Alcohol use among persons living with HIV has been linked to suboptimal adherence to antiretroviral therapy (ART) and poor health outcomes. At a population level, this may translate to HIV transmission risk if individual-level viral loads are not suppressed. Drinking behavior is often influenced by cultural norms surrounding alcohol drinking practices and may differ in the U.S.-Mexico border region where patterns of substance use may also differ from patterns in each respective country's interior. Research is lacking on alcohol use risk and health outcomes among persons living with HIV in the U.S.-Mexico border. We undertook the current study with HIV-positive Latinos in the San Diego, U.S.-Tijuana, Mexico border region to elucidate the association between recent alcohol use and HIV treatment adherence. We conducted secondary data analysis with data from a U.S.-Mexico binational parent study designed to explore barriers and facilitators to HIV care through interviewer-administered surveys. This cross-sectional study recruited a convenience sample of HIV-positive Latino adults ($N=201$) from agencies in San Diego and Tijuana. We hypothesize that participant's recent report of alcohol consumption history over the past three months would be associated with suboptimal ART adherence and differ by country of residence. Associations between alcohol consumption and ART adherence were determined by logistic regression. Our analysis revealed that alcohol consumption in the prior 3 months was associated with lower adherence to ARV, after adjusting for country of residence and cross-border activity. Over all, 36% participants who used alcohol while maintaining primary residence in the US in the last 6 months reported missing ARV medication (in the last month). This was significantly higher ($p \leq 0.001$, 95% CI) than the 34% participants missing ART, who lived in Mexico and reported drinking. With regards to cross-border mobility, 26% who used alcohol and revealed round trip border crossings (in prior 6 months), reported missing ARV medications in the last month. This was significantly higher ($p \leq 0.001$, 95% CI) than the 14% participants missing ART, who crossed border but did not drink alcohol in the last 3 months. Findings indicate that alcohol use in this border population of HIV-positive Latinos is of concern and merits further study to understand the role that alcohol consumption patterns may play in suboptimal ARV adherence in a U.S.-Mexico border context.

INTENTION TO MISUSE PRESCRIPTION OPIOIDS IS ASSOCIATED WITH PRIOR OPIOID USE AND PRESCRIPTION OPIOID MISUSE PERCEPTIONS

Alexa R. Romberg, PhD¹, Shreya Tulsiani, MPH¹, Michael Liu, MS¹, Elizabeth C. Hair, PhD¹, Donna Vallone, PhD, MPH¹¹Truth Initiative, Washington, DC

Prescription opioid misuse, addiction, and overdose among young adults have contributed to the nationwide opioid crisis. Identifying perspectives about prescription opioids that are associated with, and predictive of, misuse can inform preventive policies and interventions. This study assessed attitudes and behaviors associated with two sets of intentions that may precede prescription opioid misuse: intentions to misuse prescription opioids and intentions to save leftover prescription painkillers for future use.

Members of a nationally representative, longitudinal cohort aged 15-24 years old participated in an online survey from February to May 2018 ($N=12,374$). Intentions to misuse was measured with four items, such as "If I was not in physical pain and a friend offered me a prescription painkiller, I would take it." Intentions was dichotomized for analysis, with 0= "Do not agree" to all four items and 1= "somewhat agree" to at least one item. Agreement to the item "I would save my leftover prescription painkillers 'just in case'" was similarly dichotomized. Logistic regression models tested for association with the outcomes with prior prescribed use of opioids, prior misuse, perceived risk of harm from misuse, demographic measures and attitudinal constructs: sentiment about companies making prescription painkillers, desire to be a part of the solution of the opioid epidemic, and social acceptance of those with addiction to opioids.

Intentions to misuse was associated with prior prescribed use (3 or more prescriptions, $OR=1.48$, 95% $CI=1.24-1.77$), prior misuse of prescription painkillers ($OR=3.75$, $CI=3.07-4.58$), lower perceived risk of harm ($OR=3.58$, $CI=2.64-4.87$), stronger anti-company sentiment ($OR=1.29$, $CI=1.18-1.40$), weaker feelings about being part of the solution ($OR=0.74$, $CI=0.68-0.80$), and greater social acceptance of those with addiction ($OR=2.0$, $CI=1.82-2.19$). Results for intention to save were similar, but there was no significant association with anti-company sentiment. Additionally, intention to save was strongly associated with agreement with items measuring social norms around misuse, such as "It's not a big deal if my friends use prescription painkillers without a doctor telling them to." ($OR=5.47$, $CI=4.25-7.03$).

Interventions targeting attitudes about prescription opioids, such as perceived risk of harm from misuse and desire to be part of the solution to the opioid epidemic, may help reduce risk of prescription opioid misuse in young people.

BEHAVIOR CHANGE TECHNIQUES USED IN BINGE DRINKING INTERVENTIONS AMONG COLLEGE STUDENTS: A SYSTEMATIC REVIEW

Jessica Sorcher, n/a¹, Paige Keysor, BS¹, Paul Branscum, PhD, RD¹¹ Miami University, Oxford, OH

Background: While there have been several systematic reviews published on the effects of binge drinking interventions among college students, very few have reported the behavior change techniques (BCTs) utilized within these interventions.

Purpose: The purpose of this study was to systematically review the literature of college binge drinking interventions, and code the use of theory and BCTs to make recommendations for future researchers and practitioners.

Methods: A taxonomy of 93 hierarchical BCTs was utilized to code the interventions. To search for articles, authors followed the PRISMA guidelines and examined peer-reviewed journal articles detailing a program or intervention targeted to college students, with binge drinking behaviors as the outcome. Eleven electronic databases were used (i.e. CINAHL, Academic Search Complete, and MEDLINE), using key words 'binge drinking,' 'interventions,' and 'college students.' Articles were published between 2014-2019.

Results: Originally, 408 articles were identified from the search, however after applying exclusion criteria (i.e. based on a qualitative study, or did not describe an intervention and/or include results), nine articles were included in the review. Out of the nine studies, only two interventions were based on formal theories; one was based upon the Prospect Theory, while the other was based upon the Theory of Planned Behavior. Additionally, a total of 27 different BCTs were identified, with the most frequently coded BCTs being *Information about health consequences* (BCT 5.1) and *Information about social and environmental consequences* (BCT 5.3), appearing in six of the nine studies. On average 5.7 BCTs (+/-1.8) were reported per article.

Conclusions: This review has implications for the field of public health and behavioral medicine, as the results indicate the use of theory and BCTs needs to be expanded and refined in the literature. Specifically, researchers need to clearly delineate what methods they are employing to produce behavior change (i.e. BCT) and identify why they chose such techniques (i.e. identifying appropriate mechanisms of action). BCTs require more exposure in the field as they provide insight into effective interventions targeting health behaviors beyond binge drinking.

ABUSE, EMOTION DYSREGULATION, AND NEGATIVE ALCOHOL-RELATED OUTCOMES IN AFRICAN AMERICAN YOUNG WOMEN

Anthony Hitch, M.A.¹, Jennifer L. Brown, PhD², Ralph J. DiClemente, PhD³¹University of Cincinnati, Cincinnati, OH; ²University of Cincinnati, College of Medicine, Cincinnati, OH; ³NYU College of Global Public Health, New York, NY

Having a history of abuse and elevated emotion dysregulation (ED) severity are associated with negative alcohol-related outcomes (NARO), and ED may mediate the relation between abuse and NARO. However, no studies have explicitly examined these relations among African American young women. Thus, the aim of this study was to identify the relations between abuse, ED, and NARO among African American young women who use alcohol. We analyzed baseline data from the N-LITEN study, an STI/HIV prevention intervention for African American young women. Participants were women who self-identified as African American ($N = 560$), were 18-24 years old (M age = 20.58, $SD = 1.89$), consumed alcohol ($\geq 3x$) in the past 90 days, and reported condomless vaginal or anal sex with a male partner in the past 90 days. *History of abuse* was assessed using a categorical (yes/no) measure of emotional, physical, and sexual abuse and coded to indicate a) no abuse, b) single form of abuse, and c) multiple forms of abuse (i.e., two or more). *Problematic alcohol use* was assessed using the Alcohol Use Disorder Identification Test (AUDIT). *ED* was assessed using the Shedler-Westen Assessment Procedure (SWAP-200), Factor 5: Emotional Dysregulation scale. Nearly half (49.8%) of this sample reported a history of abuse and 67% of those with an abuse history endorsed experiencing multiple forms of abuse. Linear regression analyses evaluated hypotheses that exposure to a greater number of forms of abuse would be independently associated with higher AUDIT and SWAP-200 scores. Only history of multiple forms of abuse was associated with higher AUDIT scores, $\beta = .24$, $p < .001$, relative to no abuse. Both history of single form of abuse, $\beta = .15$, $p < .001$, and multiple forms of abuse, $\beta = .40$, $p < .001$, were associated with higher SWAP-200 scores relative to those reporting no abuse. Mediation analysis observed a small indirect effect of single abuse on AUDIT scores, $B = .54$, $SE = .22$, 95% CI [.16, 1.02], $ab_{ps} = .07$, $SE = .03$, 95% CI [.02, .12], with a moderate indirect effect of multiple forms of abuse on AUDIT scores, $B = 1.08$, $SE = .34$, 95% CI [.46, 1.64], $ab_{ps} = .13$, $SE = .04$, 95% CI [.06, .22] via ED relative to those reporting no abuse. In this sample, only exposure to multiple forms of abuse was independently associated with NARO, whereas any abuse exposure was associated with higher ED. Greater screening for ED and problematic alcohol use is needed for abuse-exposed African American young women.

THE INFLUENCE OF SOCIAL EXCLUSION AND PERCEIVED NORMS ON COLLEGE STUDENTS' WILLINGNESS TO BINGE DRINK

Charlotte J. Hagerman, M.A.¹, Michelle L. Stock, PhD¹¹George Washington University, Washington DC, DC

Social exclusion is a painful experience that increases negative affect and depletes fundamental human needs, including feelings of belonging, self-esteem, meaningful existence, and self-control (Williams, 2007). Previous literature suggests that exclusion also affects physical health by increasing willingness to use substances such as alcohol (Stock et al., 2015). However, no research has specifically examined whether social exclusion influences cognitions associated with binge drinking on college campuses, a highly common but dangerous behavior (NIAAA, 2015), and whether this is moderated by perceived drinking norms. College students' binge drinking is primarily socially motivated (Colby et al., 2009) and therefore likely to be influenced by social experiences. The present study examined whether social exclusion and perceived norms affect college students' binge drinking cognitions. Students reported their descriptive and injunctive norms about drinking in an online survey. At least one week later, participants visited the lab and were randomly assigned to be included or excluded by peers in the online ball-tossing game Cyberball (Williams & Jarvis, 2006). After, negative affect, fundamental needs, and their willingness and intentions to binge drink were assessed.

There was no main effect of social exclusion on binge drinking cognitions. However, significant interactions between exclusion and injunctive norms predicted binge drinking cognitions, such that exclusion led to *lower* willingness to binge drink at higher levels of injunctive norms ($b=-.19$, $p=.007$). Moderated mediation analyses found an opposite, indirect pathway at higher levels of injunctive norms, in which exclusion led to greater willingness to binge drink via more negative mood ($\beta=.44$, CI: .14, .75). However, these analyses also showed another indirect pathway at lower levels of injunctive norms, where exclusion led to greater willingness to binge drink via lower satisfaction of fundamental needs (i.e., belonging, self-esteem, meaningful existence, and self-control; $\beta=.69$, CI: .21, 1.14). There were no significant interactions between social exclusion and descriptive norms on binge drinking cognitions.

These findings indicate that college students show greater inclination for what they perceive to be non-normative drinking behavior following social exclusion. College campuses should facilitate activities to promote inclusion and discourage high injunctive norms about binge drinking.

A SYSTEMATIC REVIEW OF COMPREHENSIVE SUBSTANCE ABUSE INTERVENTIONS FOR INDIVIDUALS AFFECTED BY VIOLENCE AND TRAUMA

Bushra Sabri, PhD, MSW¹, Claire Greene, PhD MPH², Gregory Lucas, MD PhD¹¹Johns Hopkins University, Baltimore, MD; ²Columbia University, New York, NY

Violence victimization is common among men and women who use substances and is associated with co-occurring health issues such as PTSD, depression and HIV. Substance use interventions, therefore, should include integrated components that are designed to address co-occurring health issues among victimized substance-using individuals. This systematic review synthesized the evidence on efficacy of comprehensive, integrated, multicomponent interventions for victimized substance-using individuals. The efficacy of integrated multicomponent intervention strategies was assessed for the following syndemic conditions: mental health, substance misuse, violence, and HIV risk. We searched six academic literature databases, namely Pubmed/MEDLINE, PsycInfo, the Cochrane Register of Controlled Trials (CENTRAL), Embase, ISI Web of Science and CINAHL. The search strategy contained key terms describing violence, mental health, HIV, substance misuse, and randomized controlled trials. Electronic searches identified 13,948 results from academic literature databases (Pubmed $n=2790$, PsycINFO $n=3653$, CENTRAL $n=688$, Web of Science $n=2785$, Embase $n=3217$, CINAHL $n=815$) and 9 articles identified through cross-referencing included articles. Once duplicates were removed ($n=5922$), we reviewed the titles and abstracts of 8035 articles. Sixty-one of these were retained for full text review. After the full texts of these articles were reviewed against our eligibility criteria, we determined that 17 articles were relevant. Examples of effective components were empowerment strategies for violence, mindfulness-based stress reduction for mental health, social cognitive skill building for addressing HIV risk and psychoeducation for substance misuse. Although in this review, some components were found to be effective, we identified methodological limitations of included studies which calls for more rigorous research in this area. Further, there is lack of evidence base for multicomponent interventions for victimized substance-using individuals in developing countries. Additional studies are needed to establish rigorous evidence base for multicomponent interventions for victimized substance using individuals that help them cope effectively with their trauma of violence and address their needs.

ASSOCIATIONS BETWEEN OPIOID MISUSE ATTITUDES, INTENTIONS, AND BEHAVIORS, AND THE MODERATING EFFECT OF MENTAL HEALTH

Morgane Bennett, DrPH(c), MPH¹, Lindsay Pitzer, Ph.D.¹, Michael Liu, MS¹, Elizabeth C. Hair, PhD¹, Donna Vallone, PhD, MPH¹¹Truth Initiative, Washington, DC

Opioid misuse has increased over the past several years, and those with mental health disorders are at greater risk for misuse. This study assesses associations between attitudes towards and intentions to misuse prescription opioids, and subsequent misuse among youth/young adults.

Members of a nationally representative, longitudinal sample (ages 15-34 at baseline) were surveyed online in Spring 2018 (T1) and Spring 2019 (T2). Attitudes related to acceptance of misuse and intentions to misuse were measured at T1 and by taking the average of 3 items measured on a scale ranging from *I=do not agree* to *4=very strongly agree*. Acceptance of misuse was measured by items such as, "It's not a big deal if my friends use prescription painkillers without a doctor telling them to" ($\alpha=0.67$), while intentions to misuse was measured by items such as, "If I got a prescription painkiller from the doctor, I would share some with my friends" ($\alpha=0.80$). Misuse of prescription opioids was measured at T2 with: "In the past 12 months, on how many occasions (if any), have you taken prescription painkillers without a doctor specifically prescribing them to you?" Reported use on 1 or more occasion was defined as misuse. Anxiety and depression were measured at T1 using the Generalized Anxiety Disorder Scale and the Child Behavior Checklist. Analyses were restricted to those had never misused prescription opioids at T1 (N=8,951). Adjusted logistic regression models assessed associations between attitudes and intentions at T1 and opioid misuse at T2, as well as the moderating effect of anxiety and depression.

Results indicated significant associations between attitudes and intentions and subsequent prescription opioid misuse. For each standard deviation increase in acceptance of misuse and intentions to misuse, the odds of misuse were 1.44 and 1.31 times greater, respectively. Black and Hispanic race/ethnicity, lower SES, and higher levels of anxiety and depression were also significant predictors of misuse. Subsequent conditional models did not produce significant interaction effects.

Significant relationships between acceptance of and intentions to misuse and prescription opioid misuse suggests that interventions targeting these constructs may be successful at changing misuse behavior. Anxiety and depression were not significant moderators of these relationships, suggesting that while such interventions might work for all individuals, regardless of mental health status, more research is warranted.

HOW SELF-ESTEEM AND CHALLENGE APPRAISAL AFFECT ALCOHOL-RELATED BELIEFS, BEHAVIORS, AND CONSEQUENCES

Joe Tomaka, Ph.D.¹, Michelle Rincon, BCH, MPH¹, Stormy Monks, Ph.D.²¹New Mexico State University, Las Cruces, NM; ²Texas Tech University Health Sciences Center, El Paso, TX

This study examined how global self-esteem (GSE), contingent self-esteem (CSE), and challenge appraisal (CA) relate to alcohol beliefs, drinking behaviors, and consequences among municipal firefighters. Although self-esteem typically refers to a stable positive or negative attitude toward the self (Rosenberg, 1965), Kernis et al. (2008) used the term *fragile high self-esteem* to describe people who report possessing high self-esteem, but who also report holding these beliefs tenuously or variably, harbor insecurities that belie their explicit self-evaluations, and react defensively to negative feedback about the self (Kernis et al., 2008). This portrait differs from a more genuine, non-defensive sense of high self-esteem.

Blascovich, Tomaka, et al. have suggested that individuals who appraise novel, potentially stressful events as challenging experience significant benefits compared with those who appraise such events as threatening (Blascovich & Tomaka, 1996; Seery 2011). CA reflects an assessment that situational demands fall within one's ability to cope, whereas threat appraisal reflects the converse: That situational demands tax or exceed one's ability to cope. Several decades of research have related CA with favorable emotional, physiological, and behavioral outcomes (Blascovich, 2009).

The present study hypothesized that CSE would relate positively to alcohol consequences and facilitating beliefs (motives and expectancies), whereas GSE and dispositional challenge relate negatively to such outcomes. Municipal firefighters (N = 737) completed measures of GSE, CSE, CA, alcohol risk, alcohol-related problems, drinking motives, and alcohol expectancies as part of their participation in a regularly scheduled training session. The predictors intercorrelated moderately ($r = .32^*$ to $.43^*$). Regression analyses showed GSE to predict unique variance in alcohol problems ($\beta = -.09^*$), drinking to cope and conform ($\beta's = -.14^*$ and $-.09^*$), and tension reduction, enhanced sexuality, and negative self-evaluation expectancies ($\beta's = -.09^*$, $-.14^*$, and $-.09^*$). In contrast, CSE predicted unique variance in alcohol risk scores and alcohol problems ($\beta's = .08^*$ and $.12^*$), all four drinking motives ($\beta's = .21^*$, $.17^*$, $.14^*$, and $.19^*$), and six of seven alcohol expectancies ($\beta's = .08^*$ to $.19^*$). Finally, CA predicted unique variance in alcohol problems ($\beta = -.09^*$), drinking for social, coping, and conformity motives, ($\beta's = -.13^*$, $-.15^*$, and $-.11^*$), and tension reduction, courage, sexuality, and negative self-evaluation expectancies ($\beta's = -.09^*$, $-.13^*$, $-.15^*$, and $-.11^*$). Overall the results showed that GSE and CA to be associated with lower alcohol risks, whereas CSE enhanced such risks. Efforts to reduce alcohol-related consequences might focus on increasing promoting genuine self-esteem and encouraging challenge appraisal of life events.

DRIVING UNDER THE INFLUENCE OF CANNABIS, OTHER DRIVING RISK BEHAVIORS, AND THE FIVE-FACTOR MODEL OF PERSONALITY

Eric Benotsch, Ph.D.¹, Eryn DeLaney, B.S.¹, Chelsea D. Williams, Ph.D.¹¹Virginia Commonwealth University, Richmond, VA

Background: Currently, 34 U.S. states permit medical use of cannabis and 10 states permit recreational use. Changes in the legal status of cannabis could lead to greater instances of driving under the influence of cannabis (DUI-C). Understanding correlates and predictors of DUI-C could improve prevention programs.

Method: The present study assessed DUI-C as well as engagement in distracted driving risk behaviors such as texting while driving and the dimensions of the five factor model of personality in a diverse sample of 763 young adult college students (ages 18-25). Participants were recruited in a state that does not permit either medical or recreational use of cannabis.

Results: Overall, 31% reported cannabis use in the prior 3 months, 22% reported lifetime DUI-C and 12% reported DUI-C in the past 3 months. Participants who reported lifetime DUI-C were also more likely to report lifetime driving under the influence of alcohol (69%) compared to those who did not report DUI-C (10%), $\chi^2(1, N = 763) = 221.23, p < .001$. Participants who reported lifetime DUI-C were also more likely to report texting while driving in the past week (63%) compared to those who did not report DUI-C (48%), $\chi^2(1, N = 763) = 11.72, p < .001$. In univariate analyses, participants who reported DUI-C scored significantly higher in neuroticism and openness to experience, and significantly lower in conscientiousness, compared to individuals who did not report DUI-C. The two groups did not differ in extraversion or agreeableness. In a multivariable logistic regression analysis controlling for age, gender, race, and car ownership, openness to experience was a significant risk factor for lifetime DUI-C (OR = 1.06, 95% CI = 1.02, 1.11) and conscientiousness was a significant protective factor for lifetime DUI-C (OR = 0.92, 95% CI = 0.87, 0.98).

Discussion: Findings suggest that DUI-C co-occurs with other high-risk driving behaviors and that personality factors have utility in predicting DUI-C. Public health interventions designed to increase driving safety may wish to focus attention on this type of drugged driving.

EXPOSURE TO PERSONAL AND COMMUNITY VIOLENCE AND ASSOCIATED DRUG USE OUTCOMES

forough saadatmand, PhD¹, Jennifer Bronson, PhD², Craig Dearfield, PhD³¹Howard University, Washington, DC; ²Self, Washington, DC; ³George Washington University, Washington, DC

Background: Exposure to violence (ETV) during one's life has been associated with increased risk for substance abuse. Indeed, ETV is often found to be an independent risk factor from gender, ethnicity, other mental health diagnoses, and family circumstances. Adolescent exposure to violence is also related to substance abuse into adulthood and has been shown to have a cumulative effect. The current study adds to the understanding of how exposure to violence relates to a range of substance use outcomes and examines how this exposure interacts with other life stressors, and health and social experiences.

Method: Factor analysis was conducted to identify unique types of exposure to violence in 638 young adult (ages 18 to 25 years old) African American men and women. The resulting factors represent 1) childhood exposure to violence and 2) community exposure to violence as adults. These were regressed upon substance abuse outcomes; separate regressions were run for males and females to identify how the effects of ETV factors on the overall population compare with those among males and females.

Results: 78% of the respondents were exposed to some forms of violence during childhood and only 14% did not experience any forms of violence either as children or young adults. Within the whole sample and within gender, lower childhood ETV were significantly associated with a lower risk of engaging in dangerous substance use behaviors. Adult experiences of community violence had more significant predictors of drug use than childhood ETV. For both genders, witnessing gunfire or an assault, witnessing or being a victim of sexual assault, and carrying a weapon were consistent risk factors for dangerous drug behaviors, although specific drug use behaviors differed across genders.

Conclusions: Exposure to violence in this population of young adult African Americans served as an independent explanatory factor for specific drug use behaviors at different stages of life. Future research is needed to understand how these factors put respondents at risk for drug use behaviors or make them less likely to engage in dangerous use patterns.

TECHNOLOGY AND TELEPHONE-BASED SMOKING CESSATION TREATMENT FOR VETERANS WITH POSTTRAUMATIC STRESS DISORDER

Ellen Herbst, MD¹, Alexander Kausen, BA¹, Shahrzad Hassanbeigi Daryani, BA¹, Nathan Rossi, BA¹, Lindsey Hopkins, PhD², Jennifer Manuel, PhD¹, Tyler Wheeler, MD³, Monique Cano, MA, MS⁴, Cody Carroll, BA¹, Helen Zhou, BA⁵, Eric Kuhn, PhD⁶, Shannon McCaslin, PhD⁶, Janice Y. Tsoh, PhD²

¹San Francisco VA Health Care System, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA; ³UCLA-Kern Psychiatry Residency Program, Bakersfield, CA; ⁴Michael E. DeBakey VA Medical Center, Houston, TX; ⁵NYU School of Medicine, New York, NY; ⁶VA Palo Alto Health Care System, Palo Alto, CA

Significance: Military veterans with PTSD have smoking prevalence that exceeds 40%, two to three times that of the U.S. population. VA researchers developed an integrated care (IC) treatment protocol developed specifically for smokers with PTSD, consisting of trauma-informed cognitive behavioral therapy plus evidence-based pharmacotherapy. IC was found to double quit rates in a randomized controlled trial (RCT) of 943 veterans with PTSD when compared to VA smoking cessation clinic treatment. However, 53% of participants receiving IC did not attend all 8 treatment sessions. Moreover, office-based care is inaccessible for veterans residing in rural and remote areas. Innovative adaptations to the IC protocol may enhance treatment engagement and improve access. We aimed to examine whether adapting IC to be delivered via telephone and video would result in equivalent treatment attendance to office treatment in veterans with PTSD.

Methods: In this RCT, 20 veteran smokers with PTSD were randomized to receive the IC CBT protocol either via office-based, weekly visits (control group) or telephone or video visits (experimental group). Both groups were offered smoking cessation pharmacotherapy per current treatment guidelines. The experimental group received weekly sessions via either telephone or video, per their preference.

Results: Participants were 20 veterans (90% male), ages 28-68 ($M=49.80$, $SD=14.68$). At baseline, groups did not differ by age ($F=0.26$, $p=.618$) or FTND nicotine dependence severity ($F=2.66$, $p=.121$). There was, however, a difference in self-reported baseline smoking ($F=7.63$, $p=.013$), with control participants smoking significantly more cigarettes per day ($M=12.67$) than experimental participants ($M=6.96$). Analyses revealed no significant between-group differences in mean number of sessions attended ($F=0.56$, $p=.465$). Participants in the phone/video-based experimental condition attended a mean of 5.00 ($SD=3.06$) sessions. Control participants attended a mean of 5.90 ($SD=2.28$) in-office sessions. There were no significant condition differences for any of the eight treatment satisfaction questions (all p 's $> .150$). However, there was a large effect size (suggesting clinical significance) for overall treatment satisfaction ($F=2.29$, $p=.150$, $\eta^2=.125$), with participants in the phone/video-based experimental condition reporting greater satisfaction. Condition differences in intervention outcomes will also be analyzed and discussed.

Conclusions: Results indicate that delivery of IC via telephone or video visits with veteran smokers with PTSD is feasible, with equivalent rates of attendance in both groups. We also observed a large effect size for overall treatment satisfaction in the experimental condition. Adapting the IC protocol using innovative, convenient approaches may improve acceptability while also increasing treatment access.

ASSESSING THE ROLE OF RISK PERCEPTION IN SMOKING CESSATION: A COMPARISON OF CAUSAL- VS. TRADITIONAL STATISTICAL BASED MODELING.

Deborah Kurz, B.Sc.¹, Esther F. Afolalu, PhD², Rolf Weitkunat, Professor¹

¹Philip Morris International, Neuchatel, Neuchatel, Switzerland; ²PMI R&D, Neuchatel, Neuchatel, Switzerland

Introduction: Direct Acyclic Graphs (DAGs) can be used to visually explore causal relationships between variables in observational datasets and identify the presence of confounding based on prior knowledge and underlying assumptions. Here, we present a comparative analysis of DAGs to traditional statistical methods to identify and adjust for sources of confounding when assessing the relationship between risk perception and smoking cessation.

Methods: We analyzed data from adult cigarette smokers ($n=11,402$) in Waves 1-3 of the Population Assessment of Tobacco and Health study (PATH). The exposure was defined as the perceived health risk of cigarettes at Wave 1. The outcome was smoking cessation, defined as "former established smokers, who did not smoke at all in last 30 days" at Wave 3. We used two different approaches which considered the same initial set of 15 independent variables in order to assess the extent of a causal relationship between perceived risk and subsequent smoking cessation. The first approach was based on traditional statistical strengths-of-association-based methods, aiming to find the best multivariable logistic regression model based on model-fit and p-values. Whereas, for the second approach, a DAG was constructed to present the causal relationship between the exposure and the outcome and to find the minimal sufficient adjustment set of variables for the logistic regression model.

Results: At Wave 3 the follow-up cohort consisted of 8,575 out of which 1,018 participants had quit smoking. The results of the two approaches were systematically compared in regard to the overlap of several variables in the final logistic regression models, as well as the resulting Odds Ratio. The minimal sufficient adjustment set derived from the initial DAG had 5 variables, whereas the number of variables which stayed in the final logistic regression model derived by the traditional statistical approach were 8-11, depending on the specific procedure. We also compared the overall models with respect to plausibility and consistency with previous findings, as well as their model-fit.

Discussion: The findings showed that DAGs may be preferable to traditional statistical approaches as a means to minimize bias through inappropriate adjustments for confounding. This is especially relevant for complex research questions such as the current example aiming to delineate the intricate causal mechanisms between risk perception and smoking cessation.

UNIVERSITY STUDENTS' ATTITUDES TOWARDS TOBACCO-FREE POLICIES ON CAMPUS

Elizabeth K. Do, PhD, MPH¹, Westley L. Fallavollita, BS¹, Kendall Fugate-Laus, BS¹, Brianna Bonat, BS¹, Brianna Rossi, BS¹, Bernard F. Fuemmeler, PhD, MPH¹

¹Virginia Commonwealth University, Richmond, VA

The adoption of a tobacco-free campus policy is one strategy by which colleges and universities can prevent tobacco use and reduce its long-term health effects among students. In efforts to understanding students' attitudes toward tobacco-free campus policies and identify potential obstacles to implementing tobacco-free campus policies, a mixed methods approach was used. Research methods included "man on the street" interviews, focus groups, and a campus-wide online survey. To be eligible to participate, individuals had to be age 18 or older and currently enrolled at a four-year, urban, public university in the Mid-Atlantic region of the United States. Support for a tobacco-free campus policy was influenced by demographic characteristics (sex, race/ethnicity, and year in school), current use, and attitudes towards smoking and vaping. Although most students expressed support for policies that "ensure smoke-free air to breathe" or "reduce the risk of tobacco addiction," a number of obstacles to the adoption and enforcement of such policies were identified. These involve addressing the personal rights of tobacco users, unclear campus boundaries in an urban environment, and the growing prevalence of e-cigarette use among young adults. Students suggested that the best way to frame communication for the adoption and implementation of a tobacco-free campus policies was to focus on health benefits associated with such policies. Results highlight the importance of incorporating the student perspective into planning for a tobacco-free campus policy.

FEASIBILITY OF A VIDEO TEXTING PROGRAM FOR AFRICAN AMERICAN SMOKERS ENROLLED IN A STATE QUITLINE

Kelly Carpenter, PhD¹, Johnathan Hsu, BA², Jada Houston, n/a³, Monica Webb Hooper, PhD⁴

¹Optum Center for Wellbeing Research, Seattle, WA; ²Optum Center for Wellbeing Research, MINNEAPOLIS, MN; ³Case Western University, Cleveland, OH; ⁴Case Comprehensive Cancer Center, Case Western Reserve University, Cleveland, OH

Significance: Pervasive smoking-related health disparities exist across racial/ethnic and socioeconomic status groups in the US. African Americans, in particular, suffer disproportionately from tobacco-related illnesses. African American smokers prefer culturally specific interventions and report greater quit attempts and smoking reduction when offered these interventions. Path2Quit is a culturally specific video text messaging intervention for African American smokers. Digital interventions are common, but inequality in technology capabilities and digital literacy may preclude them from being utilized by some racial/ethnic minorities. The purpose of the present study was to evaluate feasibility of offering a digital intervention (Path2Quit) to state quitline enrollees.

Methods: Enrollees into the Louisiana State Tobacco Quitline in early 2019 who were African American with a mobile phone were contacted for screening. Eligible participants were enrolled into the automated program that sent messages twice per day with links to online video clips. Phone surveys were conducted 6 weeks post enrollment.

Results: Of the 45 screening candidates interested in the study, 10 were ineligible (22.2%) due to no wireless access (60%), not willing to watch videos (40%), or no video viewing capacity on mobile phones (30%). Of the 35 participants who enrolled in Path2Quit, 37% were female and average age was 55 ($sd = 10.6$). Participants were primarily single (69%) with education ≤ 12 years (68%) and smoked 16 cigarettes per day on average. Follow-up survey respondents ($n = 27$, 77% response rate) reported receiving texts with links to videos (25/27) and watching the videos (24/25). Respondents were highly satisfied with the program ($m = 6.4/7$, $sd = .95$) and 92% would recommend the program. Path2Quit was rated as highly useful ($m = 6.5/7$, $sd = 1.7$) and 21/24 (88%) reported taking action based on the videos. Texts and videos were rated as highly informative ($m = 6.16/7$), relevant ($m = 6.2/7$), and trustworthy ($m = 6.7/7$). Most (92%) agreed that the program increased their intention to quit and that they had made a serious effort to quit, and 14/27 (52%) had quit at the time of follow up. Few participants responded to interactive questions via text and several participants noted receiving error messages when trying to do so.

Conclusions: One fifth of quitline enrollees who were interested in the texting program did not have the technology to use it. Those who enrolled in Path2Quit found the video program useful and acceptable, although several experienced technical difficulties. Simplifying interactive components of the program may increase engagement. Further research is needed to evaluate efficacy in this population.

ESTABLISHING CROSSWALKS BETWEEN A NEW AND EXISTING PERCEIVED DEPENDENCE MEASURES ON TOBACCO AND NICOTINE CONTAINING PRODUCTS

Thomas Salzberger, PhD¹, Esther F. Afolalu, PhD², Stefan Cano, PhD³, Linda Abetz-Webb, PhD⁴, Agnes Bacso, MSc⁵, Rolf Weitkunat, Professor⁵, Karl Fagerström, PhD⁶, Jed Rose, PhD⁷, Christelle Chrea, PhD⁵

¹University of Economics and Business, Vienna, Wien, Austria; ²PMI R&D, Neuchatel, Neuchatel, Switzerland; ³Modus Outcomes, Letchworth Garden City, England, UK; ⁴Patient-Centered Outcomes Assessments, Ltd, Macclesfield Cheshire, England, UK; ⁵Philip Morris International, Neuchatel, Neuchatel, Switzerland; ⁶Fagerstrom Consulting, Vaxholm, Stockholms Lan, Sweden; ⁷Rose Research Center, Raleigh, NC

Background: Many self-reported measures are available for assessing the level of perceived dependence on specific tobacco- and nicotine-containing products (TNP), notably cigarettes. However, such product-specific measures are not fit-for-purpose for assessing dependence across diverse TNPs and in users of multiple TNPs. The ABOUT–Dependence instrument was developed to address this gap and provide comparable measurements of perceived dependence associated with the use of different TNPs. The objective of this study was to develop crosswalks between the scores of ABOUT–Dependence and existing product-specific dependence measures.

Methods: A sample of adult TNP users in the USA (N = 2434; 40% female) participated in an online survey and completed the ABOUT–Dependence instrument and other perceived dependence measures according to their current TNP-use patterns (i.e., the Fagerström Test for Nicotine Dependence [FTND], Penn State Electronic Cigarette Dependence Scale [PS ECIGDI], Cigarette Dependence Scale short version [CDS-5], Lebanon Waterpipe Dependence Scale [LWDS], and Brief Wisconsin Inventory Dependence Measure [WISDM-brief]). The composite scores of ABOUT–Dependence were co-calibrated with those of each of the other measures by psychometric analysis using the Rasch model. This procedure allowed the transformation of raw scores from various existing product-specific instruments to a common metric established by the new instrument.

Results: The ABOUT–Dependence instrument provided a more comprehensive and interpretable measure of perceived dependence by referring to individual item and response category locations for each of its three domains — *extent-of-use*, *symptoms*, and *behavioral impact*. In addition, the ABOUT–Dependence yielded better resolution than the product-specific questionnaires; for example, a score of 2 on the FTND is equivalent to a score of 12 on ABOUT–Dependence, whereas scores of 10–14 on the ABOUT–Dependence all map to a score of 2 on the FTND.

Conclusions: The ABOUT–Dependence instrument provides a reliable and sensitive measure of perceived dependence for different types of TNP users. The crosswalk developed in this study allows conversion of scores from the new instrument to established product-specific instruments and can be used for comparing perceived dependence at a group-level across studies that have used different self-reported measures.

Keywords: dependence, tobacco- and nicotine-containing products, Rasch model

ELECTRONIC CIGARETTE BRANDS: AWARENESS, USE, AND OWNERSHIP AMONG U.S. YOUTH AND YOUNG ADULTS

Alexis A. Barton, PhD, MS¹, Megan C. Diaz, PhD¹, Basmah Rahman, MPH¹, Elizabeth C. Hair, PhD¹, Barbara Schillo, PhD², Justin Haigler, MPH¹, Donna Vallone, PhD, MPH¹

¹Truth Initiative, Washington, DC; ²Truth Initiative Schroeder Institute, Washington, DC

E-cigarette use among teens in the US increased 78% between 2017 and 2018; from 12% to 21%. In December 2018, the US Surgeon General declared e-cigarette use among youth an epidemic. Regardless of voiced concerns, aggregated sales of e-cigarettes are expected to reach approximately \$9 billion in 2019, with market leader Juul expected to take over two-thirds of the market. Given the importance of brand awareness and its relationship to consumer behavior and product demand, it is critical to understand patterns of brand awareness, e-cigarette use, and ownership among different demographic subgroups of young people.

We conducted a cross-sectional, national survey of young people aged 15-24 (n=1549) using an online opt-in panel. Ever-use of e-cigarettes and recognition of 14 major brands of e-cigarettes was assessed. Participants who reported ever-use of e-cigarettes and awareness of at least one brand were then asked to report if they had ever used, currently used, or owned a device from each brand that they reported having recognized.

JUUL was the most recognized brand of e-cigarettes; 70% of 15-17-year-olds, 65% of 18-21-year-olds, and 59% of 22-24-year-olds recognized the brand. Other top brand recognitions included blu (35% recognition overall), Vuse (22%), and SMOK (21%). JUUL was also the most used brand (33% and 22% ever- and current-use) followed by SMOK (13% and 8.8% ever- and current-use). Among those who responded never having used an e-cigarette, 67% still reported recognition of at least one brand of e-cigarette. Among those who reported ever-use of e-cigarettes, 49% reported that they do not own their own device, suggesting that sharing with friends is a major component of understanding this epidemic.

Given the market domination of one brand and its high rate of recognition among young people, it becomes ever more important to understand how brand awareness affects purchasing choices, and repurchasing intentions. In addition, current and future results help inform an understanding of the appeal of different brands by demographic subgroups of young people. From a policy standpoint, results aid in the formulation of strategies to curtail marketing and product dissemination.

HARM AND ADDICTION PERCEPTIONS OF ELECTRONIC CIGARETTES: A SYSTEMATIC REVIEW AND META-ANALYSIS

W. Kyle Hamilton, BA¹, Linda Cameron, Ph.D.¹¹University of California, Merced, Merced, CA

With the rapid uptake of electronic cigarettes (e-cigs) and increase in the marketing of e-cigs as a clean alternative to traditional smoking as well as a device for smoking cessation, it is likely that the public's perceptions of potential harm and addiction changed over time since their introduction in 2007. Specifically, it is possible that the public's views of the harmfulness and addictiveness of e-cigs have decreased over time and particularly among those with experience as a vaper. To examine this hypothesis, a systematic review of the literature from January 2000 to July 2018 was conducted using both the PsychINFO and PubMed databases. Inclusion criteria included that studies provide data for harm or addiction questions as a percentage or proportion of participants. Three groups of nicotine users were coded including current smokers, dual users, and e-cig users. One group was added for the entire sample including non-nicotine users. Articles that focused primarily on smoking cessation were not included.

Current smokers ($k=5$) reported the highest pooled prevalence of perceived harmfulness of e-cigs with 50% ($z = 20.05$, $p < .0001$, $0.45 - 0.55$). Their average harmfulness perceptions increased over time at a rate of 2.5% per year ($z = 3.85$, $p = 0.0001$). Dual users ($k=3$) reported the lowest harmfulness perceptions of e-cigs with the pooled prevalence in this group 73% ($z = 19.98$, $p < .0001$, $0.66 - 0.80$) and their harm perceptions decreased on average by 3% per year ($z = -5.54$, $p < .0001$, $-0.04 - -0.02$). Similarly, e-cig users ($k=14$) reported lower harmfulness perceptions with pooled prevalence 74% ($z = 22.86$, $p < .0001$, $0.68 - 0.80$). However, these perceptions did not change over time ($Q(df=1)=0.32$, $p=0.57$). Addiction perceptions showed a different pattern with dual users ($k=2$) reporting the highest rate that e-cigs are less addictive than combustible cigarettes with a pooled prevalence of 73% ($z = 19.98$, $p < .0001$, $0.6582 - 0.8013$). E-cig users ($k=7$) reported the second-highest pooled prevalence for addiction perceptions with 46% ($z = 8.75$, $p < .0001$, $0.36 - 0.56$). Current smokers ($k=2$) reported the lowest pooled prevalence of addiction perceptions 32% ($z = 7.61$, $p < .0001$, $0.23 - 0.40$).

We've seen shifts in how nicotine users view e-cigs, of particular concern, is the perceptions of the addictiveness of nicotine. Dual users and their views that these devices are less harmful and less addictive than combustible cigarettes is an important insight into this growing group of nicotine users. The slow decrease in harmfulness perceptions among smokers is also of note as this group may over time transition into dual users. Seeing how different groups of nicotine users view the harmfulness and addictiveness of e-cigs is important to the development of future nicotine cessation programs and health communications.

A GEO-SPATIAL APPROACH TO EXPLORE THE SOCIO-ECOLOGICAL CONTEXT OF TOBACCO AND VAPE SHOP LOCATIONS

Kimlin Tam Ashing, PhD¹, Brian Tiep, MD², Jonjon Macalintal, DNP², Sophia Yeung, MHA², Ming-Hsiang Tsou, PhD³, Timothy O'Connor, PhD², Udochukwu Obodo, PhD², Faith Abuan, n/a², Bin Xie, PhD⁴¹City of Hope Medical Center, Duarte, CA; ²City of Hope, Duarte, CA; ³UCSD, San Diego, CA; ⁴Claremont Graduate University, Claremont, CA

Introduction: Despite growing public health efforts to discourage teens from using hazardous tobacco products, their use of ENDS (electronic nicotine delivery system) remain piqued due to direct youth targeting by tobacco and vaping companies. ENDS especially e-cigs most often have a fruit or candy flavor that are particularly attractive to young people and may have high nicotine – which is highly addicting.

Methods: 1) analyzed national/local nicotine product use in youth by gender, age, and racial/ethnic groups, 2) explored socio-ecological context of tobacco/vape shops via geo-spatial mapping within Los Angeles Service Planning Area 3 (SPA 3), 3) conducted environmental scan of social media platforms combined with Google and Yellow Pages searches.

Results: Population level results were drawn from US Census, 2013-2017 American Community Survey (ACS) and California Tobacco Facts and Figures, 2019. 13.5% middle schoolers and 37.7% high schoolers reported ever using e-cigarettes. Use of basic or disposable devices was associated with younger age especially among Latinos (5% reported use in the past month compared to < 3% among other ethnicities). To explore socioecological contexts of tobacco and vape shops in SPA 3. Regardless of income, a higher number of tobacco and vape shops appear to correspond with higher percentage ethnic minorities. Lower income cities tended to have more tobacco and vape shops compared to very high income cities. Tobacco products cost less in neighborhoods with a lower median household income and in neighborhoods with a higher proportion of Hispanic residents, even after adjusting for store type. Additionally, prior to the presentation, we will conduct geospatial mapping analysis: We will utilize open GIS software (QGIS) and open web map tools (Leaflet) to geocode locations of smoke/vape shops and overlay them with city demography to illustrate their spatial relationships and proximity to various neighborhoods.

Discussion: Sustained implementation of population-based tobacco, including vaping, prevention and control strategies, in coordination with the Food and Drug Administration, are critical to reducing tobacco use including vaping and initiation among all U.S. population especially ethnic minorities and youths. There are associations of Tobacco Products marketing (price, placement, promotion, or product availability) with a neighborhood demographic (socioeconomic challenged, minority race/ethnicity and high traffic volume). Vape shops are more likely to be concentrated in low resourced communities with less political clout – these areas tend to be minority dense with fewer restrictions. Findings could inform initiatives aimed at a stronger licensing requirement for vape shops and federal and state-level regulations of this industry to prevent tobacco/vape shop from targeting minority and other socially challenged groups.

MORE THAN THE SUM OF ITS PARTS: A NETWORK PERSPECTIVE ON TOBACCO WITHDRAWAL

David Lydon-Staley, PhD¹, Adam M. Leventhal, PhD², Megan E. Piper, PhD³, Robert A. Schnoll, PhD⁴, Danielle S. Bassett, PhD⁴¹University of Pennsylvania, Aberdeen, MD; ²University of Southern California, Los Angeles, CA; ³University of Wisconsin-Madison, MADISON, WI; ⁴University of Pennsylvania, Philadelphia, PA

A recently developed network perspective on tobacco withdrawal posits that withdrawal symptoms causally influence one another across time, rather than simply being indicators of a latent syndrome. Evidence supporting a network perspective would shift the focus of tobacco withdrawal research and intervention toward studying and treating individual withdrawal symptoms and inter-symptom associations. Yet, key questions remain to be addressed, including whether withdrawal symptoms and their interactions are moderated by abstinence and by cessation treatment. Here we examine the evidence for a network perspective on tobacco withdrawal. First, we use data from 668 participants (40% female, 78.29% African American) reporting on their experiences of withdrawal after 16 hours of smoking abstinence and during a non-abstinent state to examine the extent to which individual withdrawal symptoms are differentially impacted by smoking deprivation. Second, we estimate the symptom network structure of tobacco withdrawal during states of smoking satiety and abstinence. Third, we use experience-sampling data from 1210 participants (58.35% female, 86.24% white) undergoing smoking cessation treatment to estimate dynamic symptom networks that describe the interplay among withdrawal symptoms across time. Results indicate (i) differential impact of smoking deprivation on individual withdrawal symptoms, suggesting that symptoms are not interchangeable, (ii) substantial interplay among withdrawal symptoms that shows no evidence of change across periods of smoking satiety and abstinence, and (iii) reductions in the interplay among withdrawal symptoms during smoking cessation treatment. Overall, findings suggest the utility of a network perspective and encourage a greater consideration of the individual symptoms of tobacco withdrawal.

PROMOTING PATIENT-PROVIDER DISCUSSION AND SMOKING ABSTINENCE WITH INTERACTIVE MOBILE DOCTOR: A RANDOMIZED CONTROLLED TRIAL

Janice Y. Tsoh, PhD¹, Thu Quach, PhD², Isabel V. Nguyen, BS³, Khanh Hoa Nguyen, B.A.⁴, Emily Sa Nan Park, BS², Tina Diep, n/a², George Lee, MD², Agnita Pal, MEng², Tung T. Nguyen, MD⁵¹University of California, San Francisco, San Francisco, CA; ²Asian Health Services, Oakland, CA; ³University of California, San Francisco, San Jose, CA; ⁴Asian Health Services, Berkeley, CA; ⁵Department of Medicine, UCSF, San Francisco, CA

Background: Smoking prevalence among Asian American male smokers remain disproportionately high. Despite primary care setting presents an opportune time to engage smokers to promote smoking cessation, nearly half of Asian American smokers reported not receiving advice or assistance from their primary care providers (PCP) to quit smoking. Our team developed a multi-lingual interactive Mobile Doctor (iMD) program to address smoking among Asian American smokers in primary care. iMD delivers the “5 A’s” via interactive videos; it asks about smoking status; advises to quit; assesses readiness to quit; assists concerns about quitting with cessation resources information; and arranges follow-up by generating a bilingual tailored printout to enhance patient-provider discussion on tobacco use.

Objective: This study was designed to evaluate the iMD intervention in promoting patient-provider discussion and quitting smoking with Chinese, Korean, and Vietnamese male smokers. We conducted a randomized controlled trial with 174 daily smokers presented at primary care clinics of a federally qualified health center. Participants were randomly assigned to either the iMD intervention (n=89) or the control group (n=85) receiving a video education on nutrition and physical activity right before seeing their PCP. Primary outcomes were patient-provider discussion documented on electronic health records (EHR) and verified 7-day smoking abstinence (from EHR at a subsequent visit or salivary cotinine) at 6-month follow-up.

Results: The study sample included 174 male daily smokers (mean age = 55.4, range: 21 to 75 years old) with two thirds in precontemplation with no intention to quit smoking within 6 months. Chronic health conditions were common: hyperlipidemia (64%), hypertension (52%), diabetes (25%) and behavioral health diagnosis (32%). A total of 131 participants completed intervention in Cantonese (49%), Vietnamese (36%), Korean (9%) or English (6%). Intervention incompleteness was primarily due to cancellation of the PCP visit. Intent-to-treatment analysis showed, when compared to the control participants, iMD participants had a higher rate of EHR-documented patient-provider discussion on tobacco (Advise, Assess or Assist) when compared to the comparison group (73.0% vs. 50.6%, $p < 0.01$). iMD participants also reported higher satisfaction with the patient-provider discussion on tobacco (93% vs. 73%, $p < 0.01$). At 6-month follow-up, iMD participants were more likely to report achieving 7-day smoking abstinence (Odds Ratio: 4.9; 95% CI: 1.1-22.9).

Conclusion: iMD, a brief, self-administered interactive video education tool can enhance patient-provider communication on tobacco use and facilitate smoking abstinence. Findings supported feasibility and high patient satisfaction in leveraging technology to address tobacco use among Asian immigrant smokers in primary care.

PERCEPTIONS OF AMBIGUITY ABOUT CIGARETTES AND E-CIGARETTES AMONG USERS AND NON-USERS

Nicolle Simonovic, n/a¹, Jennifer M. Taber, PhD¹¹Kent State University, Kent, OH

Introduction: E-cigarettes are increasing in popularity but pose health risks. While studies have examined perceived risk of e-cigarette use, little is known about the extent to which people perceive ambiguity—limitations in the reliability, credibility, or adequacy of scientific information—about the health risks of e-cigarette use. People may perceive ambiguity about harmful products to defensively justify using them. We conducted two studies to test hypotheses that 1) People will have greater perceived ambiguity about e-cigarettes than cigarettes, and 2) People who use cigarettes and e-cigarettes will report greater perceived ambiguity about cigarettes and e-cigarettes than people who do not use those products, respectively.

Method: Study 2 was informed by Study 1 and preregistered on OSF. We recruited college students (Study 1: $n=1,515$, $M_{age}=19.28$, 82.2% female, 79.8% White) and MTurkers (Study 2: $n=483$, $M_{age}=44.23$, 54.8% male, 79.6% White) to complete a cross-sectional survey about their tobacco use and perceived ambiguity. Perceived ambiguity about cigarettes and e-cigarettes was the average of 4 items for each scale (e.g., “There are conflicting expert opinions about whether [smoking cigarettes/using electronic cigarettes] is harmful,” 1=strongly agree, 4=strongly disagree). Items were reverse scored so higher scores indicated higher perceived ambiguity.

Results: The new scales assessing ambiguity about cigarettes and e-cigarettes were reliable in both studies (all $\alpha s > .77$). We conducted repeated measures ANOVAs with ambiguity type (cigarettes vs. e-cigarettes) and four user groups (cigarette, e-cigarette, dual cigarette and e-cigarette, and non-users). Consistent with Hypothesis 1, ambiguity was greater about e-cigarettes (Study 1: $M=2.25$, $SD=.72$; Study 2: $M=2.64$, $SD=.72$) than cigarettes (Study 1: $M=1.55$, $SD=.65$; Study 2: $M=1.66$, $SD=.76$; main effect of ambiguity type: Study 1: $F(1,1510)=295.3$, $p < .001$, Study 2: $F(1,479)=515.4$, $p < .001$). There was a significant interaction only in Study 1 ($F(3,1510)=8.5$, $p < .001$). In partial support of Hypothesis 2, cigarette users ($M=1.81$, $SE=.08$) perceived greater ambiguity about cigarettes than dual users ($M=1.45$, $SE=.13$, $p=.017$) and non-users ($M=1.49$, $SE=.02$, $p < .001$), but not e-cigarette users ($M=1.65$, $SE=.03$, $p=.068$). E-cigarette users ($M=2.49$, $SE=.03$) perceived greater ambiguity about e-cigarettes than non-users ($M=2.14$, $SE=.02$, $p < .001$), but not cigarette users ($M=2.39$, $SE=.09$, $p=.273$) or dual users ($M=2.46$, $SE=.14$, $p=.818$).

Conclusions: People perceived greater ambiguity about e-cigarettes than cigarettes, and some evidence suggested that those who use particular products endorse greater ambiguity about these products. Future research might examine causal links among perceived ambiguity and tobacco use and test health communication strategies to reduce perceived ambiguity about e-cigarettes.

6:15 PM-7:30 PM

LOCAL LICENSING TO REGULATE TOBACCO RETAILERS IN CALIFORNIA: A STUDY OF POLICY DIFFUSION OVER TIME AND GEOGRAPHY

Judith J. Prochaska, PhD, MPH¹, Maya Watts, JD², Leslie Zellers, JD², Joseph Rigdon, PhD³, Amy Chieng, BA⁴, Lindsay Cloud, Esq⁵, Nina Schleicher, PhD⁴, Lisa Henriksen, PhD⁴¹Stanford University, Stanford, CA; ²ChangeLab Solutions, Oakland, CA; ³Wake Forest School of Medicine, Winston-Salem, NC; ⁴Stanford University, Palo Alto, CA; ⁵Temple University, Philadelphia, PA

Significance: Local level policy interventions in the retail environment (e.g., flavor bans, location-based restrictions) are increasing rapidly. We examined diffusion of tobacco retailer licensing (TRL) policy in California's cities and counties from the first local license (1992) to 2019.

Methods: In MonQcle, a cloud-based legal coding platform, the municipal TRL ordinances were coded at the date they first became effective and the most recent version to capture change in policy over time; 20% of all coding instances were double coded. A total TRL score (range 0-35.5) and flavor restriction subscore (0-5) were derived. We linked the TRL coding with jurisdiction-level demographic data derived from the American Community Survey (2012-2016) and 2014 jurisdiction-level adult cigarette smoking prevalence from CHIS. Total TRL and flavor scores were modeled via spatial regression implemented in the R package ‘nlme’ separately at origin, current, and change over time (current minus origin). All models adjusted for spatial autocorrelation.

Results: Prior to California's state TRL taking effect in 2004, 28 cities and 2 unincorporated counties enacted local TRL. By 2019, 167 of California's 539 jurisdictions (31%) required a local TRL (153 cities/16 unincorporated counties). In 2019, jurisdictions with TRL ($n=167$) vs without ($n=372$) tended to be urban (94% vs. 70%), with greater mean population size (122K vs. 48K), greater median household income (\$68K vs. \$66K), a lower percent of non-Hispanic White residents (42.5% vs. 50.5%); and a lower smoking prevalence (12% vs 13%), all p -values $< .02$. Of the 167 jurisdictions with TRL, 85 (51%) updated them over time. TRL origin and current scores strengthened with time ($p < .001$). TRL total and flavor scores were higher for the San Francisco Bay Area and Los Angeles relative to other areas, and the Bay Area had the greatest score increases over time.

Conclusion: The findings support a pattern of diffusion in TRL policies in California's cities and counties. Over time and in focal geographies, TRL scores strengthened. The Bay Area, in particular, has been a leading region for TRL policies and specifically for flavor bans.

LEVERAGING GENETIC DATA TO IDENTIFY NOVEL TARGETS AND DRUGS FOR TREATING TOBACCO USE DISORDER AND SMOKING-RELATED LUNG DISEASES

Joshua C. Gray, PhD¹, Mikela A. Murphy, BA², Lorenzo Leggio, MD, PhD³¹Uniformed Services University, Bethesda, MD; ²The Uniformed Services University of the Health Sciences, Baltimore, MD; ³NIAAA/NIDA, Bethesda, MD

Novel treatments for smoking cessation and sequelae (e.g., cardiovascular, respiratory, and oncologic diseases) are greatly needed. Targeting disease mechanisms with genetic support can increase success in drug development. However, translating genome-wide association studies (GWASs) of complex diseases to target discovery and medication development remains challenging. Cigarette smoking is exemplary of this challenge; large GWASs have yielded many significant SNPs, yet limited drug targets for treating smoking and smoking-related consequences have been identified. To address this gap, we conducted a two-step analysis. First, we applied a modified version of the Integrative Risk Gene Selector (iRIGS) to 55 genome-wide significant SNPs from the largest GWAS of cigarettes per day to date ($N = 337,334$). In this study, iRIGS ranked candidate genes at each SNP by integrating evidence based on genomic features (i.e., distance from gene to SNP and regulatory information) and closeness of these genes in network space, yielding 55 high-confidence risk genes (HRGs) for cigarettes per day. Second, we used the Target Central Resource Database (TCRD; a comprehensive database including investigational molecules and FDA approved drugs) to search for drug-protein interactions for these HRGs and previously identified risk genes for cigarettes per day to identify potential drugs for repurposing. In the first set of analyses, we identified several HRGs for cigarettes per day that are novel contributions to the genes from the previously published GWAS. Namely, *ETS2* (ETS proto-oncogene 2, transcription factor) has been associated with pathogenesis of pulmonary fibrosis and with response to chemotherapy treatment for lung cancer. Additionally, *EPHA5* (EPH receptor A5) and *ACVR2A* (activin receptor type-2A) mRNA levels have been linked to reward function and are modulated by cocaine administration in rodents. With regard to the second set of analyses exploring drug-protein interactions, we found some expected targets (e.g., varenicline linked to nicotinic receptors). Additionally, we identified gabapentin and pregabalin, which both target *CACNA2D2* (calcium voltage-gated channel auxiliary subunit alpha2/delta2) and have been investigated to varying degrees for treating alcohol and substance use disorders. Finally, we identified several drugs (and associated targets) that show promise for managing sequelae of smoking such as lung cancer, COPD, and tobacco smoke-induced cerebrovascular toxicity. This study demonstrates the value of incorporating regulatory information and drug-protein interaction data to highlight promising molecular targets and drugs for treating tobacco use disorder and pulmonary sequelae.

PERCEPTIONS OF SOCIAL SUPPORT IN A SMALL SAMPLE OF WOMEN WHO PARTICIPATED IN AN ONLINE YOGA INTERVENTION AFTER STILLBIRTH

Mariah Sullivan, MS¹, Jennifer Huberty, PhD², Joanne Cacciatore, PhD³¹Arizona State University, Phoenix, AZ; ²ASU, Phoenix, AZ; ³Arizona State University, Cornville, AZ

Introduction: Stillbirth is a traumatic experience for mothers that can have numerous mental health effects. Social support is important to improving mental health outcomes for women who have experienced stillbirth. Many women use online resources (e.g., discussion groups) for support. The purpose of this study was to explore the role of social support in mothers who have experienced stillbirth after participating in an online yoga intervention. Data from this study will inform a future efficacy trial using the multiphase optimization strategy (MOST) design.

Methods: This was a qualitative study. Participants ($n=10$) were recruited via email from a sub-sample of stillbirth moms ($N=46$) who participated in an online yoga feasibility study. Due to scheduling difficulties, the research team conducted two small focus groups ($n=2$; $n=4$) and four individual interviews. Participants were asked about their experience with social support (e.g., what role it has played in their grief process) and social support as it relates to the study (e.g., how their experiences would have been different if there was a social support component with the online yoga). Data were recorded and transcribed verbatim and analyzed using NVivo. Both deductive and inductive coding was used to organize the data, generate categories, and develop themes and sub-themes.

Results: Findings from this study highlights social support from friends and family that is emotional (i.e., empathy, concern) and instrumental (i.e., advice, guidance). Roughly a third of participants were satisfied, a third were partly satisfied, and 1/3 were dissatisfied with the support in the intervention. Those who were not satisfied wanted more practical guidance on the videos and reported feeling isolated. Participants felt that with social support would come accountability and motivation to participate. Participants identified five categories that they felt should be part of a social support component of an intervention. This included; (1) appropriate platform (e.g., Facebook), (2) preference specific content, (3) preference specific topics, (4) group facilitation, and (5) set expectation/guidelines of fellow group members.

Discussion: Social support is an essential component of coping with stillbirth, and researchers and practitioners should consider integrating it into interventions for this population. Results of this study may inform components or combination of components of social support for future interventions.

Objectives:

1. Understand the role that social support has in coping with the death of a child.
2. Identify the categories of a social support intervention that women who have had a stillbirth desire.

EVALUATING THE “BABY BUNDLE” RESOURCE PROGRAM: NEW PARENT NEEDS IN A LOW-INCOME URBAN COMMUNITY

Kathryn A. Knoff, BS¹, Noel Kulik, PhD, CHES²¹Wayne State University, Oak Park, MI; ²Wayne State University, Detroit, MI

Evaluating the need and type of resources necessary for mothers and fathers of newborns in low-income areas is a crucial component of effective intervention development. The Bonding Underscores Infant Learning and Development (BUILD) program recruited participants from local WIC centers in a large, Midwestern urban city in order to understand the utility of the resources provided. Each participant received a Baby Bundle Bag that included items such as diapers, wipes, changing pad, bib, a pregnancy/newborn informational book, and breastfeeding information with storage bags. A semi-structured interview evaluated the usefulness of the resources provided and explored nutrition and physical activity (PA) opportunities and other health issues in parents' daily life. Twenty BUILD participants (15 mothers, 5 fathers) agreed to be interviewed about their experience in BUILD. Participants were primarily African American (80%). Mothers' ages ranged from 24–41 years ($M = 29.93$, $SD = 5.42$) and fathers' ages from 26–55 ($M = 35.20$, $SD = 12.22$). Prevalent themes from the interviews included fathers' expression of interest in being involved with their child formally through program resources and enjoying on-the-go bags. Parents found most items to be useful, but mothers reported referring to the resource book less than using the diapers, wipes, and other baby care items. Fathers desired more literature on breastfeeding and ways to be of assistance to the mother. Both moms and dads reported regularly consuming sugar sweetened beverages, and about half of moms do not consume the USDA's Recommended Daily Intake (RDI) for fruit and 73.4% do not meet the RDI for vegetables. Though only one participant reported PA limitations ordered by their physician, most mothers do not meet PA recommendations, which may be difficult postpartum. Over half (53.3%) did not report being physically active at all (0 days PA/week), while 33.3% are active more than 30 minutes on a typical day, mostly attributed to being on their feet at work. Future research should include more input from fathers of newborns, who enthusiastically provided feedback on every aspect of the program and expressed desire to further participate. An increase in access to nutrition and physical activity resources for mothers arose in discussion, but use of books for information should be limited, as parents reported the medium as less useful than web-based or group sessions, or items they could use right away.

MENTAL HEALTH AND POLYCYSTIC OVARY SYNDROME (PCOS): EXAMINING INFORMATION SHARED TO WOMEN OF COLOR BY HEALTH CARE PROVIDERS

Mayra Zamora, n/a¹, Melanie Sabado-Liwag, PhD, MPH¹¹California State University, Los Angeles, Los Angeles, CA

Background: Polycystic ovary syndrome (PCOS) is a metabolic-endocrine disorder present in at least 6% to 10% of reproductive-aged women. Typically characterized by menstrual dysfunction, hyperandrogenism, and/or polycystic morphology, co-morbidity with mental health disorders is often observed. While previous literature has established the association between PCOS and psychological distress, it is less understood if women of color are given information on PCOS, mental health, or both by health care providers.

Methods: Sixty-five providers from twenty-seven clinics in Huntington Park, CA were contacted for recruitment. Four providers consented and participated in semi-structured interviews.

Results: All four reported menstrual dysfunction as the most common reason PCOS patients seek care, and obesity as the most common feature in patients presenting with PCOS symptoms. Only one provided patients with visual educational material on PCOS upon diagnosis. All four providers reported utilizing validated screening tools to assess patient psychological health on a routine basis, regardless of PCOS diagnosis. Three referred patients for psychological counseling; however, two reported noncompliance as an issue when referring patients to mental health services. While all four providers were aware of the connection between PCOS and psychological health, none communicate this connection to PCOS patients.

Discussion: Sharing PCOS information is often limited to patients with symptomology, and psychological screenings to annual physicals. Psychological distress as a side-effect of PCOS is not elaborated on during patient-provider interactions within the explored service area, indicating a need for better provider communication to female minority patients with PCOS about the psychological implications of the disorder.

RELATIONSHIPS OF PERCEIVED MEDICAL STRESS WITH POSTPARTUM TRAUMATIC STRESS AND DEPRESSIVE SYMPTOMS IN NICU MOTHERS

Nichelle Huber, MA¹, Meghan Sharp, PhD², Christyn Dolbier, Ph.D.¹¹East Carolina University, Greenville, NC; ²Women's Medicine Collaborative, Lifespan, Providence, RI

Introduction: Perceived stress is associated with more severe psychopathology after adverse life stressors. Mothers of infants admitted to the neonatal intensive care unit (NICU) experience unique stressors related to their baby's medical care that complicate postpartum psychological adjustment. Little research has investigated relationships between perceived medical stress and postpartum mental health in this special population, and results thus far have been mixed.

Method: Women who had given birth in the prior 4 months ($N = 184$) were recruited via social media advertisements for an online survey about perinatal experiences. The majority were White (89%), married (77%), and primiparous (64%) with Mage = 29.14. Participants completed measures assessing lifetime trauma, traumatic childbirth, symptoms of posttraumatic stress disorder (PTSD) related to childbirth and postpartum depression. Of these, 37% ($n = 63$) had a baby admitted to the NICU. NICU mothers completed a measure of perceived stress related to their baby's hospital stay in three areas: sights and sounds of the unit (SS), baby's appearance and behavior (BAB), and parental role alterations (PRA).

Results: Compared to non-NICU mothers, NICU mothers were significantly more likely to report a traumatic childbirth [67% vs. 27%, $\chi^2(1) = 26.2, p < .001$] and scored significantly higher on measures of PTSD symptoms [$t(162) = 5.10, p < .001$] and postpartum depression [$t(163) = 2.09, p = .038$]. Within the NICU mother subsample, all three NICU stress subscales significantly correlated with PTSD symptoms and the BAB subscale significantly correlated with depression. These relationships persisted in linear regressions controlling for trauma history and length of NICU stay; PTSD: SS ($B = 1.58, t = 3.22, p = .002$), BAB ($B = .79, t = 5.86, p < .001$), PRA ($B = .67, t = 2.56, p = .013$); Depression: SS ($B = .221, t = 1.14, p = .259$), BAB ($B = .18, t = 2.90, p = .005$), PRA ($B = .10, t = .925, p = .359$).

Conclusion: NICU mothers reported greater postpartum psychopathology. Experiencing greater perceived medical stress specifically related to the NICU was associated more strongly with PTSD symptoms than depression. Postpartum depression was only significantly related to stress associated with the baby's appearance and behavior. Results provide support for the inclusion of psychological services in standard NICU care. Providing resources for NICU parents aimed at decreasing NICU stress may be an important intervention target.

OPTIMIZING BENEFITS OF LEARNING ABOUT OTHERS' CANCER EXPERIENCES: DELIVERING EXPERIENTIAL CANCER INFORMATION TO PATIENTS

Christine M. Rini, PhD¹, Kristi Graves, PhD², Shannon Nugent, PhD³, Steve Buechler, PhD⁴¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Georgetown University, Washington, DC; ³VA Portland Health Care System, Center to Improve Veteran Involvement in Care, Portland, OR; ⁴Minnesota State University, Mankato, Mankato, MN

People with cancer often actively seek information from other patients about their day-to-day experiences with cancer treatment and recovery, hoping to feel more prepared for their own treatment and recovery. "Experiential information" from other patients (peers) is valued because it provides information not available from healthcare providers. Theory and research suggest it can reduce patients' sense of isolation, teach them new ways to cope with and understand their situation, and guide information gathering and decision making. Experiential information available in written form, such as on the Internet, expands access to this potentially valuable resource. However, in addition to its potential benefits, evidence shows that experiential information can be upsetting or provide advice patients view as harmful or inaccurate. It is worthwhile to consider methods for optimizing the benefits of experiential information while minimizing potential harms. This symposium will discuss these issues to consider new ways of providing experiential information as a supportive resource for patients. The first speaker will present a study that investigated cancer patients' real-time reports of their desire for different types of experiential information before and during their stem cell transplant. Collecting data from patients as they move through treatment avoids retrospective recall biases to provide a realistic view of the types of experiential information patients would want, or want to avoid, at different stages of treatment and recovery. The second speaker is part of a team that has developed an online resource through which people can get experiential information on over 120 health conditions. She will present preliminary findings from two new modules—one for Gulf War Era Veterans coping with multisymptom illness and another presenting experiences of childhood cancer and its impact on families. She will highlight the purposes these modules can serve for people coping with similar illnesses as well as other audiences. The third speaker is a sociologist who had a stem cell transplant after being diagnosed with hematologic cancer. He has shared his experience in a book and brings both his sociological and personal perspectives to the challenge of providing experiential information to patients in a way that enhances its potential benefits. The discussant will use insights from each of the presentations to discuss possible new directions for research and interventions.

