC LEUKEMIA: A CONDITIONAL PROCESS ANALYSIS

Travis Westbrook, M.A.[1], Thomas Valentine, B.A.[1], Eleshia Morrison, Ph.D.[2], Barbara L. Andersen, PhD[1]

[1]The Ohio State University, Columbus, OH; [2]Adult Pain Rehabilitation Center, Mayo Clinic, Columbus, OH

Background: Chronic lymphocytic leukemia (CLL) accounts for one-third of all leukemia diagnoses in the United States. Early stage patients are typically monitored without treatment until disease progression, a process known as active surveillance (AS). During this time, patients may experience fatigue, weight loss, enlarged lymph nodes, and night sweats. These physical symptoms have been linked to decreased quality of life among AS patients, which is impaired relative to the general population (Shanafelt et al., 2007). We sought to examine whether CLL symptoms impact quality of life via an increase in depressive symptoms. Further, as social support has been linked to psychological and physical outcomes in patients with CLL (Morrison et al., 2016), we wanted to examine whether social support may moderate the pathway from CLL symptoms to depressive symptoms.

Methods: A cross-sectional design was used. AS CLL patients (N=67; 55% male, mean age=60.4 years) completed questionnaires assessing CLL symptoms, quality of life (SF-36 MCS), depressive symptoms (CESD), and social support (ISEL total score). Mediation, moderation, and moderated mediation were conducted using conditional process analysis (Hayes, 2014). Analyses controlled for gender.

Results: Quality of life scores were variable across the sample (range=9.43-62.14 [possible 0-100]). The direct effect of depressive symptoms on quality of life was significant (*b* = -.654, 95% CI = [-.935, -.373]), such that a one-unit increase in depressive symptoms was associated with a .654 unit decrease in quality of life. The effect of CLL symptoms on depressive symptoms was significant only at low and moderate levels of social support. CLL symptoms did not influence depressive symptoms and quality of life among patients with high levels of social support, reflecting a protective effect.

Conclusions: CLL patients with high levels of social support experience lower levels of depressive symptoms in response to CLL symptoms. This protective effect is associated with enhanced quality of life for CLL patients with high levels of support. Psychosocial

interventions with CLL patients focused on improving quality of life should take into consideration patients' level of social support.

TRAUMA HISTORY, RELIGIOUS SOCIAL SUPPORT & RESILIENCE: CORRELATES OF ROLE LIMITATIONS IN OLDER GAY MEN AND LESBIANS

Sarah M. White, N/A

University of North Texas, Wylie, TX

Trauma History, Religious Social Support & Resilience: Correlates of Role Limitations due to Emotional Distress in Older Gay Men and Lesbians

Sarah White, Tosha Griggs & Mark Vosvick, Ph.D.

University of North Texas

Older gay men and lesbians (LG) with a history of trauma may experience role limitations due to emotional distress, especially if the trauma is a violent crime (Min, Tracy & Park, 2014; Herek, Gillis & Cogan, 1999). Resilience is the result of personal growth in spite of trauma history (Lyons, 2015). Historically, churches have condemned sexual minorities (Halkitis et al., 2009). However, some churches welcome LGBT individuals and older LGs may benefit from the social support of these establishments (Halkitis et al., 2009). Through a minority stress (Meyer, 2003) lens, we hypothesize crime related trauma history is positively associated with role limitations due to emotional distress. Religious social support and resilience are negatively associated with role limitations due to emotional distress.

After IRB approval, we recruited 50 gay men and 50 lesbians in DFW, (M_{age} = 58.99, *SD*= 6.48). Participants were 68% European American, 17% African American and 15% other ethnicity. A hierarchical regression analysis (*F*[9,90]=12.38, p < .001) indicated, in addition to crime related trauma (β=.16, p < .05) and resilience (β=.40, p < .001), being single (β=.40, p < .001) was also a significant predictor, accounting for approximately 51% of the variance in role limitations due to emotional distress (adjusted R^2=.51, p < 001).

In our sample, single LGs were more likely to experience role limitations due to mental distress possibly from lack of emotional support from a romantic partner (Lyons, 2016). Older LGs that scored higher on crime related trauma reported higher role limitations due to mental distress this may suggest a lasting emotional impact from the crime related trauma (Herek, Gillis & Cogan, 1999). Also, resilience was negatively associated with role limitations due to emotional distress possibly due to the strengthening of effective coping strategies (Morrow, 2001). Interventions should include techniques to strengthen resilience and provide emotional support, while addressing the unique issues of single older LGs.

ASIAN ETHNIC GROUPS' PERCEPTIONS AND UTILIZATION OF HEALTHCARE IN THE U.S.: A COMMUNITY-BASED PHENOMENOLOGICAL APPROACH

Jennifer Bordon, MA, Hung-Bin Sheu, PhD, Angela Lui, MA

University at Albany - SUNY, Albany, NY

Asian populations in the U.S. are underserved and understudied in health disparities research. Specifically, little is known about the diverse perceptions of the American healthcare system and the various statuses of mental and physical health within and among Asian ethnic groups. Thus, with a community-based sample, this study was aimed to investigate the particular experiences three Asian ethnic groups (Chinese, Filipino, and Korean) have with utilizing the American healthcare system and the respective groups' general health maintenance approaches. The sample included six focus groups (N_{total} = 33; male = 11; mean age = 47 years). Using the phenomenological approach, transcripts were analyzed to identify emergent themes. Findings show different and similar perceptions of the American healthcare system and general healthcare within and across the three ethnic communities. All groups utilized both American healthcare and indigenous methods to a degree to treat and maintain health. Some shared themes include an agreement of major barriers to accessing American healthcare (e.g., understanding insurance, difficulties navigating the healthcare systems), satisfaction and reliance on American healthcare for acute and chronic conditions, and using indigenous methods to treat and maintain health. Some themes unique to different ethnic communities include self-advocacy and being proactive for Korean and Filipino groups, the importance of patient-doctor communication for Chinese groups, and the emphasis of social support to treat and maintain health for the Filipino groups exclusively. Findings help illuminate the perceptions of the barriers and supports that may help inform policies and outreach programs to promote access and utilization of American healthcare for the understudied Asian populations. Considering the community-based approach, results are useful to better understand the unique needs from these different ethnic groups, and to further the development of measurement tools for health disparities research.

COPING STRATEGIES AMONG OLDER LATINO CAREGIVERS

Guilherme Balbim, MS, Isabela Marques, BS, Melissa Magallanes, MS, Judith Rocha, LCSW, David Marquez, PhD

University of Illinois at Chicago, Chicago, IL

The number of Americans living with Alzheimer's disease (AD) is growing fast. An estimated 5.4 million Americans of all ages have AD in 2016. Latinos are the fastest-growing population in the United States and are about 1.5 more times more likely to develop AD than Whites. Caregivers of people with AD report high levels of stress and burden, impacting their health. The purpose of this study was to analyze the coping strategies used by Latino caregivers. Participants were 16 Latino caregivers, aged 50 years and older, who had been caring for a relative with AD or related disorder (6 were caring for mother, 4 caring for husband), at least 4 hours per day, for at least 6 months. The majority of caregivers were female (12). Interviews were conducted in English and Spanish about the caregiver role, family, and social support, and coping strategies. For purpose of this study coping strategies answers were analyzed. Interviews were transcribed, translated, coded, and directed content analysis was conducted. The results depicted that Latino caregivers reported use of nine different coping strategies: (1) Rationalize: efforts to explain or justify care recipients' misbehaviors to plausible reasons, as the disease manifesting itself; (2) Avoid: refraining from noticing or recognizing stressful situations; (3) Repress: attempts of keeping away from burden-suppressing desires, feelings, actions, tears; (4) Social interactions: attempts to interact with individuals or groups about their situation; (5) Self-care: intentional actions to take care of one's own physical, mental and emotional health;(6) Spirituality: focus on faith (God, church) and the things to try to make a connection with spirituality (prayer, sacraments); (7) Leisure activities: actions in free time, far from work and duties, to relieve burdens, such as reading, watching TV and movies, listening to music, and dancing; (8) Medications: taking any form of medication to cope with stress/burden; (9) Physical activity, any body movement that works one's muscles and requires more energy than resting to cope with stress, such as walking, running and dancing. Also was reported the use of any coping strategy, showing no efforts to solve stressful situations.It is concluded that Latinos caregivers seek a broad range of strategies to cope with stress and burden. Future studies should focus on strategies to highlight sustainable coping strategies in their routine as caregivers.

DEVELOPMENT OF A CULTURALLY MODIFIED BEHAVIORAL WEIGHT LOSS MANUAL FOR OBESE AND OVERWEIGHT LATINA WOMEN WITH EATING DISORDERS.

Phoutdavone Phimphasone, M.A.[1], Fary M. Cachelin, PhD[2], Alyssa Vela, M.A.[2], Brooke Palmer, M.A.[2]

[1]University of North Carolina, Charlotte, New Haven, CT; [2]University of North Carolina Charlotte, Charlotte, NC

Obesity remains one of the greatest public health threats in the 21st century, increasing the risk for many chronic diseases, including Type 2 diabetes and CVD (CDC, 2014). Economic costs associated with treatments for obesity are also significantly high, with total medical costs reaching $147 billion/year in 2008 for inpatient and outpatient treatments and prescription drugs. Despite an increase in prevention and intervention efforts to address obesity in the past decade, the rates are still disproportionate among women and racial/ethnic minority groups. In particular, Latina women who are obese/overweight with eating disorders are less likely to seek and receive healthcare services and have a higher risk of type 2 diabetes and CVD. Therefore, there is still a need to explore sociocultural factors that influence Latina women's engagement in evidence-based treatment for obesity, as previous research demonstrates that culturally adapted interventions are four times more effective than general interventions.

The aim of this study was to identify culturally appropriate modifications of an evidenced-based behavioral weight loss program, *The LEARN Program for Weight Management,10th Edition* (LEARN; Brownell, 2004), using focus groups and qualitative analysis. Through constant comparative analysis, participants (n = 20, M_{AGE} = 30, SD = 9.87, M_{BMI} = 34.40, SD = 6.64, $M_{\text{binge eating episodes}}$= 4, SD = 4.92) identified surface and deep level changes needed for the LEARN manual. Surface level changes included: redundancy of manual, positive remarks and critiques of manual content, need for culturally relevant examples, and structure of food logs. Deep level changes included a consideration of diversity factors, Latino health beliefs and expectations, environmental facilitators and barriers, cultural meanings of food and health behaviors, and unique individual factors (e.g., family dynamics, past experiences with health monitoring and chronic illness management, and responsibilities as a caregiver).

With cultural modifications, participants reported that the LEARN manual could be an effective and feasible method to address obesity and eating disorders. Suggestions to improve adherence to such programs are offered. In order to address health disparities and reduce the prevalence rates of obesity among Latina women, it is crucial that treatments emphasize a

healthy lifestyle change approach while considering key cultural factors to improve reach and effectiveness.

LATINA ADOLESCENTS' GENERATIONAL STATUS, FAMILISMO, SOCIO-EMOTIONAL COMPETENCE, AND NEIGHBORHOOD QUALITY IN RISK BEHAVIORS

Patricia Cabral, M.A.[1], Jan Wallander, PhD[2]

[1]University of California, Merced, North Hollywood, CA; [2]Univ. California, Merced, Los Gatos, CA

Objective: We tested a longitudinal model among Latina (female) adolescents examining resilience related to sexual risk behaviors and substance use associated with *familismo* in the context of neighborhood quality, as mediated bysocial-emotional competence (SEC), and how these associations vary with acculturation.

Method: Using data from 896 Latina adolescent participants from the *Healthy Passages* study, a multi-group structural equation model was analyzed across 1st (19%), 2nd (55%), and 3rd generation (26%) Latinas. Latent constructs representing neighborhood quality and *familismo* values were measured at 5th grade (*M* age = 10.6), SEC at 7th grade (*M* age = 13.1), and sexual risk behaviors and substance use at 10th grade (*M* age = 16.1).

Results: A partially invariant multi-group structural equation model across the three generational status groups showed that, among 2nd generation Latina adolescents only, *familismo* mediated the link between neighborhood quality and substance use. Moreover, SEC mediated the resilience provided by *familismo* against substance use. Thus, both *familismo* and SEC were negatively associated with substance use among 2nd generation Latina adolescents. These associations were not found among 1st or 3rd generation Latinas, nor for sexual risk behaviors.

Conclusions: Findings illuminate the role of social-cultural factors that may support resilience against certain health risk behaviors. Specifically, among 2nd generation Latinas, *familismo* and SEC appear to confer resilience against substance use. These findings may guide strategies in reducing substance use among Latina youth.

MINORITY BREASTFEEDING DURATION: RESULTS OF THE BREASTFEEDING OPINIONS, OUTCOMES, BEHAVIORS, & SERVICES STUDY

Sarah Rhoades-Kerswill, Ph.D., Emily D. Fry, Undergraduate Student, Misty AW Hawkins, Ph.D.

Oklahoma State University, Stillwater, OK

Background: The American Academy of Pediatrics recommends breastfeeding infants for at least 12 months post-partum. However, many factors impact a woman’s intent and ability to breastfeed for the recommended timeframe, such as obesity, delivery method, the delivery term, age, and race. The current study focused on breastfeeding duration among minority women.

Objective: This study sought to further explore breastfeeding duration among a diverse sample of minority women who had their first child between 1985 and 2016. We hypothesized that the race of women, the delivery method, and obese status during pregnancy would predict breastfeeding duration of the first child after adjusting for age and delivery term.

Methods: The sample included 313 minority women who self-identified as African American, American Indian/Alaska Native (AI/AN), Asian, Indian, Latina, Middle Eastern, Pacific Islander, multi-racial, and other. Their ages ranged from 20-59 years-old. Snowball sampling was used to recruit these participants who completed an online survey of demographic and breastfeeding behaviors: The Breastfeeding Opinions, Outcomes, Behaviors, and Services (BOOBS study).

Results: Forty-four percent of the participants reported that they did not meet the breastfeeding recommendation of at least 12 months. Age of the mother was found to predict breastfeeding duration ($\beta = .15$, SE = .07 $p = .01$) with women aged 35+ breastfeeding longer (13 months) than younger women (11 months) on average. Obesity status and delivery method did not predict breastfeeding duration. However, being AI/AN did predict breastfeeding duration ($\beta = -.23$, SE = 1.78, $p < .05$). AI/AN women tended to have the shortest breastfeeding duration (on average 9 months and 53% reported breastfeeding less than 12 months). No other race was found to influence a woman’s breastfeeding duration.

Conclusions: It appears that belonging to certain racial groups, particularly American Indian/Alaskan Native may impact how long women breastfeed – even when controlling for age and delivery term. There may be cultural and other factors (such as socioeconomic status)

that influence an AI/AN woman's breastfeeding duration. Given the extensive benefits of breastfeeding for both mothers and infants, culturally sensitive interventions may be needed to enhance the outcomes of certain age and race-ethnic groups.

RACIAL/ETHNIC DIFFERENCES IN WEIGHT LOSS STRATEGIES AMONG U.S. ADULTS

Becky Marquez, PhD MPH[1], Rosenda Murillo, PhD MPH[2]

[1]University of California San Diego, La Jolla, CA; [2]University of Houston, Houston, TX

Background: Dieting, exercising, and seeking professional help have been associated with intentional weight loss among adults.

Purpose: We examined the use of diet (e.g. ate less, ate less fat, switched to low calorie foods), exercise, diet and exercise, and professional help (e.g. weight loss program, prescribed diet pills) for weight loss among non-Hispanic Whites, Mexican-Americans, and non-Hispanic Blacks trying to lose weight.

Methods: We used cross-sectional data from 7,424 male and female participants in the 2007-2010 National Health and Nutrition Examination Survey (NHANES) aged 20-65 years. Logistic regression models were used to estimate associations of race/ethnicity with strategies to lose weight.

Results: Lower proportions of Mexican-Americans (34%) and non-Hispanic Blacks (35%) than non-Hispanic Whites (39%) reported trying to lose weight. Among those who tried to lose weight, non-Hispanic Blacks (OR: 0.78, 95% CI: 0.66-0.92) were less likely than non-Hispanic Whites to use diet for weight loss. Mexican-Americans (OR: 0.66, 95% CI: 0.47-0.94) and non-Hispanic Blacks (OR: 0.73, 95% CI: 0.56-0.95) were also less likely than non-Hispanic Whites to use professional help for weight loss.

Conclusion: Targeted efforts are needed to address racial/ethnic disparities in weight loss attempts and use of recommended strategies.

THE EFFECTS OF EXPRESSIVE WRITING ON HEALTHCARE UTILIZATION, PHYSICAL SYMPTOMS, AND PSYCHOLOGICAL DISTRESS IN ASIAN INDIANS

Jagruti Bhakta, PhD

Naval Center for Combat & Operational Stress Control (NCCOSC), San Diego, CA

An accumulating body of evidence has shown that expression of emotions associated with stressful experiences by writing or talking about them results in better physical health and psychological well being. Traditionally, Asian Indians encourage the suppression of emotional conflicts and discourage the full expression of emotions. Additionally, Asian Indians are often reluctant to talk about their personal problems to others, as they fear it will bring shame to the family. Therefore, written emotional disclosure may provide a more culturally sensitive way for Asian Indians to express emotions about stressful events and traumas without being stigmatized, as it assures privacy and anonymity.

This randomized, controlled study examined the effects of a written emotional expression intervention on healthcare utilization, physical symptoms, and psychological distress in Asian Indians who reported stress related to intergenerational family conflict. Seventy participants were recruited from Asian Indian community centers, professional and student organizations, and community temples in Southern California. Thirty-eight women and thirty-two men were randomly assigned to either write about their deepest thoughts and feelings related to their intergenerational family conflict (n = 35) or to a time-management control group (n = 35). Participants wrote on three separate days over one week and assessments were completed at baseline, one-week post-writing (post), and six-weeks after writing (follow-up).

A significant group by time interaction (p = .002) was revealed on the depression subscale of the Brief Symptom Inventory (BSI). On this measure of psychological distress, participants in the expressive writing group showed improvement over time while participants in the control group remained the same from baseline to post-writing and follow-up. A significant effect of time (p < .0005) where both groups showed improvement from baseline to post-writing and follow-up was revealed on three global indices of psychological distress on the BSI, the anxiety subscale of the BSI, and on the Impact of Events Scale (IES). There were no significant findings revealed on outcome measures of physical symptoms, healthcare utilization, or on exploratory variables of acculturation and ambivalence over emotional expression.

The results from this study imply that a brief expressive writing intervention may help improve symptoms of depression in Asian Indians. This was one of the first studies to

systematically investigate the effects of expressive writing in a homogenous sample comprised of Asian Indians. While differences observed between groups were suggestive, they were not conclusive and require further examination. Future research recommendations include the use of more stringent inclusion criteria, objective measures, long-term follow-up assessments, and essay content analyses.

EVALUATION OF PATIENT OUTCOMES FOLLOWING ATTENDANCE AT A SIX-WEEK BIOPSYCHOSOCIAL MULTIDISCIPLINARY SEXUAL WELLNESS PROGRAM

Patricia Mumby, Ph.D.[1], Mary Lynn, D.O.[2], Michael Hakimi, Psy.D.[1], Corey Bolton, B.S.[3]

[1]Department of Psychiatry and Behavioral Neurosciences, Loyola University Medical Center, Maywood, IL; [2]Department of Obstetrics and Gynecology, Loyola University Medical Center, Maywood, IL; [3]Department of Psychiatry and Behavioral Neurosciences, Loyola University Medical Center, Oak Park, IL

BACKGROUND: The purpose of the present study is to prospectively assess sexual functioning and relationship satisfaction among patients who attend a multidisciplinary program for the diagnosis and treatment of sexual dysfunction. There is some research to suggest that women benefit more than men from sexual therapy programs and therefore, additional analyses were conducted to examine for gender differences in response to treatment. **METHODS:** Subjects include 21 men and 23 women who attended the sexual treatment program. Patients were 18 years of age and older, in a committed relationship, and attended the program with their partner. The program takes a biopsychosocial approach to the assessment and treatment of sexual dysfunction and includes a multidisciplinary team of gynecology, urology, psychology, psychiatry, physical therapy and nutrition specialists. Couples meet for 6 consecutive weeks with a therapist dyad and receive a psycho-social-sexual assessment, physical examination (i.e., sexological exam) and weekly cognitive behavioral sex therapy and psychoeducational lectures. Patients completed the following validated self-report measures pre- and post-treatment (pre-tx, post-tx): Patient Health Questionnaire-9 (PHQ-9; pre-tx only), PROMIS Sexual Function Profile v1.0, Dyadic Adjustment Scale (DAS), and the International Index of Erectile Function (IIEF). **RESULTS:** Paired-samples *t* test were conducted to evaluate pre-tx to post-tx sexual function/satisfaction, relationship adjustment, and erectile function. The results indicated that sexual function/satisfaction ($t(34) = -3.259$, $p < .01$) and relationship adjustment ($t(38) = -2.641$, $p < .05$) significantly improved pre-tx to post-tx. However, when analyzed by gender, females showed greater improvement in scores on the PROMIS (Females: $t(18)= -2.650$, $p < .05$; Males: $t(15) = -1.905$, $p = .076$) and the DAS (Females: $t(19) = -2.925$, $p < .01$; Males: $t(18) = -1.111$, $p = .281$). There was no significant change reported for erectile functioning pre-tx to post-tx. **CONCLUSION:** The study found statistically significant improvement pre-tx to post-tx on select aspects of sexual well-being for attendees of the program, particularly for women participants. The findings provide preliminary support for the efficacy of this multidisciplinary program and also highlight the need to further our understanding of gender differences. Future research should evaluate the causes of the gender differences in treatment response with the ultimate goal of improving sexual treatment and outcomes for men and women.