“KNOWING THE UNKNOWN:” INTEREST IN OTHER PATIENTS’ WRITTEN NARRATIVES ABOUT STEM CELL TRANSPLANT

Kristi Graves, PhD¹, Lauren A. Whitmore, MA², Taylor Schulte, n/a³, Amanda Belanger, B.S.², Lily McFarland, BS⁴, Scott Rowley, MD⁵, Michele Donato, MD⁵, Pashna Munshi, MD⁶, Christine M. Rini, PhD⁷

¹Georgetown University, Washington, DC; ²Cancer Prevention and Control, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ; ³Georgetown Lombardi Comprehensive Cancer Center, Cancer Prevention and Control Program, Washington, DC; ⁴Northwestern University; ⁵Hackensack University Medical Center; ⁶Georgetown University; ⁷Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Patients with cancer indicate that receiving information about how other patients have managed their illness and treatment is useful. Documented benefits of receiving information from peers with similar diagnoses and treatments include a reduced sense of isolation and feeling more prepared for treatment. Written narratives provide an accessible way to offer information and support from peers. We sought to evaluate interest in the timing and content of reading peer narratives among patients diagnosed with hematological cancer who were about to undergo stem cell transplant.

Methods: The present study was conducted within the context of a randomized clinical trial evaluating expressive helping narratives compared to neutral writing among patients undergoing stem cell transplant. We collected data about patient demographics and interest in peer narratives (stories) at pre-transplant baseline and post-transplant around the time of nadir, engraftment and an immediate post-intervention follow-up assessment.

Results: Among 69 patients at baseline, 46% were women, 55% were having autologous transplants and 44% were over age 60 years old. More than half of patients (53%) were moderately to extremely interested in seeing other patient stories, and 41% reported high levels of interest in seeing these stories before transplant. Most patients indicated it would be useful to read about what to expect physically (78.6%) and emotionally (64.3%) during transplant. Patients were particularly interested in stories with practical information to meet their own or their family’s needs. Interest in reading stories by other patients remained relatively consistent over time, with about half of patients moderately to extremely interested at: nadir (50%), engraftment (47%) and follow-up (54%). Although general interest in stories was not associated with patient age, gender or transplant type, female patients were more likely than male patients to report stories could help them feel better ($t=3.09$, $p < .05$).

Conclusions: Patients’ interest in reading stories written by patients who have had a stem cell transplant is consistent over the course of time from pre- to post-transplant. Narratives with practical information including what to expect physically and emotionally may be most helpful to patients prior to a stem cell transplant. Results highlight opportunities to explore intervention approaches that deliver patient narratives.

USING HEALTH EXPERIENCES RESEARCH TO ENHANCE PATIENT, CAREGIVER, AND PUBLIC’S UNDERSTANDING OF THOSE LIVING WITH CHRONIC ILLNESS

Shannon Nugent, PhD¹, Sara Knight, PhD², Erika Cottrell, PhD³, Mark Helfand, MD, MS, MPH⁴

¹VA Portland Health Care System, Center to Improve Veteran Involvement in Care, Portland, OR; ²VA Salt Lake City Health Care System; ³Oregon Health & Science University; ⁴VA Portland Health Care System, Center to Improve Veteran Involvement in care

Developed in 2001 by the Oxford University Health Experience Research Group, the Database of Individual Patient Experiences (DIPEX) approach utilizes rigorous qualitative research methods to collect and analyze in-depth interviews about patient experiences with particular health conditions. DIPEX methodology uniquely emphasizes dissemination whereby researchers produce publicly available web modules that include lay language summaries describing the range of patient experiences in a balanced and accessible format. In addition, interview transcripts are stored in a data warehouse and available for secondary analysis. In the UK, there have been modules produced on over 120 health conditions and topics, which can all be found on healthtalkonline.org. In the US, there have been two models produced, which can be found on healthexperienceusa.org; several additional US modules on a range of topics are underway.

In this symposium, we will present preliminary findings and examples from two of the US modules currently underway: (1) Listening to Gulf War Era Veterans: A Qualitative Inquiry into the Symptoms and Treatment of Those with Chronic Multisymptom Illness and (2) Understanding the Experience of Childhood Cancer and the Impact on Families. We will share video and audio clips that are illustrative of several themes that we have identified including: Process of receiving a diagnosis, experiences with treatment, and coping. We will discuss opportunities in which the information we are gathering can serve many purposes including: motivating system change; informing research, clinical practice, and policy; and providing an ongoing resource for patients, caregivers, researchers, clinicians, and healthcare system leaders, especially with regard to cancer care.

EXPERIENTIAL CANCER STORIES: NOTES ON WHAT PATIENTS NEED TO HEAR FROM SOMEONE WHO’S “BEEN THERE AND DONE THAT.”

Steve Buechler, PhD¹

¹Minnesota State University, Mankato, Mankato, MN

Cancer patients are often inundated with technical information about their diagnosis but lack personal accounts of how to deal with their disease. As a leukemia patient, transplant recipient, cancer survivor, memoir writer, peer patient visitor, and support group participant, I have heard many cancer stories over the last three years. This paper draws on my cancer odyssey and sociological perspective to cull some recommendations about what types of stories and information are likely to be more or less helpful to current patients.

I will summarize my own experience during prolonged treatment for acute myeloid leukemia when I devised a number of coping strategies that sustained me. I will discuss how writing my story for others helped me make sense out of that experience as I composed three distinct types of sociological stories. I will use my role as a peer patient volunteer and support group participant to enrich our understanding of what kinds of information are desired (and not desired) by patients and how hearing the stories of others helped me understand my own. And finally, I will incorporate preliminary insights from my participation as a community board member with the WISE project which is seeking to deliver helpful stories to cancer patients through a web-based platform.

Symposium 70

THE ROLE OF SOCIAL ENVIRONMENTAL FACTORS IN COMMUNITY AND EHEALTH INTERVENTIONS

Dawn K. Wilson, PhD¹, Nicole Zarrett, PhD¹, Kenneth Resnicow, PhD², Allison Sweeney, PhD¹, Chris Dunkel Schetter, PhD³¹University of South Carolina, Columbia, SC; ²University of Michigan, Ann Arbor, MI; ³UCLA, Los Angeles, CA

Estimates of the proportional contribution of clinical, social, environmental, genetic and behavioral domains of health status and premature death suggest that 60% of the variance in health outcomes is attributed to social, environmental and behavioral factors, while only 10% of the variance is linked to delivery of health-care (Schroeder, 2007). This distribution presents a tremendous opportunity for the field of behavioral medicine and health psychology to better understand and influence the range of health-promoting interventions delivered in the context of community and eHealth contexts. By shaping norms, enforcing patterns of social control, and providing social support and opportunities to engage in particular health behaviors, the social environment plays a central role in influencing health behaviors. In addition there is strong correlational evidence supporting the importance of social environmental factors ranging from interpersonal relationships (e.g., social support) to neighborhood factors (e.g. social cohesion, neighborhood safety). However, social environmental factors have proven to be difficult to manipulate experimentally, thus limiting conclusions about causality. This symposium proposes that more rigorous methodologies are needed to provide a stronger evidence base for the role of social environmental factors in relation to health behavior change interventions. This symposium showcases novel approaches to experimentally changing and assessing social and environmental factors through interventions programs that promote resilience and positive health outcomes across different contexts, including afterschool programs, app-based eHealth programs, and community-based programs. Three presentations will be given, by Drs. Nicole Zarrett, Ken Resnicow, and Allison Sweeney, based on their recent trials. Following these presentations our discussant, Dr. Chris Dunkel Schetter, will provide a critique and integrate her perspectives on social environmental factors in understanding resilience and health outcomes.

CONNECT THROUGH PLAY: A PHYSICAL ACTIVITY INTERVENTION FOR ADOLESCENTS THAT TARGETS SOCIAL MECHANISMS IN AFTERSCHOOL PROGRAMS

Nicole Zarrett, PhD¹, Dawn K. Wilson, PhD¹, Lauren Law, PhD², Brittany Cook, PhD³¹University of South Carolina, Columbia, SC; ²Charlie Norwood VAMC, Columbia, SC; ³University of South Carolina, West Columbia, SC

The “Connect through PLAY feasibility trial, based on social development theory and the social mechanisms highlighted by Self-Determination Theory and Achievement Goal Theory, aimed to increase the physical activity (PA) of underserved (i.e., low income, minority status) middle school youth within pre-existing afterschool programs (ASPs). The intervention targeted several critical social mechanisms within ASPs overlooked in previous interventions with the goal of developing friendship and connection to peers and staff and group belonging through PA, and positive PA peer norms and tangible support. The current paper reports findings from the recently completed feasibility trial (NIH R21 HD077357) within 6 ASPs (3 intervention vs. 3 controls) for underserved middle school youth (N=224; 56% female; 73% African-American; ASPs free/reduced lunch rates = 57-98%) that was the first intervention to date to address youth PA social mechanisms. A regression model (pooled across imputations), controlling for baseline MVPA, site, bmi, and gender significantly predicted accelerometry-measured MVPA ($F[5,219]=46.17$, $p < 0.001$, $R^2 = 0.51$), with youth in the social intervention (vs. comparison) showing an increase of 8.61 min of MVPA at post ($B=8.61$, $SE: 3.63$, $p < 0.001$). Systematic observations of ASPs using SOCARP (Ridgers et al., 2010) and the MCOT supplement (Zarrett et al., 2013; 2015) also showed positive effects for changing targeted social mechanisms including staff behaviors (e.g., prompting PA [$t(118)=2.60$, $p=.01$], praising [$t(118)=1.98$, $p=.05$], participating with youth [$t(118)=5.93$, $p=.000$]), youth behaviors (e.g., positive interactions with peers [$t(118)=3.68$, $p=.000$]), and quality of the activities (e.g., inclusiveness [$t(118)=5.04$, $p=.000$]; structured autonomy [$t(118)=7.86$, $p=.000$]). Staff readiness assessments of general and intervention-specific capacity and staff motivation indicate critical changes in staff perceptions and motivations from pre- to post-intervention as well as challenges that still need to be addressed to improve adoptability and sustainability. Findings will be discussed in terms of how they were used to inform the current R01 Efficacy trial, which expands on the intervention’s novel translational approach by targeting program staff as instrumental for sustainable changes in social mechanisms within the ASP setting for increasing the daily PA of underserved adolescents.

8:00 AM-9:15 AM

THE ROLE OF DYADIC SUPPORT AND GEOGRAPHICAL POSITIONING SYSTEMS IN EHEALTH INTERVENTIONS

Kenneth Resnicow, PhD¹, Cristian Meghea, PhD², Patrick Carter, MD³, Susan Woolford, MD³, Jon Moon, PhD⁴¹University of Michigan, Ann Arbor, MI; ²Michigan State University; ³University of Michigan School of Medicine; ⁴MEI Research, Edina, MN

Typically, support for and contextualization of behavior change efforts are provided interpersonally. However, increasingly, with the advent of technology, support and contextualization can be provided digitally. This presentation will describe novel ways our group and others are using technology (e.g., Apps and other devices) to support behavior change efforts. We will focus on two innovations; 1) GPS Aided Just-in-Time (JIT) in-vivo messaging, and 2) Digital application of dyadic support. GPS-aided JIT messaging utilizes geolocation or geofencing to prompt messages in real time, in the context of occurring or soon to occur behaviors. We will describe two Apps, both under development and/or initial testing, one that messages youth at risk for violence and substance use based on their current geolocation (e.g., a bar or park where they have had a violent incident or have used drugs) and the second, using geolocation of the participant and known fast food restaurants to message overweight adolescents about their food intake, ideally prior to ordering. Dyadic support will be addressed both through a smoking cessation App targeting both pregnant smokers and their spouses and the previously mentioned fast food geolocation App. The smoking cessation App has both a smoker and spouse version. The spouse version provides information and communication skills to support the pregnant smoker. The fast food App has both a teen and parent version, and again, the parent version provides communication tips for the parent to encourage healthy food choices of their teen in real time, in vivo. We will also address how to apply these approaches to other health behaviors and contexts and make recommendations for future research.

3

8:00 AM-9:15 AM

EVALUATING DIFFERENT APPROACHES FOR BUILDING SOCIAL SUPPORT FOR PHYSICAL ACTIVITY AMONG AFRICAN AMERICAN WOMEN IN THE DRIVE TRIAL

Allison Sweeney, PhD¹, Dawn K. Wilson, PhD¹¹University of South Carolina, Columbia, SC

Social support is well-documented as a robust correlate of physical activity (PA). By providing opportunities to share strategies and build relationships with others working towards similar goals, group-based interventions have high potential for enhancing social support for PA. This may be particularly important for African American (AA) women, for whom lack of social support is one of the most frequently cited interpersonal barriers to PA. The type of support needed can vary across individuals and the best practices for building support within group-based interventions remain unclear. Drawing from a focus group study, which found that differences in autonomous motivation were associated with distinct social support needs among AA women, the present research evaluates two approaches to building social support in group-based interventions. These approaches were evaluated in the Developing Real Incentives and Volition for Exercise (DRIVE) program, a randomized pilot study comparing two group-based interventions for AA women: 1) a Challenge program, targeted towards high autonomous motivation (viewing PA as self-determined), focuses on building enjoyment and valuation of PA, and emotional social support through a team-based positive social climate; and 2) a Rewards program targeted towards low autonomous motivation (viewing PA as a means to an end), which focuses on building interest in and competency for PA, and instrumental social support through partner-based strategies. More participants in the Rewards program reported meeting up outside of the program to be active with another DRIVE member (71%) vs. the Challenge program (35%). Alternatively, more participants in the Challenge program reported communicating with their DRIVE group at least 2 days per week (65%) vs. the Rewards program (23%). These findings demonstrate that the intervention programs were successful in reinforcing different types of support (being active together vs. communication). Importantly, both programs showed a positive increase in social support for PA from baseline to post-program and this change was positively associated with average minutes of weekly PA across 8 weeks ($r_s = .27-.32$). The speaker will use these results to guide a discussion on the value of developing and carefully evaluating different approaches to creating social support for PA, and the implications this has for improving the delivery of group-based interventions for underserved communities.

8:00 AM-9:15 AM

SOCIAL AND STRUCTURAL DETERMINANTS OF ALCOHOL AND DRUG USE AMONG RACIALLY AND ETHNICALLY DIVERSE SEXUAL AND GENDER MINORITIES

Eric K. Layland, MS¹, Roberto Renteria, MA², Cindy B. Veldhuis, PhD³, Allen J. LeBlanc, PhD⁴¹Pennsylvania State University, University Park, PA; ²Arizona State University, Tempe, AZ; ³Columbia University, New York, NY; ⁴San Francisco State University, San Francisco, CA

Alcohol and other drug use disparities among sexual and gender minorities (SGM) are attributable, in part, to diverse forms of social and structural stigma and stress. SGM are a heterogeneous population; using an intersectional perspective to consider the health impact of unique stressors allows researchers to identify unique mechanisms underlying disparities and identify potential points of intervention.

SGM of diverse racial and ethnic backgrounds may face additional stress related to their race/ethnicity and unique stigma related to the specific intersection of their race/ethnicity and SGM statuses. The research presented in this symposium examines within-group differences in racially and ethnically diverse SGM samples to understand the connections among social and structural stressors and alcohol and drug use.

In the first presentation, the interaction of both social and structural factors contributed to alcohol and drug use behavior among Latino men who have sex with men (LMSM). For LMSM, barriers to health care and a lack of community collective efficacy appear to negate the protective effects of social support. Results from this study highlight the need to consider the structural and social contexts and barriers to health uniquely experienced by LMSM when identifying protective factors and opportunity for intervention.

Second, among women in same-sex/gender relationships, individual- and couple-level stressors may discretely heighten risks for heavy drinking. Results illustrate an association between relational stress and heavy drinking across all couples. However, for women in interracial/interethnic relationships, couple-level rejection and lack of support were associated with heavier drinking. This intersectional approach to minority stress illuminates heterogeneity in the links between stress and drinking. It also uncovers possible points of intervention for women in same-sex/gender couple relationships generally, with specific implications for interracial/interethnic couples.

Finally, for Black and Latino young sexual minority men (BL-YSMM), intersecting experiences of stress, racism, and homonegativity are associated with more severe drug use. Results demonstrate the universal association of stressful events with drug use across racial/ethnic groups. Experiences of and response to discrimination differed by race/ethnicity, and drug use was linked to certain types of discrimination only among B-YSMM. This study suggests a universal intervention target (stressful events) and opportunity for tailored intervention addressing discrimination on among BL-YSMM.

Together these results point to the need for research that recognizes diversity and heterogeneity among SGM and alcohol and drug interventions that are tailored to the needs and experiences of individuals at the intersections of race/ethnicity and sexual and gender identities.

CORRESPONDING AUTHOR: Eric K. Layland, MS, Pennsylvania State University, University Park, PA; elayland@psu.edu

EXPERIENCES AND HEALTH CORRELATES OF DISCRIMINATION ARE NOT UNIVERSAL: STRESS, RACISM, AND HOMONEGATIVITY AS DETERMINANTS OF DRUG USE AMONG DIVERSE SEXUAL MINORITY MEN

Eric K. Layland, MS¹, Bethany Bray, PhD², Michele Kipke, PhD³¹Pennsylvania State University, University Park, PA; ²University of Illinois at Chicago; ³Children's Hospital Los Angeles

Background: For Black and Latino sexual minority young men (BL-YSMM), drug use disparities become especially apparent when minority stress (e.g., stressful life events, racism, homonegativity) is considered. BL-YSMM may experience intersectional discrimination targeting the intersection of their race/ethnicity and sexual identities, however, it remains unclear which minority stressors contribute to drug use specifically and whether these pathways are variant across racial/ethnic groups. Therefore, we investigated associations of stressful events and discrimination with drug use and moderation by race/ethnicity.

Methods: The sample ($n=448$) included Latino (58.9%), Black (21.0%), and Black/Latino (20.1%) YSMM aged 16 to 24. Participants reported number of stressful life events (e.g., family conflict, HIV diagnosis) in the last six months and frequency of discrimination (i.e., sexual and institutional racism, harassment and shaming homonegativity). Race/ethnicity was coded to compare Black and Black/Latino to Latino participants. Modified Poisson regression with robust error variance was used to estimate prevalence rates of past six-month and lifetime use of tobacco, cocaine, poppers, and other drugs.

Results: Stressful life events were associated with prevalence of past six-month use of all drugs (prevalence ratio [PR]: 1.16-1.33). Sexual racism was associated with greater prevalence of six-month poppers use for Black YSMM (PR: 1.92) and lifetime other drug use for Black and Black/Latino YSMM (PR: 1.50-2.35) relative to Latino YSMM. Institutional racism was associated with higher prevalence of lifetime cocaine, poppers, and other drugs use for Latino YSMM only (PR: 1.42-1.57). Shaming homophobia was associated with greater prevalence of six-month and lifetime tobacco use for Black and Black/Latino YSMM (PR: 1.24-2.19) relative to Latino YSMM. Harassment homonegativity was not associated with drug use.

Discussion: Results demonstrate similarities and differences across race/ethnic groups in drug use etiology among BL-YSMM. Stressful life events were associated with greater prevalence of all past six-month drug use across race/ethnic groups. The effects of discrimination varied by race/ethnic group and drug. Thus, unpacking the connection between stigma-related minority stress and drug use requires investigation of differences within populations experiencing health disparities (i.e., YSMM). For example, compared to Latino YSMM, Black YSMM reported lower prevalence of poppers use, yet when they experienced sexual racism, their poppers use exceeded that of Latino YSMM. Researchers must account for subgroup differences when attempting to understand how different types of minority-stressors together contribute to drug use outcomes. Future research should address how BL-YSMM may be differentially targeted by and respond to racism and homonegativity.

SOCIAL DETERMINANTS OF SUBSTANCE USE AMONG LATINO MEN WHO HAVE SEX WITH MEN

Roberto Renteria, MA¹, Sean Spille, MEd², Carolina Lara-Lerma, MA², Frank Dillon, PhD², Austin Eklund, EdM, MS³, Ryan Ebersole, MS³¹Arizona State University, Tempe, AZ; ²Arizona State University; ³University at Albany, State University of New York

Background: Latino men who have sex with men (LMSM) are at higher risk for HIV infection, a risk that is exacerbated by problematic substance use. Little research has focused on structural predictors of substance use. LMSM who report more social support use substances less; yet, it is unclear how this relationship may vary across levels of healthcare access and community collective efficacy. This study investigates whether the link between social support and substance use changes across structural variables (i.e. access to healthcare and collective efficacy). First, we tested the association of perceived social support and substance use, and then tested access to healthcare and collective efficacy as moderators.

Methods: Participants were Latino men who endorsed having sex with men in the previous 12 months (N=493). Predictors included access to healthcare, collective efficacy, and perceived social support. Outcomes included the Alcohol Use Disorders Identification Test and the Drug Use Frequency measure. A hierarchical regression analysis examined the association between perceived social support and problematic substance use. Interaction terms were created to test access to healthcare and collective efficacy as moderators in predicting substance use. All analyses adjusted for income, age, marital status, and race.

Results: Findings supported that higher perceived social support was associated with lower problematic alcohol use ($\beta=-0.4$) and lower frequency illicit drug use ($\beta=-0.3$). Both access to healthcare ($\beta=0.2$) and collective efficacy ($\beta=0.3$) were positively related to problematic alcohol use. Only access to healthcare ($\beta=0.3$) predicted more frequent illicit drug use. Both access to healthcare and collective efficacy moderated the relationship between social support and each substance use outcome such that this association was stronger among those who reported higher levels of access to healthcare and higher levels of collective efficacy.

Conclusions: Social support has been suggested to be a negative predictor of substance use; however, these results demonstrate that this link is not present among all LMSM. Social support did not predict reduced problematic substance use among those reporting lower access to healthcare and lower collective efficacy. Results suggest LMSM reporting higher access to these resources yet low social support may be particularly vulnerable to problematic substance use.

3

8:00 AM-9:15 AM

UNDERSTANDING LINKS BETWEEN STRESS AND HEAVY DRINKING AMONG QUEER WOMEN IN INTERRACIAL/INTERETHNIC INTIMATE RELATIONSHIPS

Cindy B. Veldhuis, PhD¹¹Columbia University, New York, NY

Background: Queer women (e.g., lesbian, bisexual, queer, trans/nonbinary) face unique stressors related to their marginalized status (i.e., minority stress). Little research has examined stress and alcohol use within same-sex/gender interracial/interethnic (IRIE) couples, however differential marginalization and privilege may add additional stress which may, in turn, increase risks for heavy drinking. Using an intersectional framework, we examine the associations between individual- and couple-level stressors on alcohol use in these relationships.

Methods: Data come from the SOQIR study, a study of diverse women in same-sex/gender relationships living in the NYC area recruited for an online survey (N=215). The online survey included questions about relationship quality, individual- and couple-level minority stressors, and alcohol use.

Results: Findings suggest significant differences in the associations between stressors and heavy drinking comparing IRIE and monoracial couples. In terms of individual-level minority stressors, higher levels of adult stress ($aOR1.10$) and stress related to race/ethnicity ($aOR1.28$) were associated with higher odds for heavy drinking. There were no differences comparing IRIE and monoracial couples in these associations. In examining couple-level minority stressors, we found that couple-level discrimination ($aOR1.07$) was associated with higher odds of heavy drinking. There were significant interactions between relationship type and couple-level rejection ($aOR1.10$) and couple-level support ($aOR1.22$) on heavy drinking. Follow up comparisons indicate that women in IRIE couple relationships who are heavy drinkers report significantly higher levels of couple-level rejection and a higher lack of couple-level support compared to their light drinking counterparts, and to heavy drinking women in monoracial relationships. Higher levels of relationship stress were associated with higher odds of heavy drinking ($aOR1.20$); the interaction between relationship stress and relationship type was not significant.

Conclusions: In the U.S., almost half of queer women are in cohabiting/married relationships, but little research has focused on these relationships. Far less well understood are the stressors and strains on queer women's IRIE relationships. We found multiple stressors, such as relationship stress, that may increase heavy drinking risks for all queer women. Our findings also suggest unique stressors (couple-level rejection and lack of support) that may disproportionately increase risks among women in IRIE relationships. Our findings highlight important areas for couple-level interventions.

Symposium 72

8:00 AM-9:15 AM

8:00 AM-9:15 AM

MOVING THE FIELD OF PATIENT NAVIGATION FORWARD:
INCREASING RIGOR, INNOVATION, AND SUSTAINABILITYKristen J. Wells, PhD, MPH¹, Patricia A. Valverde, PhD MPH², Elizabeth Calhoun, MEd PhD³, Andrea J. Dwyer, BS⁴, Tracy A. Battaglia, MD MPH⁵¹San Diego State University, San Diego, CA; ²Colorado School of Public Health, Aurora, CO; ³University of Arizona, Tucson, AZ; ⁴The University of Colorado Cancer Center, Aurora, CO; ⁵Boston University School of Medicine/Boston Medical Center, Boston, MA

Patient navigation is an intervention model that aims to reduce barriers to obtaining recommended health care in a timely manner and to reduce cancer-related disparities. Since its origins in the 1990s, patient navigation has demonstrated efficacy in improving multiple types of cancer care, especially in the early detection of cancer. As a result, patient navigation has been integrated into oncology standards of care, leading to widespread implementation of the intervention model across the United States. While the model has been implemented in community organizations and healthcare settings across the country, navigation programs can be difficult to sustain, especially in lower resource settings. Patient navigation delivered by lay patient navigators is especially at risk to being unsustainable as a result of disruption in funding because of the difficulty of obtaining insurance or other reimbursement for navigation services. Therefore, there is a significant need to use better understand the implementation of patient navigation programs in the United States and identify innovative approaches to maximize efficiency and sustainability. This transdisciplinary symposium will examine cross-cutting issues related to the implementation of patient navigation and will include perspectives from the fields of public health, medicine, and psychology. Through three presentations, the symposium will examine: 1) the potential of the role of technology to enhance patient navigation effectiveness and efficiency; 2) the current organizational use of patient navigation metrics in the United States and the potential for improving the delivery of navigation with better use of metrics; and 3) the critical need for patient navigation programs to plan for sustainability. A brief overview of cross-cutting issues and the overall importance of the session from a national perspective will be provided by the chair. This symposium aims to identify gaps related to sustainability of patient navigation programs and provide ideas for novel solutions which can be examined through additional research.

CORRESPONDING AUTHOR: Elizabeth Calhoun, MEd PhD, University of Arizona, Tucson, AZ; ecalhoun@email.arizona.edu

A FEASIBILITY STUDY COMPARING PATIENT NAVIGATION WITH
AND WITHOUT A SPANISH LANGUAGE CERVICAL CANCER EDU-
CATION TABLET APPKristen J. Wells, PhD, MPH¹, Laura Barnes, PhD², Gloria Arroyo, GED³, Sanjana Mendu, BS², Patricia Medina-Ramirez, MPH⁴, Janna R. Gordon, M.S.⁵, Sara Proctor, PA⁶¹San Diego State University, San Diego, CA; ²University of Virginia; ³Bay Care Faith Community Nursing; ⁴University of South Florida; ⁵SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; ⁶Catholic Mobile Medical Services, Dover, FL

Latinas in the US are more likely to be diagnosed with and die from cervical cancer than non-Hispanic white women. Patient navigation (PN) improves receipt of cervical cancer screening, but providing education about human papillomavirus (HPV) and cervical cancer is time consuming. We developed a tablet application (virtual patient educator [VPE]) to provide comprehensive cervical cancer and HPV education in Spanish. This randomized controlled trial examined feasibility of a study comparing PN alone to PN+VPE. Using convenience sampling, we recruited 64 Spanish-speaking Latinas (mean age: 41.3 years; mean education: 5.4 years) in need of cervical cancer screening according to the American College of Obstetricians and Gynecologists guidelines from two faith-based clinics in rural Florida. Participants were randomized to PN (n = 33) or PN+VPE (n = 31). A trained bilingual and bicultural lay patient navigator with more than three years of PN experience provided navigation in both study conditions. A bilingual research assistant collected survey data orally at baseline and 2-week follow-up using validated scales (Pap Test Beliefs and Cervical Cancer Screening Self-Efficacy scales) as well as questions from the Health Information National Trends Survey (HINTS; HPV knowledge). VPE acceptance was measured immediately after VPE use via 22 items of the Unified Theory of Acceptance and Use of Technology (UTAUT) questionnaire. The Patient Satisfaction with Cancer-related Care (PSCC) scale was administered at 2-week follow-up. Medical records were reviewed at 6 weeks to assess receipt of Pap test. Fisher's exact test compared receipt of Pap test at follow-up between PN+VPE and PN. Findings indicated high VPE acceptability, high satisfaction with cancer care in both groups, increased knowledge regarding HPV in both groups (PN: change from 39% to 50%; PN+VPE: change from 39% to 57%), and a trend towards higher receipt of Pap tests in PN+VPE (97%) compared to PN alone (85%; $p = .11$). While recruitment and randomization were feasible, follow-up survey data collection at 2-weeks was not; only 58% had completed follow-up surveys by 2 weeks whereas 90% had completed them by 1 month. Data collection using some HINTS questions and the Pap Test Beliefs and Cervical Cancer Self-Efficacy scales was also not feasible for various reasons, including high negative skewness (self-efficacy), low difficulty (beliefs), low variability (beliefs), and difficulty scoring the measure as planned (beliefs and HINTS). Findings from this study indicate the VPE is a feasible and acceptable addition to PN and may improve HPV knowledge and rapid receipt of cervical cancer screening. New approaches to data collection should be used in a future larger scale study examining whether use of the VPE improves PN efficiency and reduces PN costs.

2

8:00 AM-9:15 AM

A NATIONAL SURVEY OF THE USE OF ONCOLOGY PATIENT NAVIGATION METRICS AND REPORTING IN THE UNITED STATES

Patricia A. Valverde, PhD MPH¹, Elizabeth Calhoun, MEd PhD², Andrea J. Dwyer, BS³, Kristen J. Wells, PhD, MPH⁴¹Colorado School of Public Health, Aurora, CO; ²University of Arizona, Tucson, AZ; ³The University of Colorado Cancer Center, Aurora, CO; ⁴San Diego State University, San Diego, CA

Patient navigation (PN) is being implemented across the country, but it is not clear how the process of navigation delivery and outcomes of PN are being measured in oncology settings. The American Cancer Society Evidence Based Promising Practices Task Group of the National Navigation Roundtable (NNRT) collaborated with the Statistics & Evaluation Center to administer a web-based survey to member organizations and individuals across the US to identify challenges, successes, barriers, and facilitators to implementation of oncology PN metrics. This study was designed to: 1) gather information regarding approaches that navigators and program administrators use to track outcomes of PN; and 2) identify additional tools and resources needed by patient navigators and PN programs to support their work. The 15-minute survey was administered online, using a web-based, open link format. This link was distributed to member organizations to share with individuals involved in PN. The survey was open from April 17, 2019 to July 3, 2019, and 750 completed surveys were received. Participants represented organizations in all 50 states and Puerto Rico. Of the 750 respondents, 223 (30%) were administrators or supervisors of PN programs. Eighty-two percent report being funded through institutional funds. Seventy-five percent participate in the Commission on Cancer, while only 14% participate in the Centers for Medicare & Medicaid Services (CMS) Oncology Care Model. A total of 538 organizations report collecting metrics, with 77% collecting patient-level data, but only 22% collecting financial or operational data, such as ER visits and unplanned hospitalizations. In examining whether certain organizational characteristics were more strongly associated with systematic measurement of navigator productivity, we found organizations that participate in an external program (i.e., CMS's Oncology Care Model) are more likely to systematically track and report population-level care measures. This is unsurprising given that data collection and reporting is a requirement of many of these programs. However, we also found that organizations under-utilize information they are required to collect (i.e. it is used to report to funders and programs but less frequently to inform internal and/or patient operations). Participants also reported barriers to collecting metrics. In conclusion, in our nationwide study, most organizations with PN programs are collecting patient-level data, and most use these data for reporting to external programs, but not always for internal programmatic purposes. There is an opportunity for organizations to better understand and potentially improve their PN programs using metrics and further the field's understanding of PN implementation. Finally, lay PN program sustainability depends in a large part on metrics and participating in reimbursement models that can support their work.

3

8:00 AM-9:15 AM

PLANNING FOR SUSTAINABILITY FOR PATIENT NAVIGATION FOR PREVENTING CANCER SCREENING IN A STATEWIDE PROGRAM: A FRAMEWORK FOR SUSTAINABILITY

Andrea J. Dwyer, BS¹¹The University of Colorado Cancer Center, Aurora, CO

Background: Recent publications speak to increased utilization of patient navigation and favorable impact on patient outcomes but also speak to the needs of reimbursement, implementation, maintenance, and sustainability of these programs, specifically for lay navigators. An estimated 40% of all new public health interventions do not last beyond a year or two after the end of initial funding. The high costs of program termination further highlight the need to understand which factors contribute to sustainability and how they can be measured and improved.

Methods: To address this specific issue, the University of Colorado Cancer Center, with initial funding from the American Cancer Society, developed a toolkit, curriculum and an online platform to help those working in colorectal cancer screening and prevention implement sustainability planning approaches. This framework adapts the Program Sustainability and Assessment Tool, developed by Washington University in St. Louis for use in clinical and community settings and endorsed by the Centers for Disease Control and Prevention. Currently, the Colorado Cancer Screening Program (CCSP) for Patient Navigation, of the University of Colorado Cancer Center and funded by the Cancer Cardiovascular and Pulmonary Disease Program, is implementing this curriculum with 25 safety net clinic systems in Colorado, in anticipation of a ten-year grant cycle ending in 2021. Systems are scored on a 1 (lowest) to 7 (highest) scale around the domains of: Engaging Staff and Leadership; Organization Context & Capacity; Funding Stability; Engaged Community; Communication, Planning & Implementation; Workflow Integration; and Monitoring and Evaluation.

Results: The assessments and goal planning process have been fully implemented in 15 systems, including the onboarding of 10 systems this current fiscal year. Based on results available from the first group of five clinic systems, two-thirds of clinic systems have identified Funding Stability as one of their priorities for navigation sustainability; however, Workflow Integration and Outcomes and Effectiveness were identified at the same level of priority, confirming the notion that sustainability is much broader than only funding. Goal setting is established based on system priority domains, and the program staff for CCSP are providing technical assistance to help ensure sustainability of the navigator position post grant funding; the program planners and advocates are also utilizing data from this process to inform state level policies to support the role of the patient navigator in the safety net settings of Colorado.

Conclusion: Sustainability planning is necessary to ensure efforts continue after grant and foundational supports are depleted. A deliberate approach with dedicated resources and commitment to ensure sustainability must be implemented well before the end of the grant funding cycles.

8:00 AM-9:15 AM

IMPROVING ACCESS TO BEHAVIORAL INTERVENTIONS FOR VETERANS WITH CHRONIC PAIN: FROM OPPORTUNITIES IN PRIMARY CARE TO TELEHEALTH

Carrie A. Bronars, PhD¹, Jessica A. Chen, PhD², Haley Crowl, Psy.D.³, Una E. Makris, MD, MSc⁴, Robert Kerns, PhD⁵

¹Minneapolis, Minneapolis, MN; ²University of Washington, Seattle, WA; ³Veterans Health Administration, Minneapolis, MN; ⁴UT Southwestern Medical Center, Dallas VA, Dallas, TX; ⁵Yale, New Haven, CT

Chronic pain is a wide-reaching health concern that affects individuals, their families and communities. People with chronic pain are more likely to experience negative consequences related to pain, including reduced functionality, poor sleep, comorbid mental health issues, limited participation in valued activities, lost work productivity, and reduced quality of life. Veterans are disproportionately more likely to experience chronic pain compared to the general population, with 9.1% of veterans reporting severe pain compared to 6.3% among non-veterans. Further, approximately 40 to 60% veterans seen in primary care report experiencing chronic pain to their provider.

Evidence-based treatments for chronic pain emphasize the role of a biopsychosocial approach to care that endorses self-management skills and non-pharmacological options for the management of chronic pain. Unfortunately, individuals experiencing chronic pain may note significant barriers to participating in these therapeutic approaches. As a step towards increasing access, the proposed symposium highlights innovative approaches aimed to enhance treatment engagement through intervention delivery, ease of care availability, and promotion of self-efficacy for behavioral skills. Our first presenter will share rational and preliminary findings from a novel approach that seeks to connect older veterans with comorbid chronic back pain and depression to telephone coaching. These coaching calls are designed to encourage physical activity, thus ultimately improving function, mood, and pain among veterans with limited mobility, often living in rural areas. The second presentation describes rural-urban disparities in receipt of pain care in VA and the development of a hub-and-spoke telehealth model for delivering behavioral interventions for chronic pain to rural VA community outpatient clinics in four states in the Northwest. The third presentation will share data from pre-post study examining the effectiveness of an 8-week Acceptance and Commitment –based group intervention for chronic pain tailored to veterans seen in primary care. The final presentation will discuss pilot data from a program evaluation project assessing the efficacy of a team-based approach to care for veterans with complex chronic pain struggling to engage in rehabilitation efforts.

Combined these studies demonstrate the ability to provide care regardless of geographic location, availability of services, and cost of care by removing barriers that may limit participation in effective treatments for pain. Additionally, through the use of multiple treatment modalities (e.g., telephone, telehealth, groups, and teams) much needed care can be offered to a wider audience. This symposium will help disseminate approaches that improve access and reach of treatment options that may help reduce the burden of pain and improve quality of life.

CORRESPONDING AUTHOR: Carrie A. Bronars, PhD, Minneapolis, Minneapolis, MN; carrie.bronars@va.gov

HELPING VETERANS WITH COMPLEX CHRONIC PAIN ENGAGE IN TREATMENT USING A COLLABORATIVE, TEAM-BASED APPROACH IN PRIMARY CARE

Carrie A. Bronars, PhD¹, Carolyn Buesgens, NP², Elzie Jones, PharmD³, Ashley Fike, PharmD³

¹Minneapolis, Minneapolis, MN; ²Minneapolis VA Health Care System; ³Minneapolis VA Health Care System

Evidence based treatments for patients with chronic pain entails participation in active, self-management strategies and care coordination with an interdisciplinary pain team. Unfortunately, chronic pain patients often do not have these resources easily accessible to them or are reluctant to try these services. Further, primary care providers are tasked with the enormous responsibility of helping patients manage their chronic pain as well as treat their other medical conditions. In an effort to support both the veteran and their provider, development of an interdisciplinary team, embedded within primary care, was created to partner with both parties to offer comprehensive care for individuals with chronic pain. The team consists of the veteran and their support person (if available) as well as a nurse practitioner, pharmacist, and psychologist who work together to develop individualized treatment goals that encourage active self-management skills for pain. Further, the team assumes pain care for the patient which affords primary care providers much needed time to address other patient concerns.

Program evaluation project concerning the effectiveness of this team approach is currently underway. A total of 14 veterans have agreed to work with the team thus far, and recruitment for additional participants are being sought out in primary care clinics in a VA hospital as well as several affiliated community clinics. The initial sample of patients are predominately male (100%), white/non-Hispanic (100%) between the ages of 47 and 71. A majority of the sample reported experiencing multiple pain conditions, such as back (100%), neck (57.1%), knee (63.4%), and neuropathic (50%) for an average of 17 years (SD=10). Morphine equivalent dose for these patients ranged from 0 to 480 mg. Approximately, 78.5% of the sample has been diagnosed with a mental health condition.

Outcomes are assessed using a self-report measures related to physical functioning (PROMIS-Pain Interference 6b), self-efficacy for pain management (Pain-Self Efficacy Questionnaire), degree of pain catastrophizing (Pain Catastrophizing Scale), and distress (9-item Patient Health Questionnaire, 7-item Generalized Anxiety Disorder Scale) at baseline, visit 3 and visit 6. At baseline, the sample of veterans endorsed limitations due to pain (T-score M=66.3; SD=3.2), pain catastrophizing (M=29.5, SD=12.0), and low self-efficacy for pain management (M=22.5, SD=11.8) in addition to moderate symptoms of depression (M=14.5, SD=6.5) and anxiety (M=10.1, SD=6.3). Preliminary findings suggest patients are open to participating in this program. Additionally, participants sampled noted difficulties in managing their chronic pain as evidenced by their self-report. Challenges for implementation of this team-approach in primary care will be reviewed as well as future directions and next steps for extending these services.

8:00 AM-9:15 AM

USING TELEHEALTH TO BRING BEHAVIORAL TREATMENTS FOR CHRONIC PAIN TO RURAL VA CLINICS

Jessica A. Chen, PhD¹, Hannah Gelman, PhD², Lisa Glynn, PhD³, Timothy Dawson, MD³, Steven B. Zeliadt, PhD⁴

¹University of Washington, Seattle, WA; ²VA Center of Innovation for Veteran-Centered and Value-Driven Care; ³VA Puget Sound Health Care System; ⁴VA Center of Innovation for Patient-Centered and Value-Driven Care, Seattle, WA

Chronic pain is a common and costly problem, especially among veterans (Nahan, 2017; Gaskin & Richard, 2012). Patients who reside rurally report greater functional impairment associated with pain (Goode et al., 2013), less access to behavioral interventions for chronic pain (Heapy et al., 2017), and higher rates of opioid prescribing (Garcia et al., 2019) than their urban counterparts.

To address rural-urban disparities in pain care, VA Puget Sound Healthcare System launched a pain telehealth pilot program in 2016. The pilot program utilized existing resources (i.e., staff and equipment) to add videoconferencing capability to existing, in-person behavioral offerings for chronic pain, such as pain education classes and cognitive-behavioral therapy groups.

The pilot telehealth program successfully delivered over 1,300 visits to 618 unique patients over a two-year period, suggesting that videoconferencing-based telehealth was a feasible and acceptable delivery method for behavioral chronic pain services. However, this represented only a 0.2% increase in the reach of specialty pain services to rural veterans with chronic pain. In contrast, during the same time period, there was a significant ($p < .001$) 2.3% increase in the reach of specialty pain services among urban veterans in the same healthcare system. These pilot findings suggest that adding telehealth capability to existing offerings alone may not be sufficient for increasing the reach of specialty pain services to rural veterans, and that rural VA patients lag behind urban VA patients in receipt of pain care.

The focus on this talk is on a regional initiative launched by the VA Northwest Network (“VISN 20”) and VA Puget Sound Healthcare System to better expand pain care to rural veterans. We will describe an expanded, telehealth-only clinical program, TelePain, that delivers biopsychosocial chronic pain care through videoconferencing to rural VA clinics in a four-state region (Alaska, Washington, Oregon, and Idaho) utilizing a hub and spoke telehealth model. We will also describe a one-year implementation study that involves collaboration between VA implementation researchers and the TelePain clinical program. The study will utilize an evidence-based strategy, implementation facilitation, to enhance the uptake of TelePain at three initial test sites and evaluate outcomes and costs associated with implementation.

3

8:00 AM-9:15 AM

IMPORTANCE OF ACCESSIBILITY TO BEHAVIORAL INTERVENTIONS IN PRIMARY CARE AND CONSIDERATIONS FOR GROUP INTERVENTION DEVELOPMENT

Haley Crowl, Psy.D.¹

¹Veterans Health Administration, Minneapolis, MN

Between half and three-quarters of veterans receiving primary care through the Veterans Health Administration (VHA) report chronic and persistent pain (Haskell et al., 2006; Kerns et al., 2003); effective patient-centered care requires convenient access to effective pain treatments in the medical center. Behavioral interventions, such as Acceptance and Commitment Therapy (ACT) have shown promise as treatments for chronic pain (Veehof et al., 2016). Unfortunately, when these evidence-based treatments are only offered in pain centers, many veterans may lack access due to limited availability of such services and a lack of need for intensive pain center care. In an effort to provide services that are easily accessible to veterans, authors developed an 8-week Acceptance and Commitment Therapy (ACT)-based group intervention for primary care patients with chronic pain that has few exclusions and a straightforward referral process.

Despite reports of ongoing pain being a problem for a significant number of women veterans (Haskell et al., 2006), few women veterans participated in the intervention. Consultation with referring providers in mental health and primary care revealed that many women veterans declined because they did not feel comfortable participating in a group with men. As a way to increase access for women veterans and promote VHA directives to increase alternative options to mixed gender groups (VHA Directive 1330.01, Health Care Services for Women Veterans), group facilitators also began offering a women-only group with the same content material as presented in the general group. This group has been well-received by women veterans as seen in the number of referrals for female veterans.

A quality improvement project assessing the feasibility and accessibility of these groups is currently underway. Initial results suggest improvement in activity engagement, lower pain interference, improved mood, and reduced anxiety symptoms. Additionally, 41.7% of the entire sample is women, which is notable given the lack of data regarding women in research studies (Huang et al., 2019). Feedback from veterans in the women-only group was gathered using the “Start, Keep, Stop” method, and women specifically requested the continuation of the women-only group. An easily accessible ACT-based primary care group appears to have positive outcomes for all veterans, and offering a women-only group improved participation for women veterans. The author intends to review strategies for developing group content, challenges for care implementation, importance of accessibility in primary care, and considerations for female veterans.

8:00 AM-9:15 AM

DEVELOPING A NOVEL TELEPHONE DELIVERED BEHAVIORAL INTERVENTION FOR OLDER VETERANS WITH COMORBID CHRONIC BACK PAIN AND DEPRESSION: MOVING IN THE HOME

Una E. Makris, MD, MSc¹, Ailing Yang, BS², W. Cheng Yuet, PharmD³, LaDonna Saxon, PhD⁴, Liana Fraenkel, MD⁵, James LePage, PhD⁶¹UT Southwestern Medical Center, Dallas VA, Dallas, TX; ²UT Southwestern Medical Center; ³UNTHSC; ⁴Dallas VAMC, Dallas, TX; ⁵Yale, New Haven, CT; ⁶Dallas VAMC

'Moving to Improve Chronic Back Pain and Depression in Older Adults' (MOTIVATE) is a novel 8-session, 12-week, telephonic behavioral intervention targeting older adults with chronic low back pain (cLBP) and depression. Telephone delivery of this behavioral intervention is ideal especially since older adults with cLBP are often mobility limited, and many veterans live in rural areas far from community based outpatient clinics. To improve back pain-related disability and depression, a health coach utilizes motivational interviewing and goal setting to increase physical activity. Following a single-arm roll-out of MOTIVATE, we conducted interviews with stakeholders to refine its content and our procedures.

The PARiHS (Promoting Action on Research Implementation in Health Services) framework was used to develop the discussion guide and facilitate interviews with Veterans who received MOTIVATE, primary care providers (PCP), clinic directors, and a health coach. This pilot study enrolled 8 Veterans who were predominately white (75%), male (87%), with a mean age of 70 years. The mean pain intensity score was 7.3/10; back pain-specific Roland Morris Disability score was 16.5/24; and depression (PHQ-9) score was 16.7/27. Stakeholders provided valuable feedback on how to modify MOTIVATE. Veterans engaged well with the health coach, were motivated to walk with a pedometer, and felt that being more active reduced pain and depression. PCPs attribute success of the intervention to the personal qualities and engagement of the health coach. Interviews also suggested how elicited values and goals identified by the veteran can be useful to PCP and entered into the electronic medical record to assist in the management of other chronic medical conditions. The health coach noted that Veterans were able to link value concordant goals to physical activities. The MI component, used by the coach, was critical to help participants achieve a readiness to change in order to effectively set goals linked to values and work on the action plans in between sessions. Participants who were hospitalized for other comorbid conditions, had social stressors, or were not motivated or ready for change struggled to complete between-session activities and goals. Flexibility to conduct the intervention over the phone, in the home, was particularly appealing for Veterans living over 50 miles from the nearest facility.

This pilot study showed that we were able to effectively recruit older Veterans with cLBP and depression and deliver MOTIVATE via telephone. Feedback from stakeholders regarding the iterative refinement of recruitment, study procedures, and content will aid the future evaluation and implementation of MOTIVATE.

Symposium 74

8:00 AM-9:15 AM

APPLYING ECOLOGICAL MOMENTARY ASSESSMENT AND DAILY DIARY METHODS TO UNDERSTAND PARENT-CHILD DYADIC INFLUENCES ON HEALTH

Chih-Hsiang Yang, PhD¹, Nanette Lopez, PhD, MS/MS², Sydney G. O'Connor, PhD³, Christine H. Naya, MPH⁴, Kirsten Davison, PhD⁵¹University of South Carolina, Los Angeles, CA; ²Northern Arizona University, Flagstaff, AZ; ³National Institutes of Health, Washington, DC; ⁴University of Southern California, Pasadena, CA; ⁵Boston College, Chestnut Hill, MA

Health behaviors established in childhood have a profound influence on disease susceptibility later in life. In everyday family contexts, parents' health-related parenting practices and their psychological states may play a role in shaping children's health behaviors. Evidence suggests that children's physical activity, dietary intake, and sleep patterns can be explained by levels of parenting support and parental stress. On the other hand, children's stress levels may also impact parents' health outcomes. An individual's health behaviors thus cannot be fully explained in isolation without considering other family members' behavioral or psychological influences. Previous cross-sectional studies have demonstrated parental influence on children's health or the reciprocal influence between parents and children. Few studies to date have used intensive longitudinal designs to investigate how these associations may unfold at the day level or within-day level. Real-time data capture (RTDC) approaches, including ecological momentary assessment (EMA) and daily diary methods can capture behaviors and experiences in naturalistic settings overtime to uncover the micro-temporal interpersonal interplay between parents' and children's health. The three presentations in this symposium applied EMA and daily diary methods to investigate within-day and day-to-day coupling in stress, dietary behavior, and sleep quality in parent (father or mother)-child dyads. The first presentation examines whether there are between-person and within-person effects of father's encouragement and preparation of fruit and/or vegetable behaviors on their child's daily fruit and/or vegetable consumption across one week. The second presentation applies the actor-partner interdependence model (APIM) to understand whether there are interdependencies of stress and sleep health among mother-child dyads at the day level across six measurement waves (three years). The third presentation investigates the synchrony of both day-level perceived stress and the stress hormone, salivary cortisol, in mother-child dyads across four days. Collectively, the three presentations uncover the daily interpersonal influences between parents' and children's health. Collecting dyadic EMA and daily diary data is time and resource-demanding, and it requires special consideration in modeling nested intercorrelated data. However, applying RTDC methods in family dyads can advance our knowledge in understanding health behaviors occurring in family context which, in turn, provides valuable insights for promoting and sustaining healthy lifestyles within families.

DADS MATTER! THE ASSOCIATION OF EVERYDAY PATERNAL DIETARY-RELATED PARENTING PRACTICES WITH CHILDREN'S FRUIT AND VEGETABLE CONSUMPTION

Nanette Lopez, PhD, MS/MS¹, Chih-Hsiang Yang, PhD², Bridgette Do, MPH³, Genevieve F. Dunton, PhD, MPH⁴, Britni Belcher, PhD⁴

¹Northern Arizona University, Flagstaff, AZ; ²University of South Carolina, Los Angeles, CA; ³University of Southern California, Santa Monica, CA; ⁴University of Southern California, Los Angeles, CA

Failure to assess how fathers' dietary-related parenting practices contribute to children's obesogenic behaviors leaves a gap in understanding the etiology of childhood obesity. Examining within-day variability in fathers' dietary-related parenting practices may be critical to understanding how fathers' daily behaviors and fathering roles may affect their children's diet. In this study, ecological momentary assessment (EMA) methods with real-time mobile surveys were used to examine the between-subject (BS) and within-subject (WS) effects of paternal encouragement and preparation of fruit and/or vegetables (F/V) on their child's daily F/V consumption. Fathers ($n=37$, $M_{age}=34.7\pm17.0$ years) and their children ($M_{age}=12.0\pm1.0$ years, 55.6% female) completed one 7-day EMA, with up to four random prompts on weekdays and eight random prompts on weekends. Fathers reported if they had encouraged their child to eat F/V and if they had prepared or cooked F/V for their child over the previous two hours. Children reported if they consumed any F/V over the previous two hours. After controlling for temporal factors including time of day and weekend (vs weekday), results from multilevel logistic models indicated that in the WS level, greater paternal encouragement for F/Vs ($OR = 2.10$, $p < 0.05$) and paternal preparation of F/Vs ($OR = 2.44$, $p < 0.05$) were associated with greater child report of eating F/Vs. No associations were significant in the BS level. Results from this study support the positive within-person coupling between fathers' dietary-related parenting practices and children's F/V consumption. Future studies should explore the long-term effects of fathers' dietary parenting practices on their children's diets and obesity risk.

8:00 AM-9:15 AM

DAILY ASSOCIATIONS OF PERCEIVED STRESS AND EXTERNAL STRESSORS WITH SLEEP HEALTH IN MOTHER-CHILD DYADS

Sydney G. O'Connor, PhD¹, Yue Liao, MPH, PhD², Tyler B. Mason, PhD³, Britni Belcher, PhD³, Jimi Huh, PhD³, Susan Redline, MD⁴, Genevieve F. Dunton, PhD, MPH³

¹National Institutes of Health, Washington, DC; ²The University of Texas MD Anderson Cancer Center, Houston, TX; ³University of Southern California, Los Angeles, CA; ⁴Brigham and Women's Hospital, Boston, MA

Background: Adequate sleep is essential for health and well-being, and elevated stress may lead to sub-optimal sleep health. Mothers' and their children's dyadic external stressor experiences and subjective stress appraisal may have implications for not only their own sleep but also the sleep health of one another. This study used ecological momentary assessment (EMA) to examine the daily dyadic effects of stress on self-reported sleep health in mother-child dyads.

Methods: Data are from a longitudinal study of mothers and their 8-12-year-old children. Dyads completed up to six semi-annual week-long assessments using an EMA smartphone application to self-report on past two-hour perceived stress and external stressors (e.g., "tension with coworker" [mother]; "having a lot of homework to do" [child]) throughout the day as well as nightly sleep health (i.e., quality, duration). The Actor-Partner Interdependence Model framework was used to examine the daily (i.e., within-subjects; WS) and usual (i.e., between-subjects; BS) associations of external stressors and perceived stress with each dyad member's own nightly sleep (i.e., actor effects), as well as the nightly sleep of the other dyad member (i.e., partner effects), controlling for design variables and potential confounders.

Results: The analytical sample consisted of 194 dyads with 7,592 observation days (mean: 39 days/dyad). At the BS level, mothers of children who experienced a greater number of external stressors than their peers reported shorter sleep duration, on average ($b = -21.54$, $p < 0.05$). At the WS level, days with higher than usual perceived stress predicted lower sleep quality that night for both mothers ($b = -0.06$, $p < 0.01$) and children ($b = -0.08$, $p < 0.05$). Additionally, there were WS partner effects such that on days when a mother experienced greater than her own usual number of external stressors, the child had shorter than usual sleep duration that night ($b = -5.85$, $p < 0.01$), and on days when a child experienced greater than their own usual number of external stressors, the child's mother had lower sleep quality that night ($b = -0.05$, $p < 0.05$).

Conclusion: This study revealed interdependencies of stress and sleep health among mother-child dyads, in which mothers' and children's sleep health was negatively impacted by both individual and partner's stress experience. The larger family unit should be considered in behavioral interventions seeking to reduce stress and improve daily sleep health.

3

8:00 AM-9:15 AM

PSYCHOLOGICAL AND BIOLOGICAL STRESS SYNCHRONY IN MOTHER-CHILD DYADS: EFFECT MODIFICATION BY FINANCIAL HARSHIP

Christine H. Naya, MPH¹, Darby Saxbe, PhD², Genevieve F. Dunton, PhD, MPH², Britni Belcher, PhD²¹University of Southern California, Pasadena, CA; ²University of Southern California, Los Angeles, CA

Background: Mother-child synchrony—the reciprocation of shared affect and biology—influences child development and health. However, the familial factors that influence synchrony are still unclear. Lab studies have found greater synchrony in both low- and high-risk families, though “risk” has often been defined as internal challenges to a dyad’s relationship, such as psychopathology and attachment. Few have examined external challenges, such as financial stress (FS), and even fewer have captured the daily fluctuation of stress within families in a real-world setting. Therefore, this study examined the mother-child synchrony of day-level perceived stress (PS) and the stress hormone cortisol and whether this synchrony differed by FS.

Methods: Participants included 160 mother-child dyads from the Mothers and their Children’s Health Study. Each mother (mean age=42.7(±6.0)yrs) and child (mean age=11.3(±1.1)yrs, 56% female) reported PS up to eight times daily for four days via ecological momentary assessment on smartphones. On the same four days, dyads also collected salivary cortisol four times daily from which area under the curve (AUC) was calculated. FS was quantified using a seven-item FS survey questionnaire and dichotomized into High/Low based on the median score. Multilevel models were used to account for clustering of observations within dyads, and variance was partitioned to between- and within-subjects. Models tested the interaction of mothers’ day-level PS and cortisol AUC with FS in predicting children’s same day-level PS and cortisol AUC. Models controlled for day of week, child’s sex, age, race, mother’s marital status, education, and employment.

Results: Significant day-level synchrony was found for PS ($\beta=0.06$, $SE=0.02$, $p<0.01$) and cortisol AUC ($\beta=0.22$, $SE=0.03$, $p<0.01$). The interaction term by FS was significant for cortisol AUC synchrony ($\beta=-0.17$, $SE=0.07$, $p<0.05$), such that there was stronger synchrony in dyads reporting low ($\beta=0.30$, $SE=0.04$, $p<0.01$) vs. high FS ($\beta=0.08$, $SE=0.06$, $p=0.15$). There was not a significant interaction for FS and PS synchrony.

Conclusions: This is one of the few studies to date that has identified stress synchrony in mother-child dyads in a naturalistic setting using both self-reported and physiological measures. Stronger cortisol AUC synchrony in dyads with low FS may suggest the greater emotional and mental bandwidth in these families that allow for more co-regulation of physiological stress. Findings suggest the importance of considering social and financial environment when conducting family-focused stress interventions.

Symposium 75

8:00 AM-9:15 AM

PUTTING PEOPLE FIRST: IMPROVING CHRONIC DISEASE RESEARCH AND CARE VIA PERSON-FIRST LANGUAGE AND PERSON-CENTERED APPROACHES

Michael Stirratt, PhD¹, Janet S. de Moor, PhD, MPH², Deborah Young-Hyman, Ph.D.CDE, FTOS, Fellow SBM³, Jamie L. Studts, PhD⁴, Anna McColister, BA⁵, Rebecca Bartlett Ellis, PhD, RN, ACNS-BC⁶¹NIMH, Bethesda, MD; ²National Cancer Institute, Rockville, MD; ³NIH, Bethesda, MD; ⁴University of Kentucky College of Medicine, Lexington, KY; ⁵VitalCrowd Health/Four Lights Consulting, Washington, DC; ⁶Indiana University School of Nursing at Indianapolis, Indianapolis, IN

This symposium will highlight how person-first and person-centered approaches can strengthen efforts to support patient use of medicines, increase patient engagement in clinical trials, and improve health outcomes in chronic disease. Person-first language prioritizes the individual over their medical condition by naming the person first and their condition second. Since its origin with literature and advocacy around developmental disabilities, person-first language has been adopted in HIV/AIDS research (e.g., “person living with HIV”) and there are increasing moves to adopt and recommend person-first language in other areas of chronic illness (e.g., “person with diabetes” rather than “diabetic.”). Words matter and growing use of person-first language can help reduce stigma, empower individuals, and better attend to the whole person when managing chronic disease. In addition, new methods of involving patients in clinical research are evolving beyond utilizing focus groups and patient advocates to developing innovative crowdsourcing and web-based tools to ensure that patients are engaged as meaningful collaborators in the design and conduct of clinical trials. Concurrently and in parallel, patient-centered approaches have gained traction as important ways to support individuals with chronic illnesses. Patient-centered care seeks to understand the patient’s experiences and perspectives, provide clear information and treatment options to patients, respect patient autonomy and preferences, and focuses on the whole person rather than their disease or symptoms alone. A mix of patient-centered approaches have been advanced, including models of shared decision making and collaborative care. What is the evidence for their impact and value for improving chronic disease management? This symposium will seek to outline the mechanisms through which person-first language, novel methods for patient engagement in research, and person-centered approaches may improve behavioral medicine research, facilitate better health care and ultimately increase our impact on health outcomes.

The symposium will consist of four presentations (below), followed by brief comments from a discussant.

- Person-centered language facilitates shared decision making and desired outcomes in diabetes care
- The importance of patient-driven research design
- Shared-decision making and evidence for its impact on patient-centered health outcomes
- Advancing person-centered, minimally disruptive medicine

PERSON CENTERED LANGUAGE FACILITATES SHARED DECISION MAKING AND DESIRED OUTCOMES IN DIABETES CARE

Deborah Young-Hyman, Ph.D.CDE, FTOS, Fellow SBM¹¹NIH, Bethesda, MD

A model of person-based language and shared decision making treatment paradigms in diabetes care will be presented. The mechanisms by which this improves medical outcomes and wellbeing will be summarized from the extant literature. Suggestions for facilitation and overcoming barriers to implementation will be addressed. In addition, the presentation will address how this paradigm for care changes system issues for medical care and reimbursement.

8:00 AM-9:15 AM

SHARED-DECISION MAKING AND EVIDENCE FOR ITS IMPACT ON PATIENT-CENTERED HEALTH OUTCOMES

Mary C. Politi, PhD¹¹Washington University in St Louis, School of Medicine, St Louis, MO

Shared decision making provides a model for patients and their clinicians to engage in a deliberative, communicative process about health decisions in which there is no clear best option from an evidence standpoint. There is an increasing expectation, both nationally and internationally, that patients will be significant partners in decisions about their health. Therefore, it is critical to better understand the state of the science of shared decision making and how it impacts patient-centered outcomes.

8:00 AM-9:15 AM

THE IMPORTANCE OF PATIENT-DRIVEN RESEARCH DESIGN

Anna McCollister, BA¹¹VitalCrowd Health/Four Lights Consulting, Washington, DC

Most clinical research is designed to benefit and convenience of everybody involved in the process but trial participants. The outcomes measured are often chosen because they are easy to collect and conform to the narrow definitions of safety and efficacy as determined by researchers, regulators, payers and sponsors. Clinical visit schedules are based on the typical work day of researchers, without regard to the schedule demands of patients or caregivers, and compensation for participation rarely considers the opportunity costs of participants or the burden the additional time commitment places on people living with complex health conditions. Trials targeting special populations, such as older, more complex or pediatric patients can be even more burdensome, because the burden falls not only on them but on those who care for them. In addition, for researchers and sponsors, the stakes for designing a trial are high, impacting the ability for young researchers to gain funding and get published and for product manufacturers to achieve regulatory approval or pricing and reimbursement that supports business success. Few are willing to take risks with trial design, even if those risks could lead to the development of more meaningful science that is more likely to positively impact patient health and care. For government-sponsored research, even if researchers are willing to take risks and try something novel and the funding agency is willing to support a new approach, grant reviewers may not share the belief that novel approaches are needed, fearing that if they score the grant high and their peers do not that they will lose credibility. As a result, research stagnates. Novelty is punished and the rate of progress in advancing science slows. The consequences for patients of the stagnation can be tragic. This process is fixable. But, how?

Patients, caregivers and community physicians can play an important role in changing the dynamics that create and enforce mediocrity. But, for that to work, the full ecosystem of incentives, work flow and rewards needs to be addressed. For years, we've been tinkering along the margins only to wonder why our results aren't more meaningful. We need platforms and processes for incentivizing and enabling patient-driven design of all aspects of clinical research. The efforts need to be scalable, flexible, replicable and transparent. My presentation will discuss possible models and methods for defining a way forward.

Symposium 76

8:00 AM-9:15 AM

PSYCHOSOCIAL FACTORS LINKED TO PERSISTENT SYMPTOMS FOLLOWING MILD TRAUMATIC BRAIN INJURY

Jonathan Greenberg, PhD¹, Sarah Bannon, MS², Katherine Green, MSc³, Molly Cairncross, Ph.D. Clinical Neuropsychology⁴, Paul R. King, PhD⁴

¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, MA; ³University of British Columbia, Vancouver, BC, Canada; ⁴VA Center for Integrated Healthcare, Buffalo, NY

Mild Traumatic Brain Injuries (mTBIs) are common and costly. Most people demonstrate good recovery from mTBI but persistent symptoms are distressing and disabling.

Recent evidence lends support for a biopsychosocial model of mTBI. To date, predictive models have focused on biological factors, despite evidence that psychosocial variables (e.g., pre-injury mood problems) strongly contribute to the development and maintenance of persistent symptoms and negative health outcomes. Identifying modifiable risk factors is a critical aspect of improving early detection and prevention efforts. This symposium presents several studies of psychosocial risk factors linked to persistent symptoms following mTBI. First, *Katherine Green* will summarize findings from several studies of somatization and its relationship to persistent mTBI symptoms. Next, *Jonathan Greenberg* will present findings related to mediators of the link between anxiety and post-concussive symptoms. *Molly Cairncross* will then discuss the onset and course of fear avoidance behaviors in connection to mTBI outcomes and treatment. *Sarah Bannon* will discuss the social/relational context of mTBI and the bidirectional link between symptoms and relationship functioning. Finally, *Paul King* will place these findings in the context of behavioral treatment of mTBI will discuss future directions.

COGNITIVE AND BEHAVIORAL MEDIATORS OF THE ASSOCIATION BETWEEN ANXIETY AND POST-CONCUSSION SYMPTOMS

Jonathan Greenberg, PhD¹, Ryan Mace, MS², Christopher Funes, BS³, Noah Silverberg, Ph.D., R. Psych., ABPP⁴, Grant Iverson, PhD⁵, Ana-Maria Vranceanu, PhD¹

¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital, Charlestown, MA; ⁴University of British Columbia; ⁵Massachusetts General Hospital

Despite growing evidence that anxiety is critical in the development and maintenance of post-concussion symptoms following mild traumatic brain injury (mTBI), little is known about potential mechanisms through which anxiety may affect these symptoms. Here, we tested the strength and reliability of cognitive (pain catastrophizing) and behavioral (limiting behaviors) pathways mediating the relationship between anxiety and post-concussion symptoms among patients with mTBI. Patients with mTBI (N=57) completed self-report measures of anxiety, post-concussion symptoms, pain catastrophizing, and limiting behavior. Following preliminary simple-mediation models (for pain catastrophizing and limiting behavior separately), we ran a multiple-mediation model (pathways modeled simultaneously). Bootstrapping with 10,000 resampling iterations assessed mediation reliability. In preliminary simple mediation models, both pain catastrophizing ($\beta=0.24$, 95% CI=0.03-0.44, $p=.02$) and limiting behavior ($\beta=0.14$, 95% CI=0.03-0.26, $p=.01$) partially mediated the relationship between anxiety and post-concussion symptoms. In the multiple mediation model, pain catastrophizing was a less reliable but numerically stronger mediator ($\beta=0.19$, 95% CI=-0.01-0.38; $p=.05$) and explained more variance in post-concussion symptoms ($R^2=0.41$) than limiting behavior ($\beta=0.10$, 95% CI=0.02-0.21, $p=.03$; $R^2=0.22$), although mediators didn't significantly differ in strength ($\beta=0.08$, 95% CI=-0.16-0.32; $p=.49$). Results provide novel evidence for the role of pain catastrophizing and limiting behavior in explaining the association between anxiety and post-concussion symptoms. Addressing both factors may improve the recovery trajectory of individuals with mTBI. Emphasizing limiting behavior may yield more consistent and reliable effects. Results support developing interventions to directly target anxiety, pain catastrophizing, and activity engagement despite symptoms, to decrease symptom severity among patients with mTBI.

8:00 AM-9:15 AM

1-MONTH POST-CONCUSSIVE COMPLAINTS ARE LINKED TO ROMANTIC RELATIONSHIP DISTRESS IN MTBI PATIENTS RECRUITED FROM AN ED SETTING

Sarah Bannon, MS¹¹Massachusetts General Hospital, MA

Mild Traumatic Brain Injury (mTBI; concussion) impacts millions annually and is linked to a host of emotional, cognitive, and physical challenges that have the potential to undermine the stability and quality of close relationships. Despite the high prevalence and consequences of mTBI, studies of relationship adjustment following brain injury have almost entirely focused on more severe forms of TBI, where the cognitive, physical, and emotional impact of injury is more chronic and debilitating, as well as more visible to others. The current study sought to contribute to this critical gap in literature by examining the impact of mTBI on the relationship satisfaction and emotional distress of individuals recovering from mTBI. Individuals (N=20) involved in current romantic relationships were recruited from a suburban Emergency Department (ED) during their visit for injuries related to mTBI. Eligible individuals included those with ED Glasgow Coma Scale scores of 14-15 who reported an injury within 72 hours of their ED visit and endorsed involvement in a romantic relationship for more than 1 year prior to injury. We excluded individuals based on the presence of neurodegenerative disorders, history of bipolar disorder and/or schizophrenia, prisoner status or police custody, and terminal illness. mTBI symptoms were measured around the time of injury using the Rivermead Post Concussion Symptoms Questionnaire (RPQ), and again 1-month post-injury. Relationship distress was measured in a similar fashion using the Couples Satisfaction Index (CSI). Linear regression were conducted examining the cross-sectional associations between concussion symptoms and relationship distress, while controlling for the influence of pre-injury retrospective ratings of relationship distress. Regression analyses indicated that 1-month ratings of mTBI symptoms demonstrated significant cross-sectional associations with self-reported relationship satisfaction ($b = -.34$; $p < .01$), after accounting for the influence of retrospective ratings of relationship satisfaction prior to injury ($b = .76$; $p < .001$). Findings from the present study contribute to a biopsychosocial model of adjustment following mTBI, and underscore the need for further assessment interpersonal relationships after injury.