A TECHNOLOGY ASSISTED BEHAVIORAL INTERVENTION FOR EXTENDING SLEEP DURATION AMONG SHORT SLEEPERS

Kelly Glazer. Baron, PhD, MPH, CBSM[1], Jennifer Duffecy, PhD[2], Kathryn J. Reid, PhD[3], Lauren A. Caccamo, BS[4]

[1]Rush University Medical Center, Chicago, IL; [2]University of Ilinois at Chicago, Chicago, IL; [3]Northwestern University Feinberg School of Medicine, Chicago, IL; [4]Northwestern University, Chicago, IL

It is estimated that 29% of adults sleep < 6 hours and sleep duration may be a modifiable risk factor for the development of chronic illnesses, including hypertension and diabetes. Studies demonstrate health benefits of extending sleep duration among short sleepers but to date there are no theory based behavioral interventions. The rapidly expanding popularity of wearable sleep tracking devices provides an opportunity to engage users in their own sleep behavior change. We developed at tested the “Sleep Bunny” sleep extension intervention including a smartphone application, wearable sleep tracker and brief telephone coaching. The goals of this program were to increase sleep duration by one hour and increase bedtime and wake time regularity. We conducted user testing and collected feedback from 10 participants and evaluated adherence and sleep duration outcomes of two participants who completed the four-week intervention. Results suggested that users enjoyed the use of the wearable sleep tracker and found the application visually pleasing. Sleep duration improved by 1.5 hours per night from week 1 to week 4 in adults with short sleep duration who engaged in the intervention (n=2). The brief telephone coaching was viewed as helpful and feasible. Improvements in notifications and reminders may improve the experience of the intervention.

BEDTIME E-DEVICE USE AND SLEEP QUALITY AMONG YOUNG ADULTS: USING THE THEORY OF PLANNED BEHAVIOR

Xiaohui Zhao, MS[1], Xue Feng, MPH[2], rahul garg, M Pharm[3], Kimberly M. Kelly, PhD, MS[2]

[1]School of Pharmacy, West Virginia University, Morgantown, WV; [2]West Virginia University, Morgantown, WV; [3]west virginia university, morgantown, WV

Background: Understanding the factors affecting bedtime e-device use is important to improve the sleep quality of young adults in the US. *Objectives*: Our study examined: (1) the association of attitudes, subjective norms, and perceived behavioral control with bedtime e-device use and intentions to reduce e-device use; and (2) the efficacy of a brief theory-driven intervention to increase the intentions to reduce e-device use. *Methods*: We used the Theory of Planned Behavior (TPB) to conduct a cross-sectional online survey among young adults aged 18-30 years (*N*=212). We designed two scales to measure attitudes and perceived behavioral control and used a single item to measure subjective norms for bedtime e-device use. After feasibility testing (*N*=53), we randomly administered the intervention (*N*=159) to affect participants' attitudes, subjective norms, and perceived behavioral control and analyzed the participants' intentions to reduce bedtime e-device use before and after the intervention. We used Spearman's correlation for bivariate and logistic regression for multivariate analyses. *Results*: The scales for attitudes and perceived behavioral control had good internal consistency (Cronbach's α >0.65). Participants' mean age was 24.9 (*SD*=3.0), and majority were females (77.3%), White (91%), had > high school degree (98.6%), and annual household income > $24,300 (90.5%). The majority (73.3%) reported frequent (>10 days) bedtime e-device use in the past two weeks and more than half (59.1%) spent >30 min on e-device daily. We found relatively high levels of behavioral control (3.82±0.72) and subjective norms (3.75±0.94) for bedtime e-device use. Higher positive attitude and lower perceived behavioral control were significantly associated with higher e-device use and higher intentions to reduce e-device use. Participants receiving the intervention were more likely to increase in their intentions to reduce bedtime e-device use (AOR=2.23, 95%CI= [1.09-4.57]). *Conclusion*: Our brief educational intervention was efficacious in increasing the intentions to reduce bedtime e-device use among young adults. Future studies are recommended to use the TPB based interventions to reduce bedtime e-device use among young adults.

COLLEGE SLEEP HABITS: SLEEP QUALITY & DISTRESS DURING THE FIRST SEMESTER

Lauren Boddy, BA[1], Cora Burgoyne, BA anticipated May 2017[2], Natasia Adams, MA & MPH [1], Nancy A. Hamilton, PhD[1]

[1]University of Kansas, Lawrence, KS; [2]The University of Kansas, Lawrence, KS

Poor sleep quality is highly prevalent and has been linked with poor health outcomes in all age groups. It is known that college students have poor sleep habits; however, less is known about changes in sleep quality across the first semester for freshmen students. The purpose of this study was to examine changes in self-reported sleep quality, as well as biopsychosocial correlates of disturbed sleep during the first semester of college in a sample of female, freshmen students. We hypothesized that mood and stress symptoms, social support, specific health indicators, and hostility would co-vary with poor sleep quality at multiple time points. Freshmen students, enrolled at large, Midwestern university (N=76, 77% Caucasian), were assessed during the first month (T1), at midterm (T2), and during the last two weeks of the Fall semester (T3). In this sample, average Pittsburgh Sleep Quality Index (PSQI) scores at T1 (*M*=8.47, *SD*=3.11), T2 (*M*=8.92, *SD*=3.25), and T3 (*M*=9.62, *SD*=3.44) exceeded a cut off score of PSQI≥5 at all time points. Moreover, results demonstrate a linear increase in sleep disturbances across the semester (*F*(1,48)=4.25, *p*r=.41), perceived stress (Perceived Stress Scale; *r*=.38), and hostility (Cook-Medley Hostility Scale; *r*=-.74) co-varied with poor sleep quality. At T2, perceived stress (*r*=.39), stressful life events (Student Life Event Scale; *r*=.29), somatic and physical symptoms (Cohen Hoberman Inventory of Physical Symptoms; *r*=.51), and social support (Interpersonal Support Evaluation List; *r*=-.52) significantly co-varied with PSQI scores. Finally, at T3, perceived stress (*r*=.49), stressful life events (*r*=.28), somatic and physical symptoms (*r*=.53), and social support (*r*=-.53) were significantly associated with PSQI scores. Evidence for a prospective, longitudinal relationships was also found, such that poor sleep quality at T2 predicted physical and somatic symptoms at T3, controlling for T2 physical symptoms (β=1.28, $p < .05$). The results of this study demonstrate that sleep becomes more disrupted across the first semester of college and it co-varies with multiple indices of psychological distress. Further research is needed to determine the predictive relationships between these risk factors and sleep quality for female, freshmen college students.

EFFECTS OF SCHOOL START TIME ON STUDENTS' SLEEP: A META-ANALYSIS

Jennifer Bowers, B.A.[1], Anne Moyer, Ph.D.[2]

[1]Stony Brook University, Port Jefferson, NY; [2]Stony Brook University, Stony Brook, NY

Introduction

Research finds that few adolescents adhere to recommended sleep guidelines. Lack of sleep is a predictor of a number of serious physical and mental health consequences. This meta-analysis examines the effects of school start time (SST) on sleep duration of students by aggregating the results of 5 longitudinal studies, and separately, 14 cross-sectional studies.

Methods

Database searches and manual searches for citations in recently published reviews of the literature were used to identify 19 records for inclusion. Data for the following moderator variables were extracted and coded: publication status of article, delay of SST in minutes, students' grade in school, and months between Time 1 and Time 2.

Analyses were conducted using Version 2 of Comprehensive Meta-Analysis (CMA) software. Once all study effect sizes were calculated, CMA produced an aggregate effect size using weights and the random effects model. A positive effect size represents longer sleep durations for the later SST group.

Results

Longitudinal studies

The effect sizes (d) for sleep duration ranged from 0.24 to 1.07, with an aggregate effect size of $d = 0.38$, 95% CI 0.20 – 0.57, $p < 0.001$. Significant heterogeneity was found among the effect sizes, $Q(4) = 9.99$, $p < 0.05$, $I^2 = 59.97$.

Meta-regression was used to analyze moderator variables. Longer delay predicted longer sleep duration, $Q(1) = 7.56$, $p < 0.01$. The length of time between T1 and T2 was not found to be significant, $Q(1) = 0.61$, $p = 0.435$.

Cross-sectional Studies

The effect sizes (*d*) for sleep duration ranged from 0.05 to 0.96, with an aggregate effect size of $d = 0.41$, 95% CI 0.25 – 0.57, $p < 0.001$. Significant heterogeneity was found among the effect sizes, $Q(13) = 323.83$, $p < 0.01$, $I^2 = 95.99$.

Grade in school and publication status moderators were analyzed using analog-to-ANOVA. Longer delay predicted shorter sleep duration, $Q(1) = 63.36$, $p < 0.01$. Neither grade in school, $Q(2) = 2.04$, $p = 0.90$, nor publication status was significant, $Q(1) = 1.72$, $p = 0.19$.

Discussion

Results indicate that later starting school times are associated with longer sleep durations. Further investigation is needed to understand the discrepancy in directionality between cross-sectional and longitudinal studies for the delay length moderator. Although more longitudinal primary research is needed and there was unexplained heterogeneity in the cross-sectional studies, overall, this systematic analysis of SST studies suggests that delaying SST is beneficial for students' sleep, and thus their general well-being.

ETHNIC/RACIAL DIFFERENCES IN SLEEP DURATION, SLEEP QUALITY AND HEALTH

Sheena Mirpuri, PhD

Memorial Sloan Kettering Cancer Center, New York, NY

Ethnic/racial health inequalities are well-established (Williams et al., 2007), and research has more recently suggested the role of sleep in mental and physical health outcomes (e.g., Altman et al., 2012). Using a subsample from the American Time Use Survey dataset, a large, nationally representative sample (*n*=36,942 participants, M_{age}=47.63, 15-85 years old, 55.7% female), the current study investigates sleep and health disparities based on ethnicity/race and the relationships between sleep indicators and health outcomes. The majority of participants were White (65.8%), followed by Black (14.6%), Hispanic (14.2%), and Asian (3.7%) participants. Other/Mixed Ethnicity/Race (1.7%) were removed for ease of interpretation.

Addressing the first goal, significant ethnic/racial differences in sleep duration (i.e., the longest period of sleep over 24 hours) were found. White individuals reported the lowest sleep duration in minutes (*M*=523.60) in comparison to Hispanic (*M*=552.35), Black (*M*=544.53), and Asian (*M*=536.27) individuals. A larger proportion of White individuals reported obtaining the recommended amount of sleep of 7-9 hours (43%) in comparison to Asian (37.5%), Hispanic (34.2%), and Black participants (32.5%). There were also significant differences in sleep quality ("How well-rested did you feel yesterday?” on a scale from 1-4) by ethnic/racial group, such that Black (*M*=3.19) and Hispanic (*M*=3.19) individuals reported feeling more well-rested than White (*M*=3.12) individuals. In terms of general health ("Would you say your health in general is excellent, very good, good, fair, or poor?"), Asian (*M*=3.63) and White (*M*=3.57) individuals reported significantly better health than Black (*M*=3.27) and Hispanic (*M*=3.28) individuals. Almost half of Black participants reported high blood pressure in the past five years (43%) in comparison to other groups. Addressing the second goal, significant associations were found between general health and sleep quality (*r*=.24) and sleep duration (*r*=-.10). Sleep quality and sleep duration were only slightly related (*r*=.07), although the strength of this association differed by ethnic/racial group.

Our findings are consistent with prior research suggesting that sleep quality may be more predictive of overall health in comparison to sleep quantity (Pilcher et al., 1997). This study also highlights ethnic/racial differences in sleep and health indicators, emphasizing the need for future work to consider these mechanisms.

INSOMNIA, IMMUNITY AND INFECTIONS IN CANCER PATIENTS TREATED WITH CHEMOTHERAPY

Sophie Ruel, Ph.D. student, B.Sc. Inf, B.A.[1], Josée Savard, Ph.D.[2], Hans Ivers, Ph.D.[3]

[1]Laval University, Levis, PQ, Canada; [2]Laval University, Québec, PQ, Canada; [3]Laval University, Quebec, PQ, Canada

Background: Research has shown that insomnia symptoms, which are very common in cancer patients, especially in those with breast (42-69%) or gynecological cancer (50-68%), influence the immune system. However, the impact on health resulting from such immune changes has rarely been studied, especially during chemotherapy, when the immune system is already compromised. The aim of this study was to evaluate the relationships between insomnia, immunity and the occurrence of infections in women treated with chemotherapy for breast or gynecological cancer. It was hypothesised that patients with insomnia (INS) would present more immune alterations during and after chemotherapy, in addition to reporting more infections, as compared to good sleepers (GS).

Methods: 52 patients were assessed before chemotherapy (T1), on four occasions during the first two cycles of chemotherapy (i.e., immunosuppression and recovery weeks; T2-T5), at the end of the treatment (T6), and at 3- (T7) and 6-month (T8) follow-ups. Sleep was assessed using the Insomnia Severity Index, a daily sleep diary and a clinical interview, which also assessed the presence of infections. Finally, blood samples were collected at each time point (T1-T8) to measure several immune parameters (e.g., neutrophils, lymphocytes).

Results: Linear mixed-model ANCOVAs revealed significant group-by-time interactions on infection (ps≤.04) and immune variables (e.g., neutrophils, T-cells; ps≤.04). Moreover, INS reported more infectious symptoms than GS at T2 (p=.004).

Conclusions: These results partially confirm our hypotheses and indicate that the risk of infections and immune variables evolve differently in INS as compared to GS during and after chemotherapy.

RESTLESS SLEEP IS ASSOCIATED WITH WEIGHT GAIN: A WITHIN-SUBJECT ANALYSIS

Tom Quisel, BS[1], John Torous, MD[2], Luca Foschini, PhD[3]

[1]Evidation Health, Santa Barbara, CA; [2]Beth Israel Deaconess Medical Center /Harvard Medical School, Brookline, MA; [3]Evidation Health, San Mateo, CA

Background: The rising popularity of digital health trackers presents the opportunity to understand the relationship between personal behaviors and health outcomes outside of the lab or clinic. In this study, we use longitudinal weight data and minute-level sleep data from over 6,000 users of digital health trackers across the United States to examine the relationship between sleep patterns and a clinical outcome: weight gain.

Methods: We analyzed minute-level sleep and weight data collected from fitness trackers for 11,552 users of a proprietary platform that incentivizes healthier lifestyles (Achievemint.com) in the period 4/1/2015–4/1/2016. We considered users with at least 5 weight measurements spanning two or more months. Users with 5 or more nights of sleep recorded in at least two calendar months spanned by their weight measurements were included. We modeled monthly percent weight change for each user using fixed-effects panel regression analysis, performing separate regressions for each gender. We included average nightly sleep start time, sleep duration, number of naps during the day, time in bed until sleeping, number of restless episodes, as well as the standard deviation of their time asleep during the month as explanatory variables. We further included variables to control for seasonality and variation in sleep/weight measurement device and frequency.

Results: 1,087 male and 5,207 female users met the inclusion criteria. The strongest effect in the regression was an association between restless episodes and weight gain. Each additional restless episode per night was associated with a 0.058 percentage point monthly increase in weight for females (95% CI [0.046, 0.072]; $p < .001$) and a 0.052 percentage point increase for males (95% CI [0.024, 0.081]; $p < .001$). On average, users had 7.8 ± 3.2 restless episodes per night.

Conclusions: There is a significant association between frequency of restless episodes and weight gain in the population studied. By individually identifying those with sleep difficulties, our results suggest it is feasible to offer personalized care that focuses on preventative risk factors. Identifying poor sleep is the first step towards offering tailored sleep therapies such as insomnia CBT, sleep hygiene, psychological, and medical care. Our results also represent a

scalable and accessible means of generating clinically actionable health data given that many across the world increasingly own and use trackers and wearables.

SINGLE ITEM MEASURES FOR THE DETECTION OF SLEEP PROBLEMS IN UNITED STATES MILITARY VETERANS

Jaime M. Hughes, PhD, MPH, MSW[1], Christi S. Ulmer, PhD[2], Jennifer M. Gierisch, PhD, MPH[3], Mid-Atlantic VA MIRECC Workgroup, .[4], Matthew O. Howard, PhD[5]

[1]Center for Health Services Research in Primary Care, Durham VA Health Care System, Cary, NC; [2]Center for Health Services Research in Primary Care, Durham VA Health Care System, Durham, NC; [3]Duke Univeristy, Durham, NC; [4]Durham VA Health Care System, Durham, NC; [5]UNC School of Social Work, Chapel Hill, NC

Chronic sleep problems may contribute to higher rates of healthcare utilization, incident mental health disorders, and increased risk of suicide. Although sleep problems are reported by as many as two-thirds of U.S. military Veterans who served in Iraq and Afghanistan, sleep problems remain overlooked in clinical settings. To date, there are no brief sleep screeners or clinical guidelines addressing how to best screen for sleep problems in Veterans Health Administration (VHA) primary care settings. Using data from the Study of Post-Deployment Mental Health, a volunteer-research registry housed at the Mid-Atlantic VA's Mental Illness Research, Education, and Clinical Center, the objective of this research was to examine the utility of single sleep items embedded in existing psychological assessments. Three such items are embedded into the Symptom Checklist-90 and include distress related to trouble falling asleep, awakening in the early morning and sleep that is restless or disturbed. Participants were U.S military Veterans who served since September 11, 2001, had one or more deployments, and did not meet past-month criteria for a DSM-defined Axis I psychiatric disorder (N = 1,118). Participants completed a battery of questionnaires assessing demographics, physical and mental health, and sleep. The performance of the three items noted above was evaluated in relation to two reference outcomes: poor sleep (Pittsburgh Sleep Quality Index total score > 5) and DSM-defined probable insomnia disorder. Using an response score of one ("a little bit" distressing), each of the three items demonstrated moderate sensitivity values and acceptable rates of each false positives (FP) and false negatives (FN) in predicting poor sleep (sensitivity: 0.70 to 0.78; FP: 0.23 to 0.30; FN: 0.26 to 0.42) and probable insomnia (sensitivity: 0.81 to 0.89; FP: 0.42 to 0.48; FN: 0.11 to 0.32). Although additional research is needed to test the performance of these items across diverse Veteran groups, our initial findings suggest that existing items may serve as a first step in screening for sleep problems.

C272 6:00 PM-7:00 PM

THE EFFECT OF SCHOOL START TIMES ON SLEEP AND ACADEMIC PERFORMANCE AMONG ELEMENTARY AND MIDDLE PUBLIC SCHOOL STUDENTS IN THE US

Tracy Trevorrow, Ph.D., Sakiko Sugihara, BA Psychology, Stephanie Lum, N/A

Chaminade University of Honolulu, Honolulu, HI

Most K-12 students in the US are not getting enough sleep. Early school start times appear to contribute to this problem, resulting in unwanted outcomes in health, psychosocial development and learning. Only 20% of US schools start after 8:30 a.m. as recommended by the American Academy of Pediatrics.

The purpose of this study was to determine whether US school start times were associated with academic performance. We hypothesized that later school start times would be associated with improved academic performance. Only elementary and middle schools students were included due to insufficient reporting of high school outcomes.

Participants included 4th and 8th grade public school students from 49 States for the 2011-12 academic year. Student data and school start times were obtained from the National Center for Educational Statistics (NCES). A total of 50,310 elementary schools, 13,990 middle schools and 33, 269,172 students were included. The National Assessment for Educational Progress (NAEP) was used to assess academic proficiency for Grades 4 and 8 in mathematics, reading, and science.