3

8:00 AM-9:15 AM

SOMATIZATION AND ITS RELATIONSHIP TO PERSISTENT SYMPTOMS AFTER MTBI

Katherine Green, MSc¹, Noah Silverberg, Ph.D., R. Psych., ABPP²¹University of British Columbia, Vancouver, BC, Canada; ²University of British Columbia

Somatization, the process whereby emotional distress is expressed as unintentionally produced physical symptoms, can exacerbate the symptoms of organic medical conditions or can produce novel physical symptoms. Somatization may contribute to symptom persistence after mild traumatic brain injury (mTBI). The presentation will summarize the literature on the intersection between somatization and persistent symptoms after mTBI, and present recent findings from two studies from our research group: a chart review characterizing somatization in a sample of adolescents seen at a concussion clinic, and a prospective study of the relationship between patient history of functional somatic syndromes – medical conditions commonly affected by somatization – and symptom persistence after mTBI in an adult sample.

Study 1: Charts of adolescents with and without clinician identified somatization seen at a concussion clinic for persistent mTBI symptoms ($n=94$) were compared on demographics, injury characteristics, mTBI symptoms, mental health, medical service use, and school attendance. Adolescents with identified somatization, compared to those without, were more likely to have a history of premorbid chronic pain or medically unexplained symptoms, reported more severe and unusual mTBI symptoms, obtained more neuroimaging and health care after injury, and demonstrated more post-injury impairment in school attendance.

Study 2: Adults recruited from a concussion clinic ($n = 147$) were queried on their history of functional somatic syndromes (irritable bowel syndrome, chronic fatigue syndrome, and fibromyalgia), as well as their mental health history and demographic and injury characteristics. Participants also completed self-report mTBI symptom scales at study intake, and 1- and 3-month follow-up visits. A linear mixed effects model was used to evaluate the association between a history of no functional somatic syndromes, one functional somatic syndrome, or two or more functional somatic syndromes and mTBI symptoms over time. Patients with a history of two or more functional somatic syndromes were significantly more likely to experience more severe mTBI symptoms over time.

4

8:00 AM-9:15 AM

FEAR AVOIDANCE BEHAVIOR AFTER MILD TRAUMATIC BRAIN INJURY

Molly Cairncross, Ph.D. Clinical Neuropsychology¹, Noah Silverberg, Ph.D., R. Psych., ABPP²¹University of British Columbia, Vancouver, BC, Canada; ²University of British Columbia

Fear avoidance is a maladaptive coping style that occurs when negative appraisal of symptoms leads to the avoidance of activities and/or situations that are perceived to trigger them. It is related to disability in a number of health conditions (e.g., chronic pain) and emerging evidence suggests that it may be an important psychological factor that impacts outcome following mild traumatic brain injury (mTBI). A series of studies examining the association between fear avoidance and mTBI symptoms (e.g., headache, cognitive problems), the natural trajectory of fear avoidance, and its association with clinical outcomes following mTBI are presented. **Study 1:** In a sample of adults (N=53) with post-traumatic headache after mTBI, the strongest and most commonly avoided headache triggers were lack of sleep, stress, and mental exertion. Perceived sensitivity to headache triggers was correlated with avoidance of triggers ($r = 0.736$, $p < 0.001$). **Study 2:** Eighty adults with mTBI and post-traumatic headaches completed measures of cogniphobia (i.e., avoidance of mental exertion due to fear of developing a headache) and cognitive testing 2-3 months post-mTBI. Cogniphobia was associated with poorer memory performance while controlling for headache severity. Avoiding mental exertion was associated with other kinds of avoidance behavior, such as avoidance of physical activity and traumatic stress triggers. **Study 3:** Fear avoidance at mTBI clinic intake (N=87) predicted symptom severity (95% CI for $B = 1.22-6.33$) and greater disability (95% CI for $B = 2.16-5.48$) at 4-5-month follow up. Avoidance was also associated with an increased risk for depression (OR = 1.76, 95% CI = 1.02–3.02) and anxiety disorders (OR = 1.89, 95% CI = 1.16–3.19). **Study 5:** A new cohort of 84 adults with mTBI completed measures of avoidance, disability, and post-concussion symptoms at clinic intake and at 1- and 3-month follow-up. Avoidance behavior tended to decrease from clinic intake to 1-month follow-up. Higher avoidance behavior at clinic intake and increases in avoidance behavior over the month following clinic intake predicted greater disability at three-month follow-up, even after controlling for concussion symptom severity at intake. Taken together, these studies suggest that fear avoidance is important risk factor for persistent post-concussion symptoms, psychological health problems, and disability. These findings emphasize the need for behavioral interventions to target maladaptive coping styles post-mTBI.

Symposium 77

8:00 AM-9:15 AM

I GET BY WITH A LITTLE HELP FROM MY FRIENDS (OR DO I?): THE HIGHS AND LOWS OF SOCIAL SUPPORT IN PROMOTING HEALTH

Katherine Hoerster, PhD¹, Sarah B. Campbell, PhD², Kristen E. Gray, PhD, MS³, Briana L. Robustelli, PhD⁴, Ranak B. Trivedi, PhD⁵¹VA Puget Sound Healthcare System, Seattle Division, Research and Development Service, Seattle, WA; ²VA Puget Sound Health Care System - Seattle/University of Washington, Seattle, WA; ³VA Puget Sound Health Care System, Seattle, WA; ⁴VA Eastern Colorado Health Care System, Jamesville, NY; ⁵Stanford/VA Palo Alto, Menlo Park, CA

Recognizing the potency of social support in promoting optimal physical and mental health, healthcare systems and providers are increasingly involving patients' family, friends, and other peers in care. This symposium presents four studies that collectively demonstrate that prioritizing social support in care can be a powerful treatment component, while also posing both practical and complex challenges such as scheduling and navigating communication issues. Presentations will highlight key considerations for addressing and integrating social support in care, exemplified by research conducted among U.S. veterans, which is broadly applicable to behavioral medicine and health promotion research and programs. The chair (KH) will present the extant literature and a framework, followed by briefly presenting national epidemiologic findings showing that veterans have less social support than civilians across several social support domains. KG will present qualitative work reflecting the duality of social support as help and hindrance in diabetes self-management, serving as the foundation for an in-development intervention. KH and KG will highlight gender differences detected in their respective studies. BR will present qualitative findings from a group behavioral weight management intervention for people with PTSD, reinforcing KG's findings that social support can be both a potent facilitator of health behaviors, but also a source of barriers to success. SC will then describe promising quantitative results from a pilot study of a PTSD intervention focused on promoting social engagement among veterans with support deficits. Lastly, the discussant (RT), an expert in the role caregivers play in mental health and chronic disease management and caregiver-focused interventions, will synthesize the presented work and how it informs a path forward for behavioral medicine researchers and clinicians. Critical considerations will include measurement of social support in clinical care; direct involvement of social supports vs. indirectly empowering people to enhance their social support; importance of targeting specific groups with support deficits (e.g., female veterans); and novel methods of reaching and engaging social supports, such as telehealth, social media, and blogs. With healthcare systems like the Veterans Health Administration increasingly implementing social support-focused programs—such as evidence-based couple and family therapy, coaching people on how to encourage their veteran loved ones to engage in care, and integrating peer support services into medical and mental health care—it is important to strategically approach how social support is integrated into care. Thus, this symposium will highlight the nuanced and complex role of social support in promoting health, and the challenges and opportunities of addressing and integrating social support in care.

DIFFERENCES IN FUNCTIONAL AND STRUCTURAL SOCIAL SUPPORT AMONG FEMALE AND MALE VETERANS AND CIVILIANS

Katherine Hoerster, PhD¹, Sarah B. Campbell, PhD², John Fortney, PhD³, Tracy Simpson, PhD⁴, Kristen E. Gray, PhD, MS⁵

¹VA Puget Sound Healthcare System, Seattle Division, Research and Development Service, Seattle, WA; ²VA Puget Sound Health Care System - Seattle/University of Washington, Seattle, WA; ³University of Washington, Seattle, WA; ⁴VA Puget Sound Health Care System, Seattle Division, Seattle, WA; ⁵VA Puget Sound Health Care System, Seattle, WA

Background: Social support is an important correlate of health behaviors, health outcomes, and mortality. A few studies suggest veterans have lower social support than civilians, but interpretation is hindered by methodological limitations, such as lack of adjustment for important confounders. Although women in the general population have larger social networks than men, female veterans are less likely to be married and live with others, which could influence how readily they can draw on social support benefits. This study examined veteran-civilian differences on several dimensions of social support and whether differences varied by sex.

Methods: We performed a cross-sectional analysis of the 2012-2013 National Epidemiologic Survey of Alcohol and Related Conditions-III (NESARC-III), a nationally-representative in-person structured diagnostic interview. The sample included 34,331 survey respondents (male veterans=2,569; female veterans=356). Functional social support was measured with the Interpersonal Support Evaluation List-12. Structural social support, specifically social network size and diversity, was measured with the Social Network Index. We employed linear regression to estimate veteran-civilian differences in social support and examined whether differences varied by sex with interactions. Presented analyses were adjusted for socio-demographic characteristics, childhood experiences, and physical and mental health.

Results: Compared to civilians, veterans had lower social network diversity scores (difference [diff]=-0.13, 95% Confidence Interval [CI] -0.23, -0.03). Among women but not men, veterans had smaller adjusted social network size (diff=-2.27, 95%CI -3.81, -0.73) than civilians. Further analyses revealed that smaller social network sizes were most pronounced among the religious groups, volunteers, and coworkers with whom female veterans had regular contact. Although the interaction was not significant, among men, veterans had lower adjusted social network diversity scores than civilians (diff=-0.13, 95%CI -0.23, -0.03), while the difference was similar but did not reach statistical significance among women (diff=-0.13, 95%CI -0.23, 0.09). There was limited evidence of differences in functional social support.

Conclusions: After accounting for factors that influence military entry and social support, veterans reported significantly lower structural social support, which may be attributable to issues common in Veterans that affect relationships, such as reintegration challenges and geographic mobility. Findings suggest veterans could benefit from targeted programs to enhance their structural social support and improve downstream outcomes, such as veterans' disproportionate disease burden and premature mortality, with female veterans appearing to be in greatest need of such programming.

2

8:00 AM-9:15 AM

PRELIMINARY OUTCOMES OF A BRIEF INTERVENTION TO ENHANCE SOCIAL SUPPORT AMONG VETERANS WITH PTSD

Sarah B. Campbell, PhD¹, John Fortney, PhD², Lisa Batten, MHA³, Holly Rau, PhD³, Jessica A. Chen, PhD², Tracy Simpson, PhD⁴

¹VA Puget Sound Health Care System - Seattle/University of Washington, Seattle, WA; ²University of Washington, Seattle, WA; ³VA Puget Sound Health Care System, Seattle Division; ⁴VA Puget Sound Health Care System, Seattle Division, Seattle, WA

Background: Most Veterans with post-traumatic stress disorder (PTSD) are initially treated for PTSD in Primary Care Mental Health Integration (PCMHI). Poor social support in this population is a risk factor for lack of engagement, non-response to treatment, and suicide. Social support should be assessed and addressed early in treatment, per the Veterans Affairs/Department of Defense Clinical Practice Guidelines for the treatment of PTSD. Thus, there is a need for brief, acceptable and accessible social support enhancement interventions to produce optimal outcomes in PCMHI or prepare Veterans for Evidence-Based Psychotherapies delivered in specialty care.

Methods: In an open pilot trial (n = 18), an existing Behavioral Activation protocol designed for PTSD was adapted to include content explicitly intended to enhance social support. It was further tailored for PCMHI by reducing the number of sessions and time in session (6 45-minute sessions), and offering telephone modality for some sessions.

Results: In this trial, improvement from baseline to post-treatment was significant for PTSD and depression symptoms, social impairment, distrust of others, and use of emotional support to cope ($p < .05$) and was nearly significant ($p < .07$) for feelings of social connectedness, overall social support, emotional support, and tangible support. In qualitative interviews, Veterans reported increases in social ties and incorporating social activity into daily life. 94% of Veterans completed 4 sessions, and 81% of Veterans completed 6 sessions. Moreover, 73% of participants showed clinically significant decreases in PTSD symptoms and 38% no longer met criteria for PTSD after 4-6 sessions.

Conclusions: Brief BA tailored for the PCMHI environment may facilitate an increase in the use and perception of social supports. Future research should investigate modifications to the treatment that could further enhance perceived quality of social connectedness, emotional, and tangible social support, as prior research has shown perceptions of support to be more impactful than objectively measured support. Impacts: The results of the trial presented here demonstrates that BA is effective at increasing social support for this population and may therefore help mitigate a prominent risk factor for poor treatment engagement, treatment non-response, and suicide. Explicitly attending to social support is an important component of PTSD treatment. Future directions include iterative refinement of this social support-enhancing intervention based on stakeholder feedback and multi-site effectiveness research.

8:00 AM-9:15 AM

SOCIAL SUPPORT FOR VETERANS' DIABETES SELF-MANAGEMENT: HELPFUL AND UNHELPFUL SUPPORT PERSON BEHAVIORS AND DIFFERENCES BY GENDER

Kristen E. Gray, PhD, MS¹, Erica Ma, BA², Lori Bastian, MD, MPH³, Karin Nelson, MD, MSHS⁴, John Fortney, PhD⁵, Corrine Voils, PhD⁶

¹VA Puget Sound Health Care System, Seattle, WA; ²VA Puget Sound Health Care System; ³Yale School of Medicine, West Haven, CT; ⁴Health Services Research & development, VA Puget Sound Health Care System, Seattle, WA; ⁵University of Washington, Seattle, WA; ⁶William S Middleton Veterans Memorial Hospital

Objectives: Optimal diabetes self-management is complex and often requires patient adoption of many health behaviors. Involvement of support persons (e.g., partners, family, and friends) may be important to the success of self-management, but support person behaviors can also be an impediment. Some evidence also suggests women and men differ in support quantity and quality and in its influence on self-management behaviors. However, little is known about support for diabetes self-management among Veterans and whether there are differences by gender. We sought to fill these gaps using qualitative interviews to capture the richness of Veterans' experiences.

Methods: In 2018, we conducted semi-structured qualitative phone interviews with 36 Veteran VA Puget Sound primary care patients with diabetes (18 men, 18 women). Interviews explored how Veterans managed their diabetes and if and how support persons were involved in their self-management, including helpful and unhelpful/obstructive behaviors. Interviews were audio recorded and transcribed verbatim. We analyzed transcripts using a rapid process by completing templated summaries for each interview and identifying key points, which we then used to synthesize results, including gender comparisons.

Results: Veterans primarily managed their diabetes with medications and dietary changes. Most Veterans had ≥1 social support involved in their self-management, including partners, adult children, and friends. Participating in self-management tasks (e.g., shopping or cooking) and providing direction (e.g., reminders or advice) were the most commonly discussed helpful support person behaviors. Women also described emotional support and role modeling, especially from female friends and family, whereas men spoke of social supports interacting with the health care system. Men often received assistance from female partners or adult children, but women noted managing diabetes primarily on their own and experiencing insufficient support. Women also more often described unhelpful or obstructive behaviors, including nagging and sabotaging (e.g., bringing unhealthy foods into the home).

Conclusions: Most Veterans with diabetes receive self-management support from loved ones. Although much of this support is helpful, Veterans, particularly women, do not always receive adequate support and they experience unhelpful and obstructive behaviors, such as nagging and sabotaging. Diabetes interventions targeting patients alone may be insufficient to optimally modify behaviors, as Veterans' family and friends are commonly involved in self-management. Interventions involving family and friends may be effective but likely require enhancing helpful and reducing obstructive/unhelpful behaviors, especially among women Veterans. Findings are now informing development of a dyadic intervention for Veterans and support persons.

8:00 AM-9:15 AM

PERCEPTIONS OF SOCIAL SUPPORT WHILE PARTICIPATING IN A WEIGHT LOSS INTERVENTION FOR OVERWEIGHT VETERANS WITH PTSD

Briana L. Robustelli, PhD¹, Sarah B. Campbell, PhD², Preston Greene, PhD³, George Sayre, Psy. D⁴, Nadiyah Sulayman, BA⁴, Katherine Hoerster, PhD⁵

¹VA Eastern Colorado Health Care System, Jamesville, NY; ²VA Puget Sound Health Care System - Seattle/University of Washington, Seattle, WA; ³VA Puget Sound Healthcare System, Seattle Division; ⁴VA Puget Sound Healthcare System, Seattle Division, Research and Development Service; ⁵VA Puget Sound Healthcare System, Seattle Division, Research and Development Service, Seattle, WA

Objectives: Veterans with PTSD are at greater risk of being overweight or obese due to unique barriers to physical activity and healthy eating. MOVE!+UP is a 16-week behavioral weight management program designed to address these weight loss barriers. Because weight management is sensitive to social factors and many with PTSD experience interpersonal relationship challenges, MOVE!+UP emphasizes increasing social support by using a group format, includes a veteran peer support counselor, and provides social support-focused psychoeducation. Although weight loss interventions addressing social support can be effective, little is known about the specific ways in which social support functions to facilitate or hinder health behavior change efforts. The purpose of this qualitative study was to examine Veterans' perceptions of social support while participating in MOVE!+UP and to identify ways in which social support can best be targeted within this and other weight management interventions.

Methods: MOVE!+UP was piloted and refined over the course of five cohorts of veterans (N=44) enrolled in an uncontrolled pilot (2015-2018). Almost all participants (n=37) completed an approximately one-hour semi-structured interview regarding their experience in MOVE!+UP, and how they applied MOVE!+UP education, skills, and support in their daily lives. Template analysis was used to understand social factors relevant to weight management, health behaviors, and mental health.

Results: Participants appreciated many aspects of the group format: cohesiveness around a shared veteran identity with each other and the peer support counselor, learning from others facing similar challenges with PTSD and weight, and generally feeling less alone. However, several participants described disappointment with poor group attendance, lack of contact outside of group, and the presence of those perceived as "complainers." Participants also noted that relationships with non-group members such as spouses and friends could both be helpful and interfere with achieving health goals. Reminders, encouragement, and witnessing others make health behavior changes were welcomed, whereas loved ones encouraging unhealthy food choices and/or PTSD avoidance were deemed unhelpful. Some participants also noted general barriers to accessing, building, and benefiting from social support.

Conclusions: Better understanding challenges faced by those participating in behavioral weight management programs can inform future interventions seeking to capitalize on the potency of social support. The benefits of social support in weight loss programs may be optimized by including members with similar experiences; encouraging consistent, respectful attendance and participation; and delivering education about how to leverage social support from loved ones and others not participating in the program.

Symposium 78

8:00 AM-9:15 AM

8:00 AM-9:15 AM

REDUCING THE BURDEN OF EATING DISORDERS: INNOVATIVE METHODS IN EATING DISORDER RESEARCH

Tyler B. Mason, PhD¹, Lindsay Howard, M.S.², Kathryn E. Smith, Ph.D.³, Kristin E. Heron, Ph.D.⁴¹University of Southern California, Los Angeles, CA; ²Virginia Consortium Program in Clinical Psychology, Newport News, VA; ³Sanford Center for Bio-behavioral Research, Fargo, ND; ⁴Old Dominion University, Norfolk, VA

Eating disorders are significant public health problems associated with increased mortality, psychiatric morbidity, and lower quality of life. However, treatment outcomes for eating disorders remain sub-optimal and relapse and shift across various eating disorders is common. Further, many eating disorders go undiagnosed due to failure to seek treatment and stigma associated with eating disorders. Development and use of innovative research methods could lead to new diagnosis and treatment options in eating disorders. The purpose of this symposium is to present a series of studies that use novel assessment and statistical methods in eating disorders research. The first paper will present on the development of a new measure to detect individuals' attempts to underreport disordered eating behaviors. The second paper focuses on examining how novel ecological momentary assessment measures of stress predict disordered eating behaviors and appetite in patients with binge eating disorder. The third paper uses a multistate modeling approach with ecological momentary assessment data to study transitions among four states of body dissatisfaction and preoccupation with thoughts of food in continuous time among women who report binge eating. Together, these presentations will offer new approaches that can be used in future eating disorder research to optimize assessment, diagnosis, and treatment efforts for eating disorders.

CORRESPONDING AUTHOR: Tyler B. Mason, PhD, University of Southern California, Los Angeles, CA; tylermas@usc.edu

MULTI-STATE MODELING OF BODY DISSATISFACTION AND PRE-OCCUPATION WITH THOUGHTS OF FOOD USING EMA

Tyler B. Mason, PhD¹, Kathryn E. Smith, Ph.D.², Ross Crosby, Ph.D.³, Scott Engel, Ph.D.⁴, Haomiao Jin, PhD⁵¹University of Southern California, Los Angeles, CA; ²Sanford Center for Bio-behavioral Research, Fargo, ND; ³Sanford Health, Fargo, ND; ⁴Sanford Research; ⁵University of Southern California

Body dissatisfaction (BD) and preoccupation with thoughts of food (PTF) are core components of eating disorder pathology and are related to eating disorder severity. Thought-shape fusion refers to a phenomenon in which thoughts of eating forbidden foods leads to perceptions that one has gained weight and BD. Thus, thought-shape fusion suggests that BD and PTF are deeply intertwined, which is relevant given that studies have shown that individuals exhibiting greater thought-shape fusion have higher eating disorder pathology and distress. However, although thought-shape fusion suggests micro-temporal associations between PTF and BD, research has yet to study this phenomenon in daily life including the factors that precipitate states of high PTF and high BD. Ecological momentary assessment data of was collected from 30 women with binge eating for 14 days. A multi-state modeling approach was used to analyze transitions among four states: low BD and low PTF, low BD and high PTF, high BD and low PTF, and high BD and high PTF. Multi-state modeling characterized the processes in which an individual moved through a series of states in continuous time as well as momentary factors that predicted likelihood of transitioning through the four states. Results showed that once women transitioned to states of high BD, it was difficult to transition back to states of low BD. Also, results showed that higher positive affect reduced the likelihood of transitioning from low BD, low PTF to high BD, low PTF. In contrast, negative affect increased the likelihood of transitioning from low BD, low PTF to high BD, low PTF and transitioning from low BD, high PTF, to high BD, high PTF. Binge eating increased the likelihood of transitioning between low BD, high PTF and high BD, low PTF. Restricting food intake and skipping meals were associated with higher likelihood of transitioning from low BD, low PTF to high BD, low PTF and transitioning from high BD, high PTF to high BD, low PTF. Findings highlight states with high BD as particularly harmful, self-perpetuating states. Increasing positive affect, reducing negative affect, and reducing restriction may be important targets to lower BD. In addition, negative affect appears to precipitate thought-shape fusion (high BD, high PTF), while restriction is associated with transitioning from states of thought-shape fusion to states of lowered food preoccupation, which may reflect temporary reassuring effects from restriction. This research will serve to inform ecological momentary interventions for eating disorders.

8:00 AM-9:15 AM

VALIDATION OF THE UNDERREPORTING OF DISORDERED EATING BEHAVIORS SCALE USING A SIMULATION DESIGN

Lindsay Howard, M.S.¹, Kristin E. Heron, Ph.D.², Carlo Veltri, Ph.D.³¹Virginia Consortium Program in Clinical Psychology, Newport News, VA; ²Old Dominion University, Norfolk, VA; ³Saint Olaf College, Northfield, MN

The purpose of this study was to refine and validate an Underreporting of Disordered Eating Behaviors scale (UDEBS) to detect attempts by respondents to underreport disordered eating behaviors (i.e., unhealthy eating patterns that reflect symptoms of an eating disorder). The scale was originally developed based on a cross-sectional study. The goal of the present study was to further refine and validate this measure. The scale and validity measures were administered to 629 female and 181 male undergraduates using a simulation design, whereby participants were randomized to four conditions and provided coaching about their assigned condition: (1) filling out questionnaires as truthfully as possible, or as if they are trying to hide (2) Binge Eating Disorder (BED), (3) Anorexia Nervosa (AN), or (4) Bulimia Nervosa (BN). A manipulation check was used to ensure compliance to instructions. An ANOVA ran separately by gender revealed that women who were instructed to hide BED, BN, and AN reported significantly higher UDEBS total scores than women instructed to fill out the questionnaire truthfully, but there were no significant differences between the hiding conditions. Although not significant, an item by item analysis for women revealed that women randomized to the honest reporting condition endorsed items in the underreporting direction least frequently followed by hiding BED, hiding BN, and hiding AN. For men, there were no significant differences between any of the conditions, and further research should explore what may be influencing these findings. To enhance the discriminatory power of the scale, two items were removed due to frequent endorsement and small differences between conditions. The final 15-item scale indicated that women who complied with instructions to underreport produced scores that ranged from 1.44 (BED) to 1.70 (AN) times greater than the truthful responding condition on the UDEBS scale. This novel 15-item scale can assist in differentiating individuals who underreport in relation to disordered eating behaviors from those who do not, and may be particularly useful in research contexts where honest reporting is a concern as well as in clinical settings that seek to identify and treat disordered eating.

8:00 AM-9:15 AM

DYNAMIC STRESS RESPONSES UNDERLYING LOSS OF CONTROL AND OVEREATING IN BINGE EATING DISORDER

Kathryn E. Smith, Ph.D.¹, Tyler B. Mason, Ph.D.², Lisa Anderson, Ph.D.³, Lauren Schaefer, Ph.D.⁴, Scott Engel, Ph.D.⁴, Ross Crosby, Ph.D.⁵, Scott Crow, M.D.³, Carol Peterson, Ph.D.³, Stephen Wonderlich, Ph.D.⁴¹Sanford Center for Bio-behavioral Research, Fargo, ND; ²University of Southern California, Los Angeles, CA; ³University of Minnesota; ⁴Sanford Research; ⁵Sanford Health, Fargo, ND

Stress is a dynamic, multifaceted construct that influences a range of health behaviors, including eating. Consistent with affect regulation theories, ecological momentary assessment (EMA) studies demonstrate binge-eating symptoms (i.e., overeating [OE] and loss of control eating [LOCE]) often occur in response to stress and negative emotions. However, no EMA research has examined momentary affective responses to stressors in binge eating disorder (BED). This study sought to provide a nuanced depiction real-time stress and its impact on OE and LOCE in BED. EMA was used to examine 3 dynamic stress response indices (stress reactivity- the magnitude of increase in negative affect after a stressor; recovery- the extent to which negative affect returns to baseline after a stressor; and pileup- accumulation of stressors and responses in the last 12 hours) as predictors of OE and LOCE among 112 adults with BED prior to treatment. In addition, we explored the moderating effect of BMI and compared the effects of dynamic stress indices with stress intensity and number of stressors measured at single EMA recordings. Results of generalized estimating equations (GEEs) indicated that higher between- and within-person stress reactivity predicted higher LOCE and OE ($p < .001$ to $.004$), and BMI interacted with within-person stress reactivity to predict LOCE ($p = .040$). That is, the relationship between momentary stress reactivity and LOCE was stronger for individuals with lower BMI. BMI interacted with between-person stress recovery to predict OE ($p = .008-.022$), such that better stress recovery was associated with lower OE for individuals with lower BMI. Greater within-person stress pileup predicted higher LOCE and OE ($ps < .001$), and BMI interacted with within-person pileup to predict OE ($p = .007$); the relationship between momentary stress pileup and OE was stronger for individuals with higher BMI. In contrast, stress intensity and number of experienced stressors measured at single EMA recordings did not predict subsequent LOCE or OE. Together these results indicate (1) stress reactivity and pileup are salient momentary antecedents of binge eating; (2) individual differences in stress recovery are related to OE; and (3) BMI differentially influences stress-binge eating associations. Further, the lack of momentary effects using single EMA measures highlights the utility of considering the dynamic and multifaceted nature of stress responses to understand BED symptoms.

Symposium 79

8:00 AM-9:15 AM

ACCELERATING PALLIATIVE CARE SCIENCE: IDENTIFYING THE CHALLENGES OF PATIENTS, CAREGIVERS, & CLINICIANS VIA MIXED METHODS

Michael Hoerger, PhD, MSCR¹, Brittany Davidson, MD², Claire C. Conley, PhD³, J. Nicholas Dionne-Odom, PhD, RN⁴, Maija Reblin, PhD⁵¹Tulane University, New Orleans, LA; ²Duke University, Durham, NC; ³H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL; ⁴University of Alabama at Birmingham, Birmingham, AL; ⁵Moffitt Cancer Center, Tampa, FL

Palliative care is a rapidly-growing area of healthcare designed to anticipate, prevent, and alleviate the physical and emotional burden of serious illnesses. Meta-analytic evidence demonstrates the benefits of structured palliative care programs, and training programs in medicine, nursing, and social work are increasingly providing training in palliative care. Nonetheless, most of the general public does not know what palliative care is, and many fear it. Accordingly, when an individual is diagnosed with a serious illness, there are fundamental challenges in educating patients and families about palliative care, alleviating fears, and increasing engagement. The presentations included in this symposium use quantitative and qualitative data to shed light on the challenges seriously ill patients, their family caregivers, and clinicians face in the context of the provision of high-quality palliative care services. First, Dr. Davidson reports on a mixed-methods study of women with poor-prognosis ovarian cancer and their family caregivers that provides an in-depth summary of their attitudes and beliefs about care options. Second, using qualitative data from audio-recorded interviews with gynecologic oncology clinicians and patients, Dr. Conley describes patient and clinician barriers to palliative care referrals, especially the lack of patient knowledge about palliative care as a key driver for declining referrals. Next, Dr. Dionne-Odom reports quantitative and qualitative data from three studies to provide a rationale for the development of a multicomponent intervention called CASCADE that is designed to increase the involvement of family caregivers in healthcare decision making for seriously ill patients. Together, the presentations provide key insights into mechanisms that may accelerate improvements in the uptake of palliative care and quality of care provided. They demonstrate the value of behavioral science in this emerging field. Finally, as the discussant, Dr. Reblin will delineate the most significant and innovative elements of each presentation and contextualize this body of work within the broader landscape of research on palliative care. The symposium was organized in collaboration with the Palliative Care SIG-in-formation.

CORRESPONDING AUTHOR: Michael Hoerger, PhD, MSCR, Tulane University, New Orleans, LA; mhoerger@tulane.edu

HIGH RISK PLATINUM OVARIAN CANCER PATIENTS AND THEIR CAREGIVERS: IDENTIFYING NEEDS NEAR THE END OF LIFE

Brittany Davidson, MD¹, Laura Fish, PhD¹, Laura S. Porter, PhD², J. Kelly Davis, BA³, Laura Havrilesky, MD³¹Duke University, Durham, NC; ²Duke University Medical Center, Durham, NC; ³Duke University

Background: Women diagnosed with platinum-resistant ovarian cancer generally have a poor prognosis. The stress and cost of medical treatment in the context of this poor prognosis can be a burden to patients and their caregivers, negatively impacting quality of life (QOL). The aim of this study is to understand attitudes and beliefs regarding options for care among women with high-risk platinum-resistant ovarian cancer (defined as prognosis < 6 months) and their caregivers.

Methods: Individual semi-structured qualitative interviews were performed separately for patients and caregivers. Subjects completed a brief survey of standardized measures of hope, anxiety/depression and QOL. Interviews were transcribed and coded using InViVo software.

Results: Twelve patient-caregiver dyads completed surveys and interviews. Patients were most often Caucasian, non-Hispanic (85%) with a median age of 68. Caregivers were most often spouses (54%) with a median age of 56. Both patients and caregivers reported high levels of hope; most caregivers were as hopeful or more hopeful than their patient counterpart (3/13; 23% and 6/13; 46%). Four patients (31%) screened positive for anxiety; 2 of these patients also screened positive for depression. One caregiver screened positive for both anxiety and depression while an additional 3 patients screened positive for depression. Main themes identified during interviewing included: 1. Fear of removing hope 2. Holding back from partner/family 3. Ambiguity regarding knowing when to transition to end of life care

Conclusion: High-risk platinum resistant ovarian cancer patients and their caregivers have complex needs near the end of life. Facilitating communication between patients and their caregivers is critical to the receipt of goal-concordant care as women transition away from cancer-directed therapies.

2

8:00 AM-9:15 AM

PALLIATIVE CARE UPTAKE IN GYNECOLOGIC ONCOLOGY: PATIENT AND PROVIDER PERSPECTIVES

Claire C. Conley, PhD¹, Andrea Buras, MD², McKenzie McIntyre, BS², Robert Wenham, MD³, Susan Vadaparampil, PhD⁴

¹H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL; ²H. Lee Moffitt Cancer Center; ³H. Lee Moffitt Cancer Center, Tampa, FL; ⁴Moffitt Cancer Center, Tampa, FL

Background: Palliative care is a treatment approach focused on improving quality of life and providing symptom relief in the context of a serious illness. Although advanced ovarian cancer (OC) patients experience significant treatment side effects, palliative care is under-utilized. The goal of the present study was to explore facilitators and barriers of (a) palliative care referral among gynecologic oncology providers (MDs) and (b) palliative care uptake among patients with advanced OC.

Methods: Gynecologic oncology providers (N=4) and patients with advanced OC (N=8) completed in-depth, semi-structured qualitative interviews guided by the Social Ecological Model to ensure consideration of relevant patient, provider, and systems level factors. Interviews were audio recorded, transcribed verbatim and analyzed using content analysis.

Results: Providers had received palliative care training during their fellowship, felt comfortable discussing palliative care with patients, and reported discussing palliative care with ≥50% of patients. However, providers reported referring very few patients to specialty palliative care. Provider-reported barriers to referral included patients declining the services, limited availability of palliative care physicians, and a preference for gynecologic oncology providers to manage patients' symptoms. However, none of the patients had heard of palliative care prior to study participation, and none had received specialty palliative care services. Patient-reported barriers to palliative care uptake included patient knowledge, insurance coverage, distance/travel, and time needed to attend the appointment. Although patients were open to the possibility of receiving specialty palliative care, they noted that it would be beneficial to have more information on what palliative care services entail and which are available.

Conclusions: Gynecologic oncology providers are comfortable discussing and providing palliative care. However, patients lack knowledge about palliative care services, and none had seen a palliative care provider. To increase uptake of palliative care in the context of gynecologic oncology, interventions addressing both patient knowledge and gynecologic oncology provider willingness to refer patients may be needed. Results underscore the potential value of a multilevel intervention (e.g., at the patient, provider, and systems levels) to support uptake of specialty palliative care in this population.

8:00 AM-9:15 AM

DEVELOPING THE CASCADE INTERVENTION TO TRAIN FAMILY CAREGIVERS IN DECISION PARTNERING WITH PERSONS WITH ADVANCED CANCER USING THE MULTIPHASE OPTIMIZATION STRATEGY

J. Nicholas Dionne-Odom, PhD, RN¹, Andres Azuero, PhD¹, Rachel Wells, PhD, MSN, RN, CNL², Christine M. Rini, PhD³, Kate Guastaferrro, PhD, MPH⁴, Corey Lofton, BSN⁵, Kathryn Louis, MPH⁵, Sally Engler, MPH⁶, Grant Williams, MD⁵, Abby Rosenberg, MD, MS, MA⁷, Rebecca Sudore, MD⁸, Marie Bakitas, DNSc, CRNP¹

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Hoover, AL; ³Northwestern University Feinberg School of Medicine, Chicago, IL; ⁴Pennsylvania State University, University Park, PA; ⁵University of Alabama at Birmingham; ⁶UAB School of Nursing, Birmingham, AL; ⁷Seattle Children's Research Institute, Seattle, WA; ⁸University of California San Francisco

Background: A priority focus in palliative care is preparing the 2.8 million U.S. family caregivers of persons with cancer to effectively support patients in health-related decision-making from diagnosis to end of life.

Purpose: To describe a series of studies leading to the development and piloting of a multicomponent intervention (CASCADE: Care Supporters Coached to be Adept DEcision partners) to train family caregivers to effectively support patients in health-related decision-making.

Methods: We conducted 3 studies informing the CASCADE intervention: Study 1: A qualitative study of surrogate decision-makers who made decisions for individuals at end of life in the intensive care unit. We found that family preparation for decision-making needed to occur much earlier in the illness trajectory. Study 2: A qualitative study of cancer family caregivers where we identified specific informational and emotional support roles families play in supporting patient decision-making. Study 3: A randomized clinical trial of a comprehensive model of early oncology palliative care for family caregivers called ENABLE that included content on becoming better decision partners with patients. As one among many other skills taught within the model, the trial could not tell us which aspects of these decision-partnering components might influence patient and caregiver decision-making outcomes.

Results: Based on these prior studies, we developed CASCADE, an intervention to enhance the decision partnering skills of family caregivers of persons with newly-diagnosed advanced cancer. Using a 2³ (2x2x2) MOST factorial design, our current study will pilot test CASCADE with 40 family caregivers of persons with newly-diagnosed advanced cancer who will be randomized to receive one or more nurse coach-delivered decision partnering training components, based on the Ottawa Decision Support Framework and Social Support Effectiveness Theory: 1) psychoeducation on effective decision partnering principles (1 vs. 3 sessions); 2) decision partnering communication training (yes vs. no); and 3) Ottawa Decision Guide training (yes vs. no).

Conclusions: Once acceptability and feasibility are determined, the CASCADE intervention for family caregivers of persons with advanced cancer will be primed for a fully powered efficacy RCT. Our goal is to develop an optimized package of decision partnering training that can be delivered alone or as part of a more comprehensive early palliative care service model, such as ENABLE.

Symposium 80

THE NUTS AND BOLTS OF NIH PEER REVIEW: PUTTING YOUR BEST APPLICATION FORWARD

Weijia Ni, PhD¹, Michael McQuestion, PhD², Elia K. Ortenberg, PhD³, Susan M. Czajkowski, Ph.D.⁴, Sherry Pagoto, PhD⁵¹National Institutes of Health, Bethesda, MD; ²NIH/CSR, Bethesda, MD; ³National Institutes of Health/Center for Scientific Review, McLean, VA; ⁴Division of Cancer Control and Population Sciences, National Cancer Institute, NIH, Bethesda, MD; ⁵University of Connecticut, Storrs, CT

The National Institutes of Health is the largest public funder of biomedical and biobehavioral research in the United States. The mission is to enhance health, lengthen life, and reduce illness and disability. To achieve this mission, the NIH provides support for cutting-edge research and technology development in a variety of fields, ranging from translation of innovative ideas in technology to basic science on major health challenges and disease. There are many types of research and training opportunities and technology development programs that are supported by the NIH across the 24 institutes and centers that provide funding. The majority of grant applications are reviewed by the NIH Center for Scientific Review (CSR). In this symposium, attendees will get 1) an overview of the types of applications submitted to the NIH for support; 2) the basics of the NIH peer review process and criteria and scoring system for evaluating applications, and 3) tips for writing a more successful grant application. Peer review is the cornerstone of the NIH grants process, and an insider's view can lead to a better understanding of how the most meritorious projects are identified that lead to innovative research in the biomedical and biobehavioral sciences.

THE NUTS AND BOLTS OF NIH PEER REVIEW: PUTTING YOUR BEST APPLICATION FORWARD

Weijia Ni, PhD¹¹National Institutes of Health, Bethesda, MD

The majority of peer review is conducted through the NIH Center for Scientific Review (CSR), which works closely with the other 24 funding institutes and centers that ultimately fund projects of high scientific merit and high potential impact. CSR conducts the review of 90% of R01s, 85% of Fellowships, and 95% of Small Business Innovation Research (SBIR) applications as well as many other research and training opportunity activities. The playing field for NIH funding is highly competitive. There are funding mechanisms for early career investigators. Understanding about different application types, who to talk to about your application at different stages of development, finding the right review panel, and learning about the policies and procedures pertaining to review are important steps in preparing an application. In this presentation, learn about the important aspects of the grant submission process and how CSR conducts the review of applications.

2

8:00 AM-9:15 AM

THE REVIEW PROCESS AND THE ROLE OF THE SCIENTIFIC REVIEW OFFICER

Michael McQuestion, PhD¹¹NIH/CSR, Bethesda, MD

Applications reviewed by the NIH Center for Scientific Review go through a process that starts with assignment to a review panel and ends with the generation of a priority score and a written evaluation (Summary Statement). This process is overseen by a Scientific Review Officer, who enlists expert reviewers to evaluate the scientific and technical merit, and the potential contribution and impact of the application to the relevant research field(s). The goal is to ensure that applications are expertly and fairly evaluated in accordance with the NIH policies of rigor, reproducibility, transparency and research integrity. In this presentation, participants will learn about the criteria for review of an application, how reviewers shape their evaluations and the journey of an application as it moves through the review process.

3

8:00 AM-9:15 AM

QUALITIES OF A COMPETITIVE APPLICATION: TIPS FROM THE TRENCHES

Elia K. Ortenberg, PhD¹¹National Institutes of Health/Center for Scientific Review, McLean, VA

Competitive applications submitted to NIH are significant, rigorous, realistic, and well-prepared. Maximizing these qualities when writing and submitting a grant application is a key step to success. From the field, learn some tips shared by applicants and reviewers about what they do and what they look for in a well-written application. Following review of your application, receiving the summary statement can be daunting and discouraging. Learn about the next steps for your application as well as resources and ways to put your best application forward.

CAR TRAVEL IS ASSOCIATED WITH A HIGHER DAILY STEP COUNT IN OVERWEIGHT, OLDER ADULTS

Kate Lyden, PhD¹, Tracy Swibas, n/a², Kerry Hildreth, MD², Catherine M. Jankowski, PhD², Wendy M. Kohrt, PhD², Edward L. Melanson, PhD³

¹University of Massachusetts, Amherst, Denver, CO; ²University of Colorado, Anschutz Medical Campus, Aurora, CO; ³University of Colorado Anschutz Medical Campus, Aurora, CO

Car dependency and long commuting distances are believed to significantly contribute to the increasingly sedentary lifestyle of US adults. However, in older adults, car travel events may be a positive indicator of functional independence, mobility, and social inclusion. The **purpose** of this study was to investigate differences in daily step count and time spent sitting on days when older adults participate in car travel journeys vs. days when no car travel events occur.

Methods: Healthy, overweight older adults (N=16, F=81%, 67±5y, BMI=31.7±4.2 kg m⁻²) wore the activPALTM activity monitor 24-hours/day for at least 7 consecutive days. Daily car travel events and physical behavior metrics were estimated using the CREA algorithm provided in the PALbatch software (v8.10.9.43). Across all participants each day of wear was categorized by the occurrence (or lack of occurrence) of a car journey. Daily step count and total sitting time were then compared using linear mixed models.

Results: Of the 134 days of valid data, car travel journeys occurred on 103 days. Mean (SD) daily steps on car travel days were significantly greater compared to non-car travel days (6059 (2234) vs. 3729 (2521), respectively). Mean (SD) total sitting time (including during car travel) was not different on car travel days vs. non-car travel days (611 (178) minutes vs. 602 (184) minutes, respectively).

Discussion: Car travel is often perceived as a negative lifestyle behavior associated with increased sedentary behavior and inactivity. In this study of older, overweight adults, we observed the opposite effect - on days when car travel journeys occurred participants took a significantly greater number of steps and sitting time was not different than non-car travel days. These data suggest that, in this population, sitting in a car does not replace otherwise active behavior, but rather replaces other forms of seated behavior (e.g., watching TV) and leads to a greater number of steps taken. Although not tested in the current analysis, increased step count on car travel days may be indicative of different types of stepping bouts performed outside of the home vs. inside the home (e.g., longer duration stepping bouts, higher cadence stepping bouts). Future work should specifically test these hypotheses and compare the current findings in other populations.

EFFECTS OF EXPRESSIVE ARTS-BASED INTERVENTION IN QUALITY OF LIFE AND SOCIAL SUPPORT OF DEPRESSED ELDERLY

Caitlin K.P. Chan, n/a¹, Teresa T.W. Chiu, n/a², Rainbow T.H. Ho, PhD, REAT, BC-DMT, AThR, RSMT/E, CGP, CMA²

¹Centre on Behavioral Health, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong

Background: Geriatric depression has long been a prominent issue at global level due to the deteriorating physical health along with aging and its impacts on quality of life. Perceived social support is regarded as a protective factor against unfavorable health conditions among the aging population. Expressive Arts-based (EAB) group intervention emerges as an alternative treatment for geriatric depression because it provides a space for elderly to explore and express their feelings through arts creation, as well as to receive support from others. The present study aimed to explore the potential benefits of such intervention in improving the quality of life and perceived social support of elderly with mild-and-moderate depressive symptoms.

Method: A single group pre-post quasi-experimental design was adopted. One hundred and eighty nine old adults (86.8% Female; Age: M=74.7, SD=8.1) with mild-and-moderate depressive symptoms and without major cognitive impairment, from 27 elderly centers in Hong Kong, were included in this study. They were invited to participate in an 8-week EAB group intervention which was led by trained healthcare professionals in respective elderly centers, with each session lasted for 1.5 hours. Elderly's quality of life and perceived social support were measured before and after group intervention. Dependent t-test was conducted to assess changes in elderly's quality of life, quantity of social support and their satisfaction level towards perceived social support.

Results: The EAB intervention significantly enhanced elderly's overall quality of life ($t(151) = -3.98, p < .00$) and overall satisfaction of their health condition ($t(150) = -3.23, p < .00$), in which significant improvements were observed in the psychological ($t(149) = -2.64, p < .00$) and environmental ($t(150) = -4.87, p < .00$) domains of quality of life. Regarding perceived social support, the average quantity ($t(155) = -3.88, p < .00$) and average satisfaction score ($t(122) = -3.61, p < .00$) of social support increased significantly when compared to baseline.

Conclusion: The preliminary findings suggest EAB group intervention might be an effective intervention for enhancing the quality of life and social support network of elderly with depressive symptoms. The participants found their lives more satisfied, enjoyable and meaningful. They also gained a bigger network and higher satisfaction toward their social support.

FEASIBILITY OF IMPLEMENTING THERAPEUTIC YOGA IN ASSISTED LIVING FACILITIES

Em V. Adams, M.S., CTRS, C-IAYT, RYT¹, Marieke Van Puymbroeck, Ph.D., CTRS, FDRT, RYT-500², Cynthia L. S. Pury, Ph.D.², Arlene A. Schmid, PhD, OTR, FAOTA, RYT-200³

¹Lehman College, New York, NY; ²Clemson University, Clemson, SC; ³Colorado State University, Fort Collins, CO

Background: Yoga interventions have yielded substantial benefits in physical functioning and overall wellbeing for older adults with varied chronic illnesses.¹ Common positive outcomes of yoga interventions are also commonly sought outcomes for long-term care (LTC) residents including improved balance, increased functional fitness, and effective pain management.²⁻⁷ However, many studies are aimed at specific health conditions, and evidence on the feasibility of a yoga intervention for residents of LTC with wide-ranging health conditions is sparse. Therefore, the purpose of this study was to evaluate the acceptability of a therapeutic yoga intervention on the physical functioning and perceived physical functioning of assisted living residents.

Methods: This was a convergent mixed method intervention study, consisting of an eight-week seated yoga program, led by a Certified Yoga Therapist twice a week for 50 minutes each session. Participants were recruited from four assisted living facilities in the southeast. To be included participants were: willing to attend yoga class twice a week for eight-weeks; have no contraindications for exercise, and have no known diagnosis of dementia. Residents were excluded if they were: currently enrolled in another study; planned to leave the facility in the next 10-weeks, or required ventilator assistance to breathe. Quantitative measures, (the Function in Sitting Test (FIST),⁸ the Arm Curl Test (ACT),⁹ Back Scratch test (BST),⁹ Sit and Reach test (SR),⁹ and Pain Interference and Engagement (PEG) scale,¹⁰ were collected at baseline (T1) and post-intervention (T2). Additionally, focus groups were conducted after the completion of each intervention. Treatment fidelity was observed either in person or through video observations of the intervention and was documented on a fidelity checklist.

Results: A total of 15 participants completed the study. Paired t-tests revealed significant improvements in upper body strength as measured by the ACT ($t(14)=-4.811, p=.000$), and lower body strength as measured by the sit and reach test ($t(14)=-2.799, p=.014$). A Wilcoxon's signed-rank revealed a significant difference for the FIST ($Z=-2.945, p=.003$) indicating improved seated balance, and for the BST ($Z=-2.227, p=.026$), indicating increased upper body flexibility. There was no significant difference in self-reported pain interference. Three themes resulted from content analysis of the focus groups were: a) improved functional ability; b) improved activity participation; and c) increased relaxation.

Discussion: Seated yoga was acceptable and promising for improving overall functional fitness. During focus groups, residents reported high acceptability, indicating they perceived improved functional fitness. Future research is recommended that has an active treatment comparison group and that is inclusive of people with known dementia.

10:30 AM-11:30 AM

THE EFFECT OF A PHYSICAL ACTIVITY INTERVENTION ON PHYSICAL FUNCTION IN OLDER AFRICAN AMERICAN ADULTS

Leah A. Carter, M.Ed¹, Robbie Beyl, PhD¹, William Johnson, PhD¹, Melissa N. Harris, CCRP¹, Callie Hebert, M.S¹, Owen Carmichael, PhD¹, Robert L. Newton, PhD¹

¹Pennington Biomedical Research Center, Baton Rouge, LA

Introduction: Assessment of physical function is important due to its association with overall health and quality of life in older adults. Studies have also shown associations in physical activity correlating with greater independence in old age, however, outcomes in physical function due to increased physical activity among older African American adults remain. The primary objective of this analysis is to determine the effects of a physical activity intervention in older African American adults on physical function.

Methods: We recruited 56 African Americans (AA) aged 65 to 85 into the 12-week Program for African American Cognition and Exercise (PAACE) study. Participants were randomized into either a physical activity program (PAP), or a successful aging health education program (SAP). Participants in the SAP attended twelve 30-60 minute group sessions conducted at an academic institution. Participants in the PAP attended two supervised group physical activity sessions per week led by research staff at a local YMCA. The PAP, informed by older AA Adults through focus groups conducted prior to designing the intervention, was comprised of aerobic and strength training exercises. PAP Participants were instructed to engage in 2-3 additional days of physical activity at home. Physical function was assessed at baseline and follow up using hand grip strength, 2-minute walk test, and the Short Physical Performance Battery (SPPB) which includes walking speed, a balance test, and repeated chair sit to stand test, with the sum of the three individual categorical scores yielding the final SPPB score [range points: 0 (worst) to 12 (best)].

Results: Participants had a mean age of 69.2 (3.4), were 73.2% female, and the mean BMI was 32.5 (6.1). Total SPPB scores at baseline were 10.6 (0.28) and 10.7 (0.28) for PAP and SAP, respectively. Participants in PAP had significant ($p = 0.034$) increases in SPPB chair sit to stand scores at follow-up compared to those in SAP. Dominant and non-dominant handgrip strength decreased at follow-up in PAP (p values < 0.004) and SAP (p values < 0.019), but there were no between group differences in change. There were no between group differences in the SPPB balance, walk, or total scores (p values > 0.245).

Conclusions: Older African American adults randomized to a 12 week physical activity intervention improved standing performance. However, these individuals also showed a decrease in hand grip strength. There were no other changes in physical performance scores, likely because of ceiling effects.

THE CHEMO-GUT STUDY: METHODOLOGICAL CHALLENGES AND PRELIMINARY FINDINGS

Julie M. Deleemans, MSc.¹, Faye Chleilat, M.Sc., B.Sc.², Mohamad Baydoun, PhD³, Katherine-Ann L. Pedalue, BA⁴, Andrew McLennan, B.A. Psychology², Jan-Willem Henning, MBChB, FRCPC¹, Raylene A. Reimer, PhD, RD², Linda E. Carlson, PhD²

¹University of Calgary Cumming School of Medicine, Calgary, AB, Canada;

²University of Calgary, Calgary, AB, Canada; ³University of Calgary, Calgary, AB, Canada; ⁴Cumming School of Medicine, Calgary, AB, Canada

Background: Cancer among young adults has risen 38% in recent decades. Chemotherapy adversely affects the gut microbiome, inducing acute dysbiosis, and altering physiological, psychological and cognitive function. The gut microbiome is an important modulator of immune, metabolic, psychological and cognitive mechanisms. Therefore, understanding chemotherapy's long-term effects on gut microbiota and psycho-physiological outcomes is crucial to improve survivors' physical and mental health, but remains unexamined.

Methods: This longitudinal study investigates chemotherapy induced gut dysbiosis, and associations between gut microbiota, and immune, anthropomorphic, cognitive and psychological outcomes using data collected at 3 time points in the first 6 months post-chemotherapy. Participants are stage I – IV, 18–39 year old blood or solid tumor, except CNS and colorectal, cancer patients (N >50), and a healthy sibling, friend, or partner as control (N >50). Measures include: fecal gut microbiota composition using 16s RNA sequencing; Psychological and cognitive patient reported outcomes for depression, anxiety, PTSD, pain, fatigue, and social and cognitive function; Dual-energy X-ray Absorptiometry for fat and lean mass, and bone mineral concentration; Serotonin, Brain Derived Neurotrophic Factor (BDNF), cytokines (IL-6, IL-1b, TNF-a, IL-10), and C-reactive protein from serum; and long-term cortisol from hair samples.

Results: In consideration of recruitment challenges, the study protocol was modified to be more pragmatic by being more inclusive of patients within 6 months post-chemotherapy, and metastatic patients who are stable. To date, 12 patients have been contacted and 6 have been screened. Of the patients screened, the mean age is 32.67 years, and 80% are male. Diagnoses include sarcoma (n=1), hematological (n=4), and gastrointestinal (n=1) cancers. Gut-related symptoms reported after chemotherapy include heartburn, loose stool, constipation, irregular bowel movements, abdominal pain, c-difficile infection, and *helicobacter Pylori* infection lasting more than 1 year after chemotherapy has ended.

Implications: In this ongoing study, methodological changes were made to enhance recruitment feasibility. Survivors' screened report persistent post-chemotherapy gastrointestinal issues which may suggest ongoing dysbiosis of the gut microbiome that require further exploration. Understanding what bacterial species are depleted after chemotherapy, how long these effects last, and potential bio-behavioural mechanisms that drive psychological and cognitive issues among survivors will allow for targeted, integrative interventions to be developed.

10:30 AM–11:30 AM

THE ROLE OF FATIGUE AND MOOD IN PERCEIVED COGNITIVE IMPAIRMENT AMONG BREAST CANCER SURVIVORS

Julie Kircher, MA¹, Emily Janio, MPH¹, Michael A. Hoyt, Ph.D.¹, Dara Sorkin, PhD¹

¹University of California, Irvine, Irvine, CA

Nearly 75% of breast cancer survivors experience cognitive impairment or “chemobrain” either during or following chemotherapy. Chemobrain can include both patient-reported and objectively-assessed difficulties with attention, memory, and mental slowness. Prior research on objectively-assessed cognition demonstrates a weak relationship with psychosocial factors but there is some evidence for a link with patient-reported cognition; though the influence of behavioral symptoms such as persistent fatigue, distress, and depressive symptoms remain unclear. The purpose of the present study was to examine how physical and psychosocial factors relate to patient-reported cognitive problems over 12-weeks in a diverse sample of breast cancer survivors participating in a weight loss and health behavior intervention. It was hypothesized that greater levels of fatigue and negative affect would predict higher patient-reported cognitive problems over time.

The data came from the “Mi Vida, Mi Salud” intervention study, which aimed to reduce symptom burden for Latina and non-Latina breast cancer survivors. Psychosocial and physiological measures were gathered at baseline and a 12-week follow-up from 48 women (24 Latina, 24 White). Hierarchical linear regression was performed to predict perceived cognitive impairment. Ethnicity, intervention group status, body mass index (BMI) and chemotherapy receipt (yes/no), were included as covariates. Baseline levels of fatigue, negative affect, and BMI accounted for 15% of the variance in perceived cognitive impairment. The final model [$F(3, 28) = 7.15, p = .001, \Delta R^2 = .10$] revealed that only change in fatigue [$\beta = .43, t(38) = 4.11, p < .001$], and not negative affect, significantly predicted patient-reported cognitive impairment. Results reveal that both physical and emotional factors may worsen patient-reported cognitive impairment. A better understanding of the role behavioral indicators have on patient-reported cognition can help to inform health-care providers in ways to address and reduce cognitive complaints.

SOCIAL NEEDS AND HEALTH-RELATED QUALITY OF LIFE AMONG AFRICAN AMERICAN CANCER SURVIVORS

Theresa A. Hastert, PhD, MPP¹, Jean A. McDougall, PhD², Jennifer L. Beebe-Dimmer, PhD, MPH¹, Stephanie Pandolfi, PhD¹, Ann G. Schwartz, PhD, MPH¹

¹Wayne State University School of Medicine/Karmanos Cancer Institute, Detroit, MI; ²University of New Mexico School of Medicine, Albuquerque, NM

Background: Social needs may impact cancer survivors' health-related quality of life (HRQOL) above and beyond sociodemographic characteristics and cancer-related factors. The purpose of this study is to estimate differences in HRQOL based on African American survivors' experiences of social needs related to housing, utilities, transportation, and safety.

Methods: Results include survey data from 849 African American cancer survivors who participated in the Detroit Research on Cancer Survivors (ROCS) survivorship cohort, a population-based study of African American survivors of breast, colorectal, lung, and prostate cancer in Metropolitan Detroit. Social needs include survivor self-report of a utility company shutting off service in the past 12 months, worry that they may not have stable housing in the next 2 months, going without healthcare because of lack of transportation in the past year, and not feeling safe in their neighborhood. HRQOL is measured using the validated Functional Assessment of Cancer Therapy – General (FACT-G). FACT-G score differences of 3–5 points represent clinically meaningful differences in HRQOL. Linear regression models control for demographic (age, sex, education, income) and cancer-related factors (site, stage, treatments received, treatment status) as well as cancer-related financial hardship.

Results: Mean age was 60.3 years at the time of ROCS participation. Half (49.5%) of survivors were women, one-third (33%) reported incomes < \$20,000 per year, and 63% reported education beyond high school. Worry about stable housing was the most common social need (13%) followed by missing care because of transportation (10%), not feeling safe in their neighborhood (10%), and experiencing a utility shutoff (9%). Compared to those without the social need, FACT-G scores were 6.2 (95% CI: 1.0, 11.4) points lower for those who experienced utility shut-offs, 10.4 (95% CI: 5.9, 15.0) points lower for those who feared unstable housing, 12.1 (95% CI: 7.1, 17.2) points lower for those who went without healthcare due to lack of transportation, and 10.4 (95% CI: 5.7, 15.0) points lower for those generally did not feel safe in their neighborhood in fully adjusted models.

Conclusions: Among African American cancer survivors, social needs related to housing, utilities, transportation, and safety are all associated with clinically meaningful differences in HRQOL after accounting for demographic, socioeconomic, and cancer-related factors.

TRACKER WEAR AND PHYSICAL ACTIVITY MONITORING IN AN MHEALTH INTERVENTION FOR SURVIVORS OF ADOLESCENT AND YOUNG ADULT CANCER

Erin M. Coffman, MA¹, Molly A. Diamond, MPH², Kristen Polzien, Ph.D.³, Janet Tooze, PhD, MPH⁴, Denisha Little-Greene, PA, MMS⁵, John M. Salsman, PhD⁵, Carmina G. Valle, PhD, MPH²

¹UNC Chapel Hill Gillings School of Public Health, Durham, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³University of North Carolina, Chapel Hill, NC; ⁴Wake Forest School of Medicine, Winston-salem, NC; ⁵Wake Forest School of Medicine, Winston Salem, NC

Background: Most adolescent and young adult (AYA) cancer survivors do not meet national guidelines of 150 minutes of moderate-to-vigorous physical activity (MVPA) per week. Little is known about how AYAs utilize activity trackers and how tracker use relates to MVPA. This study describes adherence to tracker wear, trajectories of tracker-measured active minutes (AM), and goal attainment in THRIVE, a pilot RCT of a 3-month mHealth physical activity intervention for AYAs.

Methods: Intervention participants included in this analysis (n=30, 76% female, 76% white, 30.2 + 5.0 years and 4.0 + 2.8 years postdiagnosis) received a Fitbit with companion app, individual videochat session, 12 weekly emailed lessons with tailored feedback, and access to a Facebook group. AYAs were encouraged to track their physical activity daily and given weekly AM goals progressing to 150 MVPA minutes. Daily tracker wear and AM were assessed using Fitbits. Adherence to tracker wear included all days with >1000 steps and was dichotomized as high (5 ≥ days/week) vs low (< 5 days/week) as the reference group. Descriptive statistics were conducted for tracker wear, AM, and goal attainment, reported as mean (SE). A linear mixed model with subject level random intercepts regressed AM per week onto tracker wear.

Results: Over the 3-month intervention period, on average AYAs wore their tracker 61 of 84 intervention days (SE=18.4, 72%), with a mean of 5.08 days (SE=1.53) per week. Adherence to tracker wear peaked in week 4 with a mean of 6.40 days (SE=1.35) and declined to 4.17 days (SE=2.72) in week 12. AYAs averaged 107.89 (SE=109.29) AM/week, peaking in week 2 with 142.97 AM/week (SE=169.16) before declining to 82.70 (SE=120.95) in week 10. The proportion of participants meeting goals was highest in weeks 1 and 2 (60%) and lowest in week 10 (17%). Compared to low tracker wear, high wear was associated with an expected increase of 92.15 AM/week (SE=37.07, p=.012).

Conclusions: Tracker wear was high in this sample of AYAs and was associated with increased physical activity. Further research is needed to examine long-term use of activity trackers in physical activity interventions and identify strategies associated with increased physical activity in AYAs.

STRATEGIES TO RECRUIT YOUNG ADULT CANCER SURVIVORS TO DIGITAL BEHAVIORAL HEALTH INTERVENTIONS: WHAT MESSAGES AND CHANNELS WORK

Lindsey N. Horrell, PhD, MPH, RN¹, Allison J. Lazard, PhD², Deborah F. Tate, PhD³, Bernardine M. Pinto, Ph.D.⁴, Molly A. Diamond, MPH¹, Erin M. Coffman, MA⁵, Brooke T. Nezami, PhD, MA¹, Kristen Polzien, Ph.D.³, Karen E. Hatley, MPH⁶, Carmina G. Valle, PhD, MPH¹

¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³University of North Carolina, Chapel Hill, NC; ⁴University of South Carolina, Columbia, SC; ⁵UNC Chapel Hill Gillings School of Public Health, Durham, NC; ⁶UNC Chapel Hill, Chapel Hill, NC

Background: Young adult cancer survivors (YACS) have few age-appropriate resources to meet their unique behavioral health needs. Research is emerging to address this gap, yet engaging YACS in behavioral intervention research remains challenging. This study tested a subset of recruitment messages and channels implemented in the Improving Physical Activity after Cancer Treatment (IMPACT) study, a 12-month RCT of a mobile health intervention, to identify effective approaches to enroll YACS in intervention research.

Methods: We developed two recruitment messages incorporating intrinsic or extrinsic motivational framing and distributed advertisements through direct mail and paid social media (Facebook and Instagram) campaigns. Individuals from the UNC Tumor Registry were randomized to receive one of the ads via direct mail. Social media ads targeted adults 18 or older with interests in cancer-related topics. All ads provided a unique URL to the study website and were used to track screening survey access. Chi-square analyses and logistic regression were used to test the main and interaction effects of message (intrinsic vs. extrinsic) and channel (direct mail vs. paid social media) on the number of screening surveys initiated and YACS enrolled in IMPACT.

Results: During October and November of 2018, 1830 mailings were distributed: 944 (51.6%) intrinsic and 886 (48.4%) extrinsic. Of the intrinsic mailings, 130 screening surveys were initiated (13.8%), and 61 YACS enrolled in the study (6.5%). Of the extrinsic mailings, 105 surveys were initiated (11.9%) and 54 enrolled (6.1%). Two five-day social media campaigns were launched during March and April of 2019, yielding 931 unique link clicks, 469 (50.4%) in response to an intrinsic ad, and 462 (49.6%) in response to an extrinsic ad. Exposure to the intrinsic ad led to 13 initiated screening surveys (2.7%) and 3 YACS enrolled in the study (0.7%), while exposure to the extrinsic ad led to 18 initiated surveys (3.9%) and 5 YACS enrolled (1.1%). There was a significant main effect of channel; direct mail led to more surveys initiated ($p < 0.001$) and YACS enrolled ($p < 0.001$) than social media. Message type did not significantly impact screening and enrollment, and there was no significant interaction between message and channel.

Conclusions: Mailings yielded a higher number of YACS screening and enrolling in IMPACT than paid social media ads. Intrinsic and extrinsic appeals did not differ for recruitment outcomes, suggesting that either message type can attract YACS to intervention trials.

SLEEPLESS IN SURVIVORSHIP: EXPLORING THE RELATIONSHIP BETWEEN SLEEP DISTURBANCE AND FEAR OF RECURRENCE IN LYMPHOMA SURVIVORS

Helen R. Mizrach, BS¹, Giselle K. Perez, PhD², Daniel L. Hall, PhD², Elyse R. Park, Ph.D., MPH³, Jeremy S. Abramson, MD, MMSc.²

¹Massachusetts General Hospital/Harvard Medical School, Somerville, MA;

²Massachusetts General Hospital/Harvard Medical School, Boston, MA;

³Massachusetts General Hospital, Boston, MA

Background: Sleep disruption is a common and debilitating concern for survivors of hematologic cancers. During the post-treatment transition period, many lymphoma survivors experience distress and significant impairments in quality of life; yet, little research has examined sleep behavior during this time. Addressing poor sleep is essential to improve the health of this population already at elevated risk for persistent fatigue, co-morbid illness, and emotional disturbances. Lymphoma survivors also struggle with fear of cancer recurrence (FOR), which could negatively impact their sleep. However, little is known about the link between FOR and sleep among lymphoma survivors soon after treatment ends. To explicate these associations, we examined the relationship between sleep, FOR, and distress in lymphoma survivors who recently completed treatment.

Methods: A baseline survey was administered during a pilot RCT to 30 lymphoma survivors within 2 years of treatment completion. Survey items assessed sleep quantity and quality (Pittsburgh Sleep Quality Index), sleep disruption (Fatigue Symptom Inventory), FOR (Assessment of Survivor Concerns), anxiety (GAD-7), and perceived psychological distress (Visual Analog Scale). Descriptive statistics and zero order correlations ($\alpha=.05$) were computed for demographic and main study variables.

Results: Lymphoma survivors (mean age=53.1, 90% non-Hispanic white, 50% female) reported spending on average 8.1 hours in bed but only getting 6.5 hours of sleep. Most (93.3%) of the sample endorsed some degree of sleep disruption, while 33.3% rated their sleep quality as “fairly bad” or “very bad.” FOR was very common (96.7%), with one-third (36.7%) of the sample reporting they worry “very much” about cancer-related concerns. Total sleep was negatively correlated with FOR ($R=-.50$, $p<.01$) and anxiety ($R=-.41$, $p=.03$). Poorer sleep quality was associated with higher FOR ($R=.37$, $p=.05$), anxiety ($R=.45$, $p=.01$), and psychological distress ($R=.44$, $p=.02$). Similarly, higher sleep disruption was correlated with higher FOR ($R=.55$, $p<.01$), anxiety ($R=.47$, $p=.01$), and psychological distress ($R=.43$, $p=.02$).

Conclusion: Sleep disturbances are common and associated with FOR and psychological distress among lymphoma survivors transitioning off treatment. Future interventions to improve sleep in lymphoma survivors may consider targeting fear of recurrence to reduce distress.