Pearson correlations were computed to determine associations between school start times by state and academic proficiency. Simple linear regression was used to predict academic proficiency based on school start times.

For Grade 4, school start times were significantly correlated with NAEP scores for math proficiency, $r^2 = .48$, p2 = .40, p2 = .50, p The data supported our hypothesis regarding school start times and academic achievement for Grade 4 students but not for those in Grade 8. Elementary school students may be at particular risk for poorer academic achievement due to sleep loss from early school start times. There is a need for studies that include sleep assessment and allow for the evaluation of causal relationships between school start times and academic achievement.

C273 6:00 PM-7:00 PM

THE RELATIONSHIP BETWEEN SLEEP HEALTH AND WEIGHT LOSS HISTORY

Allison Engwall, BS, Michael Mead, BS, Leah A. Irish, Ph.D.

North Dakota State University, Fargo, ND

Obesity is a significant public health concern for U.S. adults, with approximately 27% considered to be obese and an additional 35% considered to be overweight. Obesity is a leading risk factor for a broad range of mental and physical health problems. Accordingly, weight loss attempts are common, though these attempts typically yield limited long-term success. Sleep is a crucial factor to consider in the context of weight loss attempts because poor sleep may undermine positive changes to diet and exercise, reducing the likelihood of successful weight loss. The present study aimed to evaluate the relationship between sleep health and a history of weight loss attempts. Participants included 153 adults enrolled in a commercial weight loss program who completed an online survey. On average, participants had a history of 3.15 weight loss attempts (SD=4.98). The number of weight loss attempts was negatively correlated with sleep health (r = -.26, p = .001), suggesting that better sleep health was associated with fewer weight loss attempts. These findings support the hypothesis that poor sleep may undermine weight loss attempts, resulting in lower success rates and increased number of weight loss attempts over time. Moving forward, longitudinal research would allow for improved understanding of the mechanisms underlying this relationship, and additional consideration should be given to individual characteristics that may moderate these effects (e.g., age, stress). A broader understanding of this relationship could inform interventions to improve the chances of weight loss success, thus potentially reducing the prevalence of obesity in today’s society.

TREATING SLEEP COMPLAINTS: A STEPPED CARE APPROACH

Kelsey C. Utter, Ph.D.[1], Delilah O. Noronha, Psy.D. [2]

[1]VA Palo Alto Healthcare System, Department of Veterans Affairs, Seaside, CA; [2]Department of Veterans Affairs, san jose, CA

The VA Palo Alto Healthcare System utilizes a stepped care approach for insomnia in its Primary Care-Mental Health Integration (PCMHI) program, in order to increase access and provide care that matches patient need. The model relies on treating patients under the least restrictive methods and utilizing self-correction through outcome monitoring. The following is a program evaluation that describes the PCMHI stepped protocol for insomnia, patient utilization rates, and clinical outcome data, gathered over 12 months in two community based outpatient clinics in the healthcare system. This stepped care protocol includes sleep assessments, interdisciplinary collaboration, psychoeducation, web-based self-management tools, shared medical appointments (SMAs), and Cognitive Behavioral Therapy for Insomnia (CBTI). The steps provide interventions that are matched to the patient's current need, ability, and motivation. Self-report measures, including the Insomnia Severity Index (ISI) and sleep diaries, were gathered throughout treatment to aid in planning.

During the 12 months, a total of 118 consults were received for sleep concerns; after initial psychoeducation and consultation, 69% of patients were referred to a higher level of care in the Sleep SMA (N=82). Twelve of these patients (14.6%) attended SMAs more than once, as these are designed to be an open access tool for self-mangement. After completion of at least one SMA, 7 patients were referred to CBTI as the next step of care. Analysis conducted for patients who completed the CBTI protocol (N=6) indicated statistically significant improvements in sleep efficiency ($t(5)=-2.94$, $p< .05$), improvements in total sleep time ($t(5)=-3.3$, $p < .05$), and improvements in sleep latency ($t(5)=2.76$, $p < .05$). There was no significant change in time awake after sleep onset nor ISI scores. When 2 patients who elected to terminate CBTI due to pre-existing conditions (PTSD and sleep apnea) were removed from the data, a statistically significant decrease in ISI scores ($t(3)=3.37$, $p < .05$) was also found. Average length of CBTI treatment was 9.33 sessions.

The program evaluation highlights that a stepped care approach is useful in PCMHI for treatment of insomnia, allowing treating providers to customize care based on acuity of need. Outcome analysis demonstrates that patients experience overall improvement in sleep functioning at various levels. Future suggestions for improvement of the model will be discussed.

ENVIRONMENTAL FACTORS, HEALTH BEHAVIORS, AND OBESITY: FINDINGS FROM THE HISPANIC COMMUNITY HEALTH STUDY/STUDY OF LATINO YOUTH

Alan M. Delamater, PhD[1], Ashley Marchante, M.S.[2], Elizabeth Pulgaron, PhD[2], Krista Perreira, PhD[3], Carmen R. Isasi, MD, PhD[4], Mercedes Carnethon, Ph.D.[5], Guadalupe X. Ayala, PhD, MPH[6], Linda C. Gallo, PhD[7], Linda Van Horn, PhD, RD[5], Shrikant I. Bangdiwala, PhD[3]

[1]University of Miami Miller School of Medicine, Miami, FL; [2]University of Miami, Miami, FL; [3]University of North Carolina, Chapel Hill, NC; [4]Albert Einstein College of Medicine, Bronx, NY; [5]Northwestern University, Chicago, IL; [6]San Diego State University, San Diego, CA; [7]San Diego State University, Chula Vista, CA

Background and Objective: Evidence suggests that environmental factors are related to physical activity, dietary intake, and overweight status in youth; however, clear relationships have not been established in Latino youth. We examined associations of barriers to healthy lifestyle behaviors in the school, home, and neighborhood environments with physical activity, diet, and body mass index (BMI) in Hispanic youth.

Method: HCHS/SOL Youth enrolled 1,466 Hispanic/Latino youth (728 boys and 738 girls, 8-16 years) and their parents from four cities (Bronx, Chicago, Miami, and San Diego). Parents provided demographic information. Standardized scales for assessment of environmental barriers were completed by youth and parents, and composite scores calculated to reflect barriers to healthy lifestyle behaviors in the school (e.g., fast food availability), home (e.g., unhealthy foods), and neighborhood (e.g., crime,) environments; 24-hour dietary recalls were quantified and scored with the Healthy Eating Index 2010 (HEI); 7-day accelerometry measured moderate-vigorous physical activity (MVPA); and height and weight was measured to obtain BMI %iles of youth. Hierarchical regression analyses were utilized to determine relationships of environmental barriers to MVPA, HEI, and BMI. Analyses used sample and survey-weighting procedures; demographic variables (age, sex, parental income and education) were entered in the first step of each model.

Results: More after-school environmental barriers were associated with less healthy eating ($p < .001$) and less MVPA ($p < .005$). More barriers in the home environment with regard to availability of workout equipment ($p < .01$), healthy foods in the home ($p < .001$), and food practices associated with TV-watching ($p < .001$) were associated with less healthy eating; food practices associated with TV-watching were also related to less MVPA ($p < .05$). More neighborhood barriers related to eating away from home were associated with less healthy

eating ($p < .001$) and higher BMI ($p < .01$).

Conclusion: Several youth and parent-reported barriers in the after-school, home, and neighborhood environments are associated with less healthy eating, decreased physical activity, and higher BMI in Hispanic youth. Interventions to improve health behaviors and weight in this population should include and address these environmental factors.

ADAPTATION OF THE CULTURAL FORMULATION INVENTORY TO ASSESS PSYCHOSOCIOCULTURAL FACTORS ASSOCIATED WITH PRENATAL STRESS

Kendra Campbell, Ph.D.[1], Dhara Shah, B.A.[1], Hugh Leonard, B.A.[1], Loren McKnight, M.S.[1], Kirsten Pickard, B.S. student[1], Omar Gomez, B.A.[1], Emily Krier, B.A. student[2]

[1]University of Alaska Fairbanks, Fairbanks, AK; [2]University of Alaska Anchorage, Fairbanks, AK

Exposure to psychosocial, cultural, or environmental stress during pregnancy has known adverse impacts on development. Prenatal stress can include general stressors as well as stressors specific to pregnancy, such as worry about fetal health complications. In order to optimize prenatal preventive health efforts, it is important to understand the multifaceted contextual factors affecting the pregnancy experience. We sought to understand psychosociocultural factors that affect optimal prenatal health, with a specific focus on stress. We adapted the DSM-5 Cultural Formulation Interview (CFI; American Psychiatric Association, 2013) to assess psychosociocultural barriers and facilitators associated with prevention of prenatal stress. Our sample included 14 pregnant women (mean age = 30.6; mean gestational age at CFI = 33.2 weeks) who were part of an ongoing study on prenatal stress. A directed thematic analysis was used (n = 14) to contextualize participant responses through an ecological systems model (Bronfenbrenner, 1977). Multiple themes emerged amongst participant responses. Locus of control appeared to influence participants' experience of stressors during pregnancy; that is, participants who expressed more perceived control around external stressors indicated less distress. Incongruences between and within multiple systemic factors (e.g., family cultural values versus participant individual values; perceived support from family versus perceived support from healthcare provider) emerged as barriers to optimal prevention of prenatal stress. Conversely, when systemic factors were more congruent, it appeared that optimal prenatal health was better facilitated. These findings suggest that psychosociocultural factors play an important role in the pregnancy experience, and specifically in how pregnant women are affected by or buffered from external stressors. The current results add to the body of research suggesting the importance of adequately assessing for and addressing psychosociocultural factors during routine prenatal care. Additionally, our results suggest that adapting the CFI to fit a specific issue or clinical population can offer useful clinical and research utility by adding a richer understanding of the sociocultural context.

CURRENT AND IDEAL SKIN TONE: ASSOCIATIONS WITH TANNING BEHAVIOR AMONG SEXUAL MINORITY MEN

Patrycja Klimek, BA[1], Benjamin M. Rooney, B.A.[2], Kalina M. Lamb, B.A.[3], Kelsey A. Nogg, B.A.[2], Aaron J. Blashill, Ph.D. [2]

[1]SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, La Jolla, CA; [2]San Diego State University, San Diego, CA; [3]San Diego State University, San Deigo, CA

Background: Skin cancer is the most common form of cancer. Sociocultural models of body image implicate appearance norms in the formation of skin tone ideals and attitudes toward tanning. Discrepancies between current and ideal skin tone, hypothesized to relate to body dissatisfaction and internalization of the tanned ideal, predict tanning behavior. However, little is known about skin cancer risk behaviors in sexual minority (e.g., gay and bisexual) men. This is a notable gap, given that sexual minority men report high prevalence of skin cancer diagnoses. Therefore, it was hypothesized that current skin tone will significantly moderate the relationship between darker ideals and tanning behaviors among sexual minority men.
Method: Data were collected online from 238 sexual minority men residing in San Diego County, California, who had a mean age of 24 (*SD* = 5.43). Independent variables were ideal and current skin tone ratings on a perceptual scale of 1 (lightest) to 12 (darkest) and the dependent binary variables were indoor tanning and outdoor tanning (i.e., none vs. 1 or more times over the past three months).
Results: Two separate logistic regression models were used to test main and interaction effects on indoor and outdoor tanning, and subsequent simple slope analyses indicated effects at the mean, and ± 1 standard deviation (SD) moderator values (current skin tone). Darker ideals significantly predicted increased indoor tanning (B = 1.02, Odds ratio (OR) = 2.79, z = 2.73, *p* = .006); however, this effect was qualified by a significant interaction *(*B = -0.12, OR = 0.89, z = -2.01, *p* = .045). The effect of darker ideals was strongest among individuals with lighter current skin tone *(*B = 0.79, OR = 2.21, z = 2.85, *p* = .004). Darker ideals also significantly predicted increased outdoor tanning (B = 1.34, OR = 3.81, z = 6.07, *p* < .001); however, this effect was also qualified by a significant interaction (B = -0.13, OR = 0.87, z = -4.01, *p* < .001). The effect of darker ideals was strongest among individuals with lighter current skin tone (B = 1.06, OR = 2.89, z = 6.36, *p* < .001).
Conclusion: The results indicate that sexual minority men whose skin tone does not match their ideal, whether or not they are currently light or dark skin-toned, are at greater risk for engaging in skin cancer risk behaviors. Future skin cancer prevention programs aimed at

sexual minority men may wish to consider techniques that modify internalization of skin tone ideals.

ENROLLMENT STRATEGIES OF THE HEALING AND EMPOWERING AND ALASKAN LIVES TOWARD HEALTHY HEARTS (HEALTHH) STUDY

Mariah Knox, BA[1], Nicole Jeffery, BA[2], Nicole E. Anzai, BS[2], Neal Benowitz, MD[3], Matthew Schnellbacher, MD[4], Judith J. Prochaska, PhD, MPH[2]

[1]Alaska Native Medical Hospital, Anchorage, AK; [2]Stanford University, Stanford, CA; [3]Chief, Division of Clinical Pharmacology, San Francisco, CA; [4]Alaska Native Medical Center, Anchorage, AK

High rates of smoking, inactivity, hypertension and hypercholesterolemia in Alaska Native (AN) people contribute to increased risk for cardiovascular disease and death. The HEALTHH study is a telemedicine-delivered, multibehaviorally targeted, two-group RCT in the Norton Sound Region of Alaska, with 16 villages and populations from 107 to 3,695 (average=596). The study interventions target smoking and physical activity vs. medication compliance and a heart-healthy AN diet. Eligibility include; AN adult, living in the Norton Sound region, smoking 5+ cigarettes/day, with high blood pressure or high cholesterol, English speaking, BMI < 50, not pregnant, and not in a tobacco cessation program. Study staff travel to the villages with stays ranging from 1 to 8+ days. In this rural and geographically remote area, we summarize our recruitment efforts and identify best practices for enrolment.

Since June 2015 the team has made 46 trips to the villages screening 419 individuals. Of the 245 ineligible individuals, 38% had normal blood pressure or cholesterol. Most screenings occurred on Days 2 (n=98, 25%), 3 (n=102, 26%), and 4 (n=80, 21%), with Day 1 (n=31, 8%) focused on community outreach, and coordinating with the clinic. To date, 104 participants enrolled into the study (53% women, 47% men; mean age =51, SD=14, R: 21 to 81). Enrollment has been greatest on Days 3 (n=21, 20%) and 4 (n=35, 34%), with waning return Days 5-8+ (15% to 2%). Village size is significantly correlated with enrollment (r=0.76, p

EXPERIENCES OF DISCRIMINATION IN HISPANIC AMERICANS AS A FUNCTION OF ACCULTURATION AND ENVIRONMENTAL CRIME

Stefani Betos, N/A[1], Quinn Wilson, N/A[1], Sarah D. Mills, MS, MPH[2], Scott Roesch, N/A[3], Georgia Sadler, Ph.D[4], Vanessa L. Malcarne, Ph.D.[5]

[1]SDSU, San Diego, CA; [2]San Diego State University/University of California, San Diego Joint Doctoral Program in Clinical Psychology, Los Angeles, CA; [3]SDSU and UC San Diego, San Diego, CA; [4]University of California, San Diego Moores Cancer Center, San Diego, CA; [5]San Diego State University, San Diego, CA

Discrimination is widely experienced by people from different communities and has been linked with negative health outcomes. However, environmental characteristics that provide the context for experiences of discrimination(EOD) are poorly understood. Crime has been identified as a potentially important environmental factor that can create an atmosphere of distrust and diminish social engagement, but crime has received little attention as a community-leveldeterminant of people's EOD, including in Hispanic Americans. This study examined the relationship of violentand non-violent community crime to EOD in 372 Hispanic American men and women, considering acculturation levels of the participants.

The Experiences of Discrimination (EOD) scale, using the 9-item frequency scoring (Kreiger, Smith, Naishadham, Hartman, & Barbeau, 2005), and Brief Acculturation Scale for Hispanics (BASH) were administered to determine the frequency of discrimination experienced and level of acculturation of the participants. Census data from 2013(the year preceding the administration of the EOD and BASH) were used to determine rates of violent (aggravated assault) and nonviolent crime (residential burglary) in participants' communities. ANOVAs or t-tests were conducted to determine if there were EOD differences across gender, income, education, and country of origin groups; none of the tests yielded significant results (p's were all > .05). Multi-level modeling was used to examine the relationships among BASH scores, crime variables, and EOD scores, controlling for age. Violent and non-violent crime were not significant predictors of EOD scores (aggravated assault: b = .05, p = .73; residential burglary: b= -.07, p = .53). BASH scores were positively associated with EOD scores (b = .24, p = .04). There was no significant interaction of BASH and crime scores in predicting EOD scores (aggravated assault: b = .40, p = .17; residential burglary: b < -.01, p > .99). In sum, results did not support crime as an environmental characteristic related to personal EOD, but documented that more highlyacculturated members of the Hispanic American community reported more frequent EOD. Determining whether there are other

environmental characteristics common to more highly acculturated Hispanic Americans that contribute to their EOD should be the focus of future research.

LATENT CLASSES OF PARENTING STRESS, FAMILY MEALS AND CHILD BODY MASS INDEX IN A NATIONALLY-REPRESENTATIVE SAMPLE OF MOTHERS

Eleanor T. Shonkoff, PhD[1], Chih-Ping Chou, PhD[2], Adam Leventhal, PHD[3], Ricky Bluthenthal, PhD[4], Mary Ann Pentz, PhD, MA[2], Genevieve F. Dunton, PhD, MPH[5]

[1]Tufts University, ChildObesity180, Boston, MA; [2]University of Southern California, Department of Preventive Medicine, Institute for Health Promotion and Disease Prevention Research, Los Angeles, CA; [3]USC, Pasadena, CA; [4]Keck School of Medicine, University of Southern California, Los Angeles, CA; [5]University of Southern California, Los Angeles, CA

Purpose: Parenting stress, combined with other stressors, has been linked to poorer child diet, sedentary behavior, and obesity risk. Yet previous findings are inconsistent and limited by small sample sizes. This study explored latent subgroups of mothers characterized by stress (parenting stress, maternal mental health issues, poverty, single parenting) and links to family meals and child obesity status.

Methods: Nationally-representative cross-sectional data came from mothers of children aged 10 – 17 years (National Survey of Children's Health, 2011). Stress measures included items from the Parental Stress Index & Parental Attitudes about Childrearing ($\alpha = .67$); maternal mental health; BMI ≥ 95th percentile; family meals per week; % federal poverty level; and single parent status. Latent Class Analysis identified subgroups of mothers. Multinomial logistic and linear regressions tested associations with family meals and child obesity risk, controlling for child minority status and age.

Results: The analytical sample was mothers (n = 31,239, 69% of sample) of children 13.65 yrs. on average (SD = 2.32), 52% male, and 70% white. Four latent classes emerged, distinguished by poverty level; maternal stress levels were similar across classes. Class 1 (C1), the second largest class, (30.8%) had the highest poverty. Class 2 (20.3%) had moderately higher income; Class 3 (9.6%) had moderately lower. The largest class, Class 4 (C4) (39.2%), had the lowest poverty. Compared to C1, the mid-higher and higher income classes had family meals fewer days per week (C2 $\beta = -23$, SE = .08, $p < .01$; C4 $\beta = -.39$, SE = .07, p =

Conclusions: Four subgroups of mothers of US children were identified; the main distinguishing stressor was poverty. High and mid-high poverty subgroups had more frequent family meals but higher risk of obesity. Although the literature indicates that family meals can be protective against child obesity, these nationally representative data suggest this may not

occur in higher poverty families. Perhaps other risk factors, such as lack of access to healthy food outlets or safe spaces for physical activity, outweigh the potential benefit of frequent family meals in higher poverty families. Further research is needed to understand components of frequent family meals, such as nutrient content or feeding practices, and differences across demographic groups.

MINDFULNESS AND POSITIVE AFFECTIVITY: DISPOSITIONAL PROTECTIVE FACTORS OF SELF-RATED HEALTH IN UNDERGRADUATE STUDENTS

Christine E. Smith, M.A.[1], Virginia Gil-Rivas, Ph.D.[2]

[1]University of North Carolina at Charlotte, Charlotte, NC; [2]UNC Charlotte, Charlotte, NC

Introduction: This study examined the contribution of mindfulness and positive affect on self-rated health among young adults. Dispositional mindfulness and positive affect have been found to moderate the impact of stress on psychological symptoms but relatively few studies have examined their contribution to self-rate health. In addition, few have examined the contribution of these factors to self-rated health accounting for psychological distress and poor sleep quality.