ATTITUDES AND KNOWLEDGE TOWARDS LUNG CANCER SCREENING AMONG PRIMARY CARE CLINICIANS IN NEW JERSEY: A QUALITATIVE STUDY

Stacy N. Davis, PhD, MPH¹, Jeanne M. Ferrante, MD, MPH², Tran Thai, MD³, Michael B. Steinberg, MD, MPH, FACP², Shawna V. Hudson, PhD², Anita Y. Kinney, PhD, RN, FAAN⁴

¹Rutgers School of Public Health, Piscataway, NJ; ²Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; ³Rutgers Robert Wood Johnson University Hospital, New Brunswick, NJ; ⁴Cancer Institute of New Jersey Rutgers University, New Brunswick, NJ

Introduction: The efficacy of lung cancer screening with annual low-dose computed tomography (LDCT) to increase the early detection and subsequent survival of lung cancer has been demonstrated by the National Lung Screening Trials. Unfortunately, utilization of LDCT remains suboptimal. Primary care clinician attitudes toward and knowledge of LDCT may influence patient use of LDCT. This study seeks to assess and understand the attitudes towards and knowledge of LDCT for lung cancer screening among primary care clinicians.

Methods: Semi-structured phone interviews were conducted with 30 primary care clinicians (family medicine and internal medicine) from federally qualified health centers, community, and academic primary care practice settings throughout New Jersey. Interviews were audio-taped and transcribed verbatim. Qualitative data were analyzed using content analytic procedures.

Results: Gaps in clinician knowledge of LDCT were related to the upper age limit for screening and smoking history eligibility, along with reimbursement. Nearly all clinicians felt the benefits of LDCT outweighed the risks. The primary perceived benefit of LDCT was the early detection of lung cancer. The perceived risks were radiation exposure and false positives that require invasive follow-up procedures. Clinicians expressed low clinician awareness of LDCT and low LDCT recommendation as the primary barriers to patient uptake of LDCT within New Jersey and nationwide. Additional barriers included lack of patient knowledge of LDCT, cost/insurance, fear of test results, and lack of motivation to undergo LDCT.

Conclusions: Clinicians viewed the early detection of lung cancer as the primary benefit of LDCT. Clinicians' lack of awareness and knowledge of LDCT were the key barriers to LDCT screening rates locally and nationally. Gaps in knowledge and positive attitudes towards LDCT indicate a wish for clinician education to aid in shared-decision making encounters and positively impact patient uptake of LDCT.

10:30 AM–11:30 AM

UNDERSTANDING PARTICIPATION IN A COMMUNITY-BASED PHYSICAL ACTIVITY PROGRAM FOR BREAST CANCER SURVIVORS

Alexis Whitehorn, BSc¹, Allyson Tabaczynski, BSc², Catherine Sabiston, PhD¹, Linda Trinh, PhD¹

¹University of Toronto, Toronto, ON, Canada; ²University of Toronto, TORONTO, ON, Canada

Background: Physical activity (PA) improves health-, and fitness-related outcomes in breast cancer survivors (BCS), yet few BCS are meeting PA guidelines. Community-based PA programs have the potential to increase PA behavior, but more theoretically grounded programs are needed to understand PA participation in cancer survivors. Few studies have examined motivational outcomes using the Self-Determination Theory (SDT) in a community-based setting. Therefore, understanding PA participation of BCS in a community-based setting is needed.

Purpose: To examine the associations between participation in Curves™ and motivational regulations using the SDT in BCS.

Methods: 66 post-treatment BCS were recruited from a breast clinic in Montreal, Canada and provided with a free, 1-year membership to Curves™. The Curves™ program is a women-only circuit training facility with numerous locations across North America. It includes a full body, 30-minute circuit fitness program using aerobic and resistance machines targeting strength and aerobic fitness. At the end of the membership period, BCS were administered a self-report questionnaire assessing intrinsic, external, introjected, and identified regulation using the Behavioral Regulation in Exercise Questionnaire; and a modified version of the Godin Leisure-Time Exercise Questionnaire to measure PA. Participation in Curves™ was measured by indicating the frequency of participation (i.e., 1=I didn't attend to 4=I attended as much as I could). A hierarchical linear regression was conducted to examine the association between exercise motivation and participation in Curves™.

Results: BCS were a mean age of 58.7±10.5, primarily Stage II, had a mean BMI of 28.3±6.5 kg/m², and were 58.7±39.1 months since diagnosis. Overall, 54 BCS attended Curves™ with 55.4% attending at least 2–3 days/wk and 52.3% BCS were meeting PA guidelines (150min/wk). Intrinsic regulation significantly predicted higher participation in Curves™ ($\beta=.37$; $p=.013$). No significant associations were found for external, introjected, and identified regulation and participation.

Conclusion: BCS who are intrinsically motivated are more likely to attend Curves™. Community-based PA programs provide accessible programming for cancer survivors to engage in PA. Future studies should better understand what motivates cancer survivors to be active in community-based PA programs.

TOWARD A THEORETICAL UNDERSTANDING OF YOUNG FEMALE CANCER SURVIVORS' DECISION-MAKING ABOUT FAMILY-BUILDING POST-TREATMENT

Catherine Benedict, PhD¹, Alexandria L. Hahn, MS², Alyssa McCreedy, BS³, Joanne F. Kelvin, MSN, RN, CNS⁴, Michael A. Diefenbach, Ph.D.⁵, Jennifer S. Ford, PhD⁶

¹Stanford University School of Medicine, Palo Alto, CA; ²Albert Einstein College of Medicine, The Bronx, NY; ³Feinstein Institute for Medical Research, Northwell Health, Manhasset, NY; ⁴Memorial Sloan Kettering Cancer Center, New York, NY; ⁵Northwell Health, Manhasset, NY; ⁶Hunter College, City University of New York (CUNY), New York, NY

Purpose: The importance of fertility and fertility preservation among young cancer survivors is well known. Irrespective of whether young women preserve fertility, however, family-building after cancer may be challenging. Due to gonadotoxic treatment effects, family-building often requires in vitro fertilization, surrogacy, or adoption, with associated challenges such as uncertain likelihood of success, high costs, and complicated laws regulating surrogacy and adoption. This study examined adolescent and young adult female (AYA-F) survivors' experiences and decision-making related to family-building after cancer.

Methods: Semi-structured interviews explored fertility and family-building themes (N=25). Based on an a priori conceptual model, hypothesis coding and grounded theory coding methods guided qualitative analysis.

Results: Participants averaged 29 years old (SD=6.2); were mostly White and educated. Four major themes were identified: Sources of Uncertainty, Cognitive and Emotional Reactions, Coping Behaviors, and Decision-making. Uncertainty stemmed from medical, personal, social, and financial factors, which led to cognitive, emotional, and behavioral reactions to reduce distress, renegotiate identity, adjust expectations, and consider 'next steps' toward family-building goals. Most AYA-Fs were unaware of their fertility status, felt uninformed about family-building options, and worried about expected challenges. Despite feeling that "action" was needed, many were stalled in decision-making to evaluate fertility or address information needs; postponement and avoidance were common. Many AYA-Fs indicated a desire for information and care in response to uncertainty and feared challenges, while simultaneously voicing reluctance to pursue such resources to meet their needs. Younger AYA-Fs tended to be less concerned and assumed fertility problems would be treatable in the future.

Conclusion: AYA-Fs reported considerable uncertainty, distress, and unmet needs surrounding family-building decisions post-treatment. Support services are needed to better educate patients and provide opportunity for early referral to address potential future challenges. Reproductive counseling should occur throughout survivorship care to address medical, psychosocial, and financial difficulties and to allow time for informed decision-making and the opportunity to prepare for barriers such as high costs.

AN EXAMINATION OF CAUSAL ATTRIBUTIONS OF CANCER FROM A POPULATION HEALTH ASSESSMENT

Bernard F. Fuemmeler, PhD, MPH¹, Carrie A. Miller, PhD, MPH¹, Albert J. Ksinan, PhD¹, Elizabeth K. Do, PhD, MPH¹, Bonny B. Morris, RN, MSPH², Kendall Fugate-Laurs, BS¹, Westley L. Fallavollita, BS¹, Sunny Jung Kim, Ph.D., M.S., M.A.³, David C. Wheeler, PhD, MPH¹, Bassam Dahman, PhD¹, Tamas S. Gal, Ph.D., M.B.A.¹, Gordon D. Ginder, M.D.¹

¹Virginia Commonwealth University, Richmond, VA; ²Virginia Commonwealth University, Midlothian, VA; ³Virginia Commonwealth University School of Medicine, Richmond, VA

Background: Causal attributions of cancer have the potential to increase preventive strategies to reduce cancer risks. Yet, less is known about factors associated with beliefs about cancer causation.

Purpose: The purpose of this study is to determine factors associated with causal attributions of cancer among adults within the Virginia Commonwealth University Massey Cancer Center catchment area.

Methods: Data were obtained from a cross-sectional survey of 559 respondents of the Together for Health – Virginia Study, a population-based sample of adults. Individual-level factors including demographic (age, gender, race/ethnicity, rural identity) and socioeconomic (education, income) characteristics were assessed, as well as lifestyle (tobacco use, body mass index), medical history (family or personal history of cancer), delay discounting, and individuals' attitudes towards alternative therapies. Attitudes towards cancer were measured by eight items reported on a 4-point Likert scale (strongly agree to strongly disagree). The first four items reflected participants' agreement on the following as causes of cancer: behavior, tobacco, obesity, and HPV. The other four items included statements that reflected fatalism about cancer. Structural equation models were run separately for each type of belief modeled as a latent dependent variable.

Results: Respondents were 55.6 years (SD=15.8) on average, 72.6% White, 51.6% female, and 38.3% self-reported rural identity. Fatalistic beliefs about cancer was associated with rural identity ($\beta=0.1$, $p=0.02$) and believing in alternative therapies as a primary cancer treatment ($\beta=0.1$, $p=0.03$) while older age ($\beta=-0.3$, $p<0.01$), higher levels of education attainment ($\beta=-0.2$, $p<0.01$), and having a personal history of cancer ($\beta=-0.2$, $p<0.01$) were significantly associated with lower fatalism. Stronger beliefs in concrete causes of cancer were associated with higher educational attainment ($\beta=0.2$, $p<0.01$) and income levels ($\beta=0.2$, $p=0.01$). These beliefs were lower among Black respondents ($\beta=-0.2$, $p=0.02$).

Conclusions: This study provides evidence for the relationship between causal attributions of cancer and individual factors, emphasizing the role that culture may play. Future implementation research is needed to culturally adapt prevention efforts and cancer awareness messaging and campaigns using causal attributions of cancer.

ASSOCIATIONS BETWEEN PRE-OPERATIVE EXERCISE FREQUENCY AND SUBSEQUENT SYMPTOMS AND ACTIVITY BEHAVIOR AFTER CANCER SURGERY

Krina C. Durica, M.A.¹, Michaela Danko, BS, BA¹, Raghu Mulukutla, n/a², Yiyi Ren, MS², Elynn B. Youm, BA³, David L. Bartlett, MD¹, Dana H. Bovbjerg, PhD¹, Anind K. Dey, PhD⁴, John M. Jakicic, PhD¹, Carissa A. Low, PhD¹

¹University of Pittsburgh, Pittsburgh, PA; ²Carnegie Mellon University, Pittsburgh, PA; ³Vitalant - HCWP, Pittsburgh, PA; ⁴University of Washington, Seattle, WA

Background: Abdominal cancer surgery involves high postoperative risks, but perioperative physical activity may reduce these risks and facilitate recovery. The purpose of this study was to examine associations between preoperative self-reported exercise frequency and daily symptom and activity behavior patterns during a pilot mobile intervention that prompts participants to walk after prolonged sedentary behavior.

Methods: Fourteen patients aged 25-65 ($M = 49$; 79% female) scheduled for surgical treatment of metastatic peritoneal or colorectal cancer participated in an intervention to reduce sedentary behavior before and after surgery. Starting at least two weeks before surgery through 30 days post-discharge, patients wore a Fitbit smartwatch, rated symptom severity daily on a 0-10 scale, and received prompts to walk after prolonged periods of sedentary behavior. A questionnaire was completed at the start of the study assessment period that asked patients about weekly exercise frequency prior to enrollment. Independent t-tests examined differences in self-reported symptom severity and activity behavior during the perioperative period in patients that reported exercising less than three times per week ($N = 9$) and three or more times per week ($N = 5$).

Results: Participants endorsing more frequent exercise prior to study enrollment reported significantly less severe fatigue ($M = 3.5$ vs $M = 7.1$, $t(7) = 3.96$, $p = .005$) and nausea ($M = 1.2$ vs $M = 5.4$, $t(7) = 3.72$, $p = .007$) during inpatient recovery and less severe nausea post-discharge ($M = 0.6$ vs $M = 2.6$, $t(10) = 2.44$, $p = .035$). The self-report data on frequency of preoperative exercise was also associated with higher Fitbit step counts during inpatient ($M = 2414$ vs $M = 586$, $t(8) = -2.702$, $p = .027$) and post-discharge recovery ($M = 2824$ vs $M = 1122$, $t(11) = -3.349$, $p = .006$) as well as with shorter sedentary bouts ($M = 52.2$ vs $M = 97.7$ minutes, $t(11) = 3.143$, $p = .009$) and longer active bouts post-discharge ($M = 2.0$ vs $M = 1.4$ minutes, $t(11) = -2.520$, $p = .028$).

Conclusion: In the context of a mobile technology-supported sedentary behavior intervention, individuals reporting more frequent exercise prior to cancer surgery showed less severe postoperative symptoms (fatigue and nausea) and more postoperative physical activity (more steps taken, shorter sedentary bouts, and longer active bouts). Although based on a small pilot sample and unadjusted for age or comorbidity, these findings suggest that preoperative physical activity may facilitate recovery from abdominal cancer surgery. An ongoing randomized trial will evaluate the effects of the sedentary behavior intervention on clinical outcomes after surgery.

UNDERSTANDING PATIENT LEVEL FACTORS THAT INFLUENCE COLORECTAL CANCER SCREENING AMONG LATINXS

Miriam M. Maldonado, n/a¹, Marisa S. Torres-Ruiz, MPH², Jessica Haughton, MPH, MA³, Lisa Madlensky, PhD, CGC⁴, Kristen J. Wells, PhD, MPH³, Sophia Rodriguez, BS³, Jennifer Schneider, MPHc, MAc³, Elva M. Arredondo, Ph.D.³

¹San Diego State University, Chula Vista, CA; ²San Diego State University/University of California, San Diego, San Diego, CA; ³San Diego State University, San Diego, CA; ⁴University of California, San Diego, La Jolla, CA

Background: Colorectal cancer (CRC) is highly preventable, and lower rates of CRC screening are evident in Latinxs compared to other ethnic/racial groups. Lack of education as well as cultural beliefs and myths have been associated with low CRC screening in Latinxs. The goal of this study was to understand patient level factors that influence CRC screening among Latinxs who have not been screened for CRC.

Methods: Participants were recruited in waiting rooms from a federally qualified health center (FQHC) in the Mexico-US border. Individual interviews ($n=9$ men; $n=11$ women) were conducted in Spanish with participants age 50+ years who had not had CRC or completed CRC screening (FOBT or colonoscopy) in the past. Interviews were audio-recorded, transcribed, and coded by research staff in Spanish. Data were analyzed using a rapid qualitative approach and guided by an adapted Health Belief Model (HBM) including individual perceptions, modifying factors, and likelihood of action. Codes were discussed collectively, and a matrix was created to consolidate quotes and themes that fit into the adapted HBM.

Results: Mean age of participants was 63.35 (9.30) years, and 70% achieved elementary school or less education. Four primary themes influencing CRC screening were identified: 1) lack of knowledge about CRC and screening, 2) fatalism (e.g., believing health is in the hands of God), 3) misinformation about causes of CRC, and 4) beliefs about masculinity (e.g., *machismo*). These themes fit into the HBM constructs of perceived susceptibility, perceived barriers to preventative action, and socio-psychological variables.

Conclusion: Lack of knowledge of CRC, cultural beliefs, and gender norms are barriers to CRC screening among Latinxs. These findings suggest that culturally tailored educational messages and strategies are needed to increase CRC knowledge among Latinxs living in the US-Mexico border.

AN ANALYSIS OF GHANAIAI STUDENTS' PERCEPTIONS OF THE HPV VACCINE AND CANCER PREVENTION

Cassady Mecate, BS¹, Beth A. Lanning, PhD, MCHES¹, Matthew Asare, PhD, MPH, MBA¹, Peter Agyei-Baffour, Ph.D², Margo Shanks, MPH¹¹Baylor University, Waco, TX; ²KNUST, Kumasi, Ashanti, Ghana

Introduction: Evidence shows an inverse relationship between an increase in the Human Papillomavirus (HPV) vaccination uptake and the prevalence of HPV related cancer. However, HPV vaccination rates in Ghana are low. Studies that examine Ghanaian adolescents' perceptions about HPV vaccination are limited. The purpose of this study was to assess the knowledge and attitudes of HPV vaccination of Ghanaian students.

Methods: We conducted four, thirty-minute focus group discussions with Ghanaian students. Sixteen open-ended questions were introduced to facilitate the focus group discussion among participants. The discussions were audio-recorded and transcribed verbatim.

Results: The sample (n=59) included junior high school students (n=30) and senior high school students (n=29). The participants consisted of females (n=50) and males (n=9) between the ages of 13 and 17 years. Our findings showed that sexuality education and HPV related topics are rarely taught in schools leaving students with a limited understanding of general preventive care and a lack of knowledge about the HPV vaccine. Due to limited resources, not all the hospitals in Ghana have centers where patients can get vaccinated. Additionally, sociocultural factors such as religion and the stigma associated with HPV hinder people from having open conversations about HPV vaccination behavior. Finally, we found that Ghanaian students have restricted access to affordable primary care practices and there are no standard routine medical checkups, therefore adolescents and their parents have limited outlets to discuss HPV vaccination with their providers.

Conclusion: The findings of our study demonstrate the need for more educational programs in Ghana that emphasize the importance of the HPV vaccine. Future HPV vaccination educational programs should equip students with the knowledge and resources needed to understand the importance of preventive care and overcome HPV vaccination related stigma.

CHARACTERIZING COMMUNICATION RESEARCH FUNDED BY THE NATIONAL CANCER INSTITUTE, 2013-2018: A GRANT PORTFOLIO ANALYSIS

Anna Gaysynsky, MPH¹, Camella Rising, PhD, MS, RDN², Neha Trivedi, PhD, MPH³, Emily B. Peterson, PhD⁴

¹National Cancer Institute/ ICF, Rockville, MD; ²National Cancer Institute, Division of Cancer Control and Population Sciences, Behavioral Research Program, Health Communication and Informatics Research Branch, Rockville, MD; ³National Cancer Institute, Bethesda, MD; ⁴National Cancer Institute, Newberry, FL

Background: Advancing communication science has been a priority of the National Cancer Institute (NCI) since 2001. Examining trends and gaps in funded communication research is particularly important given the rapidly changing communication environment.

Objective: To describe trends, summarize study characteristics, and identify gaps in NCI-funded communication research.

Methods: The NIH iSearch system was queried to identify NCI grant submissions from FY13-FY18 with communication keywords (e.g. "Health literacy") in the title or abstract. The search returned a total of 2,835 funded grants. After exclusion criteria were applied, 275 grants were retained for analysis. These grants were coded for topic, cancer site, cancer control continuum stage, study design, target population, socioecological model (SEM) level(s) targeted, and mention of theory.

Results: The number of communication grants funded each year remained steady between FY13 and FY18 (range: 43-51, mean: 45.8). The most frequently addressed topics were tobacco/e-cigarette use (n=100), communication behavior (n=71), and decision-making/patient engagement (n=47). Tobacco-related cancers (n=94), cancer in general (n=38), and breast cancer (n=38) were the most commonly studied cancer sites. Most grants (n=160) were at the prevention stage of the continuum, whereas end-of-life was infrequently addressed (n=15). Many grants employed randomized controlled trial (n=120) and mixed-methods approaches (n=66). However, novel study designs (e.g. Sequential Multiple Assignment Randomized Trials (SMART)) (n=5) and data linkage (n=3) were infrequently utilized. Cancer patients/survivors (n=78) and healthcare providers (n=50) were common target populations, while caregivers (n=13) and those with genetic or familial risk (n=9) were infrequently studied. While most grants did not target a particular racial/ethnic group, those that did primarily targeted African American (n=27) or Hispanic/Latino (n=26) populations. Other target groups included low SES (n=20), low literacy/English proficiency (n=17), and rural (n=11) populations. 124 grants were coded as "multilevel", while 151 grants assessed or intervened at only one level of the SEM. The individual level (n=263) and interpersonal level (n=104) were the most frequently targeted SEM levels. Among the 105 grants that mentioned a specific theory or framework, Social Cognitive Theory (n=14), RE-AIM (n=8), the Health Belief Model (n=6), and SEM (n=6) were most frequently cited.

Conclusions: The findings of this analysis suggest opportunities to advance communication science by supporting research in currently understudied areas (like communication at end-of-life), promoting additional work in underserved populations, facilitating multilevel research that incorporates higher levels of the SEM, and encouraging more systematic integration of theory.

10:30 AM–11:30 AM

ADVANCED LUNG CANCER PATIENTS' PERCEIVED MEDICAL STIGMA AND SYMPTOM EXPERIENCES

Ellen Krueger, B.S.¹, Ekin Secinti, M.S.², Catherine E. Mosher, Ph.D.¹¹Indiana University-Purdue University Indianapolis, Indianapolis, IN; ²Indiana University Purdue University Indianapolis, Indianapolis, IN

Lung cancer patients typically report greater symptom burden, emotional distress, and perceived stigma than patients of other cancer types. Internalization of perceived lung cancer stigma (e.g., shame, blame) has been associated with greater emotional distress, symptom severity, and delay in medical help-seeking. However, less is known about lung cancer patients' perceived stigma from their medical providers (i.e., medical stigma). In this study, we examined perceived medical stigma and its association with medical and symptom outcomes in advanced lung cancer.

Advanced, inoperable lung cancer patients (N = 102, 46% male, 83% White) were recruited from an academic cancer center in Indianapolis, IN to participate in this cross-sectional survey. Patients had an average age of 65 years (SD = 12). Most (78%) reported a history of smoking. Patients completed standardized measures of medical stigma, quality of life, functional status, medical comorbidities, and symptom severity (i.e., breathlessness, cough, sleep problems, fatigue, pain, emotional distress, nausea, and lack of appetite).

Most (77%) strongly disagreed with perceptions of medical stigma. This stigma was negatively correlated with quality of life, $r(100) = -.21, p < .05$, and positively correlated with fatigue, pain, anxiety, and depressive symptoms, $rs(96) = .24-.30, ps < .05$. Medical stigma was not correlated with other symptoms, smoking status, functional status, and number of medical comorbidities.

Findings suggest that the majority of advanced lung cancer patients did not perceive stigma from doctors and nurses at an academic cancer center. Prior research on medical stigma has been primarily qualitative or limited to single-item assessments. In our sample, perceiving greater medical stigma was associated with more severe symptoms. It is possible that patients perceiving greater medical stigma may be hesitant to seek symptom treatment or may be experiencing suboptimal care, leading to higher symptom burden. Longitudinal studies are needed to examine predictors of medical stigma and its impact in diverse samples of lung cancer patients.

DEPRESSION AND ANXIETY SYMPTOMS IN BEREAVED CAREGIVERS OF PATIENTS WITH ADVANCED CANCER

Bailey T. Jones, BA¹, Joseph A. Greer, PhD¹, Vicki A. Jackson, MD, MPH¹, Emily R. Gallagher, BSN, BA¹, Mihir Kamdar, MD¹, Simone Rinaldi, MSN, ANP-BC, ACHPN¹, Jennifer S. Temel, MD², Areej El-Jawahri, MD³¹Massachusetts General Hospital, Boston, MA; ²MGH, Boston, MA; ³Massachusetts General Hospital Cancer Center, Boston, MA

Background: Caregivers of patients with advanced cancer experience substantial caregiving burden and psychological distress during the illness course. However, data on depression and anxiety symptoms in bereaved caregivers and factors associated with their psychological distress are lacking.

Methods: We conducted a secondary analysis of 168 caregivers enrolled in a randomized trial of early palliative care integrated with oncology care versus oncology care alone for patients newly-diagnosed with incurable lung and non-colorectal gastrointestinal cancers and their caregivers who completed bereavement assessments at 3 months after their loved one's death. We used the Hospital Anxiety and Depression Scale (HADS) to assess patients' and caregivers' depression and anxiety symptoms at baseline within 8 weeks of diagnosis, and at 3-4 months after the patient's death (for caregivers). We asked caregivers to rate patient's physical and psychological distress in the last week of life on a 10-point scale. We used linear regression adjusting for randomization and cancer type to explore associations between patient and caregiver factors and bereaved caregivers' depression and anxiety.

Results: 30.4% (51/168) and 43.4% (73/168) of bereaved caregivers reported clinically significant depression and anxiety symptoms, respectively. Younger patient age ($B = -.06, P = 0.041$), higher patient baseline anxiety ($B = 0.28, P = 0.002$), and caregiver rating of worse physical ($B = 0.28, P = 0.035$) and psychological ($B = 0.41, P < 0.001$) distress experienced by the patient at the end of life (EOL) were associated with worse depression symptoms in bereaved caregivers. Only caregiver factors, including age ($B = -.07, P = 0.004$), female sex ($B = 1.60, P = 0.024$), and rating of worse psychological distress experienced by the patient at the EOL ($B = 0.42, P < 0.001$) were associated with worse bereaved caregivers' anxiety symptoms.

Conclusions: Bereaved caregivers of patients with advanced cancer experience substantial psychological distress which is associated with their perceptions of their loved one's distress at the EOL. Interventions to optimize EOL care for patients and reduce bereaved caregivers' psychological distress are needed.

A RANDOMIZED PILOT STUDY OF YOGA DELIVERED IN THE CLINIC DURING CHEMOTHERAPY FOR ADULTS DIAGNOSED WITH GASTROINTESTINAL CANCERS

Stephanie J. Sohl, PhD¹, Janet Tooze, PhD, MPH², Russell Rothman, MD, MPP³, Mary Dietrich, PhD⁴, Sheila Ridner, PhD, RN, FAAN⁴, Lynne Wagner, PhD², Nancy Avis, PhD²

¹Wake Forest School of Medicine, Winston-Salem, NC; ²Wake Forest School of Medicine, Winston-salem, NC; ³Vanderbilt University Medical Center, Nashville, TN; ⁴Vanderbilt University School of Nursing, Nashville, TN

Although fatigue is highly prevalent among gastrointestinal (GI) cancer patients receiving chemotherapy, there are few behavioral interventions designed to reduce this symptom during treatment. Data support efficacy of yoga for reducing fatigue when implemented as group classes in patients with breast cancer. Yet, this group delivery format is associated with lower adherence for participants who have increased fatigue and thus may unintentionally exclude those in higher need and with other barriers (e.g., travel). Yoga Skills training (YST) teaches the key elements of yoga (meditation, movements, breathing practices) and is delivered individually in the chair during chemotherapy to lessen barriers to participation. We are conducting a stratified randomized controlled pilot study of YST as compared to an empathic Attention Control (AC) in a sample of adults diagnosed with GI cancers receiving first-line Fluorouracil-based chemotherapy. The YST consists of four 30-minute sessions plus daily home practice. AC interventionists use techniques such as active listening and ask participants to keep brief daily diaries. We are assessing feasibility of recruitment, intervention adherence, questionnaire completion, and an estimate of variance for fatigue. Participants complete self-reported assessments including PROMIS fatigue at weeks 8, 10 (primary) and 14. Participants also complete semi-structured interviews to provide further feedback on study acceptability. Forty-four of 77 eligible adults agreed to participate (57%; YST n=23; AC n=21). Participants had a mean age of 58 years (range 33–89 years), and a majority were women (52%), White (86%), and had colon cancer (75%). Common reasons for declining participation included not interested (n=16) or overwhelmed (n=12). To date, adherence to the four sessions is 82% (non-adherence primarily because cancer treatment changes made sessions not possible) and 74% of participants have completed the primary outcome assessment. Fatigue at baseline (Mean=53.1) was higher than the standardized mean with less than typical variability (SD=7.2). Data collection will be complete and results un-blinded by group for presentation. Feasibility of integrating the YST with clinical care during chemotherapy is supported by acceptable rates of recruitment, adherence, and retention. These data provide valuable estimates and feedback for informing future research to assess the efficacy of the YST for fatigue.

Bender, MS, RDN², Sherilyn Cognetti, n/a⁴, Jill Kaplan, LCSW⁵, Shannon La Cava, PsyD³, Donna Peart, MS, RDN⁴, Jeanne Petrucci, MS, RDN⁶, Tamar Rothenberg, MS, RDN⁷, Amy J. Sutton, n/a⁵, Deirdre McGinley-Gieser, n/a²

¹American Institute for Cancer Research, Fairfax, VA; ²American Institute for Cancer Research, Arlington, VA; ³Cancer Support Community Los Angeles, Los Angeles, CA; ⁴Fanwood-Scotch Plains YMCA, Scotch Plains, NJ; ⁵Cancer Support Community Central New Jersey, Bedminster, NJ; ⁶Living Plate, Far Hills, NJ; ⁷Touro College and University System, Los Angeles, CA

Introduction: Eating a diet rich in whole grains, fruits and vegetables (F&V), and beans can reduce cancer risk and may reduce the risk of cancer returning. The aim was to test the effectiveness of Coping with Cancer in the Kitchen (CCK) for implementing a healthy plant-based diet and improving quality of life.

Methods: The intervention was 8 weekly 90-minute sessions with nutrition education, culinary demonstrations, and professionally facilitated social and emotional support. Cancer survivors at 2 community organizations in New Jersey and California were randomly assigned to CCK or control (printed materials only) arms. We examined treatment effects by comparing patterns of change over time in outcomes measured at baseline, 9, and 15 weeks using multilevel mixed effects linear regression.

Results: Among 53 participants (mean age 61 y; 92% female; 61% with overweight or obesity), 48/53 (91%) and 30/53 (57%) completed the 9 and 15-week surveys, respectively. Compared to the control arm, CCK caused a greater 9-week reduction in barriers to F&V consumption (-0.26 v +0.16, p=.002; average rating across 15 items). Furthermore, CCK significantly improved nutrition knowledge/skills (p=.0054) and cooking confidence (p<.001) with significantly greater gains (average 5-point Likert rating) from baseline to 9 weeks compared to the control arm (knowledge/skills: +0.76 v +0.25, p=.0064; cooking confidence: +0.68 v +0.13, p=.011). Mean (±SE) cooking confidence at 15 weeks was significantly greater in the CCK arm (4.2±0.20 v 3.6±0.20; p=.038). Although not statistically significant, the baseline to 9-week change trended in a positive direction for fatigue (-2.19 v -0.90, p=.051; 11-point Likert), quality of life (+1.54 v +0.31, p=.35; FACT-G7), psychological distress (-0.50 v +0.54, p=.15; PHQ-4), F&V/day (+0.16 v +0.009 cup equivalents, p=.29) and whole grains/day (+0.13 v +0.02 oz equivalents, p=.33; NCI Dietary Screener Questionnaire). Results from staff training and weekly semi-structured interviews with staff provided confidence the intervention was implemented with high fidelity.

Conclusion: Cancer survivors participating in the evidence-based nutrition and psychosocial intervention experienced significant changes that resulted in greater knowledge, fewer barriers, and higher confidence preparing tasty plant-based foods; however, positive changes in quality of life, emotional well-being and dietary intake were modest and did not reach statistical significance but were in the anticipated direction of effect.

USING THE MULTI-PROCESS ACTION CONTROL APPROACH IN A PHYSICAL ACTIVITY INTERVENTION FOR PROSTATE CANCER SURVIVORS: A PILOT, RCT

Linda Trinh, PhD¹, Edward McAuley, PhD², Arthur F. Kramer, PhD³, Kendrith Rowland, MD⁴, Ryan E. Rhodes, Ph.D.⁵, Dominick Strom, MS⁶, Jaime Wong, MS²

¹University of Toronto, Toronto, ON, Canada; ²University of Illinois at Urbana-Champaign, Urbana, IL; ³Northeastern University, Boston, MA; ⁴Carle Cancer Center, Urbana, IL; ⁵University of Victoria, Victoria, BC, Canada; ⁶University of Illinois at Urbana-Champaign, Romeoville, IL

Background: Physical activity (PA) has a positive impact on clinical outcomes in prostate cancer survivors (PCS). However, the majority of PCS are not meeting public health PA guidelines. For successful behavior change, it is necessary to move beyond intention-focused theories towards constructs proposed to reduce the intention-behavior gap to increase PA. One such framework is the Multi-Process Action Control (M-PAC) framework.

Purpose: To examine the effects of a supervised PA program plus standard exercise counseling (PA+EC) versus a supervised physical activity plus motivationally-enhanced behavioral counseling (PA+BC) on the motivational, regulatory, and reflexive processes from the M-PAC model in PCS.

Methods: This study was a pilot two-armed, single blind, randomized controlled trial (RCT). Twenty-six PCS were randomized a 12-week supervised PA program plus standard exercise counseling (PA + EC group; $n = 13$) or a 12-week supervised PA plus behavioral counseling based on the M-PAC model (PA + BC group; $n = 13$). The goal of both arms of the intervention was to gradually increase PA to the public health guidelines. PCS in both arms were provided with supervised PA that tapered to a home-based program. Analyses of covariance were used to compare M-PAC constructs between the two groups from baseline to 12-weeks (post-intervention).

Results: PCS had a $M_{age} = 65.6 \pm 6.8$ and mean months since diagnosis of 93.5 ± 65.6 . For motivational processes, group differences favoring the PA + BC group were noted for instrumental attitude [$M_{adj} = +0.3$; 95% CI: -0.2-0.8; Partial $\eta^2 = .06$], injunctive [$M_{adj} = +0.1$; 95% CI: -0.4-0.5; Partial $\eta^2 = .00$] and descriptive norm [$M_{adj} = +0.1$; 95% CI: -0.7-0.8; Partial $\eta^2 = .00$], and perceived behavioral control (PBC) [$M_{adj} = -0.7$; 95% CI: -1.7-0.2; Partial $\eta^2 = .17$]. For regulatory processes, higher scores for planning were noted in PA+BC [$M_{baseline} = 3.3$; $SD = 1.3$; $M_{post} = 3.9$; $SD = 1.9$]. For reflexive processes, higher scores were noted in the PA+BC for habit [$M_{baseline} = 2.6$; $SD = 1.5$; $M_{post} = 3.3$; $SD = 1.5$] and role identity [$M_{baseline} = 2.1$; $SD = 1.3$; $M_{post} = 3.1$; $SD = 1.8$]. Overall, PCS reported that the PA+BC sessions were somewhat helpful in increasing PA levels ($M_{range} = 4.3-5.0$).

Conclusions: This pilot study provides some support for the effectiveness of the interventions in producing positive changes on the motivational, regulatory, and reflexive processes, yet insight into creating more meaningful counselling sessions are recommended to inform a larger RCT.

ASSOCIATION BETWEEN PERCEIVED DISCRIMINATION IN MEDICAL CARE AND SELF-EFFICACY FOR PURSUING BREAST CANCER FOLLOW-UP CARE

Maria G. Pita, n/a¹, Jessica N. Coleman, BA¹, Gretchen Kimmick, MD, MS², Francis J. Keefe, PhD¹, Hayden B. Bosworth, PhD¹, Linda M. Sutton, MD¹, Lynda Owen, PhD, CCRP³, Vicky Gandhi, BS¹, Rebecca A. Shelby, PhD¹

¹Duke University, Durham, NC; ²Duke University Medical Center / Duke Cancer Institute, Durham, NC; ³Duke Cancer Network, Durham, NC

Patients' perception of discrimination in medical care may be an important factor associated with differences in perceived self-efficacy for pursuing breast cancer follow-up care. To examine this relationship, cross-sectional data were collected from survivors of Stage I-III breast cancer who received care at community hospital-based oncology clinics ($N = 100$). Participants were two to five years post treatment, with a mean age of 62 years ($SD = 11$). The sample identified as White (43%), Black (36%), and American Indian (21%). Almost a third (30%) of participants had a high school education or less, 41% had completed vocational training or some college, and 29% had a college degree or higher. Most participants (87%) had health insurance covering mammograms and breast cancer follow-up care. Perceived discrimination in medical care and perceived self-efficacy for pursuing follow-up care were measured. Perceived discrimination was coded as none (0) vs. any (1). A one-way ANCOVA was conducted to examine the association between perceived discrimination and self-efficacy after controlling for health insurance status (demographic covariates were included if significantly ($p < .05$) associated with self-efficacy). Almost half of the sample (42%) reported perceiving discrimination in medical care related to race or socio-economic status. Self-efficacy total scores ranged from 5.33 to 10 on a scale from 0 to 10 ($M = 9.05$, $SD = 1.00$). After adjusting for health insurance status, there was a statistically significant difference in self-efficacy for pursuing follow-up care between participants who perceived discrimination in medical care versus not [$F(1,94) = 13.56$, $p < 0.001$, $d = .76$]. Participants who perceived discrimination in care reported lower self-efficacy for pursuing follow-up care. The results indicate that perceived discrimination is associated with low self-efficacy for pursuing follow-up care among breast cancer survivors. Thus, programmatic efforts are needed to improve hospital systems' and providers' awareness of discrimination in care, increase competency, and teach strategies for mitigating the negative impact of such experiences on patients' self-efficacy for pursuing follow-up care. Teaching patients strategies to communicate concerns to their medical providers may also increase self-efficacy. More research is required to understand experiences of discrimination in care and the impact on patient self-efficacy and care engagement after breast cancer treatment.

ACCEPTABILITY OF VIDEO-CONFERENCED STRESS MANAGEMENT AND RELAXATION TRAINING (VSMART) IN OLDER WOMEN WITH BREAST CANCER

Chloe Taub, MA¹, Hannah Fisher, MS², Molly Ream, B.A.¹, Erica R. Nahin, M.S.¹, Emily A. Walsh, B.A.¹, Dolores Perdomo, Ph.D.¹, Bonnie Blomberg, Ph.D.¹, Michael H. Antoni, Ph.D.³

¹University of Miami, Miami, FL; ²University of Miami, Durham, NC;

³University of Miami, Coral Gables, FL

Introduction: Increased distress, common during breast cancer (BCa) treatment, is associated with inflammatory and immune processes implicated in disease progression. Our group has previously demonstrated that 10-week group cognitive behavioral stress management (CBSM) is efficacious at improving psychological and physiological adaptation and long-term disease outcomes in BCa patients. Since inflammation increases and immunity decreases with aging, older women with BCa have a particular need for stress management. As the older adult population and BCa incidence continue to rise in the U.S., it is imperative to explore innovative solutions to the growing need, such as remotely-delivered CBSM interventions which utilize less resources and have higher accessibility than in-person programs.

Methods: An RCT is currently being conducted testing the effects of a novel remotely-delivered group CBSM intervention (R-CBSM) on improving health and quality of life in BCa patients aged 50+. Stage 0-IIIB BCa patients who are post-surgery but have not started adjuvant therapies are randomized to 10 weeks of R-CBSM or a wait-list control that receives R-CBSM approximately six months post-baseline. Participants connect to weekly, 90-minute, video-conferenced sessions and complete out-of-session activities on tablets. Following their participation, participants complete acceptability and program evaluation surveys.

Results: Participants with available data to date (N=32) were age 52-85 (M=64). In regards to potential technological concerns with older adults, 97% of participants reported they were comfortable with the technical requirements of attending group sessions and 100% reported the tablet was easy to use. Regarding retention of non-specific therapeutic factors with remote administration, 100% of participants stated they were able to share their feelings about BCa during group, 88% reported feeling connected to the other members of the group, and 50% reported staying in touch with group members after conclusion of the program. Finally, 100% endorsed receiving benefit and 100% stated they felt better able to cope with stress after participating.

Conclusions: Preliminary results suggest high acceptability of a remotely-delivered platform for group stress management in BCa. Use of technology enables a scalable, practical and accessible delivery approach that could reach more vulnerable and underserved patients with BCa and other health conditions in the aging population.

THE INCREASING VALUE OF EHEALTH IN PATIENT-CENTERED CANCER SURVIVORSHIP CARE: CURRENT STATE AND FUTURE DIRECTIONS

Joshua Kronenfeld, MD¹, Frank Penedo, PhD², Laura B. Oswald, PhD³, Sofia Garcia, PhD⁴, David Cella, PhD⁴, Betina Yanez, PhD⁴

¹University of Miami Leonard M. Miller School of Medicine, Miami, FL;

²Sylvester Comprehensive Cancer Center, Miami, FL; ³Moffitt Cancer Center, Tampa, FL; ⁴Northwestern University, Chicago, IL

Objective: Survival benefit in cancer is often offset by multiple challenges that survivors, their families, and caregivers face across the cancer care continuum. Over the past decade, there have been increasing efforts in developing and implementing technology-based programs to reduce symptom burden and improve health outcomes. This review explored the value of electronic health (eHealth) or mobile health (mHealth) evidence-based interventions as they relate to survivorship care and their ability to mitigate many symptoms faced by cancer survivors.

Methods: A literature search was conducted through PubMed to identify relevant studies of technology- and evidence-based interventions used to improve symptoms after cancer treatment. Search terms included: 'cancer AND survivorship AND ehealth,' 'cancer AND survivorship AND mhealth,' 'cancer AND survivorship AND smartphone,' 'cancer AND survivorship AND web,' 'cancer AND survivorship AND web-based,' and 'cancer AND survivorship AND internet.' Articles included in this review were from 2009 until September 2019.

Results: A total of 29 studies were reviewed. Findings suggest that generally, eHealth interventions have shown potential at mitigating symptoms such as pain, psychological distress, fatigue, and cancer-related cognitive impairment (CRCI) across various cancer populations. Several consistent findings suggest that eHealth programs post hematopoietic stem cells demonstrated efficacy in decreasing pain symptoms; while psychological distress was decreased in patients with advanced prostate cancer following mHealth interventions. Similarly, fatigue was improved in survivors of chronic myeloid leukemia and CRCI in advanced prostate cancer was reduced. Patient reported outcomes (PROs) monitoring via eHealth programs is increasingly being used to identify symptoms or toxicities that are often underreported or identified during clinical visits to identify potential targets of intervention.

Conclusions: When eHealth interventions are designed properly, with the integration of PROs, they can help to reduce symptom burden in cancer survivors. Limitations include small samples sizes, and limited follow-up periods and provider engagement. Future work is needed to conduct studies with larger sample sizes in order to determine the clinical effectiveness of these interventions. Over the past decade, there has been increasing efforts in developing and implementing technology-based programs to reduce symptom burden and improve health outcomes, and several studies have shown a survival benefit among patients participating in these programs.

THE ROLES OF AGE, CANCER IMPACT, AND COPING STRATEGIES IN PREDICTING POSTTRAUMATIC GROWTH: A 21-MONTH PROSPECTIVE STUDY

Meng Heng Wu, BS¹, Ashley W. Wang, PhD², Cheng-Shyong Chang, MD³, Wen-Yau Hsu, PhD⁴¹Soochow University, Taiwan, Taipei, Taipei, Taiwan (Republic of China);²Soochow University, Taiwan, Taipei City, Taipei, Taiwan (Republic of China);³Chang Bing Show Chwan Memorial Hospital, Changhua, Changhua, Taiwan (Republic of China);⁴National Chengchi University, Taipei, Taipei, Taiwan (Republic of China)

Objectives: Research has shown that age is associated with levels of positive life changes, or posttraumatic growth (PTG), as a result of coping with cancer. However, it is unclear how age plays a role in the cancer coping process, which has implication in PTG. We examined whether coping strategies interact with cancer impact in predicting PTG, and explored whether age moderates the relationship of interests.

Methods: Breast cancer patients ($N = 293$; $M_{age} = 46.40$, $SD = 8.30$ range = 25-69) who had received surgery within the past 2-4 months (T1) were enrolled to complete measures of cancer impact, the Brief COPE (self-sufficient, social-oriented, and avoidant coping), and the Posttraumatic Growth Inventory (PTGI). At 21 months follow-up (T2) they completed the PTGI again. Covariates (marital status, education) and T1 PTG were entered in the first step of the multiple hierarchical regression. Cancer impact, coping, and age were entered in the second step. The interaction terms of the three predictors of interest were added in the third step.

Results: Overall, younger age predicted greater PTGI ($\beta = -0.12$, $p = 0.01$). Three-way interactions were found for self-sufficient and socially-supported coping. For younger women, cancer impact predicted greater PTG among those who used less self-sufficient and socially-supported coping ($t = 2.29$ and 1.87 , $p = 0.02$ and 0.06). On the other hand, cancer impact significantly predicted greater PTG among older women who adopted greater self-sufficient and socially-supported coping ($t = 2.63$ and 2.39 , $p = 0.01$ and 0.02). Cancer impact significantly predicted lower PTG among older women who adopted lower level of self-sufficient coping ($t = -1.98$, $p = 0.05$). The three-way interaction was not significant for avoidant coping, but a two-way interaction among age \times avoidant coping was significant, showing that higher avoidant coping predicted lower PTG among older women ($t = -2.20$, $p = 0.03$). The same relationship was not found among the younger.

Conclusions: While younger women overall report higher levels of PTG, the experience is affected by the level of coping and its relationship with cancer impact. The findings paint a more comprehensive picture of PTG pathways at different age.

SPIRITUALITY AMONG FAMILY CAREGIVERS OF CANCER PATIENTS: THE SPIRITUAL PERSPECTIVE SCALE

In Seo La, MSN, RN¹, Meg Johantgen, PhD, RN¹, Carla Storr, ScD, MPH¹, Alyson Ross, PhD, RN², Shijun Zhu, DrE, MS¹, John Cagle, MSW, PhD³¹University of Maryland School of Nursing, Baltimore, MD; ²Nursing Department, National Institutes of Health Clinical Center, Bethesda, MD;³University of Maryland School of Social Work, Baltimore, MD

Purpose: Spirituality is a critical resource for many family caregivers of patients with cancer. However, studies on spirituality in caregivers are hampered because measures of spirituality lack consistency and have been not validated in cancer caregivers. Thus, this study examined the validity of the Spiritual Perspective Scale (SPS) among cancer caregivers and explored whether measurement bias may influence differences in spirituality across caregiver and patient characteristics.

Methods: In this secondary analysis, data obtained from 124 caregivers of cancer patients participating in a prospective burden and stress study were used to evaluate the criterion and construct validity of the 10-item SPS. A Multiple Indicators Multiple Causes (MIMIC) model was tested to explore group differences in the association between a latent spirituality factor and characteristics of caregivers and patients.

Results: Overall reliability of the SPS was good (Cronbach alpha = .95). The SPS scores were predictive of higher meaning and purpose ($r = .32$, $p = .004$) and lower depression ($r = -.22$, $p = .046$) at three-month follow-up. Construct validity of the SPS with a single-factor structure was supported in cancer caregivers. A direct effect of race was not substantial and did not alter the pattern of results. While adjusting for the direct effect, caregivers who were older, female, ethnic minorities, less educated, affiliated with a religion, and who provided care to another individual in addition to the cancer patient had greater levels of spirituality. Group differences explained 36.3% of the variance of a latent spirituality factor.

Conclusions: Psychometric validation of the SPS was supported in cancer caregivers. Understanding differences in caregivers' spirituality by considering use of psychometrically sound measures and reduction of measurement bias deserves more attention to optimize spirituality assessment and support in cancer caregiving.

TEXT MESSAGE PREFERENCES FOR SURVEILLANCE COLONOSCOPY REMINDERS AMONG COLORECTAL CANCER SURVIVORS

Sarah Hohl, MPH, PhD¹, Veena Shankaran, MD², Ari Bell-Brown, MPH², Rachel Issaka, MD, MAS²¹Fred Hutchinson Cancer Research Center, Seattle, WA; ²Hutchinson Institute for Cancer Outcomes Research, Seattle, WA

Background: Surveillance colonoscopy 1-year after colorectal cancer (CRC) surgery effectively reduces CRC-mortality, yet less than half of survivors undergo this procedure. Text message reminders can improve CRC screening and other health behaviors but use of this strategy to address barriers to CRC surveillance has not been reported.

Objectives: The goal of this qualitative study was to assess CRC survivor perspectives on barriers to colonoscopy to inform the design of a theory-based, short message service (SMS) intervention aimed to increase utilization of surveillance colonoscopy.

Methods: CRC survivors in Western Washington participated in one of two focus groups to explore perceived barriers to completing surveillance colonoscopy and preferences for SMS communication. Content analysis using codes representative of the Health Belief Model and Prospect Theory constructs were applied to qualitative data.

Results: Thirteen CRC survivors reported individual (e.g., fear, low perceived susceptibility, avoidance), interpersonal, and system level barriers to surveillance colonoscopy completion. Participants were receptive to receiving SMS reminders to mitigate these barriers. Participants also suggested that SMS reminders begin no earlier than 9 months following CRC surgery, include educational content, and be personalized to patients' communication preferences.

Conclusions: Our study demonstrates that CRC survivors perceive SMS reminders as an acceptable, valuable tool for CRC surveillance. Further, there may be value in integrating theoretical frameworks to design, implement, and evaluate SMS interventions to address individual-level barriers to CRC surveillance. As physicians play a key role in CRC surveillance, provider and system-level interventions that could additively improve the impact of SMS interventions are also worth exploring.

EXPOSURE TO TRAUMA AND INFLAMMATION MARKERS OF BREAST CANCER PROGRESSION: A PILOT STUDY WITH PUERTO RICAN CANCER PATIENTS

Eida M. Castro, PsyD, MS¹, Karina I. Acevedo, MS¹, Maria I. Lazaro-Escudero, B.S.², Normarie Torres Blasco, PhD³, Guillermo N. Armaiz, PhD¹¹Ponce Health Sciences University, Ponce, N/A, Puerto Rico; ²Ponce Health Sciences University, Guaynabo, N/A, Puerto Rico; ³Ponce Health Science University, Ponce, FL

Background and Purpose: There is growing evidence that highlights inflammation as a common factor in depression, chronic psychosocial stress and tumor microenvironment. However, little is known about the role of current and past exposure to social-environmental adversity (SEA; e.g., child abuse, domestic violence) in the relationship between depression and markers of inflammation in the breast cancer (BC) tumor microenvironment.

Methods: Participants (n=32) were recruited before undergoing BC tumor surgery and completed a package of surveys through interviews that included the PHQ-8, Adverse Childhood Events (ACE) questionnaire and the Trauma History Questionnaire (THQ). Regarding BC tumor samples, 10x fields were quantified for CD68 (macrophages), CD19 (B cells) and CD3 (T cells). Pearson Correlation Tests are used to explore correlation between the variables of interest.

Results: Preliminary findings (n=22) reveal that the most common SEA experience were general disasters and trauma (n=21), physical and sexual abuse (n=16) and, Crime-related trauma (n=13). Out of those reporting childhood abuse experiences (n=16), 6 reported exposure to more than 4 ACE experiences. Mean score of PHQ-8 symptoms were low ($M=3.77 \pm 4.19$). The relationship between depression symptoms and inflammatory markers of tumor microenvironment (macrophages, B cells and T cells) was not statistically significant. However, there were statistically significant relationship between B cell lymphocytes and adverse childhood events ($p < 0.05$).

Conclusions: Significant correlations between ACE and B cells lymphocytes are promising considering that Lymphocytes has been recognized as a new hall mark in BC treatment prognosis and outcomes.

#COLONCANCER: WHO IS TWEETING WHAT?

Carrie A. Miller, PhD, MPH¹, Alesha N. Henderson, MA¹, Jeanine D. Guidry, PhD¹, Bernard F. Fuemmeler, PhD, MPH¹

¹Virginia Commonwealth University, Richmond, VA

Background: Little is known about communications related to colorectal cancer on social media. Knowledge of what colorectal cancer information is available and how it is spread on social media may inform strategies to communicate risk and prevention strategies. This information may be particularly important considering that colorectal cancer is largely preventative through lifestyle modification and widespread screening. This study focuses on how colorectal cancer is discussed on the social media platform Twitter.

Methods: A random sample of 1,000 colorectal cancer-related tweets including the hashtags #coloncancer, #colorectalcancer, and #rectalcancer were collected in early 2019 using the Netlytic platform. In a quantitative content analysis, two independent coders have analyzed a subset of 250 tweets. Coding of the remaining messages is underway and will be completed in October 2019. Tweets are coded for a variety of factors, including poster identity, tweet text and visual features, colorectal cancer-related information posted, and the presence of constructs of the Health Belief Model (HBM) and the Extended Parallel Processing Model (EPPM). Engagement with tweets will also be analyzed.

Results: Thirty-four percent of tweets were posted by a medical doctor, researcher, or other expert, while only 14.4% of messages were by lay individuals. Fewer tweets (16.8%) were posted by traditional health/medical organizations relative to non-medical organizations (31.2%). The majority of tweets included a visual (78.8%). The overall message format were typically a mix of image and text (50.3%) or primarily text-based (44.2%). The majority of tweets (61.2%) used thematic framing, while only 25.6% used episodic framing. A plurality (32.8%) of colorectal cancer content referred to treatment, while 18.4% mentioned screening, and 17.2% mentioned prevention and risk information. Considering the theoretical constructs of the HBM and the EPPM: only cues to action for screening, and severity of and susceptibility to colorectal cancer were present in at least 10% of the sample. The median retweet frequency was 2.00, the median like frequency was 5.00, and the median reply frequency was 0.

Conclusions: Colorectal cancer-related messages were primarily posted by experts and organizations. Overall engagement with tweets was low, suggesting minimal spread of information about colorectal cancer on Twitter. Theoretical constructs which aid effective communication were also infrequently present. There was a relatively high proportion of visuals present given that Twitter does not require an image. The complete study results will provide additional insights for public health professionals and health communication researchers about the conversation related to colorectal cancer on social media and ultimately, may aid the development of future social media-based interventions.

SELF-DISCLOSURE TODAY HELPS YOU SLEEP BETTER TOMORROW: DAILY INVESTIGATION AMONG COLORECTAL CANCER PATIENTS

Kaitlin Hahn, n/a¹, Youngmee Kim, PhD¹, Shiyi Wang, B.S.², Valeria Castanos, BA¹, Amanda Ting, MS¹

¹University of Miami, Coral Gables, FL; ²university of miami, coral gables, FL

Self-Disclosure Today Helps You Sleep Better Tomorrow: Daily Investigation among Colorectal Cancer Patients

Sleep disturbance is prevalent and a substantial health concern among cancer patients. Sleep disturbance includes prolonged sleep onset latency (SOL) and extended waking after sleep onset (WASO), which also contribute to poor sleep efficiency (SE). A growing body of literature has shown the significant role of interpersonal factors, such as self-disclosure with a partner, in sleep disturbance. The current study expanded the investigation to adult cancer patients.

Colorectal cancer patients (n = 48, M=55.5 years old, 40% female, 5 months post-diagnosis) completed daily self-disclosure items regarding sharing one's feelings and thoughts with partner, as well as the Sleep Consensus Diary across 14 consecutive days, from which SOL, WASO, and SE were derived.

Patients reported good SE (M=89%) but notably long SOL (M=22.74 minutes) and WASO (M=19.76 minutes). Low levels of daily self-disclosure (M=2.61) were also reported. Multilevel modeling was employed to predict SE, SOL, and WASO separately by daily self-disclosure with the partner on the same day and on the subsequent day. Greater self-disclosure was revealed to predict better SE on the subsequent day (B=0.04, p<.002) but not on the same day. Additionally, greater self-disclosure predicted shorter WASO on the subsequent day (B=-11.67, p<.002) but again, not on the same day. Self-disclosure was not significantly related to SOL.

Preliminary evidence suggests salutary effects of self-disclosure on attenuated sleep fragmentation and more efficient sleep on the days that follow. Findings highlight interpersonal contributions to cancer patients' sleep health and warrant further investigation of the psychosocial pathways of the lagged benefit of self-disclosure on sleep that utilizes subjective and objective collection methodologies. Tailored sleep interventions augmenting the communication component of cancer patients' thoughts and feelings with their partners are also warranted.

CONTENT CONSIDERATIONS FOR VIRTUAL HUMAN TECHNOLOGY EHEALTH INTERVENTIONS DELIVERING HEALTH AND NUTRITION MESSAGES

Melissa J. Vilaro, PhD, MPH, CPH¹, Danyell Wilson-Howard, PhD², Lauren Griffin, PhD¹, Fatemeh Tavassoli, n/a¹, Mohan Zalake, MS¹, Ben Lok, PhD³, Francois Modave, PhD⁴, Peter J. Carek, MD, MS, CAQSM, FAAFP, DABFM⁵, Thomas J. George, MD, FACP⁶, Janice L. Krieger, PhD⁷

¹University of Florida, Gainesville, FL; ²Behune-Cookman University, Daytona Beach, FL; ³Virtual Experiences Research Group (VERG) / University of Florida, Gainesville, FL; ⁴Center for Health Outcomes and Informatics Research / Loyola University Chicago, Maywood, IL; ⁵Family Medicine / University of Florida, Gainesville, FL; ⁶GI Oncology Program / University of Florida, Gainesville, FL; ⁷STEM Translational Communication Center / University of Florida, Gainesville, FL

Introduction: Incorporating user-generated feedback into eHealth interventions can facilitate development of credible and engaging messages that encourage promoted health behaviors. Virtual Human Technology (VHT) is an innovative technology that can facilitate web-based communication of health messages. Virtual Health Assistants (VHA) are computer-generated human characters that interactively engage users in a virtual setting and can be tailored for demographic concordance. The purpose of this study was to gather user-generated insights to develop an interactive nutrition risk module for an existing VHA-delivered colorectal cancer screening (CRC) intervention. The study is informed by the M.A.I.N model, which is used for examining credibility in web-based content. We identify specific content domains associated with credibility that should be considered when developing VHA-delivered nutrition risk information for adults.

Methods: Adults between 50–73 years old attended focus groups and think-aloud interviews to inform the development of a VHA-delivered intervention promoting CRC screening. In keeping with a user-centered design approach, participants used mobile devices to test a 12-minute CRC screening intervention that included 2 interactive questions on nutrition risk factors for CRC (e.g. alcohol and red meat). We analyzed comments pertinent to healthy eating, food, and nutrition risk using thematic analysis for emergent themes. This analysis will inform a culturally-relevant expansion of the nutrition content.

Results: Four content domains emerged as important components of credible messages delivered by a VHA: 1) accuracy (e.g. “I like my info from something that has been researched, has medical credentials, like a doctor or nutritionist”), 2) novelty (e.g. “I was surprised red meat can increase colon cancer risk. I said whoo! Because I like red meat”), 3) understandability (e.g. “Even a child could understand what she was saying”), and 4) missing content (e.g. “They should add fiber. That’s very important to me”). Risk messages led to desired outcomes (e.g. “Because of the virtual thing I saw, I think I can [get screened] now”) but also should be calibrated so users do not discredit screening (e.g. “Then you’re at high risk, the damage has already been done”). We discuss definitions of domains and implications of participant concerns specific to nutrition content.

Discussion: Credibility, a combination of trustworthiness and expertise, is important for engaging diverse audiences in health communication. Tailoring to content preferences may increase credibility of VHAs and messages embedded in such interventions. Strategies for implementing VHA-delivered messages should include assessing existing user preferences. Additionally, future research should test what content domains are most effective for producing credible risk messages and behavior change.

A PERSON-CENTERED APPROACH TO UNDERSTAND DELAY OF TREATMENT FROM COLORECTAL CANCER DIAGNOSIS BY SOCIODEMOGRAPHIC FACTORS

Francisco A. Montiel Ishino, PhD, MPH, CPH¹, Xiaohui Liu, PhD², Bonita Salmeron, B.A.³, Faustine Williams, PhD, MPH, MS⁴

¹NIH-NIMHD, North Bethesda, MD; ²NIH-NIMHD, Bethesda, MD; ³NIH-NIMHD, Towson, MD; ⁴NIH-NIMHD, Bethesda, MD

Purpose: Treatment of delay is associated with worse colorectal cancer (CRC) outcomes. Furthermore, disparities exist in treatment. The risk profiles of those delaying or not delaying treatment are relatively unknown. We used latent class analysis (LCA) to identify the patterns of highest risk in treatment delay among CRC patients while accounting for subgroup differences in sociodemographic and health insurance characteristics.

Methods: LCA refers to a technique to identify unobservable – or latent – subgroups within a population. We used LCA on the Tennessee Health Department 2005–15 Cancer Registry data to assess the impact of sociodemographic and health insurance factors on treatment delay of CRC to identify possible risk elements (N=35,412). Analyses were separated into malignant and in situ CRC by tumor behavior code. Factors available for LCA included: sex (male/female); age categories based on U.S. Preventive Services Task Force CRC screening recommendations; race; marital status; type of health insurance; county of residence (non-Appalachian/Appalachian); and treatment delay in number of days (≤30/ >30).

Results: Our LCA using Mplus 8.2 for treatment delay of CRC revealed a five-class solution with an entropy of 0.69 (N=34,126) and a four-class solution with entropy of 0.67 (N=1,286) were the best fitting models for malignant and in situ, respectively. The highest treatment delay subgroup among the malignant CRC group (3% of sample; n=1,125/34,126) had the highest conditional probabilities of being Black, residing in a non-Appalachian county, and using public health insurance. The highest treatment delay subgroup among the in situ CRC group (13% of sample; n=169/1,286) had the highest conditional probabilities of being women, widows, and using public health insurance.

Conclusion: We are among the first to examine treatment delay subgroups within malignant and in situ CRC groups using LCA. Further work will be needed to understand the longitudinal trends using latent transition analysis and time-varying effect modelling. Our findings help contribute to the growing body of work using person-centered analyses to understand health disparities to ultimately promote more efficient and efficacious interventions, and ultimately health equity.

USING PROGRESSIVE MUSCLE RELAXATION TO IMPROVE BIOBEHAVIORAL OUTCOMES IN ADVANCED LUNG CANCER

Nicole A. Arrato, M.A.¹, Stephen Lo, M.A.², Madison Grogan, BA³, Carolyn J. Presley, MD, MHS⁴, Barbara L. Andersen, PhD¹¹Ohio State University, Columbus, OH; ²The Ohio State University, Columbus, OH; ³Ohio State University Comprehensive Cancer Center, Columbus, OH; ⁴The Ohio State University Comprehensive Cancer Center and The James Cancer Hospital/Solove Research Institute, Columbus, OH

Introduction: Patients with advanced lung cancer experience severe symptoms of anxiety, breathlessness, insomnia, pain, and fatigue. Although new treatments for lung cancer are extending survival, evaluation and management of the physical and psychological symptoms associated with the disease and its treatment remain critical. Interventions, such as those involving guided imagery and meditation, have shown mixed effects and often require a substantial time commitment from patients. Progressive muscle relaxation (PMR) is an empirically supported intervention that meets the unmet clinical need for a brief and effective treatment for the reduction of symptoms in this population.

Methods: A static group comparison design was used for a quality improvement effort to enhance standard of care (SOC). Patients with newly diagnosed advanced lung cancer were offered a brief (20-minute) PMR session during their initial clinic visit for cancer treatment determination. The PMR group (n=40) received PMR and completed pre (initial visit) and post (3-4-week follow-up) assessments of anxiety (Generalized Anxiety Disorder-7 Scale), breathlessness (American Thoracic Society for the Division of Lung Diseases Questionnaire), insomnia (Medical Outcomes Study Sleep Scale), pain (Brief Pain Inventory), and fatigue (Fatigue Symptom Inventory-Revised). The control group (n=32) was assessed on one occasion only, during the 3-4-week follow-up visit. Linear regressions compared pre/post analyses for the PMR group, and post data between the two groups, controlling for age, performance status, smoking history, and toxicities. An alpha level of .10 was used for this pilot study.

Results: Breathlessness and pain improved from pre to post in the PMR group (b=2.07, p=.071; b=1.96, p=.036, respectively). There were no significant changes in anxiety or insomnia (ps > .10). Compared to SOC, patients in the PMR group reported less pain (b=2.48, p=.046) and less fatigue (b=2.44, p=.014) at post assessment.

Conclusions: PMR effectively reduced symptoms of breathlessness, pain, and fatigue among patients with advanced lung cancer. After a very brief education and practice session during the overwhelming time surrounding a diagnosis of lung cancer, PMR was able to reduce important symptoms faced by patients with this disease. Interventions introducing PMR at the initial pre-treatment appointment may provide an improvement to SOC lung cancer treatment; further work with such interventions is necessary.

JUSTICE BELIEFS REDUCE THE EFFECT OF BARRIERS ON PERCEIVED BEHAVIORAL CONTROL AND INTENTIONS FOR COLORECTAL CANCER SCREENING

Caroline Drolet, PhD¹, Todd Lucas, PhD¹¹Michigan State University, Flint, MI

Introduction: Screening for colorectal cancer (CRC) is vital for early detection and lowering the risk of mortality. CRC screening is particularly important for African Americans, who have the highest risk of death from colorectal cancer in the United States. Perceived barriers to screening (e.g., discomfort, financial costs) likely contribute to lower screening rates for colorectal cancer among African Americans, potentially by affecting perceived behavioral control (PBC) over CRC screening and, in turn, affecting intentions to obtain CRC screening. Strategies to address perceived barriers therefore may be critical. The current study explored whether tendencies to believe in justice (justice beliefs) might mitigate deleterious effects of perceived barriers on receptivity to CRC screening in an African American sample. We expected that believing the world to be personally just (fair for one's self) would attenuate the deleterious impact of perceived barriers on CRC screening PBC, thereby indirectly affecting intentions to obtain CRC screening.

Method: CRC screening deficient African American participants (N = 404, 50-75 years old) completed validated measures of perceived CRC screening barriers ($\alpha = .85$), PBC ($\alpha = .81$), and intentions to obtain CRC screening ($\alpha = .95$). Participants also completed a measure of personal justice beliefs, measuring the extent to which they perceived the world to be personally fair. Personal justice beliefs served as our expected moderator of the effect of perceived barriers on PBC and intentions.

Results: Perceived barriers and justice beliefs significantly interacted to predict PBC ($b = 0.09$, $p = .01$) and indirectly predicted intentions through PBC ($b = 0.05$, $p = .02$). Among participants low in personal justice beliefs, perceived barriers were negatively associated with PBC over CRC screening ($b = -0.37$, $p < .001$). However, among participants high in personal justice beliefs, perceived barriers did not negatively impact PBC over CRC screening ($b = -0.13$, $p = .06$). In turn, high PBC predicted higher intentions to obtain CRC screening ($b = 0.61$, $p < .001$).

Discussion: Personal justice beliefs are a psychological resource that may allow African American individuals to overcome the deleterious effects of perceived barriers on receptivity to CRC screening. Interventions aimed at encouraging CRC screening and addressing extant screening disparities might be developed to augment the strength of or access to personal justice beliefs.

NOVEL BIOMARKERS OF TREATMENT-INDUCED MUSCLE DAMAGE, CANCER-RELATED FATIGUE AND EXERCISE: AN RCT IN 90 BREAST CANCER PATIENTS

Karen M. Mustian, PhD, MPH¹, Po-Ju Lin, PhD, MPH, RD¹, Eva Culakova, PhD, MS¹, Ann Colasurdo, BA¹, Richard F. Dunne, MD¹, Chunkit Fung, MD¹, Nikesha J. Gilmore, PhD², Charles E. Heckler, PhD, MS¹, Julia E. Inglis, Ph.D., R.D.¹, Michelle C. Janelins, Ph.D., M.P.H.¹, Charles Kamen, PhD, MPH¹, Amber S. Kleckner, PhD³, Ian Kleckner, PhD, MPH¹, Melissa (Kah Poh) Loh, MD³, Gilberto Lopez, ScD; MPH; MA⁴, Luke J. Peppone, Ph.D., M.P.H.⁵, Michelle Porto, MA⁶, Erika Ramsdale, MD¹, Gary R. Morrow, Ph.D., M.S.¹

¹University of Rochester Medical Center, Rochester, NY; ²University of Rochester, New York, NY; ³University of Rochester, Rochester, NY; ⁴University of Rochester Medical Center, ROCHESTER, NY; ⁵University of Rochester MEdical Center, Rochester, NY; ⁶University of Rochester Medical Center, Rochester, NY

Background: Radiation and hormone therapy may damage skeletal muscle and lead to cancer-related fatigue (CRF). Developmental myosin light chain 5 (MYL5) and myosin heavy chain 8 (MYH8) are required for normal muscle regeneration. Up-regulated serum levels of MYL5 and MYH8 resulting from radiation and hormone therapy may increase muscle degradation and lead to CRF, especially physical CRF—one of the multidimensional subcomponents of overall CRF. In this study, we investigated the effect of a 6-week aerobic and anaerobic exercise intervention, called Exercise for Cancer Patients (EXCAP), on (1) CRF (overall and physical), (2) serum protein levels of MYL5 and MYH8, and (3) the association of CRF (overall and physical) with these novel biomarkers.

Methods: Ninety sedentary breast cancer patients (55.5 ± 9.6 years, 79% white, 52% receiving radiation therapy, 48% receiving hormone therapy) were consented and participated in this phase II RCT. Patients were randomized into two arms: (1) standard cancer treatment (Control) or (2) standard cancer treatment plus EXCAP. Serum levels of MYL5 and MYH8 by ELISA assays and CRF (total and physical) by patient-report via the Multidimensional Fatigue Symptom Inventory were assessed pre- and post-intervention.