Participants: Undergraduate students (N=201) from diverse backgrounds (63.7% White); 72.6% female; age range 18-46 years (M=19.2; *SD*=3.55).

Procedure: Self-administered electronic survey. Demographics, self-rated health, positive and negative affectivity (PANAS-Watson et al., 1988), dispositional mindfulness (FFMQ-Baer et al., 2006), perceived stress (PSS-Cohen, Karmack, & Mermelstein, 1983), depressive and anxiety symptoms (HSCL-Derogatis et al., 1974), and sleep quality (PSQI – Buysse et al., 1989). All scales indicated excellent internal reliability in the sample ($\alpha = 0.83 - 0.93$).

Results: Less than good health was reported by 10% of the sample. Regression analyses indicated that with the inclusion of covariates (age, gender, education, race, sleep quality, and symptoms of depression and anxiety) at step 1, depressive symptoms (β=.28, $p < .01$, CI = .136 - .705) significantly predicted poorer self-rated health. With the addition of dispositional and state psychological factors at step 2, only mindfulness (β= -.22, $p < .05$, CI = -.043 - -.004) and positive affectivity (β= -.19, $p < .05$, CI = -.018 - -.001) significantly predicted poorer self-rated health. Interestingly, depressive symptoms were no longer a significant predictor of self-rated health in step 2. This model explained 26% of the variance in self-rated health.

Conclusion: Findings provide additional evidence that dispositional mindfulness and positive affect contribute to self-rated health, even in the context of current symptoms of psychological distress and poor sleep quality. Evidence supports that training can inculcate changes in dispositional factors such as mindfulness. Thus, identifying protective factors that are amenable to change may guide the development of programs to increase mindfulness and promote positive affect, which may influence health in this population.

PARENT AND TEACHER SELF-PERCEPTION AS A ROLE MODEL FOR HEALTH AND DIET AND EXERCISE BEHAVIOR

Noel Kulik, PhD CHES, Jeffrey Martin, Ph D, Erin E. Centeio, PhD, Cheryl L. Somers, Ph.D.

Wayne State University, Detroit, MI

Nurses and physicians are expected to be role models of health for adults and children. However, for children, parents and teachers are often more significant role models for health. The ways in which parents and teachers view themselves as health-promoting role models, specifically related to healthy eating (HE) and physical activity (PA), is an important yet understudied area of research. Parents and teachers' self-perceptions as health-promoting role models can significantly influence their effectiveness when teaching about or advocating for health. The purpose of this study is to examine the relationship between self-perceptions as a role model and HE and PA behaviors among parents, school teachers and school administrators. Parent participants (n=205) were 38.1 (±7.1) years old, mostly mothers (n=174; 84.9%) and of White (n=93; 46.5%), Black (n=85; 42.5%) or Other (n=22; 11.0%) racial/ethnic background. Teachers/Admins (n=175) were 43.2 (±9.5) years old, mostly female (n=145; 82.9%) and of White (n=121; 69.5%), Black (n=42; 24.1%) or Other (n=11; 6.3%) racial/ethnic background. Data were collected using the Self as Role Model for Health Promotion (SARMHEP) scale, which has been designed for use with nurses. It was reduced and adapted for this study to examine parent/teacher/admin perceptions. Spearman-Brown prophecy predictions of reliability (if the subscales were expanded to the full scale) was .974 and .924 parent and teacher/admin scales, respectively. Convergent validity was established with correlations ($r = .6$, $p < .01$) with the question: "I am a strong role model for health". Scores were summed and ranged from 5-30 for parents and 5-66 for teachers/admins, with higher scores indicating more intrinsic motivation to engage in personal health practices. PA was measured using the Godin Leisure-Time Exercise Questionnaire, and HE was assessed using the following question: "How would you rate the overall nutritional content of your diet" (1: *unsure* to 5: *excellent*). Results show that for parents, perceptions of self as a role model for health is positively associated with PA ($r = .43$, $p < .001$) and HE ($r = .56$, $p < .001$). For teachers, perceptions of self as a role model for health is positively associated with PA ($r = .28$, $p < .001$), HE ($r = .34$, $p < .001$), and the number of years as a certified teacher ($r = .16$, $p < .05$). Role model perceptions did not differ by age, race/ethnicity or sex for parents or teachers. Findings from this study suggest that an awareness as a role model for health is associated with positive healthy eating and physical activity behaviors. This study is significant because little is known about the health role-modeling beliefs of parents,

teachers/administrators and behavior change, which is important to consider when planning whole-school health interventions that involve parents and the larger community.

SOCIAL INTEGRATION AND EMOTIONAL REGULATION

Kimberly Stevens, N/A[1], Zachary Gibson, N/A[2], Athena Howell, N/A[3], Matthew White, N/A[4], Julianne Holt-Lunstad, PhD[3]

[1]Brigham Young University, Poway, CA; [2]Brigham Young University, Spanish Fork, UT; [3]Brigham Young University, Provo, UT; [4]Brigham Young University, Draper, UT

Objective: Researchers hypothesize greater social support leads to “stress buffering,” protecting socially integrated adults from the physiological effects of stress. Our primary aim was to evaluate if adults with greater social integration would show less activity in ROI’s associated with emotional reactivity (Amygdala) and greater activity in areas associated emotional regulation (ACC) when asked to regulate negative emotions.

Methods: 31 participants, aged 40-68, completed the social network index (SNI). During the MRI task, participants were shown a series of photographs. There were three conditions: a neutral photo that participants viewed naturally (“look neutral”), a negative photo that participants viewed naturally (“look negative”) and a negative photo, shown after participants were instructed to regulate (or decrease) their negative reaction (“decrease negative”).

Results: Social Integration scores were not predictive of activity in the ACC or Amygdala. In an exploratory, whole brain analysis, social network size was predictive of BOLD activation in the right superior parietal lobe. Participants with a larger social network had a smaller difference in activity between the “look neutral” condition and the “decrease negative” condition, as compared to adults with a smaller social network.

Discussion: A small difference in BOLD activation in the right superior parietal lobe when the look “decease negative” condition is compared to the “look neutral” condition is indicative of less reactivity when presented with disturbing images. As the right superior parietal lobe is associated with visual working memory, it is possible that adults with higher levels of social integration have less need for vigilance to threats in their environments. This is consistent with the social support/ buffering hypothesis, indicating a social protection against the physiological effects of stress that would accompany constant vigilance. This suggests that those who are more socially integrated have less of a neural reaction to emotionally provocative stimuli, and therefore may provide potential neurobiological explanations for why some adults show better age-related trajectories that affect health than others.

SPOUSAL RETIREMENT COMMUNICATION AND DECISION-MAKING ON RELATIONSHIP QUALITY AND SELF-REPORTED HEALTH IN OLDER ADULTS

Wendy C. Birmingham, PhD[1], Lori Wadsworth, PhD[1], Erin Kaseda, N/A[2], Maren Wright. Voss, MS[3], Man Hung, PhD[3]

[1]Brigham Young University, Provo, UT; [2]Brigham Young University, Draper, UT; [3]University of Utah, Salt Lake City, UT

BACKGROUND: Research has shown a consistent association between marriage and both physiological and psychological health outcomes. However, it also shows that it isn't marriage per se that is beneficial; relationship quality (RQ) matters. One indicator of satisfying relationship quality is the utilization of verbal and nonverbal communication. Poor communication may result in poorer RQ and thus worse health outcomes. For older couples, retirement can bring significant changes to their relationship. Thus, retirement affects both the retiree and their spouse, yet, decisions regarding retirement may be made unilaterally by the retiring spouse without partner input. Such couples may report lower RQ while those who communicate effectively and make joint decisions regarding retirement issues may report better RQ which can lead to better health outcomes.

METHODS: We conducted one-on-one interviews with 240 retired and semi-retired individuals and administered surveys on RQ using the Marital Adjustment Test (MAT) and self-reported health measures.

RESULTS: Participants were aged 53-90, with 58% male, mostly white (91.8%), educated (88.0%), married (79.4%), and of higher income (70.0% >$50,000/year). Most married participants (96%) indicated they discussed retirement decisions with their spouse and most (89.6%) reported being either happy or very happy in their marriage. Couple communication was associated with participants' perceived positivity of their relationship ($p < .001$). When asked about the secret to happiness in retirement many participants discussed strong communication and relationship with their spouse: "You have to have a good relationship with your spouse." Individuals who reported better communication with their spouse also reported significantly higher overall health (p=.04), lower incidences of cardiovascular issues (97.5%) and diabetic issues (90%). Of particular interest, distressed MAT scores showed a trend toward reported high blood pressure issues (p=.07).

CONCLUSIONS: Retirement can be a stressful time in older adults' lives. RQ could suffer;

however, in our sample of older adults, communication about retirement decisions was associated with greater marital positivity and better self-reported health. In a population of healthy older adults, RQ still plays a significant role in health.

WEIGHT-RELATED BELIEFS AND BEHAVIORS IN APPALACHIA

Elise L. Rice, PhD[1], Minal Patel, PhD, MPH[2], Katrina J. Serrano, PhD[3], Chan Thai, PhD, MPH[4], Kelly D. Blake, ScD[5], Robin Vanderpool, BS, MPH, DrPH[6]

[1]National Cancer Institute, Bethesda, MD; [2]National Cancer Institute, Rockville, MD; [3]National Cancer Institute/Behavioral Research Program, Bethesda, MD; [4]Santa Clara University, Santa Clara, CA; [5]Behavioral Research Program, Division of Cancer Control and Population Sciences, National Cancer Institute, National Institutes of Health, Bethesda, MD; [6]University of Kentucky College of Public Health, Lexington, KY

Background: Extensive research has identified health disparities among residents of Appalachia, a unique 13-state geographic region of the U.S. In particular, Appalachians exhibit elevated rates of obesity and related behaviors such as physical inactivity. However, the psychological processes underlying those differences are less apparent.

Objective: The current study aims to clarify how health beliefs differ among Appalachians relative to non-Appalachians in light of related disparities in health behaviors and conditions.