Results: T-tests showed significant reductions in overall CRF and physical CRF among exercisers (all $p < 0.05$), but not in controls (all $p > 0.05$), with significant group differences (all $p < 0.05$). T-tests also revealed statistical trends for down-regulation of MYL5 and MYH8 serum protein levels from pre- to post-intervention in exercisers (all $p = 0.17$), but not in controls. Spearman correlations also reveal statistical trends, in exercisers, where decreases in MYL5 and MYH8 serum protein levels are directly associated with decreases in total CRF (MYL5 $r = 0.23$, $p = 0.17$; MYH8 $r = 0.30$, $p = 0.07$) and physical CRF (MYL5 $r = 0.29$, $p = 0.08$; MYH8 $r = 0.39$, $p = 0.02$).

Conclusions: EXCAP improves overall and physical CRF. EXCAP may also protect against cancer treatment-induced skeletal muscle damage via its effects on MYL5 and MYH8. Changes in these novel biomarkers may mediate changes in overall and physical CRF. Further phase III RCTs are needed to confirm these findings. Funding NCI UG1CA189961, NCI K07CA120025, T32 CA102618. RELATIONSHIPS BETWEEN PSYCHOSOCIAL FACTORS, TREATMENT SIDE EFFECTS, AND ADHERENCE TO HORMONAL THERAPY AFTER BREAST CANCER

Kirsti Toivonen, MSc¹, Shiva Bahaeimoghadam, BA (In progress)¹, Linda E. Carlson, PhD¹, Tavis Campbell, PhD¹

¹University of Calgary, Calgary, AB, Canada

Objective: Although adjuvant hormonal therapies (AHTs; e.g., tamoxifen, aromatase inhibitors) are effective in reducing cancer recurrence and mortality in estrogen receptor-positive breast cancer patients, nearly one-quarter of patients are unable to adhere to them. Further, prior interventions to improve adherence to AHTs have been largely based on education and reminders, and have been ineffective. The present study examines relationships between self-reported adherence, barriers to adherence, side effects, and potentially modifiable psychosocial factors such as self-efficacy for adherence, and healthcare providers' communication style. Findings may provide insight into more fruitful intervention targets and strategies to improve adherence to AHTs.

Methods: Breast-cancer survivors ($N=105$) who had finished primary treatment and were prescribed an AHT completed a self-report questionnaire (via mail or online). Self-reported adherence, barriers to adherence (intentional, unintentional, and medication/healthcare system related), self-efficacy for adherence, intrinsic motivation for adherence, depressive symptoms, self-reported side effects, and healthcare providers' encouragement of autonomy were measured.

Results: Women were on average 61.20 years old ($SD=9.08$), most often retired (49%), married (69.5%), and had a subjective socioeconomic status above average (82.1%). Most (61%) were post-menopausal at diagnosis; and 50%, 50%, 55%, and 63% had mastectomy, chemotherapy, lumpectomy, and radiation as primary treatment, respectively. Mean months since diagnosis was 36.15 ($SD=23.25$) and mean months since being prescribed an AHT was 28.37 ($SD=21.10$). Results indicate that greater healthcare provider encouragement of autonomy and greater self-efficacy for adherence were both associated with fewer unintentional, intentional, and healthcare/medication-related adherence barriers. Experiencing a greater number of side effects was associated with lower self-reported adherence, greater depressive symptoms, lower intrinsic motivation to adhere, and less healthcare provider encouragement of autonomy.

Discussion: Greater healthcare provider encouragement of autonomy and greater self-efficacy for medication adherence are associated with fewer barriers to adherence, and side effects relate to a number of factors that could influence adherence. Findings suggest that healthcare provider communication style, self-efficacy, and side effect management may be worth investigating as potential targets for behavioural interventions to improve adherence to AHTs.

CERVICAL CANCER PREVENTION BEHAVIORS AND HPV VACCINATION INTENTION

Meardith Pooler-Burgess, DrPH¹, Fran Close, PhD²¹Florida A&M University/Florida State University, Tallahassee, FL; ²Florida A&M University College of Pharmacy and Pharmaceutical Sciences Institute of Public Health, Tallahassee, FL

In May 2018, the World Health Organization (WHO) released a call to action for the global elimination of cervical cancer. In support of this call to action, a U.S. congressional briefing was held in June 2019 to endorse and advocate for the elimination of HPV-related cancers through HPV vaccination and evidence-based cancer screening. This exploratory study aimed to explore the relationship between cervical cancer prevention behaviors and HPV vaccination intention among minority women.

This study included quantitative data collection utilizing a developed questionnaire (Phase I), and qualitative data collection using semi-structured individual interviews (Phase II). By employing a sequential, mixed-methods research design, this study explored: (1) cervical cancer knowledge, attitudes and screening behavior (2) HPV knowledge, attitudes, and HPV vaccine behaviors (3) the association between cervical cancer knowledge, attitude, Pap screening behavior and HPV vaccination intention, and (4) perceived facilitators and barriers that may influence HPV vaccination.

Phase I findings revealed majority of respondents had high cervical cancer knowledge scores and favorable attitudes towards cervical cancer screenings. 76% of respondents had high cervical cancer prevention behaviors, indicating they receive routine Pap tests at least every 3 years. HPV knowledge scores and attitude towards HPV vaccination were slightly lower compared to cervical cancer. Additionally, nearly 41% of respondents with age-eligible children had negative HPV vaccine behaviors, indicating no intention to give their child the vaccine and not initiating the HPV vaccine series. Significant associations were identified between cervical cancer knowledge and cervical cancer attitude, cervical cancer attitude and cervical cancer behavior, and cervical cancer knowledge and HPV vaccine behavior. Correlation analysis showed a significant positive relationship between cervical cancer screening behavior and HPV vaccine behavior. Phase II findings revealed perceived barriers such as low perceived susceptibility, lack of HPV knowledge and awareness, and negative provider experiences hindered HPV vaccination of the child. Perceived facilitators of HPV vaccination included positive provider experiences, personal experiences with HPV, and provider recommendation.

Women that had positive cervical cancer prevention practices were more likely to be supportive of the HPV vaccine for their child. In alignment with U.S. Healthy People 2020 goals, and the recent call to action to eliminate HPV-related cancers, findings from this study can be used to inform an additional, potentially effective HPV vaccine recommendation opportunity, which in turn could considerably increase HPV vaccination among minority adolescents and decrease racial disparities in regard to cervical cancer and other HPV-related cancers.

ENGAGING 6TH THROUGH 9TH GRADE STUDENTS IN CANCER-RELATED STEM PROJECTS: A PILOT EXAMINATION OF PROJECT CLIMB MEMPHIS

Jordan A. Taylor, BA¹, Idia B. Thurston, PhD², David Schwartz, MD³, Catherine E. Womack, B.A.⁴, Nikki D. Wallace, MS Ed.⁵, Michelle Martin, PhD⁶¹University of Tennessee Health and Science Center, Memphis, TN; ²Texas A&M University, College Station, TX; ³UTHSC School of Medicine, Memphis, TN; ⁴University of TN Health Science Center, Memphis, TN; ⁵Crosstown High School, Memphis, TN; ⁶University of Tennessee Health Science Center, Memphis, TN

Introduction: Children experiencing poverty face a great cancer burden; by age 50, they are more likely to have a diagnosis of cancer than peers with greater financial means. Memphis ranks worst in child poverty rates among major U.S. metro areas (39% vs. the 22% national rate). There is a strong connection linking cancer disparities with socioeconomic, racial, and educational inequity. Programs are needed to engage youth in cancer prevention and control activities. The current deficit in underrepresented minorities in cancer-related research fields, suggests a need for programs to encourage youth engagement. Our findings are from a pilot program to engage underrepresented 6th through 9th grade students in cancer-related projects aiming to ignite their interest in science.

Methods: Youth (n=31, ages 12–17, grades 6th–9th) were recruited from a community organization and a high school in Memphis, TN to attend a full day summer camp. Youth participated in two groups (group 1, N=25; group 2, N=6) over two separate days. Camp consisted of an introduction to the Design Thinking process with interactive lessons on cancer biology, how cancer impacts their community, introduction to research, and interviewing techniques. The curriculum was designed in collaboration with a teacher from one of our community partner organizations. Students interviewed individuals in the community about cancer topics, used interview data to identify a cancer-focused problem in their community, and designed a solution. They were given iPads for online research and an assortment of arts & crafts supplies. By day's end, all students publicly presented proposals to solve these self-identified problems. Students completed quantitative and qualitative surveys at day's end. Parents completed surveys a few days post-program.

Results: The full day curriculum was designed to demonstrate parent and student interest in youth participation in cancer related activities, community partner engagement, and feasibility of our approach. Students developed a variety of solutions ranging from creation of community-based patient support groups to designing multimedia public awareness campaigns focusing on cancer treatment and risk prevention. 87% of the students felt that their ideas were valued, felt part of the team, and felt comfortable interviewing people. Majority of youth reported they liked learning about cancer. 73% of parents reported interest in their child participating in a program about cancer-related research.

Conclusions: Eliminating health disparities requires a diverse workforce. Findings showed that 6th–9th graders and their parents were interested in engaging in a program focused on cancer-related activities and research. Youth gained new knowledge, community partners helped to design the curriculum and were engaged in bringing youth to the program. The feasibility of the program was illustrated.

HEALTH CARE ACCESS AND IMMIGRATION FACTORS ASSOCIATED WITH KOREAN AMERICAN IMMIGRANT WOMEN'S MAMMOGRAPHY USE IN KOREA

Mi Hwa Lee, PhD, MSW, MA¹, Leslie Cofie, PhD, MPH¹¹East Carolina University, Greenville, NC

Background: Korean American immigrant women (KAIW) have lower mammogram screening rates than other racial/ethnic minority women. This has been attributed to limited health care accessibility factors including cost, time-consuming and complicated procedures, and language. Recent evidence suggests that Korean Americans return to their home country to access medical services such as cancer screening and treatments, which may be inaccessible in the US. However, KAIW's mammography use in Korea after their immigration to the US is unknown. In this study we examined health care access and immigration factors associated with KAIW's mammography use in Korea post US immigration.

Methods: Data were obtained from a cross-sectional survey of breast cancer screening behaviors in KAIW. KAIW (N=240), ages 40-79 years, were recruited at various community-based sites such as churches and social service centers in Los Angeles, California, in 2016. Unadjusted and multivariable logistic regression models were used to examine factors associated with KAIW's mammography use in Korea after US immigration. We used SAS® statistical software version 9.4 to analyze data.

Results: Less than a third (28.3%) of KAIW had a mammogram in Korea after immigrating to the US. Also, over two-thirds (69%) of KAIW indicated that they had their first mammogram in the US. Mammography use in Korea after immigration to the US was significantly associated with having first mammogram in Korea (versus the US), year of immigration to the US (after 1999), years living in the US (> 30 years), and type of health insurance (self-purchased insurance and employer-based). Women who had their first mammogram in Korea were more likely to get screened in Korea after they moved in the US (AOR= 0.02, 95% CI: < .001, 0.05). Also, women who had an employer support health insurance were less likely to have a mammogram in Korea after their immigration (AOR= 0.01, 95% CI: < 0.001, 0.18).

Conclusion and Implications: Findings from this study suggest that KAIW who are familiar with the medical system in Korea and have unstable health insurance may seek cancer screening outside of the US. To promote breast cancer screening among KAIW, culturally tailored interventions are needed to address health access barriers. For example, community-based patient navigators and health providers may educate KAIW on accessing free or low-cost screening, and assist in addressing language, transportation and appointment challenges.

CASTING THE NET: WHAT FEATURES DO OLDER CANCER SURVIVORS WANT IN WEB-BASED LIFESTYLE INTERVENTIONS?

Nataliya V. Ivankova, PhD, MPH¹, Laura Q. Rogers, MD, MPH², Dorothy Pekmezci, PhD², Maria Pisu, PhD², Michelle Martin, PhD³, Yu-Mei M. Schoenberger-Godwin, PhD, MPH², Ivan Herbey, MD, MPH⁴, Robert A. Oster, PhD, MS, BS², Lieu Thompson, BSc, MPH², Wendy Demark-wahnefried, PhD²

¹The University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Birmingham, AL; ³University of Tennessee Health Science Center, Memphis, TN; ⁴UAB, Birmingham, AL

Background: With the growing number of older cancer survivors, it is imperative to optimize the reach of interventions that promote healthy lifestyles. While web-based interventions hold considerable promise for expanding reach of interventions originally delivered in other settings, adapting such interventions for web-based delivery is not easy. We explored cancer survivors' views to guide the design of the web-based Aim, Plan, and Act on Lifestyles (AMPLIFY) Survivor Health diet and exercise program.

Methods: Ten focus groups were conducted with 57 cancer survivors recruited from a cancer registry in the southeastern U.S. Data were analyzed using inductive thematic and content analysis with NVivo 12.

Findings: 29 male and 28 female African-American and Caucasian survivors, mean age 63.7 years shared their views about an ideal web-based healthy lifestyle program for cancer survivors. Six themes emerged related to program content, design, delivery, technology training, engagement and interaction. Participants noted the importance of credible, high quality, and individually-tailored information delivered by health care professionals. Males were more likely to see physicians as a trustworthy information source, females were also receptive to guidance from other survivors. Privacy issues related to participation in Facebook support groups was a common concern; but interactions with other survivors in closed groups was acceptable. Lack of computer skills along with privacy and information quality concerns were potential barriers. Ease of use, appealing design, flexibility and opportunity to interact with other survivors were cited as facilitators of program engagement. Women were willing to spend more time on program activities than men. Physician's recommendation, support by health care providers and families/significant others, along with timely feedback and incentives were perceived as important to motivate participation. Many participants expressed the need for training to use computer and the website preferring individualized help over computer classes. There were variations in frequency and type of feedback about goal achievement. More women wanted frequent feedback via support groups, men preferred text messaging to group discussions.

Conclusions: Important considerations when adapting healthy lifestyle interventions for web-based delivery to diverse cancer survivors include program quality, participants' privacy, ease of use, and a prominent role of the health care provider to enhance engagement.

ACCEPTABILITY OF NARRATIVE VISUALIZATION TECHNIQUES WITH MONITORING PHYSICAL ACTIVITY DATA AMONG BREAST CANCER SURVIVORS

Jason R. Bentely, MS¹, Amanda Schroeder, BS², Lane K. Baumbach, BS³, Elizabeth J. Lyons, PhD, MPH⁴¹University of Texas Medical Branch, Houston, TX; ²University of Texas Medical Branch, Katy, TX; ³University of Texas Medical Branch, Appleton, WI; ⁴The University of Texas Medical Branch, Galveston, TX

Background: Breast cancer survivors are at risk for negative health outcomes. Engaging in routine physical activity (PA) can reduce these risks; however, PA levels are low among this population. Integrated regulation, or self-regulation where motivation relates to personal values and identity, is associated with PA over time. Narrative visualization (NV) is a technique that uses drawings, photographs, and text to contextualize PA data, which we hypothesize may facilitate integrated regulation of PA. The purpose of this study was to determine the acceptability of scrapbooking activities as an NV strategy along with standard activity monitoring.

Methods: Breast cancer survivors were given workbooks, wearable electronic activity monitors, instant cameras and film, and art supplies including a variety of stickers (e.g. emojis). Participants used these materials to complete the workbook for 7 days. The workbook pages prompted participants to re-draw their daily activity graphs from the wearable's mobile app, then annotate them with text, photographs, stickers, etc. to reflect what the data meant to them. Thematic analysis was used to analyze the photographs, drawings, and written content from the workbooks to identify emergent themes.

Results: Of the 20 consented women (mean age 67±5 yrs, 45% non-Hispanic white), 2 were lost to follow-up due to medical complications and 1 was unable to complete the procedures due to cultural barriers (preferred to communicate via spouse). The NV procedures using both photos and written prose were universally accepted. Participants took a mean of 9 photos over 7 days (range: 4–10) and completed workbook questions regarding current PA and PA goals. Thematic analysis of photos revealed that participants felt that family had the largest impact on their PA. The written portions of the workbooks discussing goals focused on increasing PA to improve health, spending quality time with family, and time for personal reflection. Weight loss was not a major theme. A balance of positively and negatively themed emoji stickers were used by all participants to portray reactions. Fitness and motivation themed stickers were also commonly used.

Conclusions: The materials provided to the breast cancer survivors allowed them to successfully use NV techniques to reflect on their PA data and behavior. These techniques show promise for promoting integrated regulation in activity monitoring interventions.

FRIENDS AND FUNCTIONING: SOCIAL SUPPORT BUFFERS THE NEGATIVE EFFECT OF SYMPTOMS ON FUNCTIONING IN PATIENTS WITH LUNG CANCER

Stephen B. Lo, MA¹, Carolyn J. Presley, MD, MHS², Madison Grogan, BA³, Barbara L. Andersen, PhD¹¹Ohio State University, Columbus, OH; ²The Ohio State University Comprehensive Cancer Center and The James Cancer Hospital/Solove Research Institute, Columbus, OH; ³Ohio State University Comprehensive Cancer Center, Columbus, OH

Background: Patients with advanced non-small cell lung cancer (NSCLC) experience high symptom burden, which negatively impacts functional status—the ability to perform daily activities needed to maintain an independent lifestyle. Although social support can buffer these negative effects on health, whether this protective effect is beneficial for patients with advanced NSCLC is unknown. This study examined the association of social support and symptoms with functional status among patients newly diagnosed with advanced (stage IV) NSCLC.

Methods: Patients with newly diagnosed stage IV NSCLC (N=186) completed self-report measures of social support (Social Network Index), mental health (PHQ-9 and GAD-7) and physical symptoms (EORTC LC-13 and symptoms questionnaire assessing common cancer-related symptoms), and functional status (EQ-5D-5L). Principal component and exploratory/confirmatory factor analyses of the physical symptom questionnaires identified 5 symptom clusters (respiratory distress, vegetative symptoms, physical distress, nausea/vomiting, and dysphagia/mouth sores). Linear regressions tested the main effect of social support and each symptom on 4 functional status outcomes (total score, mobility, self-care, and ability to perform usual activities). For each symptom, a multiple regression tested social support, symptoms, and their interaction as predictors of functional status after controlling for age, sex, and marital status.

Results: Higher social support was associated with better functioning [total score ($\beta = -.20$; $p < .01$) and improved mobility ($\beta = -.24$; $p < .01$)], while marital status was not ($ps > .07$). Conversely, all mental and physical health symptoms were associated with worse functioning across all functional outcomes ($\beta = .11$ to $.56$; $ps < .05$) with the exception of nausea/vomiting's association with self-care ($p = .13$). Social support significantly moderated the effect of symptoms on functioning. Specifically, the negative effect of symptoms (anxiety and physical distress) on functioning total scores, (depression, anxiety, respiratory distress, and physical distress) on self-care, and (physical distress) on mobility were enhanced in those with lower social support ($ps < .05$).

Discussion: Social support buffers the negative impact of symptoms on functional status in patients with advanced NSCLC at diagnosis, over and above the effect of marital status. Monitoring and developing additional social support among patients may be important to maximize functional outcomes.

STIGMATIZING ATTITUDES OF PRIMARY CARE PHYSICIANS TOWARDS PATIENTS WHO SMOKE: PREVALENCE AND ASSOCIATED FACTORS

Liz Scharnetzki, MA¹, Leo B. Waterston, M.A.², Paul Han, MD, MPH³, Neil Korsen, MD, MS⁴, Susan Leeds, MOT⁵¹MMCRI-CORE, Portland, ME; ²Center for Outcomes Research and Evaluation, Maine Medical Center Research Institute, Portland, ME; ³Maine Medical Center, Portland, ME; ⁴MMCRI Center for Outcomes Research and Evaluation, Portland, ME; ⁵MMCRI-CORE, Portland, ME

Background: Fear of stigmatization is an obstacle that may prevent patients from seeking, and health professionals from providing, beneficial health care services. A growing number of studies have assessed stigmatizing attitudes among patients and health professionals, but few have examined primary care physicians' stigmatizing attitudes towards patients who smoke. This is an important knowledge gap, given that stigmatizing attitudes may prevent physicians from delivering optimal care.

Objectives: The objectives of the current study were: 1) To describe the prevalence of stigmatizing attitudes among primary care physicians, and 2) To explore factors associated with physicians' stigmatizing attitudes.

Method: As part of a statewide survey aimed at understanding primary care physicians' attitudes towards lung cancer screening, Maine primary care clinicians completed a new 11-item measure of physicians' stigmatizing attitudes towards smokers (the Smoking Stigma Scale for Physicians, SSSP), which assessed physicians' level of agreement with various statements indicating stigmatizing attitudes.

Results: 118 physicians (59% female; 80% practicing physicians; 22% Family Medicine residents) completed the surveys (response rate 15%). The SSSP demonstrated good internal consistency ($\alpha = .814$). Overall, physicians reported a moderate degree of stigmatizing attitudes towards smokers ($M = 2.36$ on a 1–5 scale, $SD = .65$). There was no association between stigmatizing attitudes and either years of practice ($M = 14.40$, $SD = 12.50$) or physician specialty. Physician gender was significantly associated with stigmatizing attitudes; male physicians reported a greater degree of stigmatizing perceptions towards smokers ($M = 2.55$, $SD = .63$) than female physicians ($M = 2.23$, $SD = .58$; $p = .01$, $d = .53$). There was a marginally significant association between bias and physicians' perceived self-efficacy in conducting shared decision making (SDM) counseling for lung cancer screening ($p = .06$); higher smoking bias was associated with lower self-efficacy.

Conclusions: Among primary care physicians, stigmatizing attitudes towards smokers are relatively common and associated with male gender and lower self-efficacy in conducting SDM counseling for patients considering lung cancer screening. Future research should focus on improving the measurement of physicians' stigmatizing attitudes and investigating the causes and consequences of these attitudes.

LIVER CANCER PREVENTION AMONG ASIAN AMERICANS: WHAT WE'VE KNOWN AND WHAT ELSE WE CAN DO?

Y. Alicia Hong, Ph.D.¹, Hee-soon Juon, Ph.D.², Daisy Le, Ph.D.³, Van M. Ta Park, Ph.D.⁴¹George Mason University, Fairfax, VA; ²Thomas Jefferson Hospital, Philadelphia, PA; ³George Washington University, Washington, DC; ⁴University of California San Francisco, San Francisco, CA

Background: Chronic infection of Hepatitis B virus (HBV) is the leading cause of liver cancer. Two thirds of those chronically infected in the U.S. are unaware of their status. Asian Americans (AA) comprise 6% of total U.S. population but make up 60% of those infected. About 10% AA are chronically infected with HBV compared to 0.3% of general U.S. population. In the past two decades, a number of programs have been implemented this health disparity.

Methods: In this study, we first review the existing public health intervention programs of HBV screening and vaccination among AA. Then, based on our decades of working of HBV screening and treatment in AA communities and recent research on their social media and mobile use behaviors, we make recommendation for future research.

Results: We identified more than 50 peer-reviewed publications on liver cancer prevention among AA. Only 15 studies reported HBV screening and treatment, most of these studies were community screening events in major metropolises with large AA populations. Out of those tested, the HBV infection rates ranged from 5% to 33% with a median of 12%. Only four interventions were evaluated with a randomized controlled trial (RCT). Most interventions were community-based programs delivered by lay health workers (LHW). Some recent studies reported reminder prompts on electronic health records (EHR). No study employed digital tools as intervention delivery in spite of the fact that more than 90% AA own smart phones and more than 70% are active on their ethnic specific social media chat applications platforms such as WeChat (Chinese), Kakao Talk (Korean), and Zalo (Vietnamese).

Conclusion: Despite two decades of efforts to address liver cancer disparity among AA, HBV screening and treatment rates remain low. The existing LHW-led community-based behavioral interventions have demonstrated initial efficacy but were limited in reach and impact. The high ownership rate of smart phone and popular social media platforms among AA can be capitalized for more effective interventions, which can be culturally tailored for AA subgroups and personalized to meet individual preferences for optimal program outcomes.

SOCIAL MEDIA RESEARCH: NATIONAL CANCER INSTITUTE FUNDING TRENDS (2004-2019)

Anna Gaysynsky, MPH¹, Wen-ying Sylvia Chou, PhD, MPH²¹National Cancer Institute/ ICF, Rockville, MD; ²National Cancer Institute, Bethesda, MD

Background: Given the increasing interest in using social media (SM) for health research, as well as efforts at the National Cancer Institute (NCI) to support SM research, an analysis of the NCI extramural grant portfolio in relation to SM research is timely.

Objective: To analyze trends in SM-focused grant applications funded by the NCI between 2004-2019, summarize study characteristics, and identify gaps in the NCI-funded SM research.

Methods: The NIH iSearch system was queried to identify NCI grant submissions from FY04-FY19 with SM-related search terms (e.g. “Web 2.0”, “Twitter”, “Instagram”, “online support group”) in the title or abstract. The search returned a total of 738 new (Type 1) grant submissions, 93 of which were funded. Of the 93 awarded grants, 35 were excluded on abstract review (e.g. because social media was only part of the result dissemination strategy). Of the remaining 58 grants, 24 were not reviewed further because the SM component was deemed insubstantial. The abstracts/specific aims of the other 34 grants were coded for role of social media, topic, cancer continuum stage, theory, platform(s) used, methods, and target population.

Results: Grant submissions mentioning SM increased steadily, from 1 in 2004 to 115 in 2018. However, only an average of 3.4 SM-focused grants were awarded each year between 2009 and 2019 (range: 2-9). Among funded grants, SM was used as a data source in 16 grants, an intervention platform in 9 grants, a component of a larger intervention in 7 grants, and a recruitment strategy in 2 grants. The most frequent topic was tobacco/e-cigarettes (n=14), followed by indoor tanning/sun safety (n=7). Most grants (n=26) focused on the prevention stage of the continuum, and 5 focused on survivorship. Few grants addressed screening, treatment, or end-of-life. Facebook (n=10) and Twitter (n=10) were the most frequently used platforms, with few grants utilizing Instagram, YouTube, Reddit, or Pinterest. 11 grants used a health-specific social networking site (e.g. QuitNet) or a platform developed by the research team. Most grants looked at a general population, with only 7 grants targeting patients/survivors and 4 targeting caregivers/family members. 9 grants focused on younger individuals, 1 grant focused on Latinos, 1 focused on a low-income population, and 1 focused on sexual minority men.

Conclusions: Relatively few SM-focused grants have been funded over the past 15 years in cancer control despite the rising prominence of social media in society and its potential utility for research. Future work should address gaps in current research by focusing on visual platforms (e.g. Instagram), vulnerable populations, different stages of the cancer continuum, and a broader range of cancer risk factors (e.g. diet).

THE SOCIOEMOTIONAL IMPACT OF BLOOD CANCER CAREGIVING: DIFFERENCES IN THE EXPERIENCES OF PARENT AND ADULT CHILD CAREGIVERS

Carma Bylund, PhD¹, Carla L. Fisher, PhD², Amanda Kastrinos, Master's³, Maria Sae-Hau, PhD⁴, Elisa S. Weiss, PhD⁴, Michaela Mullis, M.A.⁵¹University of Florida, Gainesville, FL; ²University of Florida / UF Health Cancer Center, Gainesville, FL; ³University of Florida, Gainesville, FL; ⁴The Leukemia & Lymphoma Society, Rye Brook, NY; ⁵University of Florida, Gainesville, FL

Introduction: Family caregivers of patients with cancer face many challenges as they integrate the logistical, emotional, and financial pressures of cancer caregiving into their often very busy lives. The experience of caregiving is usually studied in the context of only one type of family relationship, most often spouses or partners. Less attention has been paid to parent/child and adult-child/parent relationships in cancer caregiving or to closely examining how their experiences and needs may differ.

Objective: To examine differences in caregivers' experiences as they care either for children or parents with blood cancer.

Methods: We conducted semi-structured individual interviews with caregivers of parents or children with blood cancer. In order to be included in the study, the parent or child must have completed primary or maintenance therapy in the past 1-18 months. We used a qualitative, thematic analysis process to address our aims.

Results: We interviewed 20 parent caregivers (PC) and 19 adult child (ACC) caregivers of patients with blood cancer. Caregivers ranged in age from 29-64 (mean=43.49). Mean age did not differ significantly based on whether they were a PC or ACC. Five major themes of differences emerged between the two types of caregivers: (1) **Prognosis:** ACCs were less anxious and fixated on cure than PCs. (2) **Disruption:** ACCs described caregiving as more of a disruption to their lives largely centered on changes in their home life. (3) **Role Shifts:** ACCs experienced role shifts or role reversals in caring for their parents, while PCs were already in a caregiving role. (4) **Family Conflict:** ACCs reported conflict with siblings and other family members in the caregiving process, while almost no PCs discussed resentment or frustration with other caregivers. (5) **Transition to Survivorship:** Although participants in both groups described trying to adjust to a “new normal” and getting back to their own activities, ACCs focused on the parent regaining independence as a mark of a transition into survivorship care.

Conclusion: Caregivers have differing experiences with caregiving based upon whether they are caring for their child or their parent. The intergenerational relationship between the patient and caregiver is critical to understanding the caregiving experience and varying needs for supportive services. Caregiver interventions and programs should be tailored according to the age and developmental needs of the patient, with consideration for the intergenerational dynamics of that particular relationship in the family.

CANCER CARE TEAM CORE COMPETENCIES IN MULTIDISCIPLINARY MULTI-TEAM SYSTEMS

Veronica Chollette, RN, MS¹, Sallie J. Weaver, PhD, MHS¹, Sophia P. Tsakraklides, PhD², Shin-Ping Tu, MD, MPH³¹National Cancer Institute, Rockville, MD; ²Westat, Bethesda, MD; ³University of California Davis, Sacramento, CA

Rapid changes in oncology and the increasing demands of integrative and complementary medicine require multidisciplinary cancer care teams to demonstrate core non-clinical competencies in order to operate effectively and according to shared-decision making principles within complex multiteam systems. Beginning with a comprehensive list of non-clinical team-based competencies from various sources categorized into six domains, a multidisciplinary group of oncology, palliative and primary cancer care professionals and patient and family member advocates refined the list after three consecutive web-based surveys following a modified Delphi study design. After each survey round, statistical and qualitative analytic approaches were applied to refine competency statements, eliminate duplicates, and add missing competencies. Consensus on the top-ranking teamwork competencies was achieved through analyzing competency statements agreed on by 70% of the panel of survey participants.

Of the 227 stakeholders who were invited to participate in the study, 104 consented. Study panelists deemed four domains and 20 associated team-based competencies important for effective coordination in the current cancer care multiteam system. Teamwork competencies related to providing patient-centered care in multiteams were rated highest ($m=4.6$, $SD=.63$), followed by communication competencies ($m=4.25$, $SD=.8$), then competencies related to coordination ($m=4.19$, $SD=.85$) and shared mental models ($m=4.15$, $SD=.76$).

This study advances the knowledge of teamwork competencies required by cross-functional teams in the fragmented multiteam system of cancer care delivery embracing integrative and complementary medicine goals. Findings may be of interest to developers of IPE team-based trainings for medical education curricula and workforce training. More research is needed to understand how frequently to train, what modes and methods of training are acceptable for clinical staff of various disciplines, and how to also train patients to participate in the coordination of their care.

THE ROLE OF THE MYC GENE EXPRESSION PATHWAY ON THE EFFICACY OF SOYBEAN VS. FISH OIL ON CANCER-RELATED FATIGUE IN CANCER SURVIVORS

Amber S. Kleckner, PhD¹, Sarah Kerns, PhD, MPH², Eva Culakova, PhD, MS², Ian Kleckner, PhD, MPH², Richard F. Dunne, MD², Julia E. Inglis, Ph.D., R.D.², Amy Vander Woude, MD³, Karen M. Mustian, PhD, MPH², Luke J. Peppone, Ph.D., M.P.H.⁴¹University of Rochester, Rochester, NY; ²University of Rochester Medical Center, Rochester, NY; ³Cancer & Hematology Centers of Western Michigan, Grand Rapids, MI; ⁴University of Rochester Medical Center, Rochester, NY

Background: Cancer-related fatigue (CRF) affects the majority of cancer survivors. We previously showed greater alleviation of CRF with soybean vs. fish oil supplementation, though the mechanism remains unclear. Myc is a transcription factor that regulates dozens of genes involved in mitochondrial energy production and is notoriously upregulated in cancer. We investigated whether soybean vs. fish oil led to differential effects on Myc gene expression that could explain the efficacy of soybean oil to alleviate CRF in breast cancer survivors.

Methods: In a phase II nationwide randomized controlled trial in the NCI Community Oncology Research Program (NCORP) network, female breast cancer survivors 4–36 months post-treatment with self-reported CRF $\geq 4/10$ were randomized to daily supplementation with 6 g soybean oil, 6 g fish oil, or 3 g of each for 6 weeks. CRF was assessed using the Functional Assessment of Cancer Illness Therapy-Fatigue; gene expression was assessed in peripheral blood using RNASeq at baseline and post-intervention. 58 Myc target genes were identified using molecular signatures (MSigDB), and patterns in Myc target gene expression were captured in a composite term using Principal Component Analysis (PCA; the first component accounted for at least 90% of variance and was used as the “gene expression” variable going forward). Linear regression models were used to explore the relationship between changes in patterns of gene expression and changes in CRF. $p \leq 0.05$ was deemed significant and the Benjamini-Hochberg procedure was used to account for multiple comparisons.

Results: Participants ($n=70$) were 61 ± 9 years old. Patterns of Myc target gene expression were correlated with change in CRF only for patients randomized to receive soybean oil (gene expression*arm interaction, $p = 0.009$, $\beta \pm SE = 1.11 \pm 0.56$); the strength of this relationship weakened with increasing dose of fish oil. When we probed individual genes, we observed that soybean vs. fish oil led to significant downregulation of 19/58 genes pre- to post-intervention, no significant change in 39 genes, and significant upregulation in no genes (adjusted $p < 0.05$). Similarly, there was a significant positive correlation between blood omega-3 concentration and gene expression of 31/58 Myc target genes at post-intervention and no significant negative correlations (Spearman's ρ values = 0.27–0.62; adjusted $p < 0.05$).

Conclusions: Soybean oil broadly downregulated Myc target gene expression, and patterns of expression were correlated with CRF in this group. Thus, these data suggest that soybean vs. fish oil was associated with deactivation of the Myc signaling pathway and contributed to alleviation of CRF, while fish oil potentially interfered with this relationship. Future research is needed to confirm these observations, though Myc signaling could serve as a promising therapeutic target to treat CRF.

PATIENT ACTIVATION: A CLOSER LOOK AT THE DIMENSIONS OF THE CONSTRUCT

Andrea Chirico, Ph.D.¹, Natalia Salamanca-Balen, MD², Thomas Merluzzi, Ph.D.²¹University of Rome, Rome, Lazio, Italy; ²University of Notre Dame, Notre Dame, IN

Background: Patient Activation (PA) represents engagement in one's health and health care. The Patient Activation Measure (PAM) was designed to assess stages of PA: 1) Belief in an Active Role, 2) Knowledge and Confidence; 3) Taking Action/ Maintaining Behaviors. This study was designed to examine these stages of activation by focusing on construct validity and psychological processes such as intentions and efficacy to engage in healthy behaviors. We hypothesized a 3-factor solution for the PAM-13, based on prior research, and positive relationships with hope, medical information seeking, maintaining an active lifestyle and negative relationships with anxiety and depression. Furthermore, we anticipated that intentions to perform a health behavior and the efficacy to do so would be highly correlated with Factor 3.

Methods: 76 persons with a cancer diagnosis completed a questionnaire that contained the PAM-13, the Hope Scale, measures of anxiety and depression (HADS), Self-Efficacy for Seeking Medical Information and Self-Efficacy for Maintaining Activity (from the Cancer Behavior Inventory), composite measures of intentions and self-efficacy for engaging in a healthy diet and exercise.

Results: Maximum Likelihood factor extraction and Promax rotation on the PAM-13 yielded 3 factors (F1, F2, F3) that corresponded to the three stages of PA (R²=62%), essentially confirming the conceptual structure of the PAM. Correlations of the factors with Hope Goals (F3:r=.314,p<.01), Hope Pathways (F3: r=.364, p<.01), Seeking Medical Information (F1:r=.353;F2:r=.403; F3:r=.394, ps<.01), Maintaining Activity (F1:r=.223;F2:r=.297;F3:r=.482, ps<.01), Anxiety (F3:r=-.295,p<.01), Depression (F2:r=-.300;F3:r=-.395, ps<.01), provided support for the construct validity of the PAM with the strongest relationships on Factor 3. Regression analyses were computed with the three PAM factors as predictors and 1) a composite of intentions to engage in a healthy diet and exercise and 2) a composite of self-efficacy for diet and exercise behaviors were criterion variables. For both intentions (F3:B=.305;95% CI: .070, 1.284) and self-efficacy (F3:B=.308;95% CI: .318, 2.823) only Factor 3 was a significant predictor.

Conclusions: The results support the structure and construct validity of the PAM in that seeking medical information and maintaining an active lifestyle were related to all three factors of the PAM and depression was related to F2 and F3. However, for anxiety, hope, intentions to engage in healthy behaviors and efficacy to do so, only F3 was a significant predictor. Therefore, overall, Factor 3, which focuses on what appears to be resilience, is the most potent factor in terms of prediction in the current study. More work needs to be conducted to evaluate the nomological net in which PAM resides, the differential predictive power of the factors, and the role of resilience in patient activation.

ACCEPTABILITY, FEASIBILITY, AND PRELIMINARY EFFECTS ASSOCIATED WITH USE OF A UVR EXPOSURE MONITORING DEVICE AMONG CHILDREN

Katy M. Nottingham, BS¹, Bridget G. Parsons, MSPH, CCRP², Kade Kofford, n/a¹, Angela Zhu, BS³, Riley Lensink, BS¹, Elizabeth S. Nagelhout, MPH, PhD¹, Douglas Grossman, MD, PhD⁴, Yelena P. Wu, PhD¹¹Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; ²Huntsman Cancer Institute University of Utah, SLC, UT; ³Primary Children's Hospital, University of Utah, Salt Lake City, UT; ⁴Huntsman Cancer Institute University of Utah, Salt Lake City, UT

Ultraviolet radiation (UVR) exposure is the primary modifiable risk factor for skin cancer. Skin cancer preventive behaviors, including use of sunscreen and protective clothing and reduction of UVR exposure, sunburns, and intentional tanning, help to decrease risk for skin cancer. Reducing sunburn during childhood is particularly critical, because occurrence of a severe sunburn in childhood nearly doubles one's risk for developing melanoma, the deadliest type of skin cancer. Objective measurement of UVR exposure is critically needed to measure outcomes of skin cancer preventive interventions. However, there are few UVR monitoring devices available, and little is known about the impact of UVR monitoring on implementation of skin cancer preventive behaviors (e.g., potential reactivity to UVR monitoring). The current study sought to test the feasibility and acceptability of an innovative UVR monitoring device among children. In addition, we evaluated potential effects on children's skin cancer preventive behaviors associated with use of the UVR monitoring device.

Participants were 25 parent-child dyads (parent mean age=42.8 years, SD=5.3, 72% female; child mean age=12.8 years, SD=2.3, 72% female). Children wore the UVR monitoring device ("My UV Patch") for three consecutive days and reported on device feasibility and acceptability. Parents and children also reported on child sun protection habits at prior to and at conclusion of the monitoring period. Descriptive statistics were used to summarize acceptability and feasibility outcomes. Paired-samples t-tests were conducted to assess within-subjects change in sun protection habits from baseline to follow-up.

The majority of children reported that the device was comfortable (64%), easy to wear (80%), and did not limit participation in regular activities (76%). Participant-reported adherence to wearing the device for the complete 3-day monitoring period was high (96%). No significant differences were detected in child- or parent-reported child sun protection habits from baseline to follow-up.

The UV monitor used in the current study appears to be a feasible and acceptable method for measuring UVR exposure in children. There was no evidence of reactivity effects associated with UVR monitoring. Objective UVR monitoring devices could be employed in intervention studies in order to objectively measure UVR exposure, and may not interfere with detection of sun protection behavior-related intervention effects.

DOES THE QUALITY OF PATIENT-PROVIDER COMMUNICATION INFLUENCE THE QUALITY OF LIFE AMONG RURAL CANCER SURVIVORS?

Leslie R. Carnahan, MPH¹, Kristine Zimmermann, MPH¹, Karriem S. Watson, DHS, MPH, MS², Carol Ferrans, PhD, RN, FAAN¹, Yamilé Molina, MS, MPH, PhD¹, Shaila Strayhorn, PhD, MPH¹

¹University of Illinois at Chicago, Chicago, IL; ²University of Illinois Cancer Center at UIC, Chicago, IL

Background: Rural cancer survivors experience higher mortality and a lower overall quality of life (QOL) compared to urban cancer survivors. While there are various reasons for these disparities, recent studies have suggested that differences in patient-provider communication quality (PPCQ) may be one contributing factor. Poor PPCQ among cancer survivors, has been associated with limited shared decision making, particularly regarding treatment-related decisions. This in turn can contribute to poorer long-term QOL among rural cancer survivors. An improved understanding of the relationship between PPCQ and the QOL among rural cancer survivors will contribute to strategies to reduce rural cancer disparities.

Purpose: To explore the relationship between PPCQ and four health-related QOL domains among rural cancer survivors: social well-being, functional well-being, mental health, and physical health.

Methods: Data was derived from the Illinois Rural Cancer Assessment (IRCA) Study. Participants completed surveys between January 2017-September 2018 via phone, internet, or paper-based surveys. QOL was measured with two instruments: FACT-G and SF-12 and PPCQ was assessed with the Medical Expenditure Panel Survey's (MEPS) Experience with Cancer Care instrument. Self-reported PPCQ was modeled as a predictor in separate adjusted linear regression models for each QOL outcome. All univariate and multivariable linear analyses were conducted using SPSS version 25.

Results: Of the 139 study participants, the fully adjusted models revealed a positive association between PPCQ and two QOL domains based on the FACT-G tool: social well-being ($\beta=0.19$, CI: 0.03, 0.36) and functional well-being ($\beta=0.20$, CI: 0.04, 0.34). No associations were observed between PPCQ and physical health or mental health-related QOL.

Conclusion: Findings from this study provide evidence that the PPCQ is important for improving both the social well-being and functional well-being among rural cancer survivors. These findings encourage future researchers and healthcare providers to work to develop strategies for improving communication with rural cancer survivors. Improvements in PPCQ within rural cancer survivor populations, promises to contribute to better patient QOL in terms of social well-being and functional well-being.

PRELIMINARY RESULTS FROM THE MYCHOICE STUDY TO IMPROVE INFORMED DECISION MAKING IN CLINICAL TRIAL PARTICIPATION

Linda Fleisher, PhD, MPH¹, Sarah Bauerle, Bass, Ph.D. and MPH²

¹Fox Chase Cancer Center, Philadelphia, PA; ²Temple University College of Public Health, Philadelphia, PA

Background: *mychoice*, a novel web-enabled communication tool designed to improve informed decision making about clinical trials, used a systematic approach with patients from diverse backgrounds (especially given the limited participation of racial and ethnic minorities) and providers from concept to prototype development to user testing. Our preliminary results from the randomized study at 4 cancer centers indicate that patients find the tool helpful in their decision making process.

Methods: A mixed methods approach, including interviews, surveys, perceptual mapping analysis, and user prototype testing guided the development of *mychoice* including information about the value of clinical trials and addresses concerns through patient testimonials and an interactive communication aid. It is now being evaluated in an RCT to determine patient satisfaction and its impact on decisional conflict and self-efficacy in talking with their provider. Participants in the RCT complete a baseline survey, are randomized to either the *mychoice* tool or standard materials on clinical trials. Immediately upon using the tool, patients are asked to provide feedback on its decision making value (Ottawa Preparation for Decision Making Scale-PREP-DM) and additional satisfaction and usage questions at one month follow-up.

Results: Participants (161 out of 270 goal) in the RCT represent a diverse population (43% are African American, 67% female, 30% less than a HS education). Almost all (94%) of those receiving *mychoice* stated that the tool was somewhat or very helpful, would recommend it to others (94%), was clear (90%). We found that African American participants also rated the tool highly. Of the 10 items in the PREP-DM, over half of the African American patients stated it helped them to recognize that a decision needs to be made, it prepared them to make a better decision, helped them think about the pro's and con's. Over 2/3 indicated that the tool helped them to personalize the pro's and con's, organize their thoughts, think about how involved they wanted to be in decision making and identify questions to ask their doctor. Similar results were seen in the total sample. Study accrual will be complete by the end of 2019, and results exploring patient satisfaction, perceived benefit in decision making, and feedback on specific element of *mychoice* as well as differences among White and African American patients will be presented.

Discussion: Using rigorous formative evaluation and mixed method approaches to guide the development of clinical trials decision tool to ensure its salience to culturally diverse patients is critical and our preliminary results indicate that the *mychoice* communication tool is highly rated and perceived to be impactful in the decision making process by both African American and White patients participating in our RCT.

DEPRESSION AND INFLAMMATION AMONG LESBIAN, GAY, AND HETEROSEXUAL CANCER SURVIVORS: TESTING TWO EXERCISE INTERVENTIONS

Charles Kamen, PhD, MPH¹, Karen M. Mustian, PhD, MPH¹, Luke J. Peppone, Ph.D., M.P.H.², Michelle C. Janelins, Ph.D., M.P.H.¹¹University of Rochester Medical Center, Rochester, NY; ²University of Rochester Medical Center, Rochester, NY

Background: Our previous research shows that lesbian/gay (LG) cancer survivors experience higher rates of depression than their heterosexual counterparts, and that standardized aerobic and resistance exercise (EXCAP[®], Exercise for Cancer Patients) is efficacious in improving depression and inflammation associated with depression in heterosexual survivors. We conducted a pilot cancer control trial testing whether the benefit of exercise on depression extended to both LG and heterosexual survivors, and whether inclusion of caregivers (CGs) enhanced effects on depression and inflammation.

Methods: In this pilot trial, 20 LG and 22 heterosexual survivors and their CGs were randomized as dyads to: Arm 1) dyadic exercise, involving both survivor and CG; or Arm 2) survivor-only EXCAP[®]. Depression symptoms (CES-D) and cytokines (serum IFN- γ , IL-6, IL-8, IL-10) were measured at baseline and post-intervention (6 wks later). We used t-tests to assess baseline disparities, ANCOVA to assess the effect of dyadic vs. survivor-only exercise on depression and inflammation, and Pearson correlations to assess mechanistic associations between changes in depression and inflammation.

Results: At baseline, LG survivors reported higher depression ($t=-2.23$, $p=0.04$), higher IL-6 ($t=-2.53$, $p=0.02$), and higher IL-8 ($t=2.37$, $p=0.03$) than heterosexuals. Among both LG and heterosexual survivors, dyadic exercise significantly improved depression relative to survivor-only exercise ($M=-5.17$, vs. $M=2.43$; $p=0.02$). Decreases in depression were associated with decreases in IL-6 ($r=0.40$, $p=.03$) and IL-8 ($r=0.39$, $p=0.04$) in both exercise groups; in analyses by sexuality group and intervention, these associations were significant only among LG survivors in the dyadic exercise condition.

Conclusions: This study replicates previous research showing disparities between LG and heterosexual survivors and offers preliminary support for the use of exercise in general and dyadic exercise in specific for reducing depression among LG and heterosexual survivors. It suggests a biological mechanism by which this improvement occurs, namely by reducing systemic inflammation. Confirmatory research is needed to replicate these findings in larger samples of LG cancer survivors.

PATIENT-REPORTED PSYCHOLOGICAL AND PHYSICAL RISK FACTORS FOR ANXIETY AND DEPRESSION IN STAGE IV NON-SMALL CELL LUNG CANCER

Tessa R. Blevins, B.A.¹, Stephen Lo, M.A.¹, Nicole A. Arrato, M.A.², Barbara L. Andersen, PhD²¹The Ohio State University, Columbus, OH; ²Ohio State University, Columbus, OH

Background: Of all cancers, lung cancer is associated with the highest levels of anxiety and depression, which may impact quality of life and survival. It is important to continually identify and assess for significant risk factors in patients with lung cancer at diagnosis, prior to treatment. This study examined possible risk factors in patients with non-small cell lung cancer (NSCLC) at diagnosis and their associations with anxiety and depression at baseline, controlling for previously empirically supported risk factors.

Methods: Patients with stage IV NSCLC ($n=186$) completed self-report measures relating to anxiety, depression, traumatic life events, social network, hopelessness, illness perceptions, cancer-related stress and symptoms, and general health at diagnosis through a phone interview. To determine covariates, correlations were run between empirically supported psychological, medical, and demographic risk factors for anxiety and depression in cancer patients and the GAD-7 for anxiety and PHQ-9 for depression. Those found significant (i.e. personal or family history of a psychiatric diagnosis, high school education, income, and marital status) were controlled for in the analyses. Multiple linear regressions were used to determine the relationships between the possible risk factors and anxiety and depression scores.

Results: Nine percent ($n=19$; $M=5.42$, $SD=5.26$) and 5.1% ($n=15$; $M=6.49$, $SD=5.23$) of patients reported severe anxiety and moderately severe depressive symptoms, respectively. For anxiety, life events ($\beta=.105$, $p=.001$), total cancer-related stress ($\beta=.528$, $p<.001$), and vegetative symptoms (fatigue, weakness, appetite, and sleep disturbance; $\beta=.183$, $p<.001$) were significantly associated. For depression, social support ($\beta=-.136$, $p=.017$), hopelessness ($\beta=.132$, $p=.028$), total cancer-related stress ($\beta=.399$, $p<.001$), vegetative symptoms ($\beta=.380$, $p<.001$), swallowing and soreness of the throat ($\beta=.168$, $p=.001$), and the identity (i.e. how a patient labels their illness; $\beta=.120$, $p=.051$) and control (i.e. how much control a patient feels they have over their illness; $\beta=-.094$, $p=.301$) components of the Brief Illness Perceptions Questionnaire were all significantly associated.

Conclusions: Analyses demonstrated previously unidentified psychological and patient-reported associations with anxiety and depression in a sample of patients with NSCLC. There should be heightened awareness of these variables in cancer patients after diagnosis and before treatment in order to protect against possible anxiety and depressive symptoms.

NATIONAL TRENDS IN CANCER SURVIVORS SUN PROTECTIVE BEHAVIORS IN THE US.

Mark D. Lowry, PhD¹, Patrick Boyd, PhD², Kasey Morris, PhD³, Frank M. Perna, Ed.D., Ph.D.²

¹National Cancer Institute, Bethesda, MD; ²National Cancer Institute, ROCKVILLE, MD; ³Surgo Foundation, Washington, DC

Background: Previous research investigating the health behaviors of cancer survivors have looked across several domains (e.g. physical activity, smoking etc.; Bellizzi et al., 2005). However, this research did not examine behaviors related to sun exposure. Skin cancer is one of the most common cancers, and in 2019 over 11,000 deaths were attributed to it (American Cancer Society, 2019). The purpose of the current research is to examine sun safety behaviors in cancer survivors and controls.

Method: Data related to sunscreen use, indoor tanning and sunburn were taken from the National Health Interview Survey (NHIS) over three time points (2005, 2010, 2015). There were 92,257 participants whose cancer status was obtained via self-report (e.g., “Have you ever had cancer?”). 8,050 participants reported having had cancer (2,428 in 2005; 2,333 in 2010; 3,289 in 2015). The data were weighted, and odds ratios were calculated using logistic and multivariate regressions in SPSS.

Results: When comparing cancers survivors to those without a history of cancer across time points, cancer survivors were more likely to report regular sunscreen use ($OR = 1.50$, $CI = 1.41, 1.59$) and less likely to engage in indoor tanning ($OR = 0.81$, $CI = 0.69, 0.94$). Significant differences were not found for the likelihood of reporting a sunburn among cancer survivors compared to controls. Examining health behaviors for cancer survivors across time (2005–2010 and 2010–2015) demonstrated a significant decrease in sunburns reported from 2010 to 2015 ($p = .025$) and a significant increase in sunscreen use reported from 2010 to 2015 ($p = .043$). No other significant changes were found across time among skin protection behaviors for cancer survivors.

Conclusions: Findings reveal that cancer survivors are more likely to use sunscreen and less likely to engage in indoor tanning. Consistent with national surveillance findings, cancer survivors were no less likely to report being sunburned. More research is needed to determine why this is the case, but it's likely that uptake of sun protective practices in addition to sunscreen may be required, and that cancer survivors may not use appropriate amounts of sunscreen or apply as recommended. This research expands on previous research by examining the sun safety behaviors of cancer survivors. It demonstrates that while cancer survivors are nominally engaging in sun protective behavior, resources may be needed to advance sun protection in this group who are at increased risk for skin cancer.

PREDICTORS OF FATIGUE AND VIGOR IN ASYMPTOMATIC STAGE B HEART FAILURE PATIENTS

Máira Tristao Parra, ScD, MSc¹, Meredith A. Pung, PhD², Kathleen L. Wilson, MS³, Christopher Pruitt, B.S.⁴, Barry Greenberg, MD⁴, Pam Taub, MD⁵, Paul Mills, PhD⁶

¹University of California San Diego, San Marcos, CA; ²University of California, San Diego, La Jolla, CA; ³University of California San Diego, La Jolla, CA; ⁴UCSD, La Jolla, CA; ⁵UC San Diego, La Jolla, CA; ⁶Family Medicine and Public Health, UCSD, La Jolla, CA

Background: Heart failure (HF) patients experience fatigue with the progression of the disease. Lifestyle behaviors such as being physically active, adequate sleep, healthy eating and emotional well-being may play a role in the perception of fatigue and vitality. Our aim was to explore the role of mood and physical activity as predictive factors of fatigue and vitality.

Methods: A cross-sectional analysis of 327 asymptomatic Stage B HF patients. We used descriptive statistics to characterize the sample and created adjusted multiple regression models to predict the dimensions of fatigue and vitality (as assessed with the Multidimensional Fatigue Symptom Inventory – short form (MFSI-sf) questionnaire). The significance was set at $p \leq 0.05$.

Results: The cohort's mean age was 66.1 (10.2) years (Caucasians (77.6%) and males (95.3%) were predominant). Patients' mean BMI was 30.1 (5.3) kg/m² and ejection fraction was 64.6% (9.0), with most patients having left ventricular (LV) enlargement within normal limits (97.7%). 70.5% had LV diastolic dysfunction. Statins were the most prevalent medications (60.3%). Predictors in the regression models for general fatigue and mental fatigue explained approximately 30% of variance (Adjusted R² = 0.297 and 0.341, respectively), with poor sleep ($\beta = 0.24$, $p = 0.02$) and depression ($\beta = 0.37$, $p < 0.001$) significantly predicting general fatigue, while IL-6 ($\beta = -0.47$, $p = 0.04$) and depression ($\beta = 0.35$, $p < 0.001$) significantly predicted mental fatigue. Better sleep ($\beta = -0.22$, $p = 0.01$) and less depressive mood ($\beta = -0.36$, $p < 0.001$) significantly predicted vigor (Adjusted R² = 0.431). Depression ($\beta = 0.44$, $p < 0.001$) was the only significant predictor for emotional fatigue (Adjusted R² = 0.447), while poor sleep and depression were significant predictors for physical fatigue (Adjusted R² = 0.339; $\beta = 0.30$, $p = 0.001$ for sleep and $\beta = 0.30$, $p < 0.001$ for depression) and total fatigue (Adjusted R² = 0.536; $\beta = 0.86$, $p = 0.01$ for sleep and $\beta = 1.82$, $p < 0.001$ for depression).

Conclusion: Our models explained more than 50% of variance for total fatigue. Surprisingly, physical activity was not an important predictor in our models. In contrast, depressive mood and poor sleep were strong predictors for different domains of fatigue and vitality in this cohort of heart failure patients.

NON-CONGRUENCE BETWEEN PATIENT, FAMILY CAREGIVER AND PROVIDER PERCEPTIONS OF CONGESTIVE HEART FAILURE

David Feller, BS¹, Sam Beschta, BS¹, Christa Wamsley, BS², Nunzio Gaglianella, MD¹, Sergey Tarima, PhD¹, Ann Swartz, PhD³, David Nelson, PhD¹, Sandile Nukuna, MS¹, Edith Burns, MD⁴

¹Medical College of Wisconsin, Milwaukee, WI; ²UW-M, Milwaukee, WI; ³University of Wisconsin-Milwaukee, Milwaukee, WI; ⁴Zucker School of Medicine at Hofstra-Northwell, Manhasset, NY

Background: Congestive Heart Failure (CHF) is a debilitating condition affecting nearly 6.5 million adults in the US, with 5-year mortality about 50%. Both light and moderate-vigorous physical activity (PA) reduces risk of hospitalization and mortality. Patients often experience symptoms of shortness of breath, fatigue, and chest pressure, which are exacerbated by PA due to de-conditioning, rather than decompensation of underlying heart function. Patients' perceptions of symptoms, expectations re chronicity and controllability, may influence treatment adherence. Congruence between provider assumptions of patients' perceptions and what the patients actually believe, should facilitate adherence and maintenance of self-management behaviors. The goal of this project was to assess agreement among patient, family and providers regarding the patients' perceptions of CHF symptoms and illness management.

Methods: Participants were recruited from a Heart and Vascular Clinic at a tertiary academic medical center. A research team member administered the brief Illness Perception Questionnaire (IPQ) adapted for CHF to patients and family members and their providers completed an on-line survey asking how their patients perceived the disease. Demographics and additional information on provider practices in recommending PA were collected.

Results: 39 patients, 23 family members and 46 providers (32 MDs, 11 NPs, and 2 PAs; in practice an average of 12.8 years) participated. Patients and family members shared similar perceptions of CHF chronicity (8.86 on scale of 1-10, 10=it will last all their life), controllability (moderate), effect on daily life (moderate negative), degree of understanding (moderate). They differed on intensity of daily symptoms (family perceived patients as more symptomatic, z score=-3.73, $p=.0002$) and helpfulness of treatment (patients rated treatment as moderately effective, but more helpful than family, $z=2.94$, $p=.003$). Providers differed from patients and caregivers on almost all measures: they thought patients had less understanding ($z=3.99$, $p<.0001$), less insight about chronicity ($z=4.92$, $p<.0001$), and less control of CHF ($z=2.93$, $p=.003$). Although providers rated PA as extremely important for CHF management, only 8% reported focusing on PA during clinic visits, compared to 54% who focused on medication.

Conclusions: To improve patient self-management, providers need to develop more accurate perceptions of patient and family perceptions of CHF symptoms and their expectations of treatment efficacy.

LOW RESILIENCE IS ASSOCIATED WITH POORER PSYCHOLOGICAL RECOVERY IN WOMEN WITH ACUTE MYOCARDIAL INFARCTION

Zoe Duberstein, BA¹, Sarah H. Sperber, BA², Tanya Spruill, PhD³, Jolaade Kalinowski, Ed.D.³, Harmony Reynolds, M.D.², Jeffrey Berger, M.D.²

¹NYU Langone, Brooklyn, NY; ²NYU Langone, New York, NY; ³NYU School of Medicine, New York, NY

Introduction: Myocardial infarction (MI) may be experienced as a traumatic event. Psychological resilience can protect patients from developing depression and stress disorders following trauma. However, little is known about the role of resilience in women's recovery post-MI. In this study, we examined associations between trait resilience levels and depressive symptoms and perceived stress during the first six months of recovery following MI.

Methods: The sample included participants enrolled in an ongoing multicenter, observational cohort study of women with MI as of August 2019. During or shortly after MI hospitalization (baseline), 373 participants completed validated measures of trait resilience (Brief Resilience Scale), stress (Perceived Stress Scale [PSS-4]) and depressive symptoms (Patient Health Questionnaire [PHQ-2]). The PSS-4 and PHQ-2 were repeated 2-months ($n=288$ to date) and 6-months post-MI ($n=38$ to date). Published cutoffs were used to define low resilience (BRS < 3), high stress (PSS-4 ≥ 6) and high depressive symptoms (PHQ-2 ≥ 2). Pearson correlation coefficients and chi-square tests were performed to examine associations between resilience, stress and depression at each time point.

Results: The 373 participants had a mean age of 62.8 years ($SD=13.2$) and included 39.1% racial or ethnic minorities. About one-quarter (23.4%) demonstrated low resilience at baseline. At the baseline, 2-month and 6-month time points, the prevalence of elevated depressive symptoms was 40.8%, 41.7% and 21.1%, respectively, and the prevalence of elevated stress was 57.4%, 42.4% and 39.5%, respectively. Lower BRS scores were associated cross-sectionally with higher stress ($r=-.503$, $p<.001$) and higher depressive symptoms ($r=-.409$, $p<.001$). Women with low (versus normal or high) resilience were more likely to have high stress (63.5% vs. 36.4%, $p<.001$) and high depressive symptoms (60.0% vs. 36.7%, $p=.013$) 2-months post-MI, as well as 6-months post-MI (80.0% vs. 25.0%, $p=.002$ [stress]; 40.0% vs. 14.3%, $p=.087$ [depression]).

Conclusions: To our knowledge, this is the first study to examine effects of psychological resilience on stress and depression over time in MI patients. Women with lower resilience were more likely to have clinically significant levels of stress and depression up to 6 months post-MI. These findings suggest that psychosocial interventions that enhance resilience may improve outcomes in women with MI.

THEMATIC ANALYSIS OF ATTITUDES TOWARD CARDIOLOGY TELEHEALTH AMONG IN-PERSON AND TELEMEDICINE VETERAN PATIENTS

Roman Palitsky, MA, MDiv¹, Brooke A. Finley, MSN, PMHNP-BC, RN-BC², Divya Kapoor, MD³¹Brown University, University of Arizona, Providence, RI; ²The Meadows Behavioral Health, Scottsdale, AZ; ³John Cochran Veterans Hospital, St Louis Veteran's Administration, Kansas City, MO

Cardiology telehealth (telecardiology) provides an efficient, cost-effective approach for delivering patient care to rural populations, often surmounting barriers like staffing shortages, transportation, and time. Patient attitudes toward telecardiology are an important determinant for its dissemination. This study sought to examine attitudes toward telecardiology among traditional in-person cardiology patients and those using telecardiology using qualitative methods.

The Cardiology Clinic vs. Telemedicine popUlation Satisfaction (CACTUS) project recruited a convenience sample of veterans who were receiving care from the same outpatient provider team via in-person cardiology at a metropolitan clinic ($n=190$, 5 female, median age range = 65–74 years) or at rural telecardiology clinics ($n=110$, 4 female, median age range = 65–74 years). After services, patients were asked to write their attitudes toward telecardiology using the following prompts: In-person: “Are you interested in cardiology telemedicine visits?” (yes, no, undecided), “Why, or why not?” (free response); Telecardiology: “Would you recommend cardiology telemedicine clinics to a friend?” (yes, no, undecided), “Why or why not?” (free response). This data was coded by two coders, blinded to condition, using an adaptive theoretical approach. First, both coders independently coded categories and later reconciled themes through discussion. This agreed-upon coding system included 16 codes, and was applied to all participant responses, with discrepancies resolved through discussion. High-frequency codes included: positive and negative attitudes toward telecardiology, positive attitudes toward in-person cardiology, desire for face-to-face contact, rapport, quality, travel, time, and lack of information. A thematic analysis was conducted, yielding the following: in-person cardiology patients expressed concern about losing in-person contact with their providers, distrust of technologically provided care, and concerns about reduced quality or personalization to their care. Conversely, telecardiology patients expressed satisfaction with the personalization, convenience, time and cost-effectiveness, and ability to access services. These findings demonstrate attitudinal barriers to the dissemination of telecardiology among current face-to-face patients despite positive reports from those receiving telecardiology services. Results also indicated that telecardiology patients' own experiences may speak to the concerns of patients who have not experienced telecardiology before. These findings may guide future telecardiology education, and the presentation of telecardiology materials for continued adoption among the rural Veteran population.

GETTING TEENS WITH CONGENITAL HEART DISEASE TO MOVE MORE: BASELINE FINDINGS OF A RANDOMIZED CLINICAL TRIAL

Jamie L. Jackson, PhD¹, Christina Korth, BS¹, Taylor Swenski, BS¹, Michelle Slawinski, MS¹, Clifford Cua, MD¹, Vidu Garg, MD¹, Kathryn Vannatta, PhD¹¹Nationwide Children's Hospital, Columbus, OH

Objective: As more congenital heart disease (CHD) survivors reach adulthood, mortality and morbidity due to preventable comorbidities are of increasing concern. The aim of the CHD Physical Activity Lifestyle (CHD-PAL) randomized clinical trial is to evaluate a PA lifestyle intervention, grounded in the Theory of Planned Behavior, that uses coaching via videoconferencing to increase moderate-to-vigorous PA (MVPA), decrease sedentary behavior, and improve exercise tolerance among high school teens with moderate and complex cardiac lesions. The current study reports baseline results for study outcomes, as well as associations between the outcomes and proposed mechanisms of behavior change targeted by the intervention.

Methods: At baseline for the CHD-PAL trial, 70 teens ($M_{age}=16$, $SD=1.0$, range 15–19; 62% male; 82% Caucasian) consented to wear an accelerometer (Actigraph wGT3X-BT) around the waist for 4–7 days (MVPA, sedentary behavior), perform an exercise stress test (VO_{2max}), and complete an online survey. The online survey included measures pertaining to the proposed mechanisms of change, based on the Theory of Planned Behavior, including attitudes towards PA (Benefits and Barriers to PA), social norms for PA engagement (Family and Friend Support for PA), and self-efficacy for PA.

Results: Average time spent daily in MVPA was 23.0 minutes ($SD=16.0$, range 0–69.5) and 633.9 minutes for sedentary behavior ($SD=186.7$, range 310.5–1190.9). The average VO_{2max} was 36.9 ($SD=9.7$, range 18.9–58.1). Only 3 teens exceeded the recommended federal guidelines for MVPA of 60 minutes per day. 40% of teens currently played an organized sport, 22% previously play a sport, and 38% had never played a sport. Higher levels of MVPA were associated with fewer barriers to PA ($r=-.32$), more family ($r=.44$) and friend ($r=.41$) support for PA, and greater self-efficacy for PA ($r=.35$). Similarly, a higher VO_{2max} was associated with fewer barriers to PA ($r=-.59$), more family ($r=.37$) and friend ($r=.35$) support for PA, and greater self-efficacy for PA ($r=.57$). Sedentary behavior was not associated with the proposed mechanisms of behavior change.

Conclusions: The vast majority of teens enrolled at baseline for CHD-PALS did not meet federal guidelines for MVPA despite 40% currently playing a sport. The proposed mechanisms of change were significantly correlated with the primary study outcome, as well as a secondary medical outcome, suggesting appropriate targets were identified.

THE PSYCHO-SOCIAL-SPIRITUAL EFFECT OF EXPRESSIVE ARTS-BASED INTERVENTION ON PRE-ELDERLY STROKE SURVIVORS: A PILOT STUDY

Temmy Lee Ting Lo, n/a¹, Rainbow T.H. Ho, PhD, REAT, BC-DMT, AThR, RSMT/E, CGP, CMA²

¹The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong

Introduction: Stroke is a severe cerebrovascular disease which may cause profound physical impairments and affect the daily functioning of stroke survivors. While restoring functional ability is critical in stroke rehabilitation, addressing the psychosocial and/or spiritual needs are crucial for achieving a holistic and comprehensive recovery. This study aims to provide psycho-social-spiritual support via Expressive Arts-based Intervention and explore the psycho-social-spiritual effects of the intervention on young and pre-elderly stroke survivors in Hong Kong.

Methods: Stroke survivors were recruited from a day rehabilitation center and in the community. Recruited survivors were 30 adult stroke survivors (33 - 65 years old) who experienced a stroke episode from two months to 16 years before. After obtaining the informed consents, participants were randomized into the intervention (N = 18) and control group (N = 12). The Expressive Arts-based Intervention consisted of 1.5 weekly sessions for eight consecutive weeks. The intervention applied multiple art modalities to provide an opportunity for stroke survivors to express and transform complex feelings after stroke. Outcome measures on hope, anxiety, depression, stress, social support, quality of life, spiritual well-being, and cognitive functioning, were assessed by self-administrated questionnaires before and after the intervention.

Results: Nonparametric tests were adopted for data analysis. Mann-Whitney U tests revealed no significant differences between the intervention and control groups at the two assessment time-points. Wilcoxon signed-rank tests showed significant increases in the levels of social support from friends ($Z = 2.183$, $p = .029$), cognitive functioning ($Z = 2.504$, $p = .012$), and a marginally significant increase in the physical component of quality of life ($Z = 1.888$, $p = .059$) in only the intervention group across the two time-points.

Conclusions: These preliminary results demonstrated that the Expressive Arts-based Intervention may enhance the levels of social support, quality of life, and cognitive functioning of young and pre-elderly stroke survivors. A larger sample size is needed to validate the above effects. Apart from the limited sample size, future studies should attempt to take into account other contextual factors such as the timing of providing these psychosocial supports and the differences between stroke survivors with different affected body sides and levels of impairments.

Acknowledgment: This work was supported by the General Research Fund, Hong Kong Research Grants Council (GRF/HKU/17609417).

PSYCHOLOGICAL CORRELATES OF CARDIOVASCULAR DISEASE: IMPROVING PREDICTIVE CAPABILITIES OF A STROKE RISK CALCULATOR

Caley Kropp, MS, MA¹, Nichelle Huber, MA², David Sager, M.A.², Connor Tripp, MS², Ashley Burch, PhD², Murrium Sadaf, MD³, Samuel F. Sears, PhD²

¹East Carolina University, San Antonio, TX; ²East Carolina University, Greenville, NC; ³Yale University, New Haven, CT

Introduction: Psychological distress is commonly comorbid with cardiovascular disease (CVD) but is often overlooked as a formal predictor or modifier of increased disease burden. Symptoms of depression, anxiety, and stress are routinely associated with increased arrhythmic burden, which can increase ischemic stroke risk. Overall, behavioral medicine providers recognize the importance of screening for psychological stress as a way to reduce disease burden and progression; however, this same recognition is not always present in medical providers. Therefore, the addition of psychological variables to a well-established cardiovascular stroke risk calculator (CHA₂DS₂-VAsC) could help to increase medical provider initiated screening and management of psychological distress in cardiology patients.

Methods: Participants (N = 157) were approached at pharmacies in Eastern North Carolina. Participants completed demographic and medical history questionnaires, the DASS-21, and were administered a single-lead mobile-ECG (mECG). All mECG readings were categorized as 'Normal' or 'Abnormal' by the mECG device, and medical referrals were provided when indicated. Binary logistic regression modeling was utilized to investigate the capability of the CHA₂DS₂-VAsC stroke risk calculator to predict abnormal mECG readings both with and without the addition of DASS-21 symptom scores.

Results: The CHA₂DS₂-VAsC stroke risk calculator was strengthened significantly by the addition of the DASS-21 symptom scores as evidenced by an increase in the chi-squared statistic, $\chi^2(10, N = 157) = 37.705$, $p < .001$ and reduction in -2 Log likelihood (157.29 to 138.317). In this model inclusive of all three psychological endpoints, the variables of hypertension ($p < .05$, $OR = 3.428$), sex ($p < .01$, $OR = 4.149$), and anxiety ($p < .001$, $OR = 1.235$) were the most significant predictors of abnormal mECG readings.

Discussion: The CHA₂DS₂-VAsC calculator is the current gold standard of ischemic stroke risk prediction. Despite burgeoning evidence of a complex relationship between the heart and mind, psychological distress remains overlooked as an independent risk factor for CVD by medical providers. This findings suggest that the CHA₂DS₂-VAsC calculator may be improved by the addition of a psychological symptom composite score.

RESPONSIVENESS OF NAUSEA TO INTERNET-BASED COGNITIVE BEHAVIORAL THERAPY IN YOUTH WITH FUNCTIONAL ABDOMINAL PAIN

Amanda L. Stone, PhD¹, Gloria Han, MA², Alexandra C. Russell, MD¹, Stephen Bruehl, PhD¹, Judy Garber, PhD³, Craig A. Smith, PhD³, Tonya M. Palermo, PhD⁴, Lynn S. Walker, PhD¹

¹Vanderbilt University Medical Center, Nashville, TN; ²Vanderbilt University, Providence, RI; ³Vanderbilt University, Nashville, TN; ⁴University of Washington School of Medicine; Seattle Children's Research Institute, Seattle, WA

Objective: Nausea and abdominal pain frequently co-occur in youth with functional abdominal pain (FAP). Nausea and abdominal pain are similar in that both symptoms result from dysfunction in the brain-gut axis and are subjective in nature. Some evidence suggests that cognitive behavioral therapy (CBT) is effective for reducing abdominal pain, but no studies have evaluated the efficacy of CBT for decreasing functional nausea in youth. The present study evaluated the extent to which an Internet-based CBT intervention for pain decreased nausea in youth with FAP.

Methods: Youth with FAP (ages 11 - 17, n = 270) were randomized to either an 8-week, CBT online program (Web-based Management of Adolescent Pain; WebMAP) or a control condition consisting of an 8-week, online Pain Education (EDU) program (NCT #02327377). Randomization was stratified by previously derived FAP subgroups based on patterns of pain, negative affect, impairment, and coping (High Pain Dysfunctional [HPD], High Pain Adaptive [HPA], Low Pain Adaptive [LPA]). Pre-, mid-, post-treatment, and 6- and 12-month follow-up assessments were administered online. The Nausea Severity Scale assessed nausea frequency, duration, and intensity. Data were analyzed with linear mixed effects models specifying random slopes and intercepts (Treatment Condition X Subgroup X Time). Youth age, sex, and treatment dose were included as covariates. Time was modeled using a piecewise approach, with a linear segment for the treatment period (pre- to post-treatment) and follow-up period (post- through 12-month follow-up).

Results: Nausea severity significantly decreased during the treatment period across both treatment conditions, $t(831) = -2.58, p = .01$. Across FAP subgroups, the main effect for treatment was not significant. A significant Treatment X Time X Subgroup interaction emerged for the treatment period. Specifically, CBT resulted in a greater decline in nausea severity for the HPD subgroup compared to the LPA subgroup, $t(831) = -2.61, p = .009$. Follow-up analyses indicated within the HPD subgroup, there was a significant treatment effect from pre- to post-treatment, $t(332) = -2.34, p = .02$, with CBT producing greater declines in nausea compared to EDU.

Discussion: For youth with FAP who present with significant psychosocial distress and high levels of co-occurring somatic symptoms (i.e., HPD subgroup), CBT interventions designed originally for youth with chronic pain also may reduce co-occurring nausea.

THE ASSOCIATION BETWEEN SEXUAL DATING VIOLENCE AND CYBERBULLYING: FINDINGS FROM THE 2017 YRBSS

Abigail Post, MPH¹, Larissa Brunner Huber, PhD¹

¹University of North Carolina at Charlotte, Charlotte, NC

Background: As technology use among U.S. students increases, cyberbullying is a growing concern in adolescent health research. Cyberbullying, known as bullying which takes place on electronic devices or internet platforms, is associated with many adverse health outcomes, such as suicide, poor mental health, and school absence. Youth who experience bullying in intimate partner relationships may also be disproportionately at risk for cyberbullying. The purpose of this study was to examine the relationship between adolescent sexual dating violence and cyberbullying among 9th to 12th grade youth.

Methods: Data were retrieved from the nationally representative 2017 Youth Risk Behavior Surveillance System (YRBSS) survey. The final analytic sample included 13,869 males and females between the ages of 14 and 18. Youth reported sexual dating violence and cyberbullying in a self-administered questionnaire. Multivariate logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals (CIs) of the relationship between the frequency of sexual dating violence and cyberbullying.

Results: Approximately 4% of youth reported sexual dating violence and 14% reported cyberbullying. In the unadjusted analysis, youth who reported sexual dating violence had statistically significant increased odds of cyberbullying (range of ORs: 4.15 to 6.34). After adjustment, youth who reported sexual dating violence 1 time had twice the odds of cyberbullying (OR=2.07, 95% CI: 1.39-3.07), as compared to those who reported 0 instances of sexual dating violence. Youth who reported sexual dating violence 2-3 times had 2.23 times the odds of cyberbullying (95% CI: 1.22-4.06) while youth who reported sexual dating violence 4 or more times had 1.49 times the odds of cyberbullying (95% CI: 0.69-3.22), as compared to youth who reported 0 instances of sexual dating violence.

Conclusion: These findings suggest a positive association between the frequency of sexual dating violence and cyberbullying and add to the current literature in adolescent health. Researchers should consider additional strategies to address intimate partner violence and cyberbullying in this vulnerable population.

RELATIONSHIPS AMONG PARENTING STRESS, PARENT-CHILD RELATIONSHIP, AND CHILD EATING BEHAVIORS IN YOUNG CHILDREN

Myoungcock Jang, PhD¹¹Chungnam National University, Daejeon, Taejon-jikhalsi, Korea

Emerging evidence suggests that the psychosocial stress of parents plays a significant role in childhood obesity. However, the nature of the relationship between parental stress, children's health behaviors, and children's BMI is still not well understood, possibly because there is a limited understanding of the mediating factors. Parenting-related stress may influence the quality of the parent-child relationship, which could be a factor influencing child eating behaviors. The parent-child relationship is a dynamic interaction between a parent and their child. High quality interactions are characterized by the parent's sensitive and appropriate responses to the child, and mutuality and synchrony within the parent-child dyad.

The purpose of the study is to examine the relationships among parenting-related stress, parent-child relationship, and child eating behaviors in young children.

Using a cross-sectional study design, mothers completed well-validated questionnaires to assess parenting-related stress, parent-child relationship, and child eating behaviors, and child BMI. Due to multicollinearity, subset of parent-child relationship (parental support[P_SUP] and satisfaction of parenting(P_SAT) and child eating behaviors (Emotional overeating [EOE], satiety responsiveness [SR]) were chosen for data analysis. Structural equation modeling was used to examine the path model.

The sample included mothers of 172 children (children sample: mean age 4.92 (SD 0.89) years; 50% girls; 71.2% white; 44% overweight or obese). Parenting-related stress was negatively associated with P_SUP ($\beta = -0.04$, $p < .01$), and P_SAT ($\beta = -0.08$, $p < 0.01$). PC_SUP and PC_SAT were negatively associated with EOE ($\beta = -0.05$, $p = 0.03$; $\beta = -0.05$, $p < 0.01$, respectively). However, neither PC_SUP nor PC_SAT was associated with SR ($\beta = -0.03$, $p = 0.07$; $\beta = -0.002$, $p = 0.90$, respectively). Furthermore, only EOE was associated with child BMI ($\beta = 0.11$, $p = 0.01$). The mediating effect of parent-child relationship (PC_SUP & PC_SAT) for the relationship between parenting-related stress and EOM was supported ($\beta = 0.01$, $p < 0.01$).

Parenting-related stress and parent-child relationship significantly influence children's emotional overeating. Furthermore, parent-child relationship is an important target point for improving children's emotional over eating behaviors among families of parents with high parenting-related stress.

NOT BREATHING EASY: CAREGIVER EXPERIENCES OF ASTHMA MANAGEMENT IN SOCIO-ECONOMICALLY DISADVANTAGED CIRCUMSTANCES

Julie S. Spray, PhD.¹, Julia Maki, PhD², Jean Hunleth, PhD, MPH³, James A. Shepperd, PhD.⁴, Erika A. Waters, PhD, MPH⁵

¹Washington University in St. Louis, Saint Louis, MO; ²Washington University in St. Louis, St. Louis, MO; ³Washington University School of Medicine, Saint Louis, MO; ⁴University of Florida, Gainesville, FL; ⁵Washington University in St. Louis, St. Louis, MO

Background: Asthma disproportionately affects socio-economically disadvantaged and African-American children, who see higher rates of asthma prevalence, emergency department visits, hospitalizations, and mortality. Despite growing recognition of the social determinants of these disparities, the clinical literature generally frames childhood asthma exacerbation as the outcome of caregiver non-adherence to doctor-prescribed pharmaceutical regimes. Such framing attributes blame to caregivers and oversimplifies the complex realities of asthma management in adverse circumstances. Obtaining caregiver perspectives on asthma management may expand conceptions of asthma management and indicate alternative venues for intervention.

Objective: To understand the lived experiences and management practices of asthma caregivers in socio-economically disadvantaged circumstances.

Method: We interviewed 42 caregivers of a child aged 0-18 with an asthma diagnosis. Caregivers were recruited from two locations (Gainesville, Florida, and St. Louis, Missouri) and stratified by economic status. 28 caregivers identified as African-American and 32 caregivers met our criteria for low SES based on a measure of ability to pay an unexpected hospital bill. Data were analyzed by 2 independent coders using standard thematic analysis and validation techniques.

Results: Our interviews located asthma management within complex lives where caregivers were challenged by financial insecurity, environments they could not change, and competing health conditions or disruptive life events. Caregivers described proactively engaging in a range of intensive asthma care work, including diagnostics, vigilance and monitoring, emotion management, and environmental and behavioral control. For example, caregivers described: setting alarms to check children's breathing throughout the night; intensive cleaning; monitoring and diagnosing children's symptoms, and attempting to regulate air quality, control others' smoking habits, and manage children's physical activity and emotions. Caregivers' routine use of "rescue" bronchodilators to prevent symptoms may indicate the need for more clinical support, rather than 'non-adherence'. Caregivers sometimes recognized that they were perceived as non-adherent by their own providers, and this framing could diminish trust between caregiver and provider.

Conclusion: Asthma caregivers in socio-economically disadvantaged circumstances manage substantive and under-recognized burdens of care work. A deeper understanding of caregivers' experiences may inform intervention development to support this care work and improve asthma outcomes.

DO PARENTS' PERCEPTIONS AND PROMOTION OF ACTIVE PLAY DIFFER BY INFANTS WEIGHT STATUS?

John P. Rech, MA¹, Kailey Snyder, PhD², Danae Dinkel, PhD³¹University of Nebraska at Omaha, Omaha, NE; ²Creighton University, Omaha, NE; ³University of Nebraska at Omaha, Omaha, NE

Background: Worldwide, more than 40 million children under the age of 5 are overweight or obese. To combat childhood obesity, there is growing evidence supporting the need to begin encouraging opportunities for active play (AP) during infancy (0-12 months). These opportunities for AP may be impacted by parents and the home environment. However, little research has explored if an infant's weight status is related to parents' perceptions of their promotion of AP and factors of the home environment.

Purpose: The purpose of this study was to explore and compare parents' perceptions and promotion of AP with normal weight (NW) and overweight (OW) infants.

Methods: Parents of OW (>95th weight-for-length percentile; n=11) and NW (n=18) infants were recruited for this study. Parents completed a semi-structured interview guided by the Theory of Planned Behavior to explore parents perceptions of AP and the Affordances in Home Environment Motor Development-Infant Scale (AHMED-IS) to assess the home living environment.

Results: When discussing AP, parents of OW infants most often viewed AP as an interaction between the parent and child (63.7%) while a higher proportion of parents of NW infants viewed AP as general movement (44.4%). Although most parents (62.1%) viewed AP's influence as largely for cognitive benefit, parents of NW infants were more likely to report physical development benefits (50% vs 27.3%). Further, OW infant parents more frequently reported using cognitive play strategies (e.g., sing songs) while engaging in AP (63.6% vs. 38.9%) rather than physical strategies (e.g., practice standing). While most parents were unable to specifically state any recommendations for AP, more NW parents reported feeling the American Academy of Pediatric recommendations were achievable (88.9% vs. 63.6%). Findings from the AHMED-IS revealed OW infants were more frequently carried in adults arms, attached to caregiver's body, or in a carrying device (p=0.038). NW infants showed to have more access to materials that stimulated locomotor movements such as walk mats and climbing equipment (p=0.003).

Conclusion: The findings from this study suggest that parents perceptions of and promotion of AP may differ based on the weight status of the infant such that NW infants may have more opportunities to stimulate locomotor movement through promotion of AP by parents and the materials they provide in the home; however, more research using objective assessments are needed.

MINDFULNESS-BASED SOCIAL-EMOTIONAL LEARNING CURRICULUM ON PRESCHOOL STUDENTS: A RANDOMIZED-CONTROLLED TRIAL

Ying Tong, PhD with Specialization in Educational Psychology¹, Adrian H.Y. Wan, PhD, M.S.W., M.A. (Trauma Psychology), PCPsych, MA (Asian Studies)², Joshua C.Y. Yau, BA², Rainbow T.H. Ho, PhD, REAT, BC-DMT, AThR, RSMT/E, CGP, CMA²¹TWGHs Ho Yuk Ching Educational Psychology Service Centre, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong

Background: Development of social and emotional competence in the preschool years contributes to academic success and healthy functioning in later years. Education in the East focuses on academic success while undermining the holistic development of children. Mindfulness-based training showed beneficial results in fostering attention, emotional regulation and in improving interpersonal skills of preschool children. This pilot study explores the potential benefits of a Mindfulness-based Social-Emotional Learning Curriculum on preschool children's social and emotional functioning.

Methods: This study adopted a randomized-controlled study design. Children attending second year of preschool in Hong Kong were randomly assigned into the intervention group (N = 75) and no-treatment control group (N = 80). 12 weekly sessions of Mindfulness-based Social-Emotional Learning Curriculum that aims to promote their self-regulatory and prosocial skills, as well as cultivate their qualities of kindness were delivered to students in the intervention group. Repeated-measure ANOVAs, controlling for baseline scores as well as child's gender, were conducted to assess for the potential effectiveness of the curriculum; while exploratory ANOVAs were also conducted to test for individual differences (grouped by percentile) in baseline social competence in response to curriculum.

Results: Significant group by time interaction with small to medium effects were found in the domains of children's social competence and prosocial behaviors as rated by their teachers. Post-hoc analyses revealed that children attended the curriculum showed significant improvements in prosocial/communication skills ($M_{Pre} = 2.77$; $M_{Post} = 2.98$), emotional regulation skills ($M_{Pre} = 2.56$; $M_{Post} = 2.76$), academic skills ($M_{Pre} = 2.62$; $M_{Post} = 2.86$), and prosocial behaviors ($M_{Pre} = 6.59$; $M_{Post} = 7.28$). Children with middle or high levels of baseline emotional regulation and academic skills in the intervention group showed more improvements in social competence compared to the control group.

Conclusion: The Mindfulness-based Social-Emotional Learning Curriculum was found viable in enhancing the social and emotional functioning of preschool children. Further research with multiple time-point measures and larger sample size are needed to investigate whether those with lower baseline functioning can experience similar improvements and explore the long-term implications of the curriculum.

THEORY-BASED, RANDOMIZED CONTROLLED TRIALS TO IMPROVE HUMAN PAPILLOMA VIRUS VACCINE UPTAKE IN THE UNITED STATES

Rowida Mohamed, n/a¹, Mona Nili, n/a¹, Kimberly M. Kelly, n/a¹¹West Virginia University, Morgantown, WV

Background: Human Papilloma Virus (HPV) vaccination presents a significant opportunity to decrease the incidence of genital warts, and HPV-attributable cancers, such as cervical and penile cancer. Despite the availability of the HPV vaccine in the US since 2006, uptake remains suboptimal. Recently, some interventions targeting parents have shown the potential to improve increase HPV vaccine uptake. These interventions may be more effective if they are grounded in an appropriate theory.

Purpose: This study aims to systematically review theory-based randomized controlled trials (RCTs) targeting parents to increase of HPV vaccine uptake and to assess the extent of theory application in development and evaluation of these interventions.

Methods: Intervention studies published from January 2006 to May 2019 were identified through a structured search in PubMed, EMBASE, SCOPUS, CINAHL, Medline, and PsycInfo. Studies were included if they explicitly utilized a behavioral theoretical model or framework, examined actual vaccine uptake rate based on objective data from patients' medical records, applied a randomized controlled research design, published as a full article in English, and sampled the US population. Selected studies were assessed for risk of bias using the Cochrane risk-of-bias tool for RCTs and theory-use using the Theory Coding Scheme developed by Michie and Prestwich in 2010.

Results: 4 studies were included for extraction and analysis. A tailored interactive educational video-based intervention had a significant result. The effect of reminders and educational brochures were mixed, which makes it challenging to draw a definitive conclusion. Brief Negotiated Interviewing did not have any significant effect. Interventions that utilize the Theory of Planned Behavior and Health Belief Model showed positive results. Although all the trials explicitly reported that the interventions used were based on a theory, none of them reported carrying out a mediational analysis of the theory constructs or discussed the results in relation to theory. None of the studies were assessed to be free of bias.

Conclusions: Although a very limited number of robust-designed theory-based interventions target parents for improving HPV vaccination uptake, using reminders and tailored interactive videos potentially can be beneficial. More well-designed RCT interventions based on thoroughly applied health behavioral models/theories are needed to target parents for increasing the rate of HPV vaccination.

SUGAR CONSUMPTION AND HEALTHY FOOD PARENTING: A DYAD STUDY

Madison Schloemer, n/a¹, Emma Studer, n/a², Emma L. Monnin, n/a³, Ashley Oakley, n/a³, Emilee Bradley, n/a¹, Julia M. Snell, n/a³, Liana Burk, n/a³, Allison Kiefner-Burmeister, Doctor of Philosophy in Psychology¹¹The University of Findlay, Findlay, OH; ²The University of Findlay, Bloomville, OH; ³University of Findlay, Findlay, OH

Childhood obesity has grown to epidemic levels and is a concern that is spreading across the world (Karnik & Kanekar, 2012). The CDC reports that 18.4% of adolescents between the ages of 2-19 are currently obese in the United States (CDC, 2019). Prior research shows that these numbers will only continue to climb, a major contributor to the rise of poor health in children that ultimately carries over into adulthood (Reilly, 2005). There are many factors contributing to this epidemic, with one of the largest players being parental feeding practices (Wardle & Carnell, 2007). In the current study, parental feeding practices and food consumption were examined along with child food consumption. It was hypothesized that food parenting behaviors would relate to child consumption of unhealthy foods.

Participants in this study were 72 seventh graders and their parents (Mage = 12.66, SD = 0.7). Participants were 68% white and 57% male with a mean BMI of 20.04. A food frequency questionnaire (FFQ) and the Comprehensive Feeding Practices Questionnaire (CFPQ; Musher-Eizenman & Holub, 2007) were completed by parents. Pearson correlations showed a relationship between parental consumption of both added sugar foods and beverages, and child consumption of added sugar foods and beverages ($r = .28, p = 0.042$; $r = .39, p = 0.004$). Additionally, parental consumption of added sugar food and beverage was positively correlated with parental perception of their child's intake of sugary food and sugary drinks ($r = 0.52, p = 0.000$; $r = 0.69, p = 0.000$). Along with parents' awareness that their child is mimicking their sugar intake, the CFPQ variable, modeling, was negatively correlated with parental added sugar food intake ($r = -0.35, p = 0.008$). Modeling of appropriate eating behavior is a key to teaching children to be healthy food consumers. The CFPQ variable for teaching about nutrition is also negatively correlated with both parental added sugar food intake and parental perception of their child's sugary food intake ($r = -0.29, p = 0.032$; $r = -0.47, p = 0.000$).

Taken together, this data demonstrates that parents who model healthy eating behavior and teach their children about nutrition both eat less sugar themselves and feed their children less sugar. Further research should be performed on parental education on sugar intake. Parents are the gatekeepers of food and appropriate nutrition and more programming should be targeted toward the full family unit.

RESILIENCE AMONG BLACK ADOLESCENTS WITH LARGE BODIES: THE ROLE OF SLEEP, QUALITY OF LIFE, AND CAREGIVER FACTORS

Idia B. Thurston, PhD¹, Kathryn H. Howell, PhD², Caroline C. Kaufman, M.S.³, Whitney Howie, MPH¹, Caitlyn Maye, BS⁴¹Texas A&M University, College Station, TX; ²University of Memphis, Memphis, TN; ³The University of Memphis, Memphis, TN; ⁴Texas A&M University, COLLEGE STATION, TX

Introduction: Black adolescents have a 34% higher likelihood of having higher body mass index (BMI) relative to White peers, illustrating a major health disparity. Previous literature primarily focuses on risk factors related to higher BMI with limited research on resilience. Existing research shows a relationship between resilience and general quality of life, however, less is clear about the potential contribution of sleep, weight-related quality of life, and caregiver risk and protective factors to adolescent resilience. We examined associations between adolescent resilience and youth sleep problems, youth weight-related quality of life, caregiver resilience, and caregiver psychopathology in a sample of Black adolescents with large bodies (i.e., BMI >95th percentile).

Methods: Black adolescents (n=32, age 11–17 years; 69% female; MBMIz=2.59, SD=0.42) and their primary caregiver were recruited from a pediatric healthy lifestyle clinic in the U.S. south. Trained research assistants interviewed youth on the Adolescent Sleep-Wake Scale-short version (ASWS-S), Impact of Weight on Quality of Life Scale (IWQOL), and Child and Youth Resilience Measure (CYRM). Caregivers provided demographic information and completed the Conner-Davidson Resilience Scale (CDRISC) and Brief Symptom Inventory (BSI). Correlations were examined and a hierarchical linear regression model was run, examining associations between youth resilience and youth sleep problems and quality of life (step 1), and caregiver resilience and caregiver psychopathology (step 2).

Results: Adolescent report of hours slept on school nights (M=7.92, range 5.5–11.0) was significantly positively correlated with youth resilience ($r = .60$). The overall regression model was also significant [$F(4, 27) = 6.15, p < .01, \text{Adj. } R^2 = 40\%$] with fewer sleep problems ($\beta = -.41, p < .05$) and higher caregiver resilience ($\beta = .46, p < .01$) being associated with greater youth resilience. Conclusions. Findings that fewer sleep problems and greater caregiver resilience are associated with higher youth resilience among adolescents with large bodies highlight novel directions for future research and interventions aimed at promoting resilience. Further, relations between hours slept and resilience in adolescents allude to the need for assessing sleep in medical and mental health settings, as well as policy recommendations on delaying school start times and other structural changes to enhance quantity and quality of sleep for adolescents.

YOGA FOR CHRONIC LOW BACK AND NECK PAIN IN MILITARY PERSONNEL: A PILOT RCT

Erik Groessl, PhD¹, Adhana McCarthy, PA²¹UC San Diego, La Jolla, CA; ²UCSD, La Jolla, CA

Chronic low back pain (cLBP) and chronic neck pain (cNP) are prevalent conditions that are leading causes of disability among active-duty military personnel. Yoga is an evidence-based non-pharmacological intervention with documented benefits in community samples. However, yoga has not been well-studied among military personnel. We conducted a pilot RCT examining the feasibility/acceptability of two types of yoga for military personnel with CLBP/cNP.

Military personnel with cLBP and/or cNP were recruited at a large military medical facility. Participants were randomized to either active yoga or restorative yoga. Participants were assessed at baseline, 12 weeks, and 6 months; were asked to attend 1–2 classes weekly for 12 weeks; and to conduct daily yoga home practice. The primary feasibility outcomes were recruitment rates, intervention attendance, retention for assessments including health outcomes, and satisfaction/acceptability.

In 7 months, 49 participants were enrolled. Approval to locate a research staff member at the military pain clinic was key to recruitment. Of the 49 randomized, 39 (80%) attended 1 or more yoga classes. An additional 7 people participants informed study staff they could not attend further yoga sessions because of deployment, injury, or other health problems. Among those who attended and did not drop out (65%), the average number of weeks attended at least 1x was 8.9 (74%). Of all participants randomized, 57% attended yoga in for 50% or more of the weeks offered. 42 (86%) participants were assessed at 12 weeks and 39 (80%) were assessed at 6 months. Satisfaction ratings were high, with 80–90% strongly agreeing on “enjoyed participation”, “liked instructors”, “continuing yoga”. Health outcomes improved over time.

In conclusion, data suggest that researchers can feasibly conduct a larger RCT comparing styles of yoga for cLBP/cNP with active-duty military personnel to confirm health benefits and understand what type of yoga is preferred.

10:30 AM-11:30 AM

STILL VISITING THE DOCTOR: THE IMPACT OF CIM AND LIFE OUTLOOK ON NUMBER OF HEALTHCARE VISITS IN A NATIONAL MIGRAINE POPULATION

Dustin Goerlitz, BA¹, Amrita Bhowmick, MBA, MPH², Amy Wachholtz, PhD, MDiv, MS¹¹University of Colorado Denver, Denver, CO; ²Health Union, LLC, Chapel Hill, NC

Introduction: Over the last decade, the use of complementary and integrative medicine (CIM) for pain management has increased dramatically. As CIM interventions often cost less than conventional medicine (e.g., physician visits and medications), it is worth examining whether those using CIM for pain management report fewer physician visits. As a common goal with CIM modalities (e.g., psychotherapy and meditation) is to increase satisfaction with life and symptom self-management, it is possible that those who have used CIM may have an increased self-efficacy to live life despite their pain (i.e., have a more positive life outlook) and thus feel less of a need for more frequent healthcare visits. In the present study we hypothesized number of healthcare visits (NHV) to be significantly different between those using and not using CIM for migraine management, as well as those with positive vs negative life outlooks.

Method: Data was collected from 4506 respondents to the 2015 MigraineinAmerica.com survey ($M_{age} = 45.72$ years, 95.4 % female, and 91.1 % Caucasian). CIM use was categorized into three groups: Never Used, Previously Used, and Currently Use. Life outlook was categorized into Positive and Negative Life Outlooks. Group differences were assessed with a two-factor ANOVA, using SPSS version 26.

Results: A 2x3 ANOVA showed significant main effects for CIM Use ($F_{(2,4116)} = 59.27, p < .001, h_p^2 = .03$), and Life Outlook ($F_{(1,4116)} = 11.96, p < .001, h_p^2 = .003$). No significant interaction was found between CIM Use and Life Outlook ($F_{(2,4116)} = .794, p = .471, h_p^2 = .000$). Bonferroni adjusted pairwise comparisons showed those who currently use CIM to have reported a greater NHV than those who previously used CIM ($p < .001$) and those who never used CIM ($p < .001$). Those categorized as having a positive life outlook additionally reported fewer NHV than those with a negative life outlook ($p < .001$), although it is worth noting the omnibus effect size for life outlook was extremely small.

Discussion: The findings from the current study shed important light on healthcare behaviors of those managing migraine symptoms with and without the use of CIM. A potential explanation for our findings is that those using CIM for migraine symptom management may often have severe symptomology, resulting in the use of multiple modalities (e.g., both CIM and conventional medicine), whereas those with less severe symptoms may feel a singular modality to be sufficiently efficacious.

RELAXATION EFFECTS OF A COMPLEMENTARY HEALTH APPROACH (UZIT) FOR SYMPTOM MANAGEMENT IN PERSONS WITH PULMONARY HYPERTENSION

Tania T. Von Visger, PhD, APRN, CCNS, CNS, PCCN¹, Susan E. Thrane, PhD, RN, CHPN², Maryanna Klatt, PhD³, Yu-Ping Chang, PhD, RN, FGSA, FIAAN, FAAN⁴, MaryBeth Happ, PhD, RN, FGSA, FAAN²¹State University of New York at Buffalo, Primary Care Research Institute, Amherst, NY; ²The Ohio State University College of Nursing, Columbus, OH; ³The Ohio State University Wexner Medical Center, Columbus, OH; ⁴University at Buffalo School of Nursing, The State University of New York, Buffalo, NY

Mindfulness-based intervention use in chronic conditions often focuses on stress reduction and symptom alleviation, aiming to achieve relaxation response. Pulmonary hypertension (PH) is a debilitating and progressive cardiopulmonary condition with high symptom burden of pain, anxiety, fatigue, and dyspnea. Despite advances in the medical management of PH, few clinicians encourage complementary health approach (CHA) use. A mixed-method pilot clinical trial documented the preliminary efficacy of a multicomponent Urban Zen Integrative Therapy (UZIT) showing symptom burden reduction and health-related quality of life improvement.

Qualitative descriptive data analysis of participants' responses to UZIT revealed that Relaxation and In-Between State (vacillates between aware and unaware) were common themes describing the experience of UZIT and important as primary endpoints of mind-body research. Original themes included: practicality, relaxation during and outside UZIT, In-Between state, benefits, uniqueness, and balance. The purpose of the study was to identify elements/phenomenon contributing to and defining the characteristics of patients' experience of relaxation, which can guide future research in tailoring this CHA for patients with severe limitation in energy reserve.

Thirteen adults with PH from the Ohio State University Wexner Medical Center PH clinics received 78 individualized UZIT sessions by trained therapists. One-hour UZIT session included: aromatherapy, gentle-body movement, restorative pose, body-awareness meditation, and Reiki. Thirty-two focused-interview transcripts from UZIT session video recordings were analyzed for thematic content using basic qualitative content analysis and constant comparison techniques.

Eight sub-themes were identified as descriptive of the experience of Relaxation and an In-Between state during UZIT (Table 1). Participants described: 1) all 5 UZIT components in relation to relaxation, 2) temporal effects related to UZIT such as short time required to achieve relaxation.

UZIT facilitated participants' Relaxation and In-Between State experiences. Thorough understanding of contributing factors and defining characteristics of Relaxation and the In-Between State can lead to UZIT best use practices or modification. These findings also elucidate key constructs relevant for future quantitative measurement of relaxation. Successful integration of CHA has the potential to empower patients in self-management without added side effects.

Table 1. Contributing Factors and Defining Characteristics

	Relaxation	In-Between State	Both
Contributing Factors	Mindful Breathing		Meditation
	Essential Oil		Reiki
	Positioning		UZIT effects last?
	Carry-Over Effects		Promptness
Characteristics		Lost in Time	Weightlessness
		Body Disconnected	Sedative
		Out-of-Body	Muscular Release
		Aware/Unaware	
		Flashes of Light	
		Sleep

SLEEP AND PSYCHOSOCIAL OUTCOMES IN PRE-HYPERTENSIVES USING A BREATHING AWARENESS MEDITATION SMARTPHONE APPLICATION

John Sieverdes, PhD¹, Jessica Chandler, PhD², Vanessa Diaz, M.D.², Luke Sox, B.S.², Frank Treiber, PhD²¹College of Charleston, Charleston, SC; ²Medical University of South Carolina, Charleston, SC

Background: Breathing awareness meditation (BAM) has been shown to reduce blood pressure and stress. Although most studies were conducted using group-based sessions, the ubiquity of smartphones provides opportunity to improve reach to those unable to meet face-to-face. Tension Tamer (TT) is a smartphone BAM app that uses timed sessions and heart rate captured by the smartphone's camera using validated reflective photoplethysmography for each BAM session to provide time/date stamped adherence records and foster app engagement. Objective of this study is to report on secondary outcomes of sleep and psychosocial functioning of a 12-month randomized controlled trial using prehypertensive adults defined by the Joint National Committee (JNC7) guidelines.

Methods: 80 adults (mean age: 42.8 yrs; 39 males; 43 White; 37 Black) with verified JNC7 defined pre-HTN on 3 consecutive sessions (mean SBP: 128.3 mmHg; 95% recruitment rate) were randomly assigned to TT or healthy lifestyle attention control group that included the Runkeeper™ app for recording the same volume of prescribed walking or running. Each group received the same twice daily dosage schedule (mth 1:15 min dose, mths 2-3 10 min dose; mths 4-12: 5min dose). Measures were taken at baseline, month 1, 3, 6, and 12.

Results: No significant change scores differences between baseline and follow-up months were observed between the TT vs the healthy lifestyle attention control group for the Pittsburgh Sleep Quality Index's summary or subscale measures, depressive symptoms (Beck Depression Inventory; all p 's > .21), worry (Penn State Worry Questionnaire - Abbreviated; all p 's > .43), anxiety (Spielberger State Anxiety Inventory; all p 's > .51), rumination (Scott-Macintosh Rumination Inventory; all p 's > .23), or stress (Perceived Stress Scale; all p 's > .13).

Conclusion: Findings suggest that although TT has been shown to improve blood pressure in pre-hypertensives, the BAM app may not provide benefits to sleep and psychosocial outcomes. Additional targeted cognitive behavioral interventional components will be needed to fully address these issues in populations of need.

PROVIDER-PATIENT COMMUNICATION ABOUT COMPLEMENTARY AND INTEGRATIVE HEALTH: A SYSTEMATIC SCOPING REVIEW

Carma Bylund, PhD¹, Evelyn Y. Ho, PhD², Christopher J. Koenig, PhD³, Emily B. Peterson, PhD⁴¹University of Florida, Gainesville, FL; ²University of San Francisco, San Francisco, CA; ³San Francisco State University, San Francisco, CA; ⁴National Cancer Institute, Newberry, FL

Background: Complementary and integrative health (CIH) practices are widely used across many populations internationally. How patients communicate with their health care providers about these non-biomedical treatments has important implications for the quality of healthcare.

Objective: We undertook a systematic scoping review to map out the evidence about the role of healthcare provider-patient communication about complementary and integrative health practices and treatments.

Methods: We identified eligible peer-reviewed studies published in English between January 2010 and April 2018 by searching keywords and synonyms about complementary and alternative medicine combined with healthcare providers-patient communication and decision-making, in the following databases: PubMed, PsycINFO, Embase, CINAHL, Cochrane Database of Systematic Reviews, Scopus and Communication Source. Studies were included if they were published in a journal and reported empirical evidence about CIH disclosure. CIH was defined as whole systems (e.g. Chinese medicine), ingestible CIH (e.g. herbs), or mind-body practices. We registered our search protocol on the Prospero database and followed the PRISMA guidelines. All screening and eligibility assessments were done independently by two reviewers. We resolved disagreements through discussion.

Results: We screened 7,882 studies and assessed 593 full-text studies for eligibility. 273 studies were included in the final review. Thematic analysis of the studies resulted in three non-mutually exclusive study subsets: 125 studies about the prevalence of patients' disclosure rates to their biomedical providers about CIH; 146 studies about the quality of the communication between patients and biomedical providers about CIH; and 72 studies about the quality of the communication between patients and their CIH providers about their CIH treatments. Analysis of the first sub-set has shown that about a third of the studies were conducted in North America and about one third in Asia. Studies reported ranges of disclosure rates ranged depending on type of CIH treatment/practice. The disease types of the studies were mixed, but the most frequent was cancer/cancer survivorship.

Discussion: There is an abundance of research on the topic of provider-patient communication about CIH practices and treatments. This scoping review is the first step in a multi-faceted systematic review project to map out and synthesize this literature. Initial findings indicate that disclosure is influenced by CIH treatment/practice, which could inform future intervention work.

THE ROLE OF ANTICIPATED AND ANTICIPATORY AFFECT IN REACTIONS TO GENOMIC SEQUENCING FEEDBACK

Arielle S. Gillman, PhD, MPH¹, Irina Iles, PhD, MPH², William Klein, PhD³, Barbara B. Biesecker, PhD, MS⁴, Leslie Biesecker, MD⁵, Katie Lewis, MS, CGC⁵, Rebecca Ferrer, PhD⁶

¹National Cancer Institute, Rockville, MD; ²National Cancer Institute, Hyattsville, MD; ³National Cancer Institute, NIH, Bethesda, MD; ⁴RTI International, Washington DC, DC; ⁵National Human Genome Research Institute, Bethesda, MD; ⁶National Cancer Institute, Pittsburgh, PA

Background: Research shows that future-oriented emotions, including anticipatory affect (e.g., present worry about a potential future outcome) and anticipated negative affect (e.g., expecting that one will react negatively in the future), differentially predict decision making (Baumgartner et al., 2008). Additionally, research on affective forecasting shows that people are generally poor at predicting their reactions to a negative emotional event (Peters et al., 2014). One example of a health decision-making context that has been shown to be influenced by future-oriented emotions is decisions to receive genomic sequencing feedback (Ferrer et al., 2015). Yet, little is known about the degree to which anticipated and anticipatory emotions are related to the consequences of a decision to receive genomic sequencing feedback—that is, an individual's social, emotional, and behavioral responses to such feedback.

Methods: This research was conducted in the context of an actual clinical genomic sequencing trial, the ClinSeq® study. 461 participants (M age=63.9, SD=5.61, 46% female) who were enrolled in the first cohort of the trial and received genomic sequencing feedback were included in the current study. Participants responded to measures assessing anticipated and anticipatory affect about sequencing results at baseline. Psychological and behavioral responses to sequencing results, including participants' reported anxiety, decisional conflict, and distress about sequencing results, whether they shared results with family members, and their intentions to continue learning results in the future, were collected immediately, 1 month, and/or 6 months after receiving results.

Results: Higher levels of anticipated (AD) and anticipatory (AY) affect at baseline were significantly associated with increased anxiety (AD $p=.02$, AY $p<.001$), decisional conflict (AD $p<.001$, AY $p=.02$), distress (AD $p=.032$, AY $p=.09$), and uncertainty (AD $p=.005$, AY $p=.013$) after receiving results, as well as lower intentions to continue learning results in the future (AD $p<.001$, AY $p<.03$). When comparing the partial effect sizes of anticipated versus anticipatory affect on these outcomes, anticipated affect consistently emerged as the stronger predictor.

Conclusions: These results contribute to a growing body of evidence surrounding the role of future-oriented emotions in genetic testing, behavioral medicine, and health decision-making more broadly. Future work should continue to examine the impact of anticipated and anticipatory emotions in behavioral medicine, including defining how the effects of specific future-oriented emotions (e.g., anticipated regret vs. anticipated upset) differ, and identifying whether interventions targeting change in future-oriented emotions may have clinically meaningful effects in the context of genetic counseling.

VALUES CLARIFICATION CHANGED ATTITUDES TOWARD SHARING INFORMATION FOR PRECISION MEDICINE RESEARCH, BUT NOT RISK PERCEPTIONS

Ryan S. Paquin, PhD¹, Brittany A. Zulkiewicz, BS², Megan Doerr, MS, LGC³, Christine Suver, PhD³, Megan A. Lewis, PhD⁴

¹RTI International, Minneapolis, MN; ²RTI International, Research Triangle Park, NC; ³Sage Bionetworks, Seattle, WA; ⁴RTI International, Seattle, WA

Background: The *All of Us* Research Program (AoURP) is an NIH-funded study that aims to enroll 1 million people living in the United States to better understand health. Given the breadth and sensitivity of data being collected, it is paramount that people who participate in AoURP do so with a full understanding of the privacy risks. We conducted an online randomized experiment to evaluate the effect of a values clarification exercise about sharing information with AoURP on people's risk perceptions and attitudes towards sharing their personal information with researchers.

Methods: Eligible participants were English-speaking U.S. adults who were *not* enrolled in AoURP. We set recruitment targets by education so that 40% of participants had a high school diploma or lower educational attainment. We randomized participants ($N = 1,181$) to two study arms. Participants in the education-only condition ($n = 584$) completed an online decision aid describing the types of information gathered from participants in AoURP and how they are used. Participants in the education with values clarification condition ($n = 597$) completed the same decision aid with an additional exercise in which they indicated which reasons for and against sharing information with AoURP were important or not important to them. We conducted ANCOVAs and logistic regressions with health literacy, the interaction of experimental condition by health literacy, educational attainment, race/ethnicity, gender, and age as covariates.

Results: We observed no differences by experimental condition in the proportion of participants who correctly identified privacy as the main risk of joining AoURP ($p = .263$). There were also no differences by experimental condition in deliberative risk perceptions ($p = .473$), affective risk perceptions ($p = .178$), or experiential risk perceptions ($p = .251$). Participants who completed the values clarity exercise had less positive attitudes toward sharing their personal information with *All of Us* researchers ($M = 4.73$, $SE = 0.06$, Range = 1–7) than did those in the education-only condition ($M = 4.90$, $SE = 0.06$), $F(1, 1159) = 3.91$, $p = .048$.

Conclusions: Research shows that privacy policies are difficult for the average person to understand. The current study showed that a values clarification exercise weakened attitudes toward sharing personal information as part of a precision medicine research study without improving participants' understanding of the associated risks.

HOPEFUL YET HESITANT: HOW AN OPTIMISTIC BIAS FOR SURVIVAL SHAPES AN END-OF-LIFE MEDICAL DECISION

Sugandha Gupta, MA¹, Aliza A. Panjwani, MA², Romario A. Nelson, BA³, Tracey A. Revenson, PhD⁴¹The Graduate Center, City University of New York, New York, NY; ²The Graduate Center, City University of New York, Columbus, OH; ³Hunter College, Brooklyn, NY; ⁴Hunter College, City University of New York, New York, NY**Background:** The tendency to overestimate the likelihood of positive events occurring, known as *optimistic bias*, has been related to misinterpreting prognostic information and making riskier medical decisions. This tendency has been demonstrated with medical decisions for oneself and a close other.**Aim:** In this mixed methods study, we examined whether individuals with an optimistic bias for their own survival and a close other's survival (surrogate decision-making) would make riskier decisions in a hypothetical end-of-life medical scenario.**Methods:** 161 participants (71% female; 43% Asian/Pacific Islander) were presented with a hypothetical end-of-life medical scenario in which a physician presented a 50% chance of survival and described risky surgical outcomes. Participants were asked to (a) estimate survival, and (b) decide whether to opt for resuscitation, despite risk of losing consciousness and suffering brain damage. In open-ended questions, participants explained their decisions. Participants were also asked to imagine their close other in the same medical scenario, and asked again to make a survival estimate and medical decision. Optimistic bias was calculated as estimates of survival >50%. Logistic regression analysis tested the effects of optimistic bias for survival on decisions to resuscitate.**Results:** 60% of the sample showed an optimistic bias both for their own survival and their close other's survival. Among those who were optimistically biased, 56% opted for resuscitation for themselves and 78% for their close other. The logistic regression was statistically significant $\chi^2(3) = 30.63, p = .000$. The model explained 14.3% of the variance in the decision to sign a do not resuscitate order, and correctly classified 63.5% of cases. Greater optimistic bias was associated with the likelihood of choosing resuscitation. Participants who opted for resuscitation were more likely to believe there would be positive surgical outcomes (for themselves and a close other). Preliminary coding of the qualitative data suggests that participants with an optimistic bias for survival made attributions to personal factors for their decision. Two explanatory styles emerged: *Defensive Pessimists*, who expressed the need or desire to prepare for the worst, and *Experiential Avoidants*, who expressed difficulty thinking about the scenario and its repercussions.**Discussion:** The findings suggest that an optimistic bias may not always reflect an adaptive coping response to difficult scenarios.

SELF-DETERMINATION THEORY CONSTRUCT ASSOCIATIONS WITH DIETARY BEHAVIOR IN EMERGING ADULTS AT RISK FOR DIABETES

Cassandra M. Gonzalez, M.A.¹, Stephanie McDonough, Ph.D.², Valery Bodziony, M.S.³, Barbara Stetson, Ph.D.⁴¹University of Louisville, Louisville, KY; ²Department of Clinical and Health Psychology University of Florida Health, Gainesville, FL; ³University of Louisville, Louisville, KY; ⁴University of Louisville Psychological and Brain Sciences, Louisville, KY**Background:** Prevalence rates of Type 2 diabetes (T2D) within young adults are on the rise. Obesity, inactivity, and family hx are leading risk factors for developing T2D. Awareness and understanding of T2D risk factors may contribute to leading a healthy lifestyle. Self-determination theory (SDT) posits the importance of motivation [autonomous/intrinsic vs. controlled/extrinsic] and perceived competence (PC), such that individuals need to feel autonomously motivated and competent to sustain behaviors. As diet is modifiable and may decrease risk, SDT can inform interventions aimed at improving dietary behavior in emerging adults.**Aim:** This study examined associations between SDT-informed healthy diet motivation (autonomous: AMot, controlled: CMot), diet PC, and dietary behavior in emerging adults at-risk for T2D.**Method:** Ss were 66 sedentary emerging adults with a family hx of T2D ($M_{age} = 20.30$; 80.3% female; 59.1% overweight/obese). Dietary behavior was assessed using the Summary of Diabetes Self-Care Activities (SDSCA-Diet) and Starting the Conversation-Diet (STC-D) measures. AMot and CMot was assessed with the Treatment Self-Regulation Questionnaire (TSRQ). PC for maintaining a healthy diet was assessed with the Perceived Competence Scale-Diet (PCS).**Results:** Ss reported high levels of fast food intake ($M = 2.17, SD = 0.95$; 51.5% reported >3 times/week) and low daily fruit/vegetable intake ($M = 1.27, SD = 0.87$; 79.7% reported < 3 servings/day). Diet PC ($M = 3.88, SD = 1.32$) was not associated with AMot ($M = 5.69, SD = 0.96$), $p = .95$, or CMot ($M = 3.55, SD = 1.25$), $p = .09$. Higher PC was associated with less fast food consumption ($r = -.308, p < .05$) and higher fruit/vegetable intake ($r = .272, p < .05$). Moreover, higher PC was associated with better dietary behaviors (SDSCA general diet $r = .447, p < .001$). Neither AMot or CMot were significantly associated with diet behaviors. Post-hoc analyses revealed a negative association between T2D risk knowledge and diet PC ($r = -.293, p < .05$).**Conclusion:** Findings suggest suboptimal diet in this emerging adult, at-risk sample. SDT suggests PC is a fundamental need required to promote sustained, intrinsic motivation. The negative associations observed between T2D knowledge and PC for a healthy diet may indicate a lack of awareness of unhealthy dietary behaviors and their influence on their personal T2D risk. T2D prevention efforts may benefit from focusing on at-risk emerging adults and their dietary knowledge and perceived risk for developing T2D.

RELATIONSHIP BETWEEN MENTAL HEALTH AND ADHERENCE AMONG INDIVIDUALS WITH TYPE 2 DIABETES IN OXCUTZCAB, YUCATAN, MEXICO

Jenifer Thomas, PhD¹, Patricia I. Gómez, MSC, DR², Samantha Baker, BSN, RN¹, Lorianne Ellingrod, MS, CMT³, Nicholas R. Erickson, CITI Training certified¹, Kenzie A. Graves, n/a¹, Jenna L. Kindt, n/a⁴, Bailey McCoy, n/a⁵, Bailee Smith, n/a⁶, Emma Snow, n/a¹, Tessa Woods, n/a⁷

¹University of Wyoming, Laramie, WY; ²Autonomous University of Yucatan, Mérida, Yucatan, Mexico; ³University of Wyoming, LARAMIE, WY; ⁴University of Wyoming, Colorado Springs, CO; ⁵University of Wyoming, Casper, WY; ⁶University of Wyoming, Wellington, CO; ⁷University of Wyoming School of Pharmacy, Cheyenne, WY

The relationship between mental health and type 2 diabetes (T2DM) is bidirectional. The risk of depression among individuals with T2DM is approximately 50%, which can decrease adherence to treatment recommendations. Physiologically, treatment adherence refers to blood glucose monitoring and control through lifestyle changes and medication. From a psychosocial point of view, adherence is assessed by self-efficacy and social support. Mental health status provides important information about treatment adherence and may be overlooked in disease management programs. T2DM research in the Yucatan primarily examines therapeutic adherence and does not consider the role of mental health. In Mexico, T2DM is costly and disease rates are expected to increase. Therefore, it is imperative to understand the physiologic and psychosocial factors that contribute to adherence. The purpose of this study was to examine the relationship between depression, anger, anxiety, and therapeutic adherence among individuals with T2DM. The present study used a cross sectional research design. Individuals with T2DM were recruited from the “Prospera Human Development Program” in Oxcutzcab. 111 participants completed the State-Trait Anxiety Inventory, State-Trait Anger Expression Inventory, Beck Depression Inventory, Scale of Adherence to Diabetes Mellitus Type 2 Treatment, and Morisky Green Levine Medication Adherence Scale. Chi-square test of independence analyses found statistically significant relationships between state anger and hygiene and self-care ($\chi^2 [2,111] = 17.68, p = 0.00$), state anxiety and diet ($\chi^2 [2,111] = 8.63, p = 0.01$), and depression and family support ($\chi^2 [4,111] = 10.76, p = 0.03$). Post hoc comparisons revealed significant differences in hygiene and self-care for individuals with low and high state anger but not medium state anger. Significant differences in diet was found for individuals with low and medium state anxiety but not high state anxiety. Family support did not differ for levels of depression. To address the relationship between adherence behaviors and mental health, healthcare providers should incorporate mental health assessment and education into disease management. Appointments and programs can begin with mental health screening and address mental health and T2DM literacy through education and support. Future research should integrate mental health programming into current disease management programs and examine the impact on adherence behaviors.

REMOTE PEER LEARNING FOR US-CAMBODIA LAY HEALTH WORKERS MANAGING DIABETES (PLUS CAMBODIA)

Julie Wagner, Ph.D.¹, Megan Berthold, Ph.D., LCSW², Thomas Buckley, MPH, RPh³, Theanvy Kuoch, MA, LPC⁴, Mary Scully, APRN⁴, Sengly Kong, Ph.D.⁴, Lorraine Fraser-King, n/a⁵, Ien Srey Horn, n/a⁵, Lim Keuky, DEA Endocrinology⁵

¹UConn School of Dental Medicine, Farmington, CT; ²UConn School of Social Work, Hartford, CT; ³UConn School of Pharmacy, Storrs, CT; ⁴Khmer Health Advocates, West Hartford, CT; ⁵Cambodian Diabetes Association, Siem Reap, Siem Reap, Cambodia

Aims: This study used a single-group, pre-post design to pilot a peer-learning intervention between community health workers (CHWs) in the US and Village Health Support Guides (Guides) in Cambodia to improve outcomes for Cambodians with type 2 diabetes (T2D).

Methods: American investigators trained CHWs, face-to-face, in principles of Peer-to-Peer Learning. Next, using tablets, CHWs trained Cambodian Guides, remotely, in a culturally derived cardiometabolic patient education curriculum called Eat, Walk, Sleep (EWS). Guides practiced delivering EWS sessions with Cambodian investigators until ready to work directly with patients. Finally, Guides met with patients, face-to-face, monthly for 6 months to deliver EWS, while still receiving ongoing support from CHWs. Measures: CHWs and Guides responded to surveys with scales 1-4 with higher scores more desirable; 25-item diabetes knowledge quiz, 10-item job satisfaction (“on most days are you enthusiastic about being a CHW/Guide?”), 10-item self-evaluation (“are you confident?”), 12-item attitudes regarding tablets (“will learning the tablet be easy?” [baseline] vs “was learning the tablet easy?” [post]). For patients, at baseline and post, study staff obtained blood pressure, anthropometrics, and blood samples for A1c. Paired t-tests with $\alpha < .05$ were used to compare values at baseline and post (6-months).

Results: The 2 CHWs were women, age M=61.5 years, both divorced with 8-12 years education, 1/2 with T2D. Both had been CHWs for >10 years. Both had used and owned a smart phone. 1/2 used and owned a tablet, desktop and laptop computer, the other had used them but did not own them. Scores on all surveys improved for the CHWs, though no statistical tests were run due to the n=2 sample size: knowledge 78.0% [0.0] vs 98.0 [0.0] Cohen's d=7.1), job satisfaction (32.0 [5.7] vs 39.0 [1.4] d=1.6), self-evaluation (32.0 [2.8] vs 37.0 [0.0] d=1.8), tablet attitudes (33.5 [3.5] vs 48 [0.0] d=4.1). The 5 Guides had age M=41 years, 4/5 women, 4/5 married, years as a Guide M=14.2, 4/5 had < 8 years education, 2/5 relied on bicycle for transportation. All owned and used a cell phone, 3/5 owned a smart phone, none had used or owned a computer or tablet. Except for job satisfaction, scores significantly improved for Guides: knowledge (53.6% [15.6] vs 95.2 [3.3]); self-evaluation (27.8 [1.5] vs 29.8 [0.4]), tablet attitudes (32.6 [2.3] vs 36.0 [4.4]). For patients, n=60 consented and 2 withdrew leaving n=58. They were age M=53.9, all treated with oral agents, 64% women, 78% married, modal education < 6 years. Patients showed significantly decreased systolic (122.7 [14.6] vs 119.5 [15.6]) and diastolic (80.3 [8.3] vs 77.8 [7.8]) blood pressures mmhg, A1c% (9.21 [2.1] vs 7.6 [1.7]), and a non-significant decrease in body mass index (25.9 [3.8] vs 25.7 [4.0]).

Conclusions: Cross-country peer-learning is promising and could eventually help other diaspora communities.

THE INTERACTION OF DIABETES AND BIOPSYCHOSOCIAL FACTORS IN SHAPING AGE TRAJECTORY OF DISABILITY DEVELOPMENT

Ching-Ju Chiu, n/a¹, Yi-Hsuan Tsai, n/a²

¹Institute of Gerontology, College of Medicine National Cheng Kung University, Tainan, Tainan, Taiwan (Republic of China); ²Center for Geriatric and Gerontology, Kaohsiung Veterans General Hospital, Tainan, Tainan, Taiwan (Republic of China)

Background: This study aims to identify: 1) effect of normal aging versus diabetes mellitus on the development of disability from midlife to older age; 2) the extent to which and the duration of different psychobehavioral correlates in buffering diabetes-related disability development.

Methods: Participants aged from 50 to 97 years old were drawn from Taiwan Longitudinal Study in Aging (TLISA). Disability was measured in 1999, 2003, and 2007, while health promotion behaviors and psychological factors were measured in 1996, 1999, and 2003 to be lagged time-varying covariates in random effect model analyses.

Results: Data on 581 diabetes patients and 3934 participants without diabetes were analyzed. For diabetic patients, mobility impairments occurred at the age of 57–58, which was 5 years earlier than those without diabetes; ADL disability occurred at the age of 73–74, which was 10 years earlier than those without diabetes; IADL disability occurred at the age of 61–62, which was 9 years earlier than those without diabetes. Age-related disability in diabetic patients was significant only in the mobility model ($\beta_{DM*age}=0.088$, $p<.001$). The disability progression speed in diabetic patients was 1.5 times faster than that in those without diabetes. Exercise postponed the occurrence of disability in diabetic patients for 9.9–13 years in the ADL model ($\beta_{DM*Exercise1}=-1.134$, $p=.0215$; $\beta_{DM*Exercise3}=-0.872$, $p<.001$). In the mobility and IADL models, exercise had a dose effect. Exercising more than 6 times a week postponed mobility impairments for 5.7 years ($\beta_{DM*Exercise3}=-1.248$, $p=.011$) and IADL disability for 4.4 years ($\beta_{DM*Exercise3}=-0.799$, $p=.034$). In the multiple factor model, exercise for more than 6 times a week decreased two third of the speed of mobility impairments ($\beta_{DM*Exercise3*age}=-0.129$, $p=.013$). Strong social support (score ≥ 10) postponed ADL disability for 19.4 years ($\beta_{DM*socalsupport}=-0.081$, $p<.0001$) and IADL disability for 12 years ($\beta_{DM*socalsupport}=-0.114$, $p=.003$). Depression accelerated ADL disability at least 15 years ($\beta_{DM*CESD}=0.0523$, $p=.0041$) and the speed of disability 4.5 times faster every year ($\beta_{DM*CESD*age}=0.008$, $p<.0001$). When the factors of exercise, social support, and depression coexisted, each of them was significant in the models. When all factors coexisted, stress was significant decreased ADL ($\beta_{DM*stress}=-0.348$, $p=0.026$) and IADL ($\beta_{DM*stress}=-0.465$, $p=0.040$) disability risk.

Conclusion: The current study shows that exercise, adequate stress and social support play important roles in postponing disability in diabetic patients. Depression triggers disability and accelerate disability progression rate in diabetic patients. Diabetic patients are strongly suggested to exercise more than six times a week.

SOCIAL RELATIONSHIPS AND METABOLIC SYNDROME IN CAMBODIANS WITH DEPRESSION AND DIABETES RISK: BASELINE DATA FROM THE DREAM STUDY

Julie Wagner, Ph.D.¹, Megan Berthold, Ph.D., LCSW², Thomas Buckley, MPH, RPh³, Theanvy Kuoch, MA, LPC⁴, Mary Scully, APRN⁴, Sengly Kong, Ph.D.⁴, Angela Bermudez-Millan, Ph.D.⁵, Kagnica Seng, B.A.⁶

¹UConn School of Dental Medicine, Farmington, CT; ²UConn School of Social Work, Hartford, CT; ³UConn School of Pharmacy, Storrs, CT; ⁴Khmer Health Advocates, West Hartford, CT; ⁵UConn School of Medicine, Farmington, CT; ⁶Central Connecticut State University, West Hartford, CT

Aims: Social alienation (SA) is a form of interpersonal and societal estrangement linked to history of victimization. We examined associations between SA, social support (SS) and metabolic syndrome (MetS) among Cambodian genocide survivors.

Methods: Participants recruited in New England were adult Cambodian-Americans alive during the Pol Pot era (1975–1979), with elevated diabetes risk per self-reported risk quiz, and who endorsed either medication for depression or persistent elevated depressive symptoms per Hopkins Symptom Checklist. Measures. Four SA items were feeling ‘detached or withdrawn’, ‘loss of openness’, ‘isolated’, and ‘lonely’. Responses were standardized and summed; factor analysis showed a single factor; Chronbach’s alpha = 0.69. Five SS items assessed instrumental, informational, emotional, companionship, and affection support; responses were summed. Factor analysis showed a single factor; Cronbach’s alpha = 0.76. MetS was defined by International Diabetes Federation Asian cutpoints: waist circumference > 90cm (men) > 80cm (women) or body mass index > 30 plus any 2 of: triglycerides > 150, high density lipoproteins < 40 (men) < 50 (women), systolic blood pressure > 130 or diastolic > 85, and fasting glucose > 100. A MetS continuous score summed number of criteria, 0–7.

Results: Participants (n = 187) were age M = 55.2 (8.8) years, 78% women, 50% married, 87% Buddhist, modal income < \$20,000, education M = 6.9 years, 87% spoke Khmer at home, MetS score M = 2.1 (1.2). MetS score was correlated with SA, $r = 0.17$, $*p < .05$, but not SS, $r = -0.09$, $p = .20$. Univariate ANOVA with SA as the independent variable, MetS score as the dependent variable, covarying age and gender, was significant, $F(3,188) = 2.96$, $*p < .05$. SA was a significant predictor of MetS score, $*p < .05$. Neither age nor gender were predictors, p ’s > .10. An SA*gender interaction term was significant, $*p < .05$ showing a stronger relationship between SA and MetS among men than women. A separate model with SA as the independent variable, MetS score as the dependent variable, covarying age, gender, and SS was marginally significant, $F(4,188) = 2.30$, $p = .06$. SS was not a significant predictor of MetS, $p = .56$. An SA*SS interaction term was not significant, $p = .66$.

Conclusion: Among Cambodian-Americans with depression and diabetes risk, social alienation increased risk for MetS and this relationship was stronger in men. Social support was not related to MetS and did not buffer against the deleterious effects of social alienation.

STARVATION AND LATER RISK FOR PSYCHOLOGICAL DISTRESS AND DIABETES AMONG SURVIVORS OF THE POL POT REGIME

Julie Wagner, Ph.D.¹, Richard Feinn, Ph.D.², Megan Berthold, Ph.D., LCSW³, Thomas Buckley, MPH, RPh⁴, Theanvy Kuoch, MA, LPC⁵, Mary Scully, APRN⁵, Sengly Kong, Ph.D.⁵, Angela Bermudez-Millan, Ph.D.⁶, Kagnica Seng, B.A.⁷

¹UConn School of Dental Medicine, Farmington, CT; ²Quinnipiac School of Medicine, North Haven, CT; ³UConn School of Social Work, Hartford, CT; ⁴UConn School of Pharmacy, Storrs, CT; ⁵Khmer Health Advocates, West Hartford, CT; ⁶UConn School of Medicine, Farmington, CT; ⁷Central Connecticut State University, West Hartford, CT

Aims: Famine exposure may increase risk for type 2 diabetes later in life. We examined whether, among Cambodian-Americans, history of starvation is associated with present day trauma symptoms and A1c level.

Methods: Participants were adult Cambodian-Americans with elevated diabetes risk per self-reported risk test, and who endorsed medication for depression or persistent elevated depressive symptoms per Hopkins Symptom Checklist. They were recruited from New England into a clinical trial and provided baseline biological measures and responded to surveys. Measures: Participants reported level of starvation during four time periods: before 1970 (peacetime), 1970-75 (American bombing campaign, widespread hunger), 1975-79 (Pol Pot regime, mass starvation) and 'now'. Level of starvation was assessed using a 5 point scale with simple pencil drawings of body shapes ranging from overweight (1) to emaciated (5). Trauma symptoms were measured using the Khmer language Harvard Trauma Questionnaire (HTQ) and the Broken Courage and Self-erosion subscales of the Bakstbat questionnaire which assesses a Cambodian culture-bound syndrome similar to but distinct from post-traumatic stress disorder. Anthropometrics were measured by trained study staff with calibrated equipment twice and averaged. A1c was measured using high pressure liquid chromatography.

Results: Participants (n=189) were 78% female, age M=56 (SD=9) years, BMI M=27 (SD=4), A1c M=5.5 (SD=0.4). Modal body shape by time period was normal (43%) before 1970, normal and thin (33% each) 1970-75, emaciated (65%) 1975-79, and normal and slightly overweight (41% and 39%) now. Body shape 'now' significantly correlated with current anthropometrics: waist circumference ($r=-.34$, $p<.01$), body weight ($r=-.50$, $p<.01$), waist-to-hip ratio ($r=-.34$, $p<.01$), and BMI ($r=-.50$, $p<.01$). Body shape 1975-79 significantly correlated with current trauma symptoms: HTQ ($r=.40$, $p<.01$), Broken Courage ($r=.28$, $p=.01$), and Self-erosion ($r=.23$, $p=.02$), whereas body image during other periods did not (all p 's $>.30$). Linear regression models adjusted for age and current waist circumference found that body shape 1970-75 ($\beta=.20$, $p=.008$) and 1975-79 ($\beta=.21$, $p=.005$) predicted A1c, whereas before 1970 and 'now' did not.

Conclusion: The body image scale is a valid measure as indicated by correlations with anthropometrics. History of more severe starvation 4-5 decades ago is predictive of higher present day trauma symptoms and higher A1c.

IDENTIFYING TREATMENT ADHERENCE PROFILES AMONG TYPE 2 DIABETES PATIENTS USING LATENT PROFILE ANALYSIS

Kathryn Bunda, BA¹, L. Alison Phillips, PhD¹, Nicole L. Hayes, MA¹

¹Iowa State University, Ames, IA

Medication and physical activity (PA) are beneficial for Type 2 Diabetes (T2D) management. Lifestyle changes can reduce T2D incidence more than medication alone, but health practitioners tend to prescribe medication over lifestyle changes, given better patient adherence to medication compared to PA (Armstrong et al., 2010; Knowler et al., 2002; Sabate, 2003). Thus, practitioners may view medication as a more important component of treatment than PA; whether some patients make a similar trade-off, and what characterizes such patients, is unknown. Some patients may engage in the multiple treatment behaviors that are prescribed to them, whereas others may prioritize one treatment behavior over others. We hypothesize that categories of patients exist (i.e., adherent to both medication and PA; adherent to medication but not PA; adherent to PA but not medication; adherent to neither medication nor PA). We also hypothesize that adherence profiles will be categorized by how patients conceptualize their illness (i.e., timeline, identity, concerns, consequences, perceived control: see Common-Sense Model of Self-Regulation (CSM-SR); Leventhal, Phillips, & Burns, 2016). Additionally, we will explore whether adherence profile will predict HbA1c, an objective measure of T2D management. In a sample of 76 patients with T2D, medication adherence and PA were assessed objectively for one month, using MEMS bottles and accelerometers, respectively. Latent Profile Analysis was conducted to examine adherence profiles. The best fitting model had of two profiles (AIC= 1636.95; BIC= 1653.27; entropy= .879; LMR= 25.17, $p=.037$). Adherence profiles were categorized by differences in PA: low PA profile averaged 3140.76 steps per day; high PA profile averaged 9357.23 steps per day. Mean medication adherence was similar across both profiles (i.e., low PA profile: adherent 72.79% of days; high PA profile: adherent 89.36% of days). We ran a one-way MANOVA to determine whether adherence profiles differed on CSM-SR variables (i.e., timeline, identity, concerns, consequences, perceived control). The overall model was not significant, $F(5,66) = 0.761$, $p = .581$, $\eta^2 = .055$. There were no significant between-subjects effects of adherence profile on CSM-SR variables. Lastly, HbA1c levels were not significantly predicted by adherence profile, $F(1,71) = 3.30$, $p = .073$, $\eta^2 = .044$. Thus, some patients may be more adherent to certain components of their treatment plans, but what characterizes these adherence decisions remains unclear. It is possible that adherence in our sample was too high to detect differences among CSM-SR variables and HbA1c, warranting further research in a sample with higher variability. Adherence profiles may provide a foundation for future interventions to improve treatment adherence.

ANXIETY AS A MODERATING MEDIATOR IN THE ASSOCIATION BETWEEN EFFORTFUL CONTROL AND ADOLESCENT TYPE 1 DIABETES-RELATED DISTRESS.

Tori Humiston, M.S.¹, Billie J. Goddard, B.A.¹, Laura B. Cohen, B.A.¹, Natalie E. Benjamin, M.S.², Amy Hughes Lansing, Ph.D.¹¹University of Nevada, Reno, Reno, NV; ²Marquette University, Milwaukee, WI

Introduction: Research indicates that nearly one-third of adolescents experience type 1 diabetes-related distress. This distress has been associated with lower rates of glycemic control, self-efficacy, and self-care (Hagger, Hendrick, Sturt, Skinner, & Speight, 2016). In addition to diabetes-related distress, individuals with diabetes are at higher risk of developing anxiety (Buchberger, Huppertz, Krabbe, Lux, Mattivi, & Siafarikas, 2016). Research suggests effortful control, the ability to modulate cognitions, emotions, and behaviors toward a goal, is associated with both improved glycemic control (Berg et al., 2014; Lansing et al., 2016; Perez et al., 2016) and outside of the diabetes context decreased anxiety (van Oort et al., 2011). Yet, there is little research examining the intersection of effortful control, anxiety, and diabetes-related distress. It was hypothesized that increased effortful control would be associated with decreased diabetes-related distress in part through decreased anxiety, and that the conditional indirect effect would be stronger when anxiety was higher than average compared to lower than average.