Methods: The present analyses explored health beliefs in a sample of American adults (n=14,451) who responded to the Health Information National Trends Survey between 2011 and 2014, 8% of whom (n=1,015) resided within Appalachia. Specifically, respondents indicated how much they thought both health behaviors and genetics determined whether a person would develop obesity. They also reported on their typical patterns of physical activity, sedentary behavior, and fruit and vegetable consumption, as well as their height, weight, and general health, among other variables. Weighted regression analyses were used to test whether Appalachians differed from non-Appalachians on measures of calculated BMI, healthy lifestyles, confidence in their ability to take care of their health, and perceptions of risk factors for obesity.

Results: The average BMI was higher among Appalachians than non-Appalachians (β=0.98, p=.03). Additionally, Appalachians were less likely to report that health behaviors like diet and exercise are related to obesity (β=-0.38, p=.03), though they were not more or less likely than non-Appalachians to attribute obesity to genetics (β=-0.11, p=.42), nor were they more or less confident in their ability to take care of their health (β=0.09, p=.53). Appalachians reported engaging in strength training less frequently than non-Appalachians (β=-0.35, p=.01), although

there were no differences in physical activity per week (β=5.36, p=.88) or consumption of fruits and vegetables (β =-0.01, p=.97) in the current sample.

Conclusions: The results of this study suggest that Appalachians may undervalue behavioral determinants of health, potentially complicating efforts to reduce obesity and encourage healthy activities throughout the region.

WILL WORK FOR FOOD: HOURS WORKED AMONG COLLEGE STUDENTS IS LINKED TO POORER HEALTH BEHAVIORS AND OUTCOMES

Meg Bruening, PhD, MPH, RD[1], Irene van Woerden, MS[2]

[1]Arizona State University, Phoenix, AZ; [2]ASU, Tempe, AZ

Objective: The transition to college is marked by shifts in health behaviors and outcomes, including poor nutrition, physical activity (PA), and weight gain. How working for pay contributes to these shifts has not been studied. As a result, this study sought to examine how working for pay is related to health behaviors and outcomes among college freshmen.

Methods: During fall of 2015, diverse freshman students (n=1403; 65% female; 50% white) participating in the SPARC (**S**ocial impact of **P**hysical **A**ctivity and nut**R**ition in **C**ollege) study completed web-based surveys; anthropometrics were measured by trained research assistants at the same time. Mixed multivariate logistic regression models were used to examine the relationship between hours worked (0 hrs, 0.5 to 19.5 hours, ≥20 hrs per week) and eating behaviors, physical activity, sleep, stress, food insecurity, and measured weight status, adjusting for sociodemographics, and clustering of students within residence halls.

Results: Most students (73%) did not work for pay; the mean hours worked among working students was 18.±8. As compared to students working 0.5 to 19.5 hrs, students not working at all had a significantly higher odds of ≥3 hrs of screen time (OR=1.3; 95% CI: 1.01, 1.9) and reporting getting enough sleep (OR=1.6; 95% CI: 1.2, 2.2). As compared to students working 0.5 to 19.5 hrs, students working more than 20 hrs reported lower odds of fast food intake (OR=0.6; 95% CI: 0.4, 0.9), and higher odds of food insecurity (OR=1.7; 95% CI: 1.1, 2.6) and perceived stress (OR=1.5; 95% CI: 1.1, 2.1). Hours worked was not associated with breakfast, fruit or vegetable intake, PA, or weight status.

Conclusions: Despite being full time students, many students may need to work more than 20 hours per week, which was related to higher stress and food insecurity. Not working was related to more sedentary behavior and higher quality of sleep. Interventions are needed to support students working more than half time and to support less sedentary behavior among non-working students. Future research should address the long-term health and academic effects of working for pay among students.

EFFECTS OF DANCE MOVEMENT THERAPY ON SUBJECTIVE STRESS AND CORTISOL SLOPE AMONG BREAST CANCER PATIENTS UNDERGOING RADIOTHERAPY

Rainbow T. H. Ho, PhD, Ted C. T. Fong, MPhil, Irene K. M. Cheung, MSW

Centre on Behavioral Health, Hong Kong, N/A, Hong Kong

Background: Breast cancer patients are at risk for psychosocial distress, which may lead to neuroendocrine dysfunction. Dance Movement Therapy (DMT) is a movement-based psychosocial intervention that incorporates exercise, artistic, and recreational components. This study aimed to examine the effectiveness of DMT on perceived stress and diurnal cortisol slope.

Methods: This clinical trial randomized 121 Chinese breast cancer patients undergoing radiotherapy treatment into the DMT (n = 63) or control group (n = 58). The intervention comprised six 1.5-hour group sessions held twice a week over the course of radiotherapy. The participants completed self-report measures on perceived stress, health and sleep characteristics at baseline. Salivary cortisol samples were collected at five time points and perceived stress at the end of the intervention. Moderated mediation analysis was used to evaluate the DMT effect on the diurnal cortisol slope.

Results: Overall, DMT showed a marginal beneficial effect on diurnal cortisol slope (B = –0.66, 95% CI = –1.36 to 0.06, β = –0.17). Baseline perceived stress significantly and negatively moderated the effect of DMT on diurnal cortisol slope (B = –0.21, 95% CI = –0.36 to –0.05, β = –0.35). At one SD above the pss1 mean, the cortisol slope of the DMT group (M = -6.93) was significantly steeper than the control group (M = -5.35) with 95% CI for the difference of -1.58 = -2.59 to -0.61. The indirect effect of DMT on cortisol slope via Time 2 perceived stress was not statistically significant.

Discussions: The DMT program had a modest overall effect on diurnal cortisol slope in breast cancer patients but appeared to be effective in modulating the neuroendocrine response of those who were distressed. The present findings suggest that perceived stress may play a moderator but not mediator role in the DMT effect on diurnal cortisol slope.

NEUROTICISM, AND OPENNESS TO EXPERIENCE PREDICTIVE OF CARDIOVASCULAR REACTIVITY TO A STRESS TASK.

Daniel Stephenson, M.S., Kevin Larkin, Ph.D.

West Virginia University, Morgantown, WV

Numerous studies have demonstrated that various personality factors are related to health outcomes (e.g., Hampson & Friedman, 2008; Turiano et al., 2011). However, the mechanisms through which personality affects health are not clear. Our study sought to explore one possible mechanism by which personality traits may affect health: via increased or decreased reactivity to a stress task. The Midlife Developmental Inventory (MIDI), which assesses extraversion, agreeableness, neuroticism, conscientiousness, agency, and openness to experience, was given to 77 undergraduate students. Cardiovascular reactivity was measured for all participants during performance of a mental arithmetic task during which participants were verbally harassed by the experimenter.

To examine which personality traits were related to reactivity to stress, hierarchical regressions were performed for each cardiovascular parameter (systolic, diastolic, and mean arterial blood pressure, heart rate). Resting cardiovascular parameters were entered in the first step, and all personality traits were entered in the second step. Results revealed that neuroticism was positively related to both iastolic blood pressure (DBP; $\beta = .270$, $p = .015$) and mean arterial pressure (MAP; $\beta = .222$, $p = .031$). Openness to experience was inversely related to MAP ($\beta = -.478$, $p = .017$).

These results show that various personality factors are indeed related to cardiovascular reactivity to stress. These findings indicate that stress reactivity is one likely mechanism by which personality traits affect health. Additionally, this finding highlights the importance of including personality factors as potential covariates when conducting cardiovascular reactivity research.

SOCIAL MEDIA AS A SHIELD: FACEBOOK MAY BUFFER ACUTE STRESS

Holly Rus, B.A. , Jitske Tiemensma, PhD

University of California, Merced, Merced, CA

Background: Facebook is commonly used as a tool in behavioral health interventions. However, a conflicting body of research suggests that Facebook use may both enhance and undermine psychosocial constructs related to well-being. Despite these associations, to date there has been hardly any objective measurement of the potential impact of Facebook use on health in the context of stress. This pilot study aimed to examine the impact of Facebook use on stress reactivity. Methods: 48 Facebook users (10 males, mean age 19.8±2.3) were randomly assigned to either the experimental group (Facebook use) or the control group (quietly sitting with digital reading materials) during 18 minutes before experiencing the Trier Social Stress Test (TSST). All participants completed measures of mood and subjective well-being. Objective physiological markers (blood pressure, heart rate, and salivary cortisol) were collected at baseline and several times during recovery. Results: Groups did not differ on any measure at baseline. During the TSST, the experimental group showed a decrease in heart rate, whereas the control group showed a steep increase (pConclusion: This exploratory study showed that participants who used Facebook before experiencing acute social stress showed a more blunted response to the TSST with regard to heart rate and salivary cortisol compared to the control group. Results suggest that Facebook use may act as a buffer against acute stress. Findings hold value for informing the use of social media in behavioral medicine.

THE EFFICACY OF INTERNET-BASED INTERVENTIONS FOR STRESS MANAGEMENT: A META-ANALYSIS

Malwina Tuman[1], Anne Moyer, Ph.D.[2]

[1]Stony Brook University, Glen Head, NY; [2]Stony Brook University, Stony Brook, NY

Exposure to chronic stress can be deleterious to psychological, somatic, and behavioral health, and even lead to premature death. In recent years, the Internet has become a platform for many health-related activities, including becoming a medium for the delivery of psychological interventions. Such interventions can be delivered on computers, tablets, or mobile phones, and have been found to be effective in addressing a variety of health-related problems. Additionally, interventions delivered via the Internet offer the potential to overcome barriers associated with pursuing in-person psychological care. Many stress management techniques, such as exercising or meditating, can be time consuming. Given that the lack of time often is a source of stress, additional solutions, including Internet-based ones, that offer greater time effectiveness, flexibility and readiness of use are needed. Although much of the research examining Internet- based interventions has been conducted with clinical populations, recently, more studies have been devoted to the development and testing of Internet-based programs for the general public, such as interventions for stress management. This review quantitatively synthesizes 18 randomized clinical trials (RCTs) examining the efficacy of interventions for stress management delivered via the Internet. The aggregate effect size was medium ($d = .69$, $p < .0001$) indicating that, on average, individuals assigned to the intervention showed significantly lower stress levels than controls post-intervention. Moderator analyses showed that the type of population (employees produced the strongest effect size relative to students or adults in the general population), the intervention technique (mixed approach techniques were superior to single intervention techniques), the treatment length and the number of intervention sessions (the greater the length and the more interventions sessions, the greater the treatment effectiveness) impacted the strength of the effect. Overall, Internet-based interventions emerge as a promising tool for targeting stress, particularly those that are multifaceted, involve a higher dose of intervention, and perhaps are targeted toward groups experiencing specific types of stressors.