Methods: Adolescent participants from a type 1 diabetes summer camp (n=79, M age=15.1, 61% Female) completed a multi-measure survey including a subscale of the Early Adolescent Temperament Questionnaire-Revised, measuring effortful control (Ellis & Rothbart, 2011), Problem Areas in Diabetes (Polonsky, et al., 1995), and the Revised Children's Manifest Anxiety Scale, Second Edition (Reynolds & Richmond, 2008).

Results: Regression analyses indicated that greater effortful control was associated with decreased diabetes-related distress ($b=11.30$, $t(72)=2.78$, $p=.01$) and that greater anxiety was associated with increased diabetes-related distress ($b=.98$, $t(74)=6.30$, $p<.001$). The association between effortful control and diabetes-related distress became nonsignificant ($b=-3.29$, $t(72)=-1.10$, $p=.28$) when anxiety ($b=.99$, $t(72)=5.38$, $p<.001$) was simultaneously entered, consistent with anxiety as a mediator of that association. Furthermore, anxiety also moderated the association between effortful control and diabetes-related distress ($b=-.82$, $t(72)=-2.69$, $p=.009$), such that the association between effortful control and diabetes-related distress was only significant at greater than average levels of anxiety.

Conclusions: Individuals with higher than average levels of anxiety and low levels of effortful control may be at elevated risk for increased diabetes-related distress compared to those with higher than average levels of anxiety and greater effortful control and those with lower than average levels of anxiety at all levels of effortful control.

OLDER BLACK MEN'S PERSPECTIVES ON FACTORS THAT INFLUENCE TYPE 2 DIABETES (T2D) SELF-MANAGEMENT AND PEER-LED INTERVENTIONS

Jaclynn M. Hawkins, MSW PhD¹¹University of Michigan, Ypsilanti, MI

Background: Older African American men are at increased risk of Type 2 Diabetes (T2D) but demonstrate high rates of poor illness management. They also participate in interventions targeting illness management at extremely low rates and are at high risk for dropout from clinical trials. One modifiable factor that has been identified in the literature that contributes to these disparities is health beliefs particular to men. Yet, despite the fact that illness management interventions have been developed to meet the needs of African Americans, none have followed recommendations to use gender-sensitive programming to meet the needs of men. The primary aim of this study was to advance our understanding of the intersection of age, race/ethnicity and gender on T2D self-management among older African American men with T2D and to explore their preferences for a peer-led T2D self-management intervention.

Methods: and analysis: Two focus groups were conducted with older African American men (n = 16) over a 6-month period. Sessions lasted 90 minutes, were audiotaped, and analyzed using thematic content analysis techniques using a phenomenological approach.

Findings: Three themes emerged which included (a) the influence of gender values and beliefs on health behavior; (b) quantity and quality of patient-provider communication; (c) social and structural barriers to T2D self-management; and (d) preferences for peer-led T2D self-management interventions.

Conclusions: Results suggest that gender values and beliefs, patient-provider communication and social and structural barriers may have implications for T2D self-management in older African American men and that this population may be receptive to a peer-led T2D self-management intervention.

AN INNOVATIVE APPROACH UTILIZING AADE7 AND GROUP MEDICAL VISITS

Ruby Miller, DNP APRN FNP-BC¹¹Southeastern Louisiana University, Independence, LA

Diabetes is a chronic condition that is primarily self-managed and lifestyle modifications such as diet, exercise, and weight management are necessary to reduce morbidity and mortality. Rural populations with low socioeconomic status are at high risk of poor diabetes control, decreased self-management, and development of complications.

Purpose: The purpose of this project was to implement and evaluate an evidence-based group medical visit program for adult patients with type 2 diabetes in a rural health clinic.

Participants: Convenience sampling of sixty-five participants attended group medical visits weekly for a six-week period. Participants were adults, eighteen years of age and older, diagnosed with uncontrolled Type 2 diabetes mellitus and Hemoglobin A1C (HbA1C) > 7.5.

Methods: Data were collected for the HbA1C values at baseline, three and six months post intervention. To measure knowledge of each participant, a diabetic knowledge test was administered before participating in the group medical visits and upon completion of the program.

Data Analysis: Descriptive statistics and paired sample *t*-tests were computed to analyze data.

Results: The project demonstrated improvement in diabetic knowledge and HbA1C levels at baseline, three months and six months post intervention.

Conclusion: Self-care management behaviors improved with enhanced knowledge and demonstrated improvement in HbA1C. Results of this project found to be comparable and indicates group medical visits offer an opportunity to bridge the gap in diabetic education and self-care management in diabetes.

Keywords: group medical visits, Type 2 diabetes, self-care management, behavior change, AADE7 Self-Care Behaviors

DIABETES RISK FACTORS AND CELLULAR AGING IN OVERWEIGHT AND OBESE ADULTS: NHANES 1999-2002

Cindy Leung, ScD, MPH¹, Joyce Lee, MD, MPH¹¹University of Michigan, Ann Arbor, MI

Objective: High body mass index (BMI) and type 2 diabetes have both been independently associated with telomere length, a marker of cellular aging, in population-based studies. However, overweight and obesity are important risk factors for subsequent risk of type 2 diabetes and accelerated telomere shortening may provide a link between these chronic conditions. We examined cross-sectional associations between diabetes risk factors and leukocyte telomere length (LTL) in national sample of overweight and obese adults.

Methods: Data for the study came from the 1999-2002 National Health and Nutrition Examination Surveys (NHANES). The study population comprised 1,170 overweight and obese (BMI >25 kg/m²) adults (ages 20-50 years) without a prior diagnosis of diabetes. LTL was assayed from DNA samples purified from whole blood, collected from adult NHANES participants who consented to genetic analysis. Diabetes risk factors included fasting glucose, fasting insulin, homeostatic model assessment for insulin resistance (HOMA-IR), and hemoglobin A1c (HbA1c). Multivariable logistic regression models were used to examine associations between diabetes risk factors and log-transformed LTL, adjusting for sociodemographic characteristics, health behaviors, and BMI. Complex survey weights were used in all analyses.

Results: After adjusting for sociodemographic characteristics and health behaviors, higher fasting insulin was associated with shorter LTL ($\beta = -0.001$, 95% CI -0.003, -0.000, $P = 0.049$) and higher HOMA-IR was associated with shorter LTL ($\beta = -0.005$, 95% CI -0.009, -0.001, $P = 0.02$). Fasting glucose and HbA1c were not significantly associated with LTL.

Conclusions: In overweight and obese non-diabetic adults, markers of insulin resistance but not fasting glucose were associated with shorter LTL. These results suggest that telomere shortening may be a mechanism linking high BMI to elevated risks of type 2 diabetes. Future research should explore these associations in a longitudinal study to better understand the extent to which telomere shortening is on the causal pathway between obesity and type 2 diabetes.

BARRIERS, FACILITATORS, ACCESS AND DISTRESS EXPERIENCED BY PEOPLE WHO ARE BLIND AND HAVE DIABETES

nazanin Heydarian, PhD¹, Allyson S. Hughes, PhD²¹University of Texas at Austin, Austin, TX; ²TID Exchange, Cambridge, MA

Background: Although diabetes is the leading cause of blindness and people who are blind are twice as likely to be diagnosed with diabetes than non-disabled people, there is limited literature examining how people who are blind and have diabetes manage their chronic disease.

Methods: This study examined chronic disease self-management strategies and barriers experienced by people who are blind and have diabetes. Thirty-one such participants responded to an online survey about their experiences managing their diabetes.

Results: A thematic analysis on open-ended responses revealed the following overarching categories: Access and Reliability (29% of responses), Facilitators to Self-management (27%), Distress (24%), and Barriers to Self-management (20%). Participants expressed concerns regarding the cost, availability with insurance, accuracy, and inaccessibility of medical technology. Participants described how they check their blood sugar, take their medication, eat a healthy diet, and exercise. A few participants did mention intersectional distress related to managing their diabetes as blind people. Finally, participants described barriers to self-management including managing a healthy diet and checking blood sugars.

Discussion: Moving forward, researchers and policy-makers should work with people who are blind and also have diabetes in order to develop medical technology and policy that support the development and dissemination of reliable, accurate, and adequate medical technology. These findings also have implications for training healthcare providers to prepare people who are blind to independently manage their diabetes.

TRADITIONAL AND CONTEMPORARY CORRELATES OF BODY IMAGE DISSATISFACTION IN A PREDOMINANTLY LATINX COLLEGE SAMPLE

Roberto Sagaribay III, B.A.¹, Jennifer De Alba, n/a¹, Emilio Posada, n/a¹, Nallely Ramirez, n/a¹, Luis Corona, n/a¹, Theodore V. Cooper, PhD¹¹University of Texas at El Paso, El Paso, TX

To be concerned about one's body shape has shown to be a risk factor for substance use problems. Current research on the growth, problematic usage, and addictive properties of social media has resulted in new literature that investigates its association with body image dissatisfaction. The present study aimed to assess these traditional and contemporary addictive behavioral correlates of body image dissatisfaction in a Hispanic/Latinx college student sample.

College students ($N = 742$, $M_{age} = 21.17$, $SD = 3.89$, 71.6% female, 84.1% Hispanic/Latinx) completed the informed consent process and completed the following assessments: demographics, the Body Shape Questionnaire (BSQ), smoking status, alcohol, diet pills, and energy drink past month usage, social media use frequency, selfie and groupie posting and viewing frequency, the Selfitis Behavior Scale, and the Bergen Social Media Addiction Scale.

The first linear regression, which assessed the relationship between the traditional addictive behaviors and body image dissatisfaction, was not statistically significant, $p > .05$. The second linear regression assessed the relationship between social media behaviors and body image dissatisfaction. Participant age ($\beta = .090$, $p < .05$), sex ($\beta = .191$, $p < .01$), social media addiction ($\beta = .207$, $p < .01$), and selfie viewing ($\beta = .130$, $p < .05$) were significantly associated with increased body image dissatisfaction.

That only social media addictive behaviors were correlated with increased body image dissatisfaction may suggest a possible shift in coping behaviors from traditional addictive behaviors. That body image dissatisfaction was associated with older and female participants suggests findings are consistent with the literature in other ethnic/cultural groups. That social media addiction and selfie viewing were associated with increased body image dissatisfaction suggests a possible negative effect of increased exposure to idealized images on social media platforms, which may be highlighting the thin ideal. The constant enforcement of this belief system may be negatively influencing body image perceptions for those who do not perceive meeting their desired shape. Prospective studies should assess the temporal relationships between social media behaviors and body image dissatisfaction.

THE ROLE OF PSYCHOLOGICAL NEEDS AND SELF-REGULATION WITH FOOD ADDICTION SYMPTOMS: A SELF-DETERMINATION THEORY PERSPECTIVE

Urvashi Dixit, B.A.¹, Emily Jansen, B.S.¹, Katelyn Melcher, B.A.¹, Hailey Ellingson, n/a¹, Hannah Lewis, n/a¹, Lara J. LaCaille, PhD¹, Rick A. LaCaille, PhD¹

¹University of Minnesota Duluth, Duluth, MN

Introduction: Research has consistently highlighted that the transition to college confers increased risk for unhealthy eating and weight change for a significant subset of students. Self-Determination Theory (SDT) has helped to elucidate self-regulation/motivational factors and basic psychological needs that are beneficial to mental and physical health outcomes. Importantly, satisfaction of needs (i.e., competence, relatedness and autonomy) has been associated with a healthier diet and eating patterns, whereas need thwarting experiences may be implicated in the etiology of disordered and dysregulated eating. As needs become thwarted, individuals may be at risk of engaging in compensatory behaviors such as excessive or uncontrolled eating. Attention has been increasingly directed toward behavioral addictions within the current diagnostic nosology (DSM-5), with one such form presenting as food addiction – directed toward uncontrolled and problematic consumption of highly processed foods (e.g., pizza, chocolate, chips). On the surface, food addiction appears consistent with compensatory behaviors that stem from need thwarting, though to our knowledge the relationships between food addiction, self-regulation and basic psychological needs have not been examined. Thus, the current study examined the relationships between these variables.

Methods: Undergraduate freshmen ($n = 350$; 55% females) in their first semester of college completed questionnaires on global psychological need satisfaction and frustration, weight management self-regulation, food addiction symptoms (Modified Yale Food Addiction Scale), and BMI.

Results: Relatedness satisfaction ($r = -.13$, $p = .01$) and food addiction symptoms ($r = .17$, $p = .002$) were associated with BMI. Food addiction symptoms appeared more clearly associated across bivariate correlations (controlling self-regulations $r_s = .24$ to $.32$, $p_s < .001$; needs satisfaction $r_s = -.16$ to $-.31$, $p_s < .01$; needs thwarting $r_s = .23$ to $.47$, $p_s < .001$). Hierarchical multiple regression indicated that of the SDT constructs, competence thwarting robustly predicted greater food addiction symptoms ($\beta = .38$, $p < .001$) followed by relatedness thwarting ($\beta = .15$, $p < .05$) and BMI ($\beta = .13$, $p < .01$). Regression analyses indicated that introjection and external regulation partially mediated the relationship between relatedness thwarting and food addiction symptoms, though this effect appeared trivial.

Discussion: Psychological needs and motivational regulations proposed by SDT are linked to food dependence symptomatology. Other factors may also influence the development of these symptoms and more research is warranted to understand how these form over time.

VISUAL CUES AND FOOD INTAKE: A PREREGISTERED REPLICATION

Nadia C. Dellawar, A.A.¹, Brooke C. Cullen, A.A.², Alyssa K. Choi, B.A.³, Sonia Avila Contreras, A.A.², Jamie A. Chamberlain, n/a³, Elena M. Eu, n/a⁴, Grace Li, n/a², A. J. Tomiyama, Ph.D.²

¹University of California, Los Angeles, La Palma, CA; ²University of California, Los Angeles, Los Angeles, CA; ³San Diego State University, San Diego, CA; ⁴University of California, Los Angeles, Rancho Palos Verdes, CA

Background: A landmark study by Wansink, Painter, and North (2005) found that visual cues affect food intake, while controlling for BMI, sex, and retrospectively reported baseline hunger. Specifically, they found that a biased visual cue (imperceptible self-refilling soup bowl) increased food intake compared to an accurate visual cue (normal soup bowl). Due to questions raised about the validity of the findings, we conducted a preregistered direct replication (<https://osf.io/ux42g>) to examine if actual food intake and estimated food intake significantly differed based on the visual cue condition.

Method: Participants ($N = 255$; age range = 18 to 54; mean BMI = 24.15; 80.3% female) were recruited to eat soup for lunch in groups of four. Participants were randomized to one of two conditions: 1) accurate visual cue (normal soup bowl) or 2) biased visual cue (self-refilling soup bowl). Those in the biased visual cue condition ate from modified soup bowls that imperceptibly refilled. ANCOVAs assessed the effect of condition (accurate vs. biased) on the study outcomes, controlling for BMI, sex, and retrospectively reported baseline hunger.

Result: Participants in the biased visual cue condition ate more soup as measured in ounces [11.49 ± 6.82 vs. 9.39 ± 6.59 oz; $F(1, 245) = 6.29$, $p = .013$] and calories [258.62 ± 153.53 vs. 211.36 ± 148.17 cal; $F(1, 245) = 6.29$, $p = .013$] than those in the accurate visual cue condition. Although they consumed 22% more, they believed they had consumed less in ounces [4.83 ± 6.84 vs. 7.11 ± 8.60 oz; $F(1, 249) = 5.32$, $p = .022$] but not in calories [110.67 ± 117.60 vs. 123.55 ± 100.71 cal; $F(1, 249) = 0.59$, $p = .443$] compared to those in the accurate condition.

Conclusion: We replicated the finding that a biased visual cue increases food intake. Participants who ate from the self-refilling soup bowl ate more in ounces and in calories than those who ate from the normal soup bowl, although the effect sizes we observed were smaller than that of Wansink's (e.g., 47 kcal difference here versus 113 kcal in Wansink et al.). In contrast to the original study, we found that those who ate from the self-refilling bowl estimated that they ate fewer ounces of soup than those who ate from the normal bowl. Overall, our results support the original finding that visual cues impact food intake over satiety. This replication effort is important because the original study has been cited over 600 times and has influenced policy (e.g., USDA, the military, and school lunchrooms) and consumers (e.g., 100 calorie snack packs).

WASTE WATCHERS: A FOOD WASTE REDUCTION INTERVENTION FOR ARIZONA FAMILIES

Christopher Wharton, PhD¹, Maricarmen Vizcaino, PhD¹, Andrew Berardy, PhD¹, Adenike Opejin, MS¹¹Arizona State University, Phoenix, AZ

Introduction: In the US, 45 million tons of food are wasted at the household level, equating to roughly \$28 per week for the average family of four. Because the largest proportion of wasted food in the home comprises fruits and vegetables, these losses represent missed opportunities to eat healthfully. Further, they may contribute to climate change as organic matter breaking down in landfills is the third largest source of anthropogenic methane emissions in the US. Recent estimates suggest up to 60% of home food waste is avoidable, making households an ideal location for intervention to decrease environmental impact and family income losses, and support healthy eating simultaneously.

Methods: Fifty-three adults, self-identified as the primary food purchasers in their home, participated in the Waste Watchers study. The intervention consisted of asking participants to interact with a website designed for this study that provided key information and strategic tools presented in a variety of formats including downloadable content, podcasts, infographics, videos, and text-based information. Researchers developed a standard protocol which was used to train participants on how to collect and log their family's food waste at home throughout the duration of the study. Participants also completed surveys on food waste behaviors and behavior change constructs (e.g. norms, intentions) pre- and post-intervention, and engaged in an in-depth exit interview during the follow-up. Quantitative data was assessed with Wilcoxon rank tests and Spearman correlations due to non-normality. Qualitative data was transcribed verbatim, coded, and examined for major themes.

Results: At the end of the study, a significant decrease in logged food waste was observed (19.19 oz vs. 10.36 oz, $z = -2.39$, $p = .017$). Significant improvement was also observed in all behavior change constructs under study (all $p < .01$), and these constructs in turn were significantly associated with lower food waste ($r_s = -.28$ to $-.42$, all $p < .05$). Major themes emerging from interviews included increased awareness, behavior change, saving money, and family involvement.

Discussion: A 5-wk online food waste intervention was effective in changing behavior-related psychological constructs and food waste-related behavior among Arizona families. Our team will continue exploring the effectiveness of our intervention on other populations and is currently developing a model that guides future food waste research.

PINNING, PLANNING, PREPARING MEALS: PARENTAL CHILDHOOD FEEDING PRACTICES AND PINTEREST

Jeanine D. Guidry, PhD¹, Carrie A. Miller, PhD, MPH¹, Bernard F. Fuemmeler, PhD, MPH¹, Rashelle B. Hayes, PhD¹, Kellie Carlyle, Ph. D.¹¹Virginia Commonwealth University, Richmond, VA

Social media platform Pinterest is used extensively for searching for and sharing recipes, yet little is known about the specific use of the platform for this purpose, and about the specific child feeding practices of Pinterest-using parents. With childhood obesity being an epidemic - 20.8% of children in eighth grade are obese and an additional 17.0% are overweight – understanding how parents may use Pinterest as a recipe source and how that may be associated with their child feeding practices is important.

Child health factors and practices are explored through a survey among a national sample of 1119 U.S. Pinterest using parents of children ages 3-14. Participants completed a Qualtrics survey focused on child feeding practices as well as their use of Pinterest related to recipes and preparing meals.

Early results show that 83.6% of respondents actually make recipes they find on Pinterest: 30.8% at least monthly, 37.6% at least weekly, and 15.2% daily; in addition, 50% post new recipes, and 75% share recipes on the platform. Half reported their child is a picky eater on some level, and 61.4% answered that if they did not regulate their children's eating, they would eat too much junk food. This study is ongoing – the complete results will report on specific types of foods present in households, over-and underweight concerns, and eating habits of both adults and children in the household, and on any present associations with the frequency and type of Pinterest use related to recipes and preparing meals.

USING GROUP CONCEPT MAPPING TO IDENTIFY BARRIERS TO AND FACILITATORS OF USING A MOBILE FRUIT AND VEGETABLE MARKET INTERVENTION

Rachel Mealy, M.S.¹, Akilah Dulin, Ph.D.¹, Shannon Whittaker, MPH², Michelle Cardel, PhD, MS, RD³, Jeremy Wang, AB¹, Patricia M. Risica, DrPH⁴, Kim M. Gans, PhD, MPH⁵

¹Brown University, Providence, RI; ²Yale School of Public Health, New Haven, CT; ³University of Florida, Gainesville, FL; ⁴Brown School of Public Health, Providence, RI; ⁵UConn, Storrs, CT

Using Group Concept Mapping to Identify Barriers to and Facilitators of Using a Mobile Fruit and Vegetable Market Intervention

Background: Interventions addressing neighborhood- and individual- level barriers to fruit and vegetable intake within racial/ethnic minority and low-income communities have demonstrated mixed success. Therefore, the objective of this study was to identify the barriers to and facilitators of using Fresh to You, a mobile fruit and vegetable market delivered to ethnically diverse, low-income housing communities as part of the Live Well/Viva Bien intervention.

Methods: We used Group Concept Mapping, a structured, participatory research methodology designed to represent group ideas visually. Ninety residents from five housing communities that received Fresh to You markets participated in concept mapping sessions. Participants generated, sorted and rated statements concerning barriers to and facilitators of market utilization. In post hoc analyses, we compared the rating data between residents with high and low levels of market utilization.

Results: Eight clusters emerged from concept mapping including: 1) financial/promotion barriers; 2) produce barriers; 3) scheduling/knowledge barriers; 4) logistic/awareness barriers; 5) produce/staffing barriers; 6) multilevel market facilitators; 7) market promotion facilitators; and 8) market accessibility facilitators. There was a strong correlation of agreement in the perceived importance of the clusters ($r = 0.94$) between groups with high and low levels of market utilization. Additional post hoc analysis identified the most important (and actionable) statements across high/low market utilization groups; all but two of these 26 statements were facilitators. The facilitator statements identified by participants related to the diversity, quality, aesthetics and low cost of fruits and vegetables and to family health promotion (e.g., concern for family health). Participants identified community norms (i.e., seeing other people shopping in the markets) as facilitators of their own market utilization behaviors.

Discussion: These results indicate the need for more asset-based community-engaged approaches that focus on facilitators of market utilization in low-income communities receiving healthy food environment interventions. Furthermore, the common facilitators identified as most important across differing market utilization groups could inform the development and implementation of future fruit and vegetable interventions in low-income communities.

WHAT'S IN A BINGE? CHARACTERIZING THE CONTENT OF BINGE EPISODES AMONG A TREATMENT-SEEKING SAMPLE OF INDIVIDUALS WITH BED

Lindsay Gillikin, B.A.¹, Stephanie Manasse, Ph.D.¹, Megan Michael, B.S.², Adrienne Juarascio, Ph.D.¹

¹Drexel University, Philadelphia, PA; ²Drexel University, Baltimore, MD

Binge eating disorder (BED; characterized by recurrent episodes of loss of control eating) is strongly associated with numerous health (e.g., Type II diabetes) and psychological consequences. However, despite the large body of research in this area, there has been very little research on the composition (e.g. types of food) of binge eating episodes. Strengthening empirical knowledge of this kind would help to maximize the effectiveness of treatments that seek to target patients' relationships with specific foods (i.e. inhibitory control training, food exposure). Despite the strong implications of this work, no study to date has examined the composition of binge episodes in a BED population. One reason that this may be the case, is that there is no existing measure that characterizes the content of binge episodes. As such, we adapted a Food Frequency Questionnaire (FFQ), asking participants to report food consumed during binge episodes, in order to examine the composition of binge episodes in a treatment seeking BED sample ($n=55$). Results indicated that participants, on average, reported bingeing on 25.35 ($SD=14.30$) unique foods in the previous month. The foods that appeared most frequently across all participants, in descending order of the number of participants that reported bingeing on the given the food, included: cheese, cookies/brownies, chocolate candy, potato chips, and pizza. Next, our team categorized the FFQ items into sweet snacks, savory snacks, and entrees to examine the distribution of these categories. On average, participants reported bingeing on 5.22 ($SD=2.52$) unique sweet snack foods, 6.25 ($SD=2.76$) unique savory snack foods, and 7.75 ($SD=6.48$) unique entrée foods over the past month. Nearly all participants experienced at least one binge episode that was comprised of sweet snacks (96%; $n=53$) and one of savory snacks (96% $n=53$). Fewer, but still the vast majority of participants (87%, $n=48$) reported bingeing on foods categorized as entrees. In summary, patients with BED tend to binge on a high variety of foods. Knowledge regarding the composition of binge episodes will help to inform future assessment protocols and interventions such as food exposure and inhibitory control training (ICT). Future research seeks to utilize these findings to develop assessment protocols that more effectively capture the composition of binge episodes in order to customize ICT and food exposure treatments to the individual, maximizing their effectiveness.

AFFECTIVE REACTIVITY MEDIATES RELATIONSHIP BETWEEN STRESSORS AND BINGE EATING: AN ECOLOGICAL MOMENTARY ASSESSMENT STUDY

Paakhi Srivastava, Ph.D.¹, Elizabeth Lampe, B.A.², Megan Michael, B.A.¹, Stephanie Manasse, Ph.D.², Adrienne Juarascio, Ph.D.²¹WELL Center, Philadelphia, PA; ²Drexel University, Philadelphia, PA

Binge eating disorder affects up to 3.6% of Americans at some point during their lifetime and is thought to be maintained by increases in negative affect. Although affective reactivity, or increases in negative affect in response to a stressor (AR), is known to predict momentary risk of binge eating, little is known about antecedents of AR that increase momentary risk of binge eating. This study is among the first to assess the impact of different stressors on AR and subsequent binge eating using ecological momentary assessment. Adult women with clinically significant binge eating ($N=16$, BED [43.75%]; BN [56.25%]) recorded their mood, eating, and four types of stressors (i.e., interpersonal, work/school, financial, and other [e.g., daily life hassles]) over two weeks. Because there is no standard definition of a significant level of stress in the literature, we defined a clinically significant level of stress as an increase in negative affect of at least 1SD above an individual's mean level. Multilevel modeling evaluated the relationship between presence of stressors at time1, change in negative affect from time1-time2 (AR), and binge eating reported at time3 while controlling for binge eating prior to time3. Work/school stressors (33.33%) occurred more than interpersonal (25.39%), other (20.63%), and financial stressors (3.17%). Multiple stressors were also reported at 34% of surveys. AR significantly mediated the relationship between increases in interpersonal stressors ($\beta=0.13$, $\chi^2=3.73$, $p=0.05$, $OR=1.13$) and work/school stressors ($\beta=0.06$, $\chi^2=4.23$, $p=0.04$, $OR=0.94$) and subsequent binge eating. AR did not significantly mediate the relationship between financial stressors ($\beta=0.09$, $\chi^2=1.76$, $p=0.18$, $OR=0.94$) or other stressors ($\beta=0.01$, $\chi^2=0.001$, $p=0.97$, $OR=0.99$) and subsequent binge eating. These findings demonstrate that AR mediates the relationship between interpersonal stressors and work/school stressors and binge eating. Thus, it may be important for treatment providers to target interpersonal and work/school stressors when addressing mood-related binge eating. The results of this study are an important step in developing momentary interventions to 1) minimize the risk for triggers for negative affect and 2) deliver personalized and targeted strategies to manage stressful events. Further research should identify types of interpersonal stressors (e.g., family relationships, friendships) that may differentially promote AR and precipitate binge eating.

IMPACT OF A COMMUNITY HEALTH CAMP ON ADOLESCENT NUTRITION KNOWLEDGE, COMMUNITY HEALTH AWARENESS, SELF-EFFICACY AND BEHAVIOR

Noel Kulik, PhD, CHES¹, James Mallare, B.S, CHES¹, Stephanie Osborn, MPH²¹Wayne State University, Detroit, MI; ²Community Health Pipeline, Detroit, MI

In urban areas, youth often face significant health disparities and preventable poor health outcomes because of health, education, social and economic disparities, including higher than average rates of obesity, physical inactivity and unhealthy eating. Well-trained community health practitioners who are able to work in lower income and marginalized communities are needed to elicit long-lasting sustainable change and disrupt health inequity. Unfortunately, many young people do not know about the field and practice of community health. The Youth Advancing Community Health (YACH) program provided no-cost, city-wide experiential learning activities for adolescents, which were designed to increase healthy eating, promote food access within the city, and provide exposure to a variety of community health methods and career paths focused on food and nutrition. This study reports on outcomes (knowledge, awareness, self-efficacy, behavior) from the YACH week-long summer camps. Paired samples t-tests were used to evaluate change from pre (T1) to post (T2) program on all variables. Eighty-three students registered for the camp, and 52 youth had both T1/T2 data available for analysis. Questionnaire and program completion did not vary by age, GPA, grade, gender, race or free/reduced lunch status. The analysis sample was primarily African American ($n=35$; 72.9%) and female ($n=39$; 78.0%) with an average age of 15.4 ± 1.2 years. Participants were from multiple high schools in a large metropolitan area, had an average GPA of $3.2 \pm .61$ and 78.7% ($n=37$) received free/reduced lunch. Nutrition knowledge score (min: 0, max: 10) ranged from 1-8 at T1 and from 0-10 at T2. After one week of programming, participants knowledge (T1: $M = 5.10$, $SD = 1.89$; T2: $M = 6.04$, $SD = 1.95$) significantly increased ($t(50) = -3.10$, $p = .00$, $d = .43$), as did self-efficacy to improve eating habits ($t(47) = -2.64$, $p < .01$, $d = .38$) and cook healthy foods ($t(48) = -2.52$, $p < .01$, $d = .36$). Awareness of the field of community health (CH) ranged from 1-4 at both T1 and T2, and significantly increased (T1: $M = 2.53$, $SD = .69$; T2: $M = 3.31$, $SD = .85$; $t(48) = -4.76$, $p = .00$, $d = .68$). When asked if they plan to eat more fruits and vegetables 78.4% said yes, 15.7% said maybe, and 56% said they planned on starting a home garden. Results show that a short program using community health methods and tools and a focus on food can yield significant improvements in adolescent knowledge, attitudes and behavior.

GROCERY SHOPPING BEHAVIORS IN INDIVIDUALS WITH FOOD INSECURITY

Jaime A. Coffino, MA, MPH¹, Madison R. Dudek, n/a², Julia M. Hormes, Ph.D.³¹University at Albany, SUNY, Providence, RI; ²Brown University, Wrentham, MA; ³University at Albany, SUNY, Albany, NY

Introduction: Grocery shopping behaviors (e.g., cooking frequency, frequency of trips) have been associated with healthfulness of food purchases and thus have implications for weight and diet-related health. Food insecurity has been associated with increased risk for overweight and obesity and this population often has to overcome financial, geographic, and education barriers to make healthy food choices. Individuals with food insecurity are more likely to live in food deserts (i.e., lack of surrounding healthy food providers) and rely more frequently on corner stores that are less likely to carry fresh produce. The aim of this study was to examine grocery shopping behaviors and assess the feasibility of online grocery shopping in individuals with food insecurity to better inform diet and weight-related interventions in this population. We hypothesized that participants cook and grocery shop frequently but that a majority of participants do not utilize online grocery shopping services.

Methods: 53 participants with food insecurity from single-person households (age = 45.85±12.70; BMI = 28.54±6.37; 75% male) recruited from food pantries in New York completed a baseline survey prior to participating in an intervention aimed at improving the healthfulness of grocery purchases.

Results: Nearly all participants (98%) reported that they had access to a kitchen in their home and a majority of participants reported cooking either always (48%) or often (33%) during the week. A majority of participants reported grocery shopping at least twice a month (68%) and over half of the participants reported that they have a budget for grocery shopping (59%), with an average monthly budget of \$127.17 (SD= \$81.83). Most participants reported that they have never used online grocery shopping services (89%) but over half of participants reported that they would consider using online services (60%).

Discussion: Most participants reported cooking frequently during the week and nearly all participants had access to a kitchen in their home, which further demonstrates the importance of interventions that target diet in the home. Additionally, most participants reported that they would consider using online grocery shopping services, which could potentially serve as a new platform for interventions in this population. Researchers have recently developed online grocery shopping interventions for this population so it is promising that a majority of participants are open to using these services.

FOOD-RELATED VALUES AND ABILITIES AMONG FOOD SECURE AND INSECURE COLLEGE STUDENTS

Lisa S. Miller, PhD¹, McKenna Koprowski, BA¹, Sally Chesnut, n/a¹, Lauren Christie, n/a¹¹University of California, Davis, Davis, CA

Food insecurity disproportionately affects low-income and minority students and increases risk of poor academic (e.g., GPA, time to graduate, drop-out rates) and health outcomes 1, 2. While there are programs available (e.g., food pantries, food discounts), many students do not access resources 3. Research is needed to better inform how to meet the needs of FI students.

We examined food-related values and abilities among food secure (FS, n=50) and insecure (FI, n=19) college students. We used the Meaning of Food in Life Questionnaire (MFLQ4) to assess food values in 3 distal- (social (food tied to relationships), moral (food choices affect the world), sacred (spiritual beliefs)) and 2 proximal- (health (nourishing my body), and aesthetic (meal as work of art)) domains. We assessed objective (nutrition knowledge test) and subjective (self-reported nutrition label use, nutrition knowledge, and healthy-eating confidence) factors. Food insecurity was assessed using an 8-item measure 5; never or rarely experiencing food insecurity=FS; sometimes or often = FI.

Food values were analyzed in a 2(Security Status: FS, FI) x 5(Domain: 1-5) MANOVA. We found an effect of domain, $F(5,61)=2.42$, $p<.05$, $\eta^2=.16$, with between-subjects effects for Aesthetics only, $F(1,65)=10.4$, $p<.01$, $\eta^2=.14$. In a series of ANOVAs, we found that self-reported use of labels did not differ by status, $F(1,65)=2.1$, but FI reported lower levels of nutrition knowledge than did FS, $F(1,65)=6.5$, $p<.01$, $\eta^2=.09$. Confidence in one's ability "to eat the foods that I know to be more healthful" did not differ between groups, $F<1$; however, "to plan and prepare nutritious meals at home" was lower among FI than FS, $F(1,65)=5.7$, $p<.05$, $\eta^2=.09$. Finally, FI scored lower on the nutrition knowledge test than did FS, $F(1,65)=7.2$, $p<.01$, $\eta^2=.10$.

We had expected proximal- to be lower than distal- domains among FI students. While true for the aesthetics, FI and FS students did not differ on the health domain. Similarly, self-reported use of labels, reflecting motivation more than skill 6, did not differ between groups, but self-reported and objective measures of nutrition knowledge were lower for FI than FS. Thus, FI students value health, are motivated to use nutrition information, and are self-aware of their knowledge and meal-preparation short-comings. Findings suggest that meeting the needs of FI students may include helping them learn skills needed to improve healthy eating.

LONGITUDINAL ASSESSMENT OF EAT-26 AND WEL IN A BEHAVIORAL WEIGHT LOSS INTERVENTION

Natalie M. Papini, M.A.¹, Lauren T. Ptomey, PhD, RD², Nanette Lopez, PhD, MS/MS¹, Joseph Donnelly, EdD², Stephen Herrmann, PhD³¹Northern Arizona University, Flagstaff, AZ; ²University of Kansas Medical Center, Kansas City, KS; ³Profile by Sanford, Sioux Falls, SD

Background: There is conflicting evidence on whether behavioral weight loss programs improve or worsen eating disorder symptomology. Eating self-efficacy may influence calorie consumption and could be a mechanism through which those susceptible to binge eating reduce loss of control eating behaviors. This study examined changes in eating attitudes and self-efficacy for eating control in participants enrolled in an 18 month behavioral weight loss program.

Methods: Adults with overweight and obesity (N= 393; BMI= 34.87 ± 4.80 ; age= 43.83 ± 10.10) participated in the 18-month intervention. The weight loss phase, 0-6 months, consisted of energy restriction (1,200-1,500 kcal/day) achieved using portion-controlled meals and increased physical activity. During weight maintenance, 7-18 months, participants consumed a diet designed to maintain weight loss. Educational sessions were conducted weekly during the weight loss phase and reduced to twice per month during months 7-9, monthly during months 10-12, and every other month during months 13-18. The 26-item Eating Attitude Test (EAT-26) and the 20-item Weight Efficacy Lifestyle (WEL) questionnaire were administered at baseline, 6, 12, and 18 months. Mixed effect models were used to examine longitudinal changes in the EAT-26 and WEL scales. Age, sex, and BMI were included as covariates in the models. Completion of weight measures at 18-months was considered a potential moderator.

Results: There were significant increases in the EAT-26 scores ($p < .001$) and WEL scores ($p < .001$) across time. EAT-26 scores were significantly different from one another at all time points (M = 4.52, 11.86, 10.51, 9.31; SE = .23, .43, .37, .37). WEL scores were significantly different in all time points, except between 12-months and 18-months (M= 143.17, 147.52, 136.58, 134.62; SE= 1.45, 1.13, 1.55, 1.56). There were no moderating effects of completion for either model.

Conclusions: Increases in the EAT-26 scores demonstrate that as participants lose weight and restrict energy intake they may develop disordered eating attitudes or behaviors. The WEL model indicates that self-efficacy drops once participants enter the 12-month maintenance phase when the intervention intensity (frequency of meetings) decreases. Future research should examine components of weight loss programs that impact disordered eating patterns, and how self-efficacy for eating control could be informative based on the type of disordered behaviors and attitudes that emerge.

RETHINKING ABANDONMENT OF HEALTH APPS USING EATING DISORDERS AS A CASE STUDY

Elizabeth V. Eikey, n/a¹¹University of California, Irvine, San Clemente, CA

System abandonment is an increasing concern, especially for health and health-care care where continuity of care is central to chronic care management and health behavior changes. However, system lapses and even abandonment can be beneficial to some users when we consider mental health and well-being a primary goal of any health system. Given the popularity of health apps that track diet, physical activity, and weight, one case is presented - diet and fitness apps in the context of eating disorders - to highlight the need to expand what encompasses "happy abandonment" by prioritizing mental health. In order to investigate the role of app lapses and abandonment, qualitative think-aloud exercises and interviews were conducted with 24 college women with eating disorder-related behaviors who had experience using diet and fitness apps. Audio was transcribed and then analyzed using thematic coding.

Findings reveal that diet and fitness apps support users in achieving goals that are explicitly supported by the app, such as improved awareness of food and calorie content, consistent and long-term app engagement, and changed behavior (e.g., reduced calorie intake, increased calorie expenditure, weight loss) through persuasive visualizations, but at the same time unintentionally negatively impact users' mental health. Rather than support users to be healthier, self-tracking exacerbated and sometimes even triggered eating disorder-related behaviors, such as restriction, compensatory behaviors, rigid diet, obsessive thoughts, and extreme negative emotions. Because of this, users often took a break from or abandoned diet and fitness apps. Sometimes users themselves decided abandonment was necessary, and other times, a loved one decided for them. Users reported that ceasing app use functioned as a form of "happy abandonment" by improving their mental health and general well-being. This research has socio-technical implications for how we promote engagement and encourage use. Thus, we should consider ways to build in lapses and even abandonment as part of a user's journey with the system to ensure health and well-being.

SECURE MESSAGING FOR MEDICATION RECONCILIATION TO PREVENT RE-HOSPITALIZATION

Julianne E. Brady, MA¹, Amy Rubin, PhD¹, Catherine Yeksigian, MPH¹, Alissa L. Russ-Jara, PhD, UXC², Alan J. Zillich, Pharm.D., FCCP², Laura K. Triantafylidis, Pharm.D., BCGP¹, Gary Lane Smith, Pharm.D.¹, Amy Linsky, MD, MSc¹, Erin E. Beilstein-Wedel, MA¹, Jonathan Moyer, MS³, Maureen Layden, MD, MPH⁴, Steven R. Simon, MD, MPH³

¹VA Boston Healthcare System, Boston, MA; ²Purdue University, College of Pharmacy, Indianapolis, IN; ³University of Massachusetts Amherst, Amherst, MA; ⁴VA Central Office, Washington, DC; ⁵VA Boston Healthcare System, Brockton, MA

Background: Medication discrepancies occurring during transition from acute hospital settings to home often lead to adverse drug events and re-hospitalization. The Secure Messaging for Medication Reconciliation Tool (SMMRT) was developed to identify and reconcile medication discrepancies during transition from hospital to home using secure messaging within the VA's electronic patient portal. This study aimed to evaluate the SMMRT's usability and effectiveness via qualitative interviews.

Methods: 240 patients were recruited from VA acute hospital settings or sub-acute rehab centers before discharge. Patients were randomly assigned to receive Usual Care (UC) or UC + SMMRT intervention. Patients assigned to the intervention used the SMMRT listing their medications via secure messaging after discharge. Patients were asked to confirm their medication list and return the tool for review by a clinical pharmacist to reconcile discrepancies. Twenty patients were randomly selected to offer their perspectives on the usability and effectiveness of SMMRT through in-depth interviews. Interviews were conducted within two months of completion of the intervention and patients were asked to reflect on their experiences using the tool.

Results: Twenty male patients with an average age of 62 years were interviewed. Racial background was reported as 65% white and 35% "other." Prior use of secure messaging was reported by 80% of patients interviewed, while 20% reported rarely using a computer with no secure messaging experience. 88% looked at the SMMRT on their home computer, yet only 45% returned the SMMRT via secure messaging. Patients who did not return the SMMRT reported barriers with using the technology (70%) and time constraints after discharge (30%). Patients who did not return the SMMRT talked about their difficulty with computers, e.g.: "I'm not a computer man. I can turn them on and off pretty good." Those who returned the SMMRT without difficulty said things like, "I thought it was simple and no problem at all." Other comments included "It helped me to understand my dosages a little better and get my regimen on track."

Conclusion: While most patients used the SMMRT to review their medications once home, technology related issues, likely due to the varying levels of computer literacy among our study population, were found to be the greatest barriers to returning the tool for clinical review.

SCREEN TIME, MENTAL AND PHYSICAL HEALTH: ARE ALL SCREENS CREATED EQUAL IN YOUTH?

Megumi Iyar, M.A.¹, Stefanie Ciszewski, M.A.¹, Carmela A. White, M.A.², Liam King, B.A.³, Alyssa Koziol, B.HK.¹, Christine Tallon, M.Sc.⁴, Daniela Nowak-Flück, PhD.³, Matt Rieger, B.Sc.¹, Ali McMamus, Ph.D.¹, Lesley Lutes, PhD, R. Psych¹

¹University of British Columbia - Okanagan, Kelowna, BC, Canada; ²University of British Columbia - Okanagan, Calgary, AB, Canada; ³University of British Columbia, Kelowna, BC, Canada; ⁴University of British Columbia - Okanagan, Kelowna, BC, Canada

Over the past decade, concurrent with advancements in technology screen use has increased dramatically. Widespread use has spurred a growing body of literature aimed at understanding the possible influences of screen time; however, the speed of technological advancement has so outstripped research progress that the nuance of how specific elements of screen-based life shape psychological and physical health during development are poorly understood (Orben & Przybylski, 2019; Stiglic & Viner, 2019). Current guidelines recommend limiting screen time to less than 2 hours for 5 to 17-year olds (American Academy of Pediatrics, 2016; Tremblay et al., 2016). The empirical support for these recommendations is unclear and more research is needed to better understand the quantity of differing screen media and its impact on physical and mental well-being (Ferguson & Beresin, 2017).

The purpose of this study was to examine screen time media and its association with psychological and physical health indicators. Whereas previous research and guidelines have focused primarily on total screen time and television viewing, this study investigated the possible contribution of a) watching television, b) playing videogames or using a computer, and c) using a tablet or smartphone (mobile screen).

Participants were 369 children and youth aged 7 to 16 ($M = 12 \pm 1.7$) years, recruited from elementary and middle schools. Self-report ratings were collected for leisure-time hours per day spent with the three modes of screen media. Outcome measures include self-report sleep, diet, health quality of life, life satisfaction, and perceived stress. Accelerometer assessed steps/day were also assessed.

Descriptive analyses showed the mean hours per day watching television, playing video/computer games and using smartphones recreationally, were 1.81 ($SD = 1.34$), 1.98 ($SD = 1.61$), and 2.33 ($SD = 1.53$), respectively. Correlations were conducted between different screen time media and measures of psychological and physical health. All three modes of screen media were associated with poorer diet and lower life satisfaction. However, unlike television watching, playing video/computer games and using mobile screens were associated with poorer diet, and health-related quality of life, higher perceived stress, and less physical activity. Regression analyses indicated that after controlling for age and sex, mobile screen use explained additional unique variance.

Overall, these results suggest that specifying the type of screen media used may be more essential for adequately capturing the complexity of factors that contribute to health and well-being than total screen time than using total screen time. Future research can further extend our understanding by examining the specific content of screen media that is being accessed and the possible influence this may have on physical and mental health in young people.

PRESENCE OF SAFETY DISCLAIMERS IN INSTAGRAM POSTS ABOUT PHYSICAL ACTIVITY DURING PREGNANCY

Brooke Libby, MPH¹, Paige L. Piera, n/a², Marta M. Holovatska, B.S.³, Madison Bracken, MA⁴, Valeria Herrera, BS, RDN⁵, Ran Xu, PhD⁶, Tiffany A. Moore Simas, MD, MPH, MEd⁷, Sherry Pagoto, PhD⁶, Molly E. Waring, PhD⁶

¹University of Connecticut, Groton, CT; ²University of Connecticut, Bethel, CT; ³University of Connecticut, South Windsor, CT; ⁴University of Connecticut, West Hartford, CT; ⁵University of Connecticut, Hartford, CT; ⁶University of Connecticut, Storrs, CT; ⁷UMass Medical School/UMass Memorial Health Care, Upton, MA

Physical activity (PA) is recommended during pregnancy and has numerous health benefits, yet not all exercises are safe throughout pregnancy or for all women. The majority of young women use Instagram, and pregnancy is a popular topic. Women may try exercises seen on Instagram that are not appropriate for them, especially if a user with health-related expertise recommends the activity. We conducted a content analysis of Instagram posts about PA during pregnancy to examine the presence of PA safety disclaimers. We reviewed public Instagram posts by searching pregnancy-related hashtags in fall 2018, resulting in a sample of 600 posts about PA during pregnancy. We excluded posts no longer available online at time of content analysis (n=8) and then randomly selected one post per user, resulting in an analytic sample of 511 posts. We coded safety disclaimers, user claims of expertise, and other post characteristics by reviewing post text, images, hashtags, and user profile (all posts double-coded; 84-100% agreement; discrepancies adjudicated by 3rd reviewer). Safety disclaimers were defined as language about avoiding/modifying exercises, warning signs/symptoms, or encouragement to check with a medical professional before attempting the activity. We grouped claims of health-related expertise as licensed professionals (e.g., OBGYN, MD, RN), credentials not requiring licensure (e.g., personal trainer, health coach), or no expertise claimed. We compared the presence of safety disclaimers by post characteristics using chi-squared tests. Few (13.7%) of posts included a safety disclaimer. Presence of PA safety disclaimers differed by claims of health-related expertise (15.4% of posts by users claiming licensed credentials, 22.8% of posts by users claiming non-licensed credentials, 8.9% of posts by users with no claimed expertise; $p=0.0002$). Nearly a quarter (23.7%) of posts recommending exercise had a safety disclaimer vs 10.4% of posts sharing a personal pregnancy experience and 0% that were neither sharing personal experience nor recommending exercise ($p=0.0001$). Presence of safety disclaimers did not differ by whether the user was pregnant (13.7% pregnant vs 13.9% not; $p=0.9548$). Few public Instagram posts about PA during pregnancy include a safety disclaimer. Prenatal care providers may wish to talk to pregnant women about vetting information they see online regarding PA as part of encouraging women to be physically active during pregnancy.

SUPPORTING PATIENTS TO STICK WITH IT: A POST-COMPLIANCE TELEHEALTH PROGRAM FOR PATIENTS WITH OBSTRUCTIVE SLEEP APNEA

Gina Merchant, PhD¹, Yang Yan, MS¹, Melanie Taylor, MBA¹, Michael LeBlanc, BS¹, Sakeena De Souza, MS¹, Priyanshu Gupta, MS¹

¹ResMed, San Diego, CA

Background: Obstructive sleep apnea (OSA) is characterized by repeated cessations of breathing while sleeping. Left untreated, consequences of the disease are profound. Patients diagnosed with OSA are most often prescribed continuous positive airway pressure (PAP) therapy. Adherence to therapy declines precipitously over time with some estimates indicating just 50% of patients are using therapy regularly after one year. Most medical device suppliers and insurers are focused on getting patients through the compliance period. Following the compliance period, patients may or may not receive support to stay on therapy. This pilot program is testing whether an existing compliance support program can be expanded to the post-compliance period, and intervene among patients who show signs of dropping off of therapy (via a prediction model).

Methods: A sleep coach team trained in motivational interviewing techniques and self-determination theory reaches out to patients on ResMed devices. Patients are eligible to be contacted if they: are post the 90-day compliance period; have met compliance within the last six months; have received at least one previous coaching session in the last six months; and, based on recent therapy use, are predicted likely to quit therapy in the next 30 days. Once contacted, sleep coaches ask a series of survey questions to prompt a coaching conversation as well as collect data on barriers to therapy use. Patients are asked to set a therapy goal, and sleep coaches follow up within one week after initial contact. After eight weeks, a second survey is administered.

Results: Patients included in this preliminary analysis are those who have completed a baseline survey (N = 70). The most frequently endorsed barrier to maintaining therapy use was travel followed by recent illness, hospitalization or surgery. Patients also commonly reported physical and/or technical barriers including mask fit, therapy comfort, and mask leak. In terms of expectations of therapy use, patients' lowest endorsement was related to the belief that consistent therapy use would improve their ability to concentrate. Most patients reported only occasionally devising and sticking to a plan to incorporate therapy use into their bedtime routine. Approximately half of the patients surveyed agreed to set a goal to use therapy more regularly. Descriptive statistics as well as change in barriers to therapy use will be examined when the pilot is complete in January, 2020. The primary outcome of interest, objectively measured therapy use, will also be examined for change over time.

Conclusion: PAP therapy is difficult to sustain over time. Telehealth coaching services may be able to address some, but not all, of patients' barriers to nightly therapy use.

THE REACH STUDY: LONG-TERM EFFECTS OF A TAILORED TEXT MESSAGING INTERVENTION FOR DIABETES SELF-CARE AMONG DIVERSE ADULTS

Lyndsay A. Nelson, PhD¹, Robert A. Greevy, PhD¹, Andrew Spieker, PhD¹, Kenneth A. Wallston, PhD¹, Sunil Kripalani, MD¹, Tom A. Elasy, MD¹, Lindsay S. Mayberry, MS PhD¹

¹Vanderbilt University Medical Center, Nashville, TN

Non-adherence to self-care for type 2 diabetes (T2D) is associated with adverse outcomes; the prevalence of non-adherence is high, especially among racial/ethnic minorities and patients with low socioeconomic status. Given its ubiquity, text messaging is a practical approach for extending self-care support and improving adherence for patients most at risk. Text messaging interventions have improved adherence, but few have been evaluated in long-term trials or with diverse populations. We conducted a 15-month randomized controlled trial to evaluate the effects of a theory-based, tailored text messaging intervention on diabetes self-care and A1c.

We recruited patients with T2D (N=512) from community health centers and an academic medical center. Participants were randomly assigned to REACH (Rapid Education/Encouragement And Communications for Health) or a control condition. REACH participants received text messages assessing and promoting self-care for 12 mos. All participants completed surveys and A1c tests at baseline and 3, 6, 12, and 15 mos. Surveys included measures assessing medication adherence and diabetes self-efficacy. We used generalized estimating equation and linear regression models to test the effects of REACH on diabetes outcomes.

Participants were 54% female, 53% non-White, and on average, 56.0 (SD 9.5) years old. Nearly half (42%) had ≤ a high school degree, 56% had annual incomes < \$35K, and 49% were underinsured. At 12 mos., median response rate to interactive texts was 91% [IQR: 75–97]. At 15 mos., retention was 90% across conditions. REACH improved A1c (%) compared to the control group at 6 mos. ($-0.31, p = 0.039$); we observed greater reductions in A1c at 6 mos. among patients with higher baseline A1c. We did not find evidence of effects on A1c at 12 and 15 mos. Relative to controls, REACH improved medication adherence at 6 mos. (0.41 days/week, $p < 0.001$) and 12 mos. (0.27 days/week, $p = 0.020$), though we did not find evidence of an effect at 15 mos.; diabetes self-efficacy improved at 6 mos. (0.71, $p = 0.022$) only.

The REACH Study had excellent long-term retention and intervention engagement among diverse adults with T2D. The intervention improved medication adherence, self-efficacy and A1c at 6 mos.; however, we did not find evidence for sustained effects on self-efficacy or A1c. Text messaging interventions are highly scalable with potential to impact population health and may engage patients at high risk for poor outcomes. Research seeking to sustain effects at 12 mos. and beyond may need to incorporate additional intervention components.

RECRUITMENT AND RETENTION STRATEGIES FOR RESEARCH WITH RURAL PREGNANT ADOLESCENTS: QUALITATIVE INTERVIEWS WITH WIC PROVIDERS

Abigail Gamble, PhD, MS¹

¹University of Mississippi Medical Center, Jackson, MS

Background and Purpose: Public health stakeholder engagement is integral to developing effective public health interventions. The perspectives of women in the Supplemental Nutritional Program for Women, Infants and Children (WIC) have often been sought when designing WIC-based interventions; however, the perspectives of WIC providers are underrepresented. The purpose of this study was to explore the context of counseling adolescent WIC clients and to identify strategies for recruitment, retention and engagement of adolescents in a WIC-based mobile health (mHealth) antenatal exercise intervention.

Objective: To elucidate strategies tailored for low-income and racial minority adolescent WIC clients in the Mississippi Delta.

Methods: Qualitative interviews were conducted with WIC providers (N=9) serving mostly Black clients across 14 of 18 Mississippi Delta Counties. The Delta is a geographically and culturally distinct rural region in northwest Mississippi where the population is predominantly Black, of low-socioeconomic status, and bears a disproportionate burden of poor health outcomes compared to the rest of the state. The Interview Protocol Refinement Framework was used to develop the interview guide and a qualitative descriptive approach guided analysis.

Results: Four themes emerged: early recruitment and retention through WIC are possible; family involvement and compensation may bolster participation in a WIC-based intervention; transportation and misperceptions about exercise may be barriers to engagement; and a mobile intervention approach may be effective when intervening with adolescents.

Discussion: Four testable hypotheses (*Hyp*) for future study were developed. *Hyp1:* Recruiting adolescents in early pregnancy to participate in a WIC-based exercise intervention study is feasible. *Hyp2:* Supplementing adolescent-focused intervention strategies with an interpersonal parental component supports adolescent engagement and retention. *Hyp3:* Compensating adolescent/parent-dyads with items related to caring for an infant enhances recruitment and retention. *Hyp4:* A mHealth intervention disseminating brief, positive messages fosters participant engagement and retention. WIC providers offered critical insight in understanding the context for a mHealth exercise intervention implemented through WIC. Investigators are currently conducting interviews with adolescents and parents to corroborate these hypotheses and garner further insight.

Conclusion: Formative research to understand the experiences and perspectives of front-line public health practitioners offers valuable insight when planning for an intervention study. Public health entities serving vulnerable populations at high risk for adverse health outcomes may be ideal settings for the recruitment, retention and engagement of populations underrepresented in health research.

DOES RURAL LATINO TECHNOLOGY USE DIFFER ACROSS AGE GROUP? A FORMATIVE STUDY

Belqeis Abatiyow, n/a¹, Rachel Ceballos, PhD¹, Sarah Hohl, MPH, PhD¹, Elizabeth McCarthy, n/a¹¹Fred Hutchinson Cancer Research Center, Seattle, WA

Introduction: The use of mobile health (mHealth) interventions as a strategy to improve population health has grown considerably as access to smartphones and internet access has become more ubiquitous. mHealth interventions may be especially relevant for those living in rural areas where there are geographic barriers to health care access. Furthermore, the cultural appropriateness of mHealth interventions for Latinos—the fastest growing population in the U.S.—has not been widely studied. Thus, this concurrent mixed methods study assessed how rural-dwelling Latinos engage with technology regarding health and determine if and how engagement differs by age group.

Methods: We administered a survey of 31 demographic and technology engagement questions and conducted one-on-one semi-structured interviews in Latinos living in a primarily agricultural region of Washington State. We calculated descriptive statistics to describe differences in engagement across four age categories: 18-29, 30-39, 40-49, and >50. Transcribed interviews were uploaded into Atlas.ti. Two coders applied a content analysis approach to identify emergent themes across and within age groups.

Results: Thirty participants completed a survey and interview. Participants ranged between 18-80 (mean=43.5), were mostly female (86.7%), and averaged 11 years of formal education. Compared to the 30-39 and >50 age groups, a higher proportion of participants 18-29 and 40-49 reported weekly access to a computer, and 100% of participants reported at least weekly internet access. Across all age categories, a greater proportion of participants reported looking for health information using their smartphone compared to using a computer. Participants aged 40-49 demonstrated the lowest proportion of those who download apps to improve their health and the highest proportion of those who used social network applications. In qualitative interviews, participants of all ages said they used on-line technology to become more educated about health behavior change; they preferred video technology and private messaging over internet searches, text messages, or discussion boards. Participants tended to conduct internet searches about complementary therapies for cancer and approaches for prevention and management of chronic disease. Participants (>40) described searching for health information for themselves, whereas participants aged 18-39 reported primarily searching for relatives.

Conclusion: The vast majority of rural Latinos in Washington State reported regular access to the internet, primarily via smartphone. Differences between age groups was observed in terms of how participants used the information they obtained via technology, but not necessarily how they accessed that information. These data can be used to inform mHealth interventions to improve health outcomes among this underserved community.

RESULTS FROM A RANDOMIZED CONTROLLED TRIAL ON TWO-WAY SMS TEXT MESSAGING BETWEEN NURSE CARE MANAGERS AND PATIENTS

Stephanie Finneran, PhD¹, Kristin McCall-Kiley, MSW, MASD¹, Katrina Romagnoli, PhD¹, Ellen Beckjord, PhD, MPH¹¹UPMC Health Plan, Pittsburgh, PA

Most Americans not only send and receive text messages, but text messaging has been the most common form of communication for over a decade (Gallup, 2014). However, these communication trends have presented challenges within health-care systems that must comply with privacy and compliance regulations such as HIPAA. At UPMC Health Plan, we conducted surveys with 242 clinical staff in 2017 to assess texting behavior. These data revealed that our practice-based nurse care managers (PBCMs)—who are part of the PCMH model of care and provide care coordination and case management services—were often sending and/or receiving text messages with members. This research further revealed clinical staff had a strong desire for more education and guidance regarding texting with members. Based on these initial findings, we conducted a Randomized Controlled Trial (RCT) in 2018 to understand the feasibility and efficiency of text messaging between PBCMs and members. PBCMs were randomly assigned to the experimental group, in which they were encouraged to text with members and provided with training and materials prepared in collaboration with our compliance team, or to a control group where they were instructed to continue business as usual. In total, we had 51 PBCMs complete at least one of the three biweekly surveys over the 6-week pilot period. Interestingly, we found no significant difference between the percentage of PBCMs who texted at least once with a member, in which 59% of the experimental and 46% of the control group reported one or more instances texting with a member, $\chi^2(1, 51) = .9, p = .4$. Those in the experimental group sent a marginally higher average of texts per week ($M = 3.1, SD = 2.3$) compared the control group ($M = 1.5, SD = 1.4$) average texts per week, $F(1, 18) = 3.58, p = .07$. Further, PBCMs were texting twice as many members in the experimental group ($M = 1.3, SD = .8$) compared to the control group ($M = .6, SD = .4$), $F(1, 18) = 2.9, p < .05$. We conducted a qualitative analysis of open-ended response items related to PBCMs experiences with texting and identified various themes, such as improved work efficiency and reaching members who would otherwise be lost contacts. These pilot findings have helped inform new guidelines and training which are now being deployed across various clinical staff in conjunction with our privacy and training teams. Further implications and future research will be discussed.

10:30 AM–11:30 AM

A MICRO-RANDOMIZED TRIAL OF JUST-IN-TIME ADAPTIVE INTERVENTION MESSAGES NUDGING WEIGHT-RELATED BEHAVIORS IN YOUNG ADULTS

Carmina G. Valle, PhD, MPH¹, Brooke T. Nezami, PhD, MA¹, Karen E. Hatley, MPH², Julianne M. Power, MS¹, Deborah F. Tate, PhD³¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²UNC Chapel Hill, Chapel Hill, NC; ³University of North Carolina, Chapel Hill, NC

While digital tools enable the design of just-in-time adaptive interventions, there is limited evidence guiding the content of intervention messages. The current study tested the efficacy of just-in-time intervention message options on daily weighing, activity, and dietary behaviors.

We recruited young adults to participate in a 12-week intervention using the Nudge mobile app, which included weekly lessons and tailored feedback, self-monitoring, and in-app intervention messages. Participants received a wireless scale, activity tracker, and tracked “red” foods (high-calorie, high-fat foods) in the app. Participants had 3 goals: weigh daily, a daily active minutes (AM) goal that gradually increased if met, and a daily red food (RF) limit. At 4 daily decision points, participants were micro-randomized to receive or not receive 1 of 7 types of intervention messages targeting specific behavior change techniques (BCTs). Each intervention option had unique decision rules for availability. We evaluated the effect of receiving and viewing messages on daily achievement of weighing, AM goals, staying at/below RF limit, total AM, and total RFs consumed (GEE, controlling for availability and accounting for repeated within-person measurements).

Participants were 52 young adults ($M_{age} = 29.5 \pm 3.8$ years; $M_{BMI} = 31.9 \pm 4.3$ kg/m², 79% female, 35% minority). Out of 84 total days, participants on average weighed 66.7 ± 18.2 days, tracked AM on 68.7 ± 16.3 days and RFs on 54.8 ± 23.0 days. Of 6182 total messages delivered, 4112 (66.5%) were viewed. On average, participants viewed 67.5% of messages received ($M_{received} = 118.9 \pm 19.0$, $M_{viewed} = 79.1 \pm 28.7$). Receiving and viewing any message type (vs. randomized to not receive one) was associated with: increased likelihood of weighing the same day ($B = 0.40$, 95% CI: 0.12, 0.68) and staying at/below the RF limit ($B = 0.26$, 95% CI: 0.12, 0.41), 4.54 more daily AM (95% CI: 2.22, 6.88), and fewer RFs consumed ($B = -0.16$, 95% CI: -0.30, -0.04). When exploring outcomes by message type, achievement of AM goals was influenced by messages about past success, implementation intentions, and goal progress feedback, while RF consumption and tracking was influenced by messages regarding social comparison, past success, goal progress feedback, and tracking reminders ($ps < .03$). Viewing messages on outcome feedback and reinforcements was not associated with behavior changes. The effects of receiving and viewing intervention messages on behavior changes did not dissipate over time. Total message views were associated with weight loss after 12 weeks ($n = 50$; $B = -0.043$, $p = .01$).

Viewing BCT-targeted messages in an app that nudged achievement of daily weight-related goals effectively promoted behavior changes. Future studies should identify ways to increase message views, compare the effects of various message types on behavior change progress, and examine moderators of message effects.

LOOK BEFORE YOU LEAP: IS AN MHEALTH INTERVENTION TO INCREASE IRON FOLIC ACID SUPPLEMENT DEMAND AND USE IN RURAL INDIA FEASIBLE?

Ichhya Pant, MPH, DrPH(C)¹, Rajiv N. Rimal, PhD², Hagere Yilma, MPH³, Gopal Krushna Bhoi, Master in Social Work (MSW)⁴¹GWU School of Public Health, Arlington, VA; ²Johns Hopkins University, Baltimore, MD; ³The George Washington University, Washington, DC; ⁴DCOR Consulting, Bhubaneswar, Orissa, India

Background: Anemia is endemic among women of reproductive age (WRA) in India and Odisha with approximately half of all women impacted. The RANI project aims to increase iron folic acid use among WRAs in Angul, Odisha with mobile phone messages along with several other social and behavioral strategies. However, India has one of the widest digital gender divide with 67% of men owning mobile phones in comparison to just 33% of women.

Objectives: As such, we 1) assessed whether this nationally prevalent digital gender divide manifests regionally in Odisha as well, and 2) explored the feasibility of implementing an mHealth intervention.

Methods: We analyzed formative data from 2018 where a random sampling method was utilized to collect data on mobile phone use from 30 WRAs (15–49 years old), 30 males, and 30 mother(s)-in-law (MIL). Descriptive and Analysis of Variance (ANOVA) were conducted to assess differences among group means in mobile phone use. A step-wise multi-variate regression was conducted to identify predictors of phone use. Lastly, we conducted a literature review focusing on medication adherence mHealth interventions conducted in low-resource settings.

Results: MILs had significantly lower levels of phone use ($F = 31.40$, $p < 0.001$) in comparison to WRAs and males. Older females were significantly less likely ($\beta = -0.67$, $p < 0.05$) to use their phones regularly than older males. In contrast, being a member of Self-Help Groups was a significant predictor ($\beta = 0.22$, $p < 0.05$) of using phones more regularly. The literature review identified digital illiteracy, restrictive gender norms, illiteracy, geographical location, income, and network coverage as additional barriers that may impact the feasibility of our proposed mHealth intervention.

Conclusions: Informed by these findings, we decided to continue exploring the feasibility of an mHealth intervention by collecting and analyzing additional data. Our findings highlight the importance of looking before you leap when planning digital interventions in low-resource settings.

CHARACTERIZING USAGE OF A WEB-BASED TOOL FOR PARENTS OF LOW-INCOME MINORITY PREADOLESCENTS AT-RISK FOR CHILDHOOD OBESITY

Katrina F. Mateo, MPH, PhD(c)¹, Katarzyna Wyka, PhD², May May Leung, PhD, RDN³¹Hunter College (CUNY) / CUNY Graduate School of Public Health and Health Policy, New York, NY; ²CUNY Graduate School of Public Health and Health Policy, New York, NY; ³Hunter College (CUNY), New York, NY

Background: Childhood obesity research highlights the role of parents as a key support mechanism in improving child dietary outcomes. Web-based/mHealth interventions may be an engaging approach to promote positive dietary-related behaviors among parents of at-risk youth. *Intervention INC* is an intervention that includes access to weekly online parent newsletters to support healthy feeding practices, as well as an interactive web-based child nutrition comic aimed at improving dietary behaviors among urban Black/African American (AA) and Latino preadolescents. In addition to assessing key outcome measures, it is critical to analyze usage of these technology-optimized interventions to contextualize its adoption and impact on behaviors. As part of a pilot two-group randomized study, we aimed to characterize parent usage of *Intervention INC* by analyzing user log data collected over a 6-week intervention period.

Methods: Parents/guardians (n=45) of Black/AA and Latino children ages 9–12 were randomized to receive *Intervention INC* (online newsletters with healthy feeding tips, printable recipes, and links to healthy product coupons and community events, plus access to child comic). User log data was generated via a custom-built platform that captured every action (“click”) by participants including unique URLs and click date/time. As a key preparatory step, data transformation grouped URLs into “meaningful labels” relevant for usage analysis of key content. Participant-level click frequencies by intervention week/day were calculated to assess total usage, proportion of participants adherent to weekly use, patterns of individual use, and then define user types. Participant interviews post-intervention were also analyzed to confirm user types.

Results: Participant characteristics included: mean age 40.1±7.7 years, 96% female, 47% Black/AA, 40% Hispanic/Latino, 27% with less than a high school education; and 71% with a household income < \$40,000. Total weekly usage by all participants was highest in Week 3 (1900 clicks) and lowest in Week 5 (789 clicks). Total daily usage was highest on Day 1 of each week when an email/text reminder notification was sent to participants. Adherence to weekly use of the tool decreased after Week 1, with 100% viewing the newsletter and 91% the comic in Week 1, but an average of 44% returning to view newsletter content and 32% returning to view comic content over Weeks 2–6. Few participants accessed the weekly coupon, event link, or “print recipe” option (weekly average of 30%, 20% and 1% of participants, respectively). Based on usage patterns and interview data, different user types (i.e. “early dropouts,” “occasional-users,” regular-users) were identified.

Conclusions: Usage analysis of *Intervention INC* identified patterns of use by different user types. Insights will inform analysis of key outcome data and future enhancements to the intervention.

10:30 AM–11:30 AM

#DOUBLETAP4HEALTH: PILOT OF A COMMUNITY-BASED SOCIAL MEDIA HEALTH PROMOTION PROGRAM FOR ADOLESCENTS

Patrece Joseph, M.A.¹, Sasha A. Fleary, PhD²¹Child Health Equity Research Lab, Medford, MA; ²Tufts University, Medford, MA

Background: Multiple interventions target adolescents’ obesity-related preventive health behaviors (PHB) via psychoeducation, group exercise classes, targeting parents, and peer-based teaching. A growing catalog of interventions also use media (i.e., gaming and social media) to engage adolescents in obesity-related behavior change. However, the relationship between media and obesity is complex. Media use encourages engagement in obesity-related risk behaviors (e.g., high consumption of junk food) and is an obesity-related behavior itself (i.e., most media use is sedentary activity). Conversely, adolescents rely on media to acquire and share information about health behaviors. Targeting media health literacy (MHL; skills to recognize, critique, and apply media-delivered health information to decision-making) may provide adolescents with skills to (1) counter negative media messages and false information and; (2) apply health knowledge to engaging in obesity-related PHB.

Method: Five adolescents ($M_{age} = 14.40$, $SD = .89$, 100% Black or African American, 60% boys) participated in the pilot intervention, which included five sessions on MHL and behavioral strategies for engaging in obesity-related PHB. To practice MHL skills adolescents executed a health promotion campaign on Instagram. Measures were collected at pre- and post-test and included stage of change for, and engagement in obesity-related PHB (sleep, physical activity, health eating, and media use), health knowledge, and media literacy. Effect sizes were calculated.

Results: Due to the small sample size, only effect sizes were computed. Between pre- and post-test adolescents’ stage of change for fruits and vegetables intake ($d = .43$), junk foods intake ($d = .22$), sleep ($d = .63$), and sedentary activity ($d = .56$) improved, while their physical activity stage of change ($d = .40$) declined. Adolescents’ physical activity ($d = .20$), sedentary activity ($d = .45$), sleep ($d = .16$), sugar-sweetened beverages intake ($d = .12$), and junk food intake ($d = .25$) decreased from pre- to post-test, and their fruits and vegetables intake marginally increased ($d = .004$). Compared to pre-test, post-test health knowledge scores were lower ($d = .43$) but media literacy scores increased ($d = .21$). Overall adolescents had positive views of the intervention: they liked 80% of activities presented.

Discussion: These pilot results highlight the intervention’s potential to improve adolescents’ engagement in obesity-related PHB by targeting MHL skills. However, the physical activity and health knowledge content should be modified using feedback from participants prior to further intervention testing. Future studies should assess the effect of the intervention using an adequately-powered randomized controlled trial and employ social network methodology to examine the effects of adolescents’ social media campaign on their peers/friends’ behaviors.

ORGANIZATIONAL READINESS FOR CHANGE AS A PREDICTOR OF MEASUREMENT FIDELITY WITHIN LOW-RESOURCE COMMUNITY PROGRAMS

Cristina Gago, MPH, CHES¹, Jacob P. Beckerman-Hsu, MPH², Adam Gavarkovs, ScM, MA³, Xinting Yu, MD PhD⁴, Alyssa Aftosmes-Tobio, MPH⁵, Evelin Garcia, BA⁵, Kindra Lansburg, MPH⁶, Chimamaka Nnodim-Amadi, BA⁷, Janine Jurkowski, PhD, MPH⁸, Kirsten Davison, PhD⁵

¹Harvard University, Boston, MA; ²Harvard TH Chan School of Public Health, Boston, MA; ³Harvard TH Chan School of Public Health, Toronto, ON, Canada; ⁴Brigham and Women's Hospital, Brookline, MA; ⁵Boston College, Chestnut Hill, MA; ⁶ABCD Head Start, Boston, MA; ⁷Community Action Agency of Somerville, Inc., Somerville, MA; ⁸University at Albany School of Public Health, Rensselaer, NY

Introduction: Organizational readiness for change (ORC) is a commitment shared by organizational members to embrace program-level change. While ORC screening is widely implemented in the health service and clinical sectors, it is utilized less frequently in low-resource settings such as community-based programs. Second, while it is recognized that ORC affects program implementation, its impact on measurement fidelity (e.g., the collection of intervention outcome data) has rarely been considered. Focusing on a childhood obesity prevention intervention implemented in 23 Head Start centers, this study examines the relationship between center ORC and the percentage of eligible families completing the annual family enrollment survey, which integrated study outcomes. We predicted that families from centers with low ORC would exhibit lower survey completion rates.

Methods: Head Start staff from intervention centers completed a brief, adapted measure of ORC prior to intervention implementation ($n = 67$; mean per center = 7; range per center = 1–17). Constructs measured included emotional engagement, role-overload, principal support, change-specific efficacy, and appropriateness. Center-level mean, minimum and maximum ORC scores were calculated. Center-level variation in measurement fidelity, or the percentage of eligible families who completed the annual survey (which integrated outcome evaluation items), was the primary outcome of interest. Multilevel logistic regression was used to examine the center-level variation in ORC scores in relation to center-level measurement fidelity.

Results: Minimum ORC scores significantly predicted center-level variation in measurement fidelity, with lower ORC scores linked with lower survey completion rates (OR = 0.04, SE = 1.05, $p = 0.002$). However, this relationship was not identified for mean (OR = 0.27, SE = 1.88, $P = 0.49$) or maximum (OR = 2.60, SE = 0.96, $P = 0.32$) ORC scores.

Conclusions: Results suggest that the “weakest link” (i.e., the lowest individual-level staff readiness score) in a community implementation partner is most predictive of measurement fidelity at the program-level. Identifying and supporting individuals within partner organizations with low ORC may improve the validity of the program's evaluation.

BARRIERS TO THE IMPLEMENTATION OF THE REAL MEDIA PROGRAM TO PREVENT SUBSTANCE USE IN THE YOUTH 4-H ORGANIZATION

Hajar Shirley, MS¹, Shannon D. Glenn, BA², Anne E. Ray, PhD, M, Ed¹, Kathryn Greene, PhD³, Michael Hecht, PhD⁴

¹Rutgers University, Piscataway, NJ; ²Rutgers School of Public Health, Middletown, NJ; ³Rutgers University, New Brunswick, NJ; ⁴Real Prevention, Clifton, NJ

Background: REAL media is an e-learning program to prevent youth substance use, grounded in media literacy theory and designed in partnership with and for the 4-H youth organization. Implementation is reliant on active involvement from state and local 4-H leaders during the recruitment phase to successfully enroll youth into the program. Upon enrollment, REAL media allows for self-paced instruction, requiring minimal engagement with 4-H leaders beyond facilitating youth involvement. In a recent RCT to evaluate REAL media, recruitment and implementation challenges were greater than expected which was surprising considering the commitment from the 4-H organization at the outset as well as a program design that required little time on the part of 4-H staff. Accordingly, the objective of this research was to examine barriers to the implementation of REAL media across participating clubs.

Methods: Data were collected from 4-H leaders ($N=31$) who were enrolled in the REAL media project as part of a larger RCT and completed a post implementation. Content analysis and thematic synthesis was used to examine survey responses, using the Consolidated Framework for Implementation Research (CFIR) as a theoretical framework.

Findings: Results indicated that leaders experienced inner setting barriers (e.g. difficulty obtaining parental consent on youth participation and recruiting youth) as well as technical challenges.

Conclusion: This research suggests that technology characteristics as well as organizational (e.g. communication across the organization about the program) and environmental (e.g. leadership engagement) alignment with barriers resulted in unanticipated implementation challenges among 4-H leaders. This has important implications for implementation of e-learning based prevention curricula with youth populations, and suggests that despite advantages of leveraging technology, in-person facilitation may be beneficial, and ongoing data collection to monitor implementation success is important for improving future efforts.

ASSOCIATIONS BETWEEN PROGRAM IMPLEMENTATION AND MEMBER HEALTH BEHAVIORS IN THE FAITH, ACTIVITY, AND NUTRITION PROGRAM

Bernhart John, MPH, PhD¹, Sara Wilcox, PhD¹, Ruth Saunders, Ph.D.¹, Patricia A. Sharpe, PhD, MPH¹, Jessica Stucker, MSW¹, Brent Hutto, n/a²¹University of South Carolina, Columbia, SC; ²USC Arnold School of Public Health, Columbia, SC

Introduction: Health programs delivered through faith-based partnerships have great potential for reaching underserved populations and leading to positive health behavior changes. The Faith, Activity, & Nutrition (FAN) Program helps churches make policy, systems, and environmental changes for physical activity (PA) and healthy eating (HE) through four program components for PA and HE: (1) offering opportunities and programs, (2) setting guidelines (policies), (3) enlisting pastor support, and (4) sharing messages. To facilitate scaling up programs, more work is needed to understand relationships between implementation and program outcomes.

Purpose: This study examined relationships between member perceptions of program implementation and member PA and HE behaviors and PA and HE self-efficacy.

Methods: Church members (n=811) attending intervention churches participating in phase 1 of the FAN dissemination and implementation study, a group randomized control trial, completed questionnaires 9-12 months after implementation. Members answered questions regarding perceived implementation of three program components of FAN (opportunities, pastor support of program, messages), and PA and HE behaviors and self-efficacy. Mixed linear and logistic models were used to assess relationships between member perceptions of implementation and church member outcomes, controlling for member age, gender, and education, while also accounting for member clustering within the church.

Results: At follow-up, member perceptions of implementation of HE opportunities, but not messages or pastor support, was positively associated with HE self-efficacy ($F=17.16$, $p < 0.001$), cups per day of fruit and vegetables ($F=23.74$, $p < 0.0001$) and meeting fruit and vegetable recommendations (≥ 5 cups/day; $OR = 1.63$, 95% $CI = 1.16, 2.30$). Neither PA behaviors nor self-efficacy were associated with PA opportunities, messages, or pastor support.

Discussion: Member perceptions of fruits and vegetables being offered at church, but not perceptions of pastor support or promotional messages, were associated with eating fruits and vegetables, meeting fruit and vegetable recommendations, and healthy eating self-efficacy. This suggests providing opportunities may be an important strategy for promoting healthy eating in faith-based settings.

10:30 AM-11:30 AM

IMPROVING CLINICAL USE OF PREBIOTICS AND PROBIOTICS IN NEONATAL AND INFANT NUTRITION THROUGH CONTINUING EDUCATION ACTIVITIES

James D. Morgante, PhD¹, Angie Ladas, n/a¹, Adelfo San Valentin, n/a¹, Krista Sierra, n/a¹¹Haymarket Medical Education, Paramus, NJ

Gut microbiota is recognized as a virtual organ with effects extending past the gastrointestinal tract. Microbial colonization of the infant's gut begins prenatally, rapidly proliferating throughout infancy. Initial colonization is essential as the types of organisms with which the gut is colonized can have a profound effect on overall health and disease prevention.

Breastfeeding persists as the standard for infant nutrition, exclusively recommended for the first six months of life. In typically developing, full-term, breast-fed infants, the intestine is rapidly colonized with a variety of beneficial probiotic organisms, especially *Bifidobacterium* and *Lactobacillus*. Comparatively, preterm infants' intestine tend to be colonized by other types of bacteria, including coliforms, enterococci, and other *Bacteroides* species. Lower prevalence of *Bifidobacterium* and *Lactobacillus* in preterm infants has prompted the use of probiotics in the prevention of necrotizing enterocolitis (NEC).

Breast milk is central to addressing nutritional needs in the neonatal intensive care unit (NICU), however, administration of probiotics as a method of preventing NEC and other adverse neonatal outcomes is clinically supported with a beneficial risk-benefit balance. Moreover, many mothers do not breast-feed for as long as recommended or at all, and instead rely on formulas for nutrition, including in the NICU setting when one's own or donor milk is not available or feasible to provide. Because of the pace of research and product development, clinicians may not be familiar with the proliferation of infant feeding and supplementation choices.

To address this clinical gap, we developed, implemented, and evaluated the effectiveness of four instructional webinars, all informed by relevant professional association guidelines on the use of prebiotics and probiotics in neonatal and infant nutrition. Collectively, they aimed to explain the: (1) role of the microbiome and gut microbiota, (2) current understanding of the pathogenesis of NEC and implications for prevention and treatment, and (3) use of prebiotics and probiotics in the NICU.

Participating clinicians ($n = 471$) mostly identified as nurses or physicians with pediatrics and primary care specialties. To assess education effectiveness, intent-to-change questions were asked after webinars, regarding past and planned use of clinical practice strategies. Paired-sample t-tests compared use, revealing significant increases in planned practice for assessed strategies in prebiotics and probiotics in neonatal and infant nutrition (past: $M = 3.10$ (Sometimes), $SD = 1.023$; planned: $M = 3.51$ (Very Often), $SD = 0.980$; $t(470) = -9.948$, $p < .001$). Results suggest the webinars positively affected clinicians' perceived intent to incorporate into practice new understandings of the role of the gut microbiome on neonatal growth and development.

DISCREPANCIES BETWEEN FAMILY HEALTH HISTORIES COLLECTED BY A VIRTUAL VERSUS HUMAN GENETIC COUNSELOR: COMPUTER OR HUMAN ERROR?

Catharine Wang, PhD, MSc¹, Michelle Trevino-Talbot, MPH², Michael R. Winter, MPH¹, Howard J. Cabral, PhD, MPH¹, Tricia Norkunas Cunningham, MPH, MS¹, Michael Paasche-Orlow, MD, MA, MPH³, Timothy Bickmore, PhD⁴, Deborah J. Bowen, Professor⁵

¹Boston University School of Public Health, Boston, MA; ²Boston University, Boston, MA; ³General Internal Medicine, Boston University School of Medicine, Boston, MA; ⁴Northeastern University, Boston, MA; ⁵University of Washington, Seattle, WA

Although digital tools are readily available to facilitate the collection of family health histories (Welch et al, 2018), few have undergone systematic evaluations to determine the accuracy of the family histories that are collected, particularly among underserved patient populations. Family histories collected by genetic counselors are often deemed as the “gold standard” for accuracy, yet little is known about the potential sources of error that may occur in family history documentation regardless of how it is collected. The present study compared 135 family health histories collected by both a virtual counselor and a human genetic counselor as part of a randomized trial in order to evaluate the following: 1) type of discrepancies that exist, 2) variation of discrepancies across health conditions, and 3) source of discrepancies (error). Overall, family histories collected by the virtual counselor were in agreement with histories collected by the human genetic counselor (weighted kappas range: .58 - .71 for general health conditions among first degree relatives), however, discrepancy patterns were noted across conditions. Several conditions including addiction, alcoholism, heart disease, and hypertension were more frequently documented by the virtual counselor than the genetic counselor. The opposite was true for mental health conditions and diabetes, which were more frequently documented by the genetic counselor. An audit of genetic counselor (GC) interviews (20% selected) identified several sources of error which might explain the discrepancies noted: 1) GC omission (didn't ask about heart disease or hypertension), 2) patient nondisclosure (GC asked but patient didn't disclose addiction/alcoholism) and 3) GC failed to record condition after patient disclosed. Comparing across collection methods revealed possible program design issues in how the virtual counselor inquired about a condition that may have contributed to some discrepancies. Study findings highlight the potential value of using virtual counselors to collect family history information that might be inconsistently ascertained by a human or potentially stigmatizing and embarrassing to disclose. These results can inform the development and refinement of digital tools that may serve as a critical supplement in the collection of family health histories in clinical practice.

RAISING AWARENESS OF SUGAR CONSUMPTION AND CHRONIC DISEASE RISK: AN ECOLOGICAL APPROACH TO HEALTH COMMUNICATION

Kimberly Arellano Carmona, MPH¹, Deepti Chittamuru, PhD¹, A. Susana Ramirez, PhD, MPH¹

¹University of California, Merced, Merced, CA

Background: Sugar-sweetened beverages (SSBs) are the largest source of added sugars in the Latino diet, contributing to high rates of chronic disease and cancer risk. Latinos' excessive SSB consumption is the result of targeting by the soda industry. Similarities to sugar and tobacco have been made. Tobacco behavior change was a result of multilevel interventions supported by strong public policies. A critical first step was raising awareness of the harms of smoking. Similarly, efforts aimed at reducing SSB overconsumption are gaining momentum as SSBs are increasingly recognized as a chronic disease risk factor. Thus, raising awareness of the association between SSBs and chronic disease among Latinos may help reduce its consumption.

Aim: To examine the effect of culturally relevant messages on knowledge about health problems caused by excessive SSB consumption among young adult Latinas (N=433, aged 18-29) using a pre and posttest survey design.

Methods: Participants viewed persuasive online messages about individual harms of SSB. The main outcome was knowledge of the association between SSB consumption and a variety of chronic diseases. We hypothesized that messages would increase knowledge about the negative health consequences explicitly mentioned in the videos.

Results: At baseline, participants had high levels of knowledge regarding SSB-related diseases. However, less than half of participants reported an association between SSB consumption and cancer – highlighting that unlike tobacco, individuals may not be fully aware of the link between sugar and cancer. Because of these ceiling effects, a Chi-square test was conducted to compare the number of participants reporting that SSBs can cause cancer before and after watching online messages. Participants reported a significant increase in knowledge about the association of SSBs and cancer (from 0.49 to 0.61) after viewing messages, $\chi^2(1, N = 431) = 190.53, p < 0.001$.

Conclusion: More participants reported an association between SSB consumption and cancer after watching messages, even though cancer was never explicitly mentioned. This points to a “negative halo effect” that might have caused an association between SSB consumption and cancer among participants. Targeting SSB consumption behaviors through messages that are culturally relevant to Latinos may help to improve understanding of the health harms associated with SSB consumption among this high-risk group, particularly cancer.

PSYCHOMETRIC EVALUATION OF THE PERSONAL FEELINGS
QUESTIONNAIRE-2 (PFQ-2) SHAME SUBSCALE AMONG FEMALE
SEX WORKERS IN MEXICO

Cristina Espinosa da Silva, MPH¹, Heather Pines, PhD, MPH¹, Thomas Patterson, PhD¹, Shirley Semple, PhD¹, Alicia Harvey-Vera, PhD, MPH², Steffanie Strathdee, PhD¹, Gustavo Martinez, MD³, Eileen Pitpitan, PhD⁴, Laramie R. Smith, PhD¹

¹University of California, San Diego, La Jolla, CA; ²Universidad Xochicalco, La Jolla, CA; ³Federacion Mexicana de Asociaciones Privadas, La Jolla, CA; ⁴San Diego State University, La Jolla, CA

Background: The Personal Feelings Questionnaire-2 (PFQ-2) was developed as a measure of shame among college students but has not been validated within stigmatized populations for whom shame may increase risk for HIV and other sexually transmitted infections. We examined the psychometric properties of the Spanish-translated 10-item PFQ-2 shame subscale in a sample of female sex workers (FSWs) in two U.S.-Mexico border cities.

Methods: From 2016-2017, 602 HIV-negative FSWs were recruited through time-location sampling in Tijuana (n=302) and Ciudad Juarez (n=300) to participate in an efficacy trial evaluating a 24-month theory-based text messaging behavior change maintenance intervention. Interviewer-administered surveys collected information on shame (10-item PFQ-2 subscale with 5-point Likert-type responses), socio-demographics, and psychosocial factors. Exploratory factor analysis (EFA), item performance, internal consistency, differential item functioning (DIF) by city, and convergent validity were assessed for the shame subscale.

Results: One misfit item was removed during EFA due to a low factor loading (< 0.30). The option characteristic curves for the 5-point responses indicated that item performance could be improved by collapsing to 3-point responses. EFA on the remaining 9-item subscale with 3-point responses supported a single construct underlying shame in this sample and indicated good internal consistency (McDonald's Hierarchical Omega=0.69; Total Omega=0.88). Mean shame scores were 6.9 (SD=4.2) and 4.4 (SD=3.3) in Tijuana and Ciudad Juarez (range= 0-27), respectively. Analysis of DIF indicated that FSWs in Tijuana and Ciudad Juarez differed systematically in their responses to four items, although the opposing directions of the item-level differences resulted in a negligible effect on overall scores. Correlations between the 9-item shame subscale and the PFQ-2 guilt subscale ($r = 0.79, p < 0.01$), Beck Depression Inventory ($r = 0.69, p < 0.01$), and Pearlin Emotional Support scale ($r = -0.28, p < 0.01$) were in the expected directions and demonstrated convergent validity.

Conclusions: The Spanish-translated 9-item PFQ-2 shame subscale showed good reliability and convergent validity in a sample of FSWs in Mexico, suggesting that it may be a useful measure of shame among FSWs and should be explored in other stigmatized populations. The significant DIF detected by city indicates that future analyses using the 9-item shame subscale should consider potential regional differential functioning.

PERCEIVED DISCRIMINATION MEDIATES THE IMPACT OF COM-
BINED VULNERABILITY ON PHYSICAL COMORBIDITY AND LIFE
SATISFACTION

Juliette McClendon, PhD¹, Utibe R. Essien, MD, MPH², Ada O. Youk, PhD³, Said Ibrahim, MD, MPH, MBA⁴, Leslie R. Hausmann, PhD⁵

¹National Center for PTSD, VA Boston Healthcare System, Boston, MA; ²University of Pittsburgh School of Medicine, Pittsburgh, PA; ³University of Pittsburgh, Graduate School of Public Health, Pittsburgh, PA; ⁴Weill Cornell Medicine, New York, NY; ⁵University of Pittsburgh, Pittsburgh, PA

Although discrimination contributes to racial health disparities and is associated with worse physical health and mental well-being, few studies consider how race intersects with other vulnerable statuses to impact discrimination and health outcomes. We examined the mediating role of perceived discrimination in explaining the impact of combined vulnerability statuses on physical illness comorbidity and life satisfaction using baseline data from 517 older adult Veterans (48% white, 52% African American) participating in a randomized control trial of a behavioral intervention for osteoarthritis pain.

Measures included the Everyday Discrimination Scale, Charlson (Physical) Comorbidity Index (PCI), and the Satisfaction With Life Scale (SWLS). Demographic variables examined as potential vulnerabilities included self-reported African American race, female gender, annual income < \$25K, high school education or less, unemployment due to disability, and body mass index (BMI) based on medical records. Linear regression analyses and Sobel tests were used to test direct and indirect effects of combined vulnerabilities on PCI and SWLS.

Of the potential vulnerability statuses examined, discrimination was significantly associated with African American race ($B = .23, p < .001$), income less than \$25K ($B = .21, p = .001$), and disability ($B = .24, p < .001$), as well as the interaction between African American race and female gender. We thus created a vulnerability index comprising race, gender, disability and income. Approximately a third of participants had 0 (27%), 1 (33%) or 2 (27%) vulnerabilities; those with 3 or 4 were combined for analyses (13%).

In regression models controlling for age, BMI and site, a greater number of vulnerabilities was associated with more discrimination ($B = .13, p < .001$). Greater vulnerability had a significant total effect on higher PCI ($B = .15, p = .02$) and lower SWLS ($B = -1.27, p < .001$). More discrimination mediated the impact of greater vulnerability on higher PCI ($Z = 2.37, p = .02$) and lower SWLS ($Z = -.27, p < .001$). When discrimination was accounted for, the direct effect of greater vulnerability on higher PCI was not significant ($B = .11, p = .06$), whereas it remained significant for lower SWLS ($B = -1.00, p < .001$). Discrimination explained 22.0% and 21.6% of variance in the PCI and SWLS, respectively.

Perceived discrimination mediates the impact of having a greater number of vulnerabilities on higher physical comorbidity and lower life satisfaction. Discrimination and its psychosocial sequelae are important targets for reducing health disparities.

AVOIDANCE OF CARE IN LATINX MIGRANT FARM WORKERS

Sara Reyes, n/a¹, Arthur “Trey” Andrews III, n/a¹¹University of Nebraska-Lincoln, Lincoln, NE

More than two decades of research have persistently demonstrated disparities in access to healthcare among Latinx populations (Alcalá, H.E. et al., 2016). This may be particularly true of immigrant Latinxs who work in high-risk, low-wage occupations, including in migrant farmwork. Latinx migrant farmworkers have similarly experienced drastic disparities in care access with a variety of proposed mechanisms, including low wages, lack of insurance, documentation status and geographical location/mobility (Vargas Bustamante, A., et al., 2012). The current study sought to identify stressors that predict avoidance of care in migrant farm workers. Participants were 236 Latinx migrant farm workers in the rural Midwest who completed an interview focusing on stress, health, and working conditions. The interview included items on healthcare utilization (having a routine place to seek care in the past year and avoidance of care due to cost), insurance status, poverty, fears related to documentation status, discrimination, mental health and demographics. Logistic regression models examined predictors of avoiding care due to cost and having a routine place to access care. Discrimination ($\alpha=.16$, $aOR=1.05$, $p=.044$) and legal status fears ($\alpha=.23$, $aOR=1.19$, $p=.004$), but not insurance status, US nativity, or language ($ps>.05$) were associated with avoidance of healthcare services due to cost. Only insurance status ($\alpha=.40$, $aOR=6.80$, $p<.001$) was significantly associated with having a routine place to seek care. Overall, results suggest different patterns for predictors of avoidance of care due to cost when compared with having a routine place to seek care. Specifically, factors such as discrimination and legal status fears were associated with greater odds of avoiding care due to cost, while the direct cost-related variables (e.g., insurance, poverty) were not. Results for having a routine place for care suggested an opposite pattern, with only insurance status as a significant predictor.

COMMUNITY-BASED HEALTH NEEDS ASSESSMENT OF AN INDIGENOUS COMMUNITY IN GUATEMALA

Sara Gómez-Trillos, BA¹, Alejandra Hurtado de Mendoza, Ph.D.¹, Francisco Cartujano Barrera, MD², Evelyn Arana-Chicas, DrPH², Silvia Angélica Xinico Aju, MA³, Marc Rosenthal, MD, DMD⁴, Valerie Lundy, n/a⁵, Dejana Braithwaite, Ph.D.¹, Ana Paula Cupertino, Ph.D.²

¹Lombardi Comprehensive Cancer Center, Georgetown University Medical Center, Washington, DC; ²John Theurer Cancer Center, Hackensack Meridian Health, Hackensack, NJ; ³Alianza Nacional de Organizaciones de Mujeres Indígenas por la Salud Reproductiva, la Nutrición y Educación (ALIANMISAR), Observatorio en Salud Sexual y Reproductiva (OSAR), Chimaltenango, N/A, Solola, Guatemala; ⁴Susquehanna Oral and Facial Surgery and Dental Implant Center, Williamsport, PA; ⁵Susquehanna Oral and Facial Surgery and Dental Implant Center, Williamsport, PA

Health disparities exist in rural vs urban areas in low-middle income countries. In Guatemala, health disparities are even more complex given the large underserved and geographically isolated indigenous populations.

Objective: To conduct a community-based health needs assessment in an indigenous rural community in Lake Atitlán, Guatemala.

Methods: Working with a Community Advisory Group that consisted of key local stakeholders, we designed and coordinated the development of a four day needs assessment, which included a health survey and dental screening. The health survey collected information about health care access, cancer prevention, lifestyle, and sociodemographic information. In addition, we partnered with a dental team to provide universal dental screenings and access to fluoride.

Results: 247 adults completed the health survey in their preferred language (Spanish or Kaqchikel). Most participants were female (94.30%) and Mayan (95.80%) and the mean age was 43.04 ($SD=18.46$). Most participants reported no access to health insurance (97.50%) and a primary care physician (84.20%). Cancer screening rates were nearly nonexistent for lung (97.7%), colon (96.35%), prostate (85.71%), breast (93.53%), and cervical (83.19%). Most participants reported being physically active (61.70%), nonsmokers (98%), and never consuming alcohol (80.20%). All participants agreed to be contacted for future studies. The dental team provided 360 adult and 937 child oral health screenings, 800 children received fluoride treatment, and 1500 toothbrushes were distributed. They identified around 3016 dental procedures are needed, including filling and extractions.

Conclusions: Lack of healthcare access for this population is outstandingly high. However, protective behaviors are prevalent and may influence the overall health status of the population. We found a large need in oral health and cancer prevention screening. Future studies should focus on building sustainable infrastructures to implement cancer and oral surveillance, prevention, and treatment. Interest in participating in future research studies was high, suggesting the feasibility of continuous community-based research in the region.

UNDERSTANDING THE COPING MECHANISMS OF LATINO PATIENTS WITH ADVANCED CANCER

Carolina Zamore, BA¹, Normarie Torres-Blasco, PhD², Francesca Gany, MD, MS¹, Rosario Costas-Muniz, PhD¹

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Ponce Health Sciences University, Ponce, N/A, Puerto Rico

Background: Latinos are the largest minority group in the U.S., estimated at 59.8 million individuals, a number which is expected to double over the next four decades. Coping with advanced cancer can be challenging and overwhelming, particularly for underserved populations, such as the Latino population in the U.S. However, few studies have focused on the coping mechanisms used by Latinos to cope with cancer.

Objective: This study explores the coping mechanisms Latino patients utilize to cope with their advanced cancer diagnoses.

Methods: Twenty-four semi-structured interviews were conducted with Latino patients with advanced cancer diagnoses, who were recruited from cancer clinics in 1) New York City and 2) Ponce, Puerto Rico. Transcriptions of the interviews were analyzed using open coding thematic analysis, and the main coping trends were categorized utilizing Folkman and Lazarus' Transactional Model of Stress and Coping and Park and Folkman's Meaning-Making Model. Coping mechanisms were classified in accordance with the constructs of these models: 1) Meaning-Based Coping, 2) Emotion-Focused Coping, and 3) Problem-Focused Coping.

Results: In total, 28 coping mechanisms were identified across transcripts. 14 were identified as instances of Meaning-Based Coping (e.g. 'creating purpose', 'choosing attitude', 'optimism/hope'). 10 emerging themes were associated with Emotion-Focused Coping (e.g. 'focusing', 'tranquility', 'relaxation', 'escape/avoidance', 'normalizing', 'acceptance', 'family support', 'keeping occupied', 'engaging in crafts, hobbies and handmade projects' and 'help from others'). 5 were identified as potential factors of Problem-Focused Coping (e.g. 'desire to live/survival', 'educating yourself', 'learn', 'preparing', and 'fighting spirit').

Conclusions: The Transactional Model of Stress and Coping and the Meaning-Making Model as frameworks provide insight on the coping mechanisms used by Latino patients with advanced cancer. The data provides evidence that Latino patients may use meaning-based coping more frequently than emotion-focused and problem-focused coping. Future studies should explore the benefits of incorporating meaning-based coping during psychotherapy to better meet the needs of Latino cancer patients.

EFFECTS OF DRAMA TRAINING ON SOCIO-PSYCHO-BEHAVIORAL WELL-BEING OF DISABLED: A PILOT STUDY

Caitlin K.P. Chan, n/a¹, Derek S.Y. Lum, n/a¹, Rainbow T.H. Ho, PhD, REAT, BC-DMT, AThR, RSMT/E, CGP, CMA²

¹Centre on Behavioral Health, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong

Introduction: Due to physical or cognitive barriers, people with disabilities (PWD) often feel inferior. Such experience not only affects their interpersonal relationships, but also makes them difficult to integrate into society. Drama training can provide an interactive platform for people to learn how to deal with difficulties through mutual communication so as to enhance self-confidence and self-esteem. A drama training programme was provided to facilitate the psychosocial development among PWD. This study aimed to examine the effectiveness of the programme in improving self-esteem, coping strategies and personal well-being of PWD.

Research Design: The mixed-method study recruited 29 PWD from two rehabilitation centres in Hong Kong. Participants were assigned to intervention (n=15) and control group (n=14) after matching on demographics (e.g., IQ level, age, gender and types of disabilities). The intervention group received drama training on a weekly basis, 3 hours per session, for 1.5 years. Participants' coping strategies, self-esteem and personal well-being were assessed before and after the intervention. Repeated-measures ANOVA were conducted to examine the changes of the outcome variables. Individual interviews were also held with each PWD from the intervention group and drama director; while 2 separate focus group interviews were conducted to mentors of the drama training and caseworkers of the rehabilitation centres respectively. Thematic analysis was performed to analyse the interview data.

Results: After the drama training programme, the intervention group displayed a significant decrease in the coping strategies of "self-blame", $F_{(1, 27)} = 4.88$, $p < .05$, partial $\eta^2 = .15$; and a marginal significant decrease in "denial", $F_{(1, 27)} = 3.95$, $p = .06$. Their sense of future security and self-esteem were improved by 51.85% and 5.46% respectively although statistical significance was not reached. The interview findings also reflected that participants' self-confidence, problem-solving skills, emotional well-being, social skills and expressivity were improved.

Conclusions: Despite the small sample size, the findings suggest beneficial effects of the drama training program in improving the self-esteem, coping strategies and personal well-being of the PWD. Through re-enacting the difficult moments in daily life, the participants were able to develop adaptive coping behaviors, thereby enhancing their confidence and psychosocial well-being.

FOSTERING HEALTH AND WELLBEING AMONG LOW-WAGE FOOD SERVICE WORKERS: USING FORMATIVE RESEARCH TO GUIDE INTERVENTION DESIGN

Eve M. Nagler, ScD, MPH¹¹Dana–Farber Cancer Institute, Boston, MA

Background: Low-wage workers are often employed in high-risk jobs characterized by challenging physical demands, job insecurity, repetitive work, and low job decision latitude. These low-wage jobs are especially common in food service, which employs 9.5 million workers in the US. This paper describes the formative research conducted to develop an intervention designed to improve musculoskeletal disorders, worker wellbeing, employee engagement, and turnover intentions among low-wage food service workers. Improving working conditions for these workers can help to build a culture of health and safety and create an environment where workers can thrive.

Methods: Investigators at the Harvard Center for Work, Health & Wellbeing conducted formative research, including non-participant observations in food service sites; 9 semi-structured interviews with district and general managers; and focus groups with front-line workers in 5 cafeterias in Greater Boston using an interview/focus group guide. The guide focused on working conditions that impact worker health and wellbeing and how these conditions could be improved. We used standard analytic methods for analysis of qualitative data collected in the form of texts, including transcripts of the audio-taped interviews using NVivo software. Analyses were guided by a conceptual framework to inform intervention development.

Results: We identified 3 working conditions to target: safety and ergonomics; work intensity; and job enrichment. We also identified essential elements that would enhance intervention implementation: communication infrastructure between managers and workers; leadership commitment, and employee participation in planning and implementing the intervention. We designed a 13-month intervention, addressing each working condition as a module that was delivered sequentially in 5 cafeterias. The intervention operated at two levels: Employee/general manager teams—who identified and brainstormed solutions to address the root causes of working conditions at their site and develop action plans; Coordinating Committee—to engage management and worksite stakeholders in regular communication about the intervention.

Conclusions: The formative research provided a means of engaging workers and managers in identifying working conditions of importance to them in their day-to-day experiences on their jobs. Demonstrating the feasibility and benefits of modified working conditions may contribute to future uptake of these initiatives.

ATTITUDES, BELIEFS, KNOWLEDGE, AND SELF-CARE BEHAVIORS OF AFRICAN AMERICANS: THE DETROIT YOUNG ADULT ASTHMA PROJECT (DYAAP)

Rhonda Dailey, MD¹, Wanda Gibson-Scipio, PhD, FNP-BC, FAANP, ATSF², Jean-Marie Bruzzese, PhD³, Veronica Dinaj Koci, PhD¹, Karen Kolmodin MacDonell, PhD¹

¹Wayne State University, Department of Family Medicine and Public Health Sciences, Detroit, MI; ²Wayne State University, College of Nursing, Detroit, MI; ³Columbia University School of Nursing, New York, NY

Background: Urban African American Emerging Adults (AAEA) suffer disparities in asthma prevalence, morbidity, and mortality compared to Whites, often the result of inadequate asthma management. Contributing factors may be disease-related knowledge, self-care behaviors and beliefs, and experiences in healthcare. Little is known about these factors in AAEA, and understanding them is an essential first step in helping this vulnerable group.

Methods: AAAs (n=85) ages 18–29 with moderate to severe persistent asthma and low controller medication adherence who were part of a clinical trial of an intervention to improve medication adherence. We report on baseline measures obtained before treatment entry including self-care practices and beliefs about asthma, healthcare, and controller medication. Asthma control was assessed with the Asthma Control Test and spirometry.

Results: Most (78%) were female [mean age=23.1 (SD=3.4)]; had at least some college (60%); and employed (57%). Most (57%) were diagnosed by age five. The majority (75%) had poorly controlled asthma and 24% had a lung capacity of less than 70%.

Most have family (87%) or friends (56%) with asthma. Only 8% had taken an asthma course. General asthma knowledge was poor [M=8.2 (SD=1.6)]. While 68% believed that asthma is permanent, 44% thought it can be cured. Asthma information was sought from doctors (84%), specialists (67%) and search engines (50%). Recognizing early signs of asthma episodes were taught by a health professional (66%), family member (46%), or self-taught (44%), but inhaler use education primarily from a physician (39%). Only 26% use a peak flow meter. Breathing techniques (68%) and vitamins (22%) were the most popular alternative treatments.

Despite 73% reporting they were confident that they can take medication as prescribed, 24% forgot to use it in the past 4 weeks, and 50% were careless about using it. Half (56%) worried about its long-term effects; 54% indicated that their lives would be impossible without medications.

Conclusion: Results enhance our understanding of asthma knowledge, beliefs and self-care of AAAs with persistent asthma. Despite the disparate risk faced by this group, few studies have included them and/or explored their experiences with asthma and healthcare. We found that many have limited knowledge, incorrect beliefs about asthma and seek information from potentially unreliable resources. Interventions focused on asthma control should address these gaps.

RESPONSIVENESS TO MOTIVATIONAL INTERVIEWING AMONG LATINA OVARIAN CANCER SURVIVORS PARTICIPATING IN THE LIVES STUDY

Irlena A. Penaloza, BS¹, Meghan Skiba, MS, RDN², Samantha Werts, BS³, Julie West, RD⁴, Sarah Wright, BS⁵, Melanie Hingle, PhD, MPH, RDN⁶, Cynthia Thomson, PhD, RDN, FTOS⁷, Tracy E. Crane, PhD, RDN⁸

¹The University of Arizona, TUCSON, AZ; ²University of Arizona College of Public Health- Health Promotion Sciences, TUCSON, AZ; ³University of Arizona College of Public Health, TUCSON, AZ; ⁴University of Arizona College of Public Health, Tucson, AZ; ⁵The University of Arizona Cancer Center, Tucson, AZ; ⁶University of Arizona, Tucson, AZ; ⁷Mel & Enid Zuckerman College of Public Health Distinguished outreach faculty University of Arizona, TUCSON, AZ; ⁸Biobehavioral Health Sciences Division, College of Nursing Health Behavior Health Promotion, Mel & Enid Zuckerman College of Public Health Department of Nutritional Sciences, College of Agriculture & Life Sciences Member, Data Science Institute, TUCSON, AZ

Background: In the United States, cancer is the leading cause of death among Latinas. It is estimated one in four cancer case could be prevented with modifiable lifestyle behaviors. However, approaches for changing these behaviors may be different based on cultural factors. Motivational interviewing (MI) is an evidenced-based approach for changing lifestyle behaviors and is composed of 5 constructs, which are evocation, collaboration, autonomy, direction and empathy. However, previous research, as well as our own anecdotal observations, has found that Latinas may be less responsive to usual behavior change techniques.

Objective: Determine the difference in MI scores between non-Hispanic white women and Latinas who have completed treatment for ovarian cancer participating in a large, well-powered RCT (GOG-0225).

Methods: Women randomized to the intervention arm received lifestyle counseling from MI trained health coaches. Counseling sessions were randomly selected from a subsample of ten Spanish-speaking Latinas, 21 English-speaking Latinas, and ten age-matched non-Hispanic white women during the first six months of intervention. Counseling sessions were scored using MITI 3.0 (5-25, higher score indicating better MI fidelity). Language preference (English or Spanish) was used as a proxy for acculturation. Differences in total MITI scores between groups were evaluated using ANOVA, while individual constructs were evaluated using the Kruskal-Wallis test.

Results: Mean MITI scores were 17.6 (SD ± 8.4), 20.9 (SD ± 1.2) and 21.0 (SD ± 0.67) for Spanish-speaking Latinas, English-speaking Latinas and non-Hispanic white women, respectively. Spanish-speaking Latinas' MITI scores were significantly lower ($p < 0.001$), with a β -coefficient value of -3.4 (95%CI: -4.3, -2.5) than non-Hispanic white women, while English-speaking Latina MITI scores were not significantly different than non-Hispanic white women. Direction, evocation, and collaboration were significantly different between groups ($p < 0.001$).

Conclusion: Significant differences between MITI scores were observed in Latina cancer survivors based on language preference. Efforts to tailor behavioral interventions for race and culture are needed, potentially with special attention to direction, evocation and collaboration.

EXAMINING RURAL/URBAN DIFFERENCES IN PROVIDER PERCEPTIONS OF HPV VACCINATION IN ADOLESCENT BOYS AND GIRLS

Monica Kasting, PhD¹, Katharine J. Head, n/a², Rivienne Shedd-Steele, BA³, Gregory Zimet, PhD⁴

¹Purdue University, West Lafayette, IN; ²Indiana University-Purdue University Indianapolis, Indianapolis, IN; ³IU Simon Cancer Center, Indianapolis, IN; ⁴Indiana University School of Medicine, Indianapolis, IN

Purpose: HPV vaccination uptake is consistently lower in rural areas as compared to urban/suburban areas. It is important to assess if there are similar or different barriers and facilitators of vaccine uptake in these populations, in order to design effective interventions that target the specific needs of local populations.

Methods: We surveyed 94 clinic vaccine coordinators from 64 of Indiana's 92 counties. The survey included open-ended questions regarding barriers they face to vaccinating girls and boys in their communities as well as areas for improvement. Participants were excluded if they did not indicate a geographic location ($n=4$). Data were analyzed using thematic analysis and responses for participants were compared by the clinic geographic location: rural ($n=45$) and urban/suburban ($n=45$).

Results: All respondents were female, 82% were non-Hispanic White, and 58% reported being registered nurses. The most commonly reported barriers for vaccinating both boys and girls were a lack of education and misinformation on the internet. While 60% of stakeholders indicated the barriers for boys and girls were the same, there were geographic differences with 75% of rural stakeholders reporting little or no differences in barriers between sexes and 51% of urban/suburban stakeholders saying there were differences. One barrier that was different in vaccinating boys and girls was that parents (and some providers) were still unaware the vaccine is recommended for boys. Furthermore, 60% of respondents mentioned that a major barrier to vaccinating girls was either a concern about increased sexual activity or a belief that it was unnecessary because the patient was not currently sexually active; this belief was not mentioned frequently for boys and did not differ between geographic locations. Regardless of geographic location, the most commonly reported way to improve HPV vaccination was increasing education, followed by improving provider recommendation, and making it mandatory for school entry.

Conclusions: The reported barriers to HPV vaccination and ways to improve vaccination rates were similar between rural and urban/suburban stakeholders. The urban/suburban locations reported gender differences in barriers more frequently than rural providers. This may indicate that there needs to be different approaches to educating vaccination providers on making high quality HPV vaccine recommendations depending on whether the provider works in a rural or urban/suburban area.

UNDERSTANDING THE RELATIONSHIP BETWEEN HEALTH LITERACY AND QUALITY OF LIFE OF LATINO CANCER PATIENTS

Maria Claros, B.S.¹, Rosario Costas-Muniz, PhD², Normarie Torres-Blasco, Ph.D.³¹Memorial Sloan Kettering Cancer Center, North Bergen, NJ; ²Memorial Sloan Kettering Cancer Center, New York, NY; ³Ponce Health Sciences University, Ponce, N/A, Puerto Rico

Background: Health literacy (HL)—the ability to understand health information—is a critical component in treatment decision-making of Latinos with advanced cancer (AC), which influences their quality of life (QOL). However, little is known about the association between HL and QOL among Latinos with AC. With 41% of Latino adults lacking basic HL and Latinos more likely to be diagnosed with AC, HL is an essential target of intervention for improving QOL. The purpose of this study is to examine the extent HL is associated with QOL among Latino patients with AC and to explore its correlation to language preference.

Methods: A cross-sectional survey study was conducted with 82 Latinos diagnosed with advanced stage and solid tumor cancers between 2015 and 2019. Participants were recruited from a major cancer center ($n=48$), and two cancer clinics, one located in New York City ($n=22$) and the other in Ponce, Puerto Rico ($n=12$). Participants were asked what language they felt most comfortable speaking. QOL and HL were measured with the Functional Assessment of Cancer Therapy-General (FACT-G) and the Single Item Literacy Screener (SILS), respectively. One-way analysis of variance (ANOVA) and independent-samples t-test were conducted to analyze the data.

Results: Fifteen percent reported English, and 85% reported Spanish as their preferred languages. Spanish-speaking Latinos diagnosed with AC reported significantly lower functional QOL compared to English-speaking Latinos [$t(76)=-2.53$, $p=.01$]. Participants with lower HL reported lower QOL [$F(73)=2.69$, $p=.05$], functional [$F(73)=3.72$, $p=.012$], and social/family [$F(73)=3.99$, $p=.01$] well-being than those with higher HL. Birthplace was not associated with QOL.

Conclusions: QOL is independently associated with language and HL among Latino cancer patients. Spanish-speaking Latinos with AC are at a higher risk of poorer QOL outcomes. Given the lower functional QOL of Spanish speakers and lower overall QOL of Latinos with low HL, it is essential to address linguistic and literacy needs of Latinos with AC to improve their cancer experience and the ability for self-management and care. Future research is also necessary to understand the different domains of QOL and its influence on HL.

THE ASSOCIATION BETWEEN LGBTQ+ COMMUNITY INVOLVEMENT AND HIV TRANSMISSION RISK BEHAVIORS AMONG SEXUAL MINORITY MEN

Chris A. Albright, B.S.¹, Aaron J. Blashill, Ph.D.², Jamie-Lee Pennesi, Ph.D.², Hee-jin Jun, Ph.D.², Tiffany A. Brown, Ph.D.³¹San Diego State University/UC San Diego Joint Doctoral Program in Clinical Psychology, La Jolla, CA; ²San Diego State University, San Diego, CA; ³UCSD, San Diego, CA

Background: Sexual minority men remain disproportionately burdened by HIV despite recent prevention efforts. Although involvement in the LGBTQ+ community has been found to be a protective factor against many adverse health outcomes, research examining the association between community involvement and HIV transmission risk behaviors has yielded conflicting results. This study aims to examine whether the importance one places on various aspects of community involvement is associated with HIV transmission risk behaviors.

Method: This study was conducted using baseline data from an ongoing eating disorder prevention randomized controlled trial, which includes 139 gay and bisexual men aged 18-35 living in San Diego, California. Community involvement was measured using the Importance of Gay/Bisexual Community Activities (IBGCA) scale, which was distilled into two factors: “community activism” and “partying” that emerged through exploratory factor analysis. We performed a zero-inflated poisson regression to examine the association between community activism, partying, and their interaction term, with HIV transmission risk behaviors, which was operationally defined as engaging in condomless anal sex while not taking PrEP. We also added number of sexual partners and frequency of community involvement as control variables in the model.

Results: A significant interaction term emerged ($b = -.267$, $SE = .133$, $z = -2.24$, $p = .025$). This interaction term was subsequently probed via simple slope analyses set at ± 1 SD of the importance of community activism. Results indicated that at low levels of community activism, partying was significantly positively associated with HIV transmission risk behaviors ($b = .555$, $SE = .135$, $t = 4.11$, $p < .001$), whereas at high levels of community activism, the association between partying on HIV risk was no longer significant ($b = .127$, $SE = .176$, $t = .721$, $p = .472$).

Conclusion: This study shows that the importance sexual minority men place on various aspects of community involvement is associated with HIV sexual risk behaviors, which has important public health implications. While valuing LGBTQ+ community activities that often involve alcohol/substance use and hook ups is associated with increased HIV transmission risk behavior, simultaneously finding meaning in LGBTQ+ community activism could help protect against this association. Therefore, encouraging community activism could be a target for intervention.

UNDERSTANDING ADVANCED PLANNING PRACTICES IN A SAMPLE OF OLDER ADULTS LIVING WITH HIV/AIDS IN NEWARK, NEW JERSEY

Kristen D. Krause, MPH¹, Perry N. Halkitis, PhD, MS, MPH², Allie N. Bullock, BA³¹Center for Health, Identity, Behavior and Prevention Studies, East Orange, NJ; ²Rutgers University School of Public Health, Piscataway, NJ; ³Center for Health, Identity, Behavior and Prevention Studies, Newark, NJ

Background: By 2025, people aged 50 and older will constitute the majority of those living with HIV/AIDS (PLWHA) in the US. This aging population of PLWHA face different physical, mental, and psychosocial health challenges related to living with HIV/AIDS, the general aging process, and the long-term impact of being on antiretroviral treatment (ART). Many who were diagnosed prior to the implementation ART in 1995 were effectively given a death sentence due to the short life expectancy of living with untreated HIV/AIDS. As such, individuals who did not expect to reach older adulthood now face the realities and obstacles around advanced care planning (e.g. life insurance/retirement funds, advanced directives/living wills, power of attorney, etc.) when living well past their diagnoses was something they expected to do. This qualitative interview sought to understand the experiences of older PLWHA in one of the 57 geographic areas that has been prioritized by the federal 'Ending the HIV Epidemic' plan.

Methods: Recruitment efforts occurred from March – June 2019 in the greater Newark, New Jersey metropolitan area. We conducted 40 qualitative interviews with older (50+) adults living with HIV/AIDS. Upon providing written consent, each interview lasted 45–90 minutes following a semi-structured interview guide. Three trained research assistants conducted the interviews. They were transcribed by research interns and independently verified by members of the research staff.

Results: The ranges of the participants' age were 51–69 years old (18 women and 22 men). 47 participants identified as Black non-Hispanic, with the remaining 3 identifying as White non-Hispanic or 'Other.' One of the main themes that emerged from the preliminary data analysis is a fear of not being financially stable to enter later adulthood (65+) with regard to life insurance policies, retirement funds, or medical savings accounts. Additionally, while some participants indicated they have close family members or friends to rely on for various types of assistance (housing, day-to-day, end-of-life, etc.) if their health declines, several indicated that they have not thought about advanced care planning because they are just trying to survive and live day-to-day.

Conclusions: As the population of PLWHA continues to age, it is imperative that healthcare professionals across disciplines incorporate advanced care planning into conversations during routine medical and social support visits so that they feel more equipped and better prepared to reach that point.

TO TAILOR OR NOT TO TAILOR: THAT IS THE QUESTION WHEN CONSIDERING E-HEALTH READINESS AMONG PEOPLE LIVING WITH HIV

Stephanie Marhefka, PhD, MS¹, DeAnne Turner, PhD, MPH², Elizabeth Lockhart, PhD, MPH¹¹University of South Florida College of Public Health, Tampa, FL; ²Yale AIDS Prevention Training Program (Y-APT) Center for Interdisciplinary Research on AIDS (CIRA) Yale University, New Haven, CT

Background: The Technology Readiness Index 2.0 (TRI 2.0) may provide guidance in understanding people's willingness to adopt future technologies. Yet the measurement structure of the TRI 2.0 has not been confirmed among people living with HIV and prior work suggests for people living with HIV, disease-specific considerations are linked to willingness to uptake ehealth approaches. The study purpose was to: 1) assess the fit of the TRI 2.0 for people living with HIV, using confirmatory factor analysis; 2) assess the fit of an adapted version of the TRI 2.0 (referred to in text as the TRI-HIV) using confirmatory factor analysis; and 3) compare the fit of the TRI 2.0 with the TRI-HIV.

Methods: N=408 people living with HIV residing in the state of Florida and engaged in Ryan White case management completed a telephone-based survey regarding technology use and willingness to use technology among people living with HIV. Technology readiness was measured with: 1) the TRI 2.0, as well as 2) an adapted version of the TRI 2.0 (henceforth TRI-HIV), which included some TRI 2.0 items as well as new items, similar to the TRI 2.0, that were tailored specifically to using technology for HIV-related ehealth. These items were created by adding something HIV-specific to the general TRI 2.0 items; changes were informed by findings from open-ended interviews conducted to inform survey development. For example, while the TRI 2.0 item said "If you provide information to a machine or over the Internet, you can never be sure if it really gets to the right place," the TRI-HIV item was "If you provide information about your HIV status over a computer or Internet, you can never be sure who will find out." Fit of the existing measurement structure was tested with confirmatory factor analysis for two models: 1) TRI 2.0 and 2) the TRI-HIV.

Results: When the original TRI 2.0 instrument was applied to our sample of people living with HIV, the data fit the existing measurement structure of the TRI 2.0 (CFI=0.967; TLI=0.960; RMSEA=0.035 [0.022-0.046]). Tailoring items specifically for people living with HIV did not improve model fit (CFI=0.953; TLI=0.943; RMSEA=0.038 [0.026-0.049]).

Conclusions: The TRI 2.0 measurement structure fit well with our population of people living with HIV. Tailoring questions specifically for our population did not significantly increase model fit, suggesting that tailoring TRI 2.0 items for HIV-specific ehealth concerns may unnecessary. Alternatively, it may be worth conducting exploratory factor analysis (EFA) on the TRI-HIV to determine if another factor structure would better fit. Future research should apply EFA to the TRI-HIV and also investigate how the TRI-HIV and the TRI 2.0 as well as factors outside of technology readiness constructs (optimism; discomfort; innovation; insecurity) that may affect willingness to take part in HIV-related ehealth interventions.

10:30 AM–11:30 AM

UNDERSTANDING BARRIERS AND FACILITATORS TO PREVENTION OF MOTHER-TO-CHILD TRANSMISSION OF HIV SERVICES IN WESTERN INDIA

Kristen J. Wells, PhD, MPH¹, Cristian Garcia, Bachelors of Arts²¹San Diego State University, San Diego, CA; ²San Diego State University, El Cajon, CA

Introduction: Most of the 0.14 million HIV-positive children living in India contracted the human immunodeficiency (HIV) virus from their mother while in the womb, during labor, or through breastfeeding. Mothers can significantly reduce the risk of HIV transmission by initiating and adhering to the prevention of mother-to-child transmission of HIV (PMTCT) services, but only 60% of pregnant women living with HIV in India used these services in 2017. Given the scarce literature on PMTCT utilization in India, the present qualitative study used the Social Ecological Model (SEM) to identify barriers and facilitators to seeking PMTCT services that mothers face in western India.

Methods: Through purposive sampling, 15 fathers and 16 mothers (age range 20 to 45 years; 51% had less than a 7th standard education; 75% had a baby delivered at a public hospital) were recruited to participate in semi-structured in-depth interviews assessing barriers and facilitators to PMTCT services. Interviews were audio recorded and transcribed verbatim. Direct content analysis was used to identify *a priori* and emerging themes based on the SEM. One author independently coded 31 interviews and then discussed coding with two more authors. Participants also completed a demographic survey, and these data were summarized using descriptive statistics.

Results: At the individual level, barriers to PMTCT services were lack of money for transportation, poor physical health, and feeling distressed/anxious, whereas facilitators were the hope they felt for the new baby and experiencing unusual health symptoms that caused them to seek medical services. At the interpersonal level, barriers to PMTCT services were poor peer/family and partner support, whereas facilitators were positive partner support, peer/family support, and positive doctor/staff support. At the institutional level, availability of multiple services in one location, affordability of PMTCT services, and good quality of care were facilitators to PMTCT services, whereas obtaining prenatal care in the private sector was a barrier. At the community level, outreach workers facilitated PMTCT utilization, whereas HIV stigma was a salient barrier.

Conclusions: The present study was the first to examine barriers and facilitators to obtaining PMTCT services in western India, and it adds to our understanding of facilitators and barriers to PMTCT services. This study has important implication for health care institutions, as it recognized that health care providers have a significant role in facilitating PMTCT services. Findings from the present study can be used to enhance and develop locally relevant community-based strategies/interventions for improving PMTCT utilization in India. Future research should develop and test interventions to help India achieve optimal adherence to guidelines for the PMTCT of HIV.

THE INTERACTIVE EFFECTS OF DEPRESSION AND SUBSTANCE USE AMONG OLDER ADULTS LIVING WITH HIV

Laurel Weaver, MA¹, H. Jonathon Rendina, PhD, MPH²¹Graduate Center of the City University of New York, New York, NY; ²Hunter College and The Graduate Center, CUNY, New York, NY

Background: HIV-positive individuals are living longer, healthier lives, but neurocognitive impairment (NCI) remains a prevalent health burden among older adults living with HIV (OALWH). At present, the precipitating and perpetuating factors of HIV-associated NCI in OALWH are largely unknown, although accumulating evidence indicates that overlapping psychosocial issues may play a primary role in cognitive health outcomes. The current study aimed to explore the association between depression, substance use, and NCI in OALWH.

Method: A sample of New York City-based OALWH (N=99) with chronic and current substance use issues completed a series of neurocognitive assessments and self-report surveys. The majority of the sample was Black (74.4%), male (66.7%), and reported post-secondary education (53%). On average, the sample was 54.6 years old ($SD = 4.0$) and had been living with HIV for 16.7 years ($SD = 7.0$). HIV disease characteristics, race, sex, and education were included as covariates in subsequent general linear models.

Results: Results indicated that approximately half (49%) of the overall sample demonstrated global NCI, and the majority exhibited mild impairment in the domains of verbal learning (60%), verbal memory (70%), and motor speed (67%). Nearly half (48.5%) of participants reported significant depressive symptoms. Multivariate analyses revealed a main effect of depression on NCI – specifically in the domains of executive function and motor speed. While there was no main effect of substance use, a significant interaction between depression and substance use emerged. Participants who reported depressive symptoms and either stimulant or marijuana use yielded lower global and cognitive domain-specific scores than participants who used these substances but were not depressed.

Conclusion: These results suggest that depression is directly associated with NCI and furthermore, that depression interacts with specific substances of abuse to exacerbate cognitive impairment in OALWH. Further research is needed to improve understanding of these associations to facilitate improved prevention and treatment strategies for HIV-associated NCI.

CULTURAL AND SYNDemic FACTORS INFLUENCE PREP WILLINGNESS, INTENTIONS, AND UPTAKE AMONG PARTNERED LATINX SEXUAL MINORITY MEN

Stephen Bosco, M.A.¹, Gabriel Robles, PhD², Tyrel J. Starks, PhD³¹The Graduate Center, CUNY, Brooklyn, NY; ²Hunter College, New York, NY, NY; ³Hunter College, New York, NY

Background: While HIV incidence remained generally stable since 2011, rates increased by 13% among Latinx sexual minority men (LSMM). PrEP is highly efficacious at preventing HIV, yet uptake among eligible SMM has been slow, and slower among LSMM specifically. Many new HIV infections among SMM occur between main partners and guidance for dissemination specifically recommends PrEP for partnered men who have sex outside their relationships. The Motivational PrEP Cascade identifies significant declines of PrEP-eligible individuals across stages from willingness, intention, to uptake. Syndemic Theory has been utilized to explain disproportionate rates of HIV in marginalized communities; however, minimal work has examined the impact of syndemic conditions on the PrEP cascade. Among LSMM, cultural factors (machismo and caballerismo) might also influence motivations of PrEP uptake. Given that LSMM have higher rates of HIV infection and are less likely to use PrEP, it is critical to identify barriers to PrEP uptake among this high-priority community.

Methods: Data were gathered from a US-wide online study of 625 LSMM in a same-sex relationship. We focus here on the 368 LSMM reporting an HIV-negative status and PrEP eligible based on CDC guidelines. The mean age was 30 and mean relationship length was 45 months. Participants completed demographics, the Machismo for Latino Men scale, and measures of syndemics (depression, childhood sexual abuse, intimate partner violence, substance use) and PrEP willingness, intentions, and uptake.

Results: More than half (61%) of the men were PrEP-eligible, 53% reported willingness to start PrEP, 26% intended to start PrEP, and 21% are on PrEP. Over half (51%) reported experiencing 5 or more out of 10 syndemic conditions. Chi-square tests examined the influence of >5 syndemics on PrEP-eligibility, willingness, intention, and uptake. LSMM reporting 5 or more syndemics were more likely to be PrEP-eligible and to indicate greater intent to start PrEP. There was a significant association of machismo ($\exp(B)=1.02$ $p<.05$) and caballerismo ($\exp(B)=0.97$ $p<.01$) on PrEP eligibility. Similarly, caballerismo was negatively associated with the odds of intending to start PrEP ($\exp(B)=0.98$ $p<.05$) while machismo was not associated with PrEP intentions. There were no significant effects of cultural and syndemic factors on PrEP uptake.

Conclusions: Our findings highlight the role of cultural and syndemic factors on PrEP uptake among LSMM, influencing both PrEP eligibility and intentions, but not willingness. An integration of cultural ideals of masculinity (e.g., Machismo) may be particularly useful in addressing negative views of PrEP in LSMM. Future work to address protective cultural values in the face of adversity represents a beneficial route for reducing HIV among LSMM.

10:30 AM–11:30 AM

PSYCHOSOCIAL PREDICTORS OF SELF-REPORTED HIV STATUS

Ore Shalhav, MPH¹, Ali Talan, DrPH², H. Jonathon Rendina, PhD, MPH³, Nicola F. Tavella, MPH, CPH⁴¹PRIDE Health Research Consortium, Hunter College, CUNY, NEW YORK, NY; ²Hunter College, New York, NY; ³Hunter College and The Graduate Center, CUNY, New York, NY; ⁴PRIDE Health Research Consortium, Hunter College, CUNY, New York, NY

Background: HIV testing is a form of self-care and prevention as individuals who partake in regular testing are engaged in managing their health and preventing infection of partners. Differences in self-reported HIV status (negative versus unknown) indicate differences in HIV testing behavior. HIV testing uptake may be predicted by an individual's sexual-risk behavior, sociodemographic characteristics, and psychosocial factors. These factors may likewise predict HIV risk more broadly.

Methods: Data are from UNITE, a cohort study of SMM from across the United States ($N=7951$; $M_{age}=32.7$; $SD=11.4$) who reported negative or unknown HIV status at baseline. We conducted chi-square analyses to examine group difference on self-reported HIV status. We also conducted a binary logistic regression to examine the association between psychosocial factors and self-reported HIV status, adjusting for sociodemographic characteristics and sexual risk behavior. Sexual risk behavior was measured by self-reported number of male casual partners and condomless anal sex acts within the last 6 months.

Results: We found that 78.5% of the sample reported a negative status and 21.5% reported an unknown status. Significant differences by sociodemographic characteristics and psychosocial factors (e.g., "outness" sexual shame, sexual pride, perceived HIV risk) were identified. Our regression analysis indicated that sexual risk behavior did not predict self-reported status. Participants who were more "out" with regards to their sexual orientation ($AOR=.84$, $p=.00$) and reported more sexual pride ($AOR=.91$, $p=.01$) had significantly lower odds of reporting an unknown status. Participants with greater perceived HIV risk ($AOR=1.06$, $p=.00$) and more sexual shame ($AOR=1.21$, $p=.00$) had significantly higher odds of reporting an unknown status.

Conclusion: Our model demonstrated that all 4 psychosocial factors correlate with self-reported HIV status when controlling for sociodemographic characteristics and sexual risk behavior. Those who are less out, feel less sexual pride, and more sexual shame are less likely to know their status, yet engage in similar sexual risk behavior as those who do. Surprisingly participants with unknown status reported higher perceived risk of HIV, which suggests that perceived risk rather than actual risk is more predictive of lack of engagement in testing. Therefore, interventions to increase testing may benefit from emphasizing sex-positivity rather than risk.

A SYSTEMATIC REVIEW OF QUANTITATIVE STIGMA MEASURES AMONG YOUNG SEXUAL MINORITY MEN

Jorge Cienfuegos-Szalay, MPH¹, Ore Shalhav, MPH², Ali Talan, DrPH¹, H. Jonathon Rendina, PhD, MPH³¹Hunter College, New York, NY; ²PRIDE Health Research Consortium, Hunter College, CUNY, NEW YORK, NY; ³Hunter College and The Graduate Center, CUNY, New York, NY

Introduction: Young sexual minority men (YSMM) have the highest rates of new HIV infections in the U.S., with Black and Latino YSMM specifically being disproportionately affected in comparison to their White counterparts. Research suggests that one of the major drivers of the disparity is intersectional stigma. Intersectionality theory suggests that interlocking stigmatized identities (e.g. race, ethnicity, sexual orientation, gender expression) produce unique detrimental effects. The confluence of multiple identities in addition to sexual minority status and gender expression place Black and Latino YSMM at increased risk of suffering negative health outcomes. Given the lack of quantitative stigma measures developed through an intersectional framework, the focus of this study was to conduct a systematic review to identify currently available measures for multiple forms of stigma among YSMM.

Methods: PubMed and PsycInfo were used to identify peer-reviewed papers that contained a quantitative measure of stigma focused on at least one domain of interest (e.g., race/ethnicity, sexual orientation, or gender expression) with samples that included YSMM. A variety of search terms were used to ensure the search was comprehensive and a range of eligibility criteria were used to include studies in the systematic review. Scales were categorized by race/ethnicity, sexual orientation, and gender.

Results: Initial search results yielded 283 relevant articles of which 127 met inclusion criteria. Within these, 105 scales or items were identified that measured at least one form of stigma (e.g., intrapersonal, interpersonal, structural). As related to stigma, 20 measures focused on gender, 26 focused on race/ethnicity, and 34 focused on sexual orientation. Stigma measures related to multiple minority identities included 11 on race/ethnicity and sexual orientation, 8 on sexual orientation and gender, 3 on race/ethnicity and gender, and 3 on all three categories.

Conclusion: Measuring YSMM's experiences of stigma has been critical in advancing their psychosocial and physical well-being. However, of the measures identified, most focused on experiences of stigma directed at a singular identity (e.g., sexual orientation). While some attempted to address the effects of stigma on individuals with multiple stigmatized identities, very few were designed through an intersectionality framework. This speaks to the need for creating psychometrically-sound, empirically-validated instruments that take into consideration the intersecting identities YSMM may hold in order to address the unique effects of stigma these individuals experience.

ASSESSING KNOWLEDGE, BEHAVIOR, AND SEXUAL DECISION-MAKING SKILLS AMONG YOUNG BLACK COLLEGE STUDENTS AT RISK FOR HIV

Yarneccia Dyson, Ph.D., MSW¹, Samuella Ware, MPH, CHES²¹UNC-Greensboro, Greensboro, NC; ²The University of North Carolina Greensboro, Greensboro, NC

Black (or African American) men and women between the ages of 18 and 29, including college students, in North Carolina bear a disproportionate burden of sexually transmitted diseases (STD) (NCDHHS, 2015). Urban areas in the Piedmont Triad Area of Greensboro, North Carolina have large populations of college students with elevated risk of infection for STD, including HIV. The Centers for Disease Control and Prevention (CDC) advises that sexual risk behaviors associated with these outcomes include: having more than one sexual partner, changing sexual partners frequently, and having oral, vaginal or anal sex without a condom (CDC, 2016). The current triangulated mixed methods study explored the STD knowledge, attitudes, and behaviors, and sexual risk of Black college students enrolled at Historically Black Colleges and Universities (HBCU) and Minority Serving Institutions (MSI) (MSI). The data collection tools included a 70-item online confidential survey, individual interviews (Women Only), and focus groups. Further, this project implemented *Healthy Love*, a single session, CDC evidence-based behavioral and biomedical intervention that was designed to increase safer sex or protective behaviors for STD and HIV among Black women. The implementation of this intervention with our sample that included Black men is the first to deliver this critical programming to this under-researched population.

The sample comprised 4 HBCU's and one MSI, all located in the South, which bears the greatest burden of HIV infection and transmission. Fifty one percent of the sample were women followed by 48% who identified as men and 1% who identified as other. Participants were given pre-and post-tests before the delivery of the intervention that measured STD knowledge, attitudes towards condom use, and sexual risk. The findings from the pre and post-test indicated that students' knowledge about sexually transmitted diseases increased (mean difference -2.89) and the endorsement of high-risk sexual behavior decreased (mean difference 4.66). The study participants endorsed high risk sexual behaviors including the use of an illicit substance at the time of intercourse, unprotected sexual encounters, and ambiguity as it relates to HIV testing and knowing their status. The overarching goal of this study was to test the efficacy of the *Healthy Love* prevention intervention when implemented in this population. The findings from this study indicate the need for culturally tailored and gender specific biomedical behavioral HIV prevention interventions that directly targets the unique sexual health needs of Black College Students.

PREP PERCEPTIONS AMONG PROVIDERS AND ASSOCIATIONS WITH FORMAL TRANSGENDER HEALTH TRAINING

Paul A. D'Avanzo, MS¹, Sarah Bauerle, Bass, Ph.D. and MPH², Jesse A. Brajuha, MPH³, Guittierrez Luis, MPH, MA⁴, Jae M. Sevelius, PhD⁵

¹Temple University College of Public Health Department of Social and Behavioral Sciences, Philadelphia, PA; ²Temple University College of Public Health, Philadelphia, PA; ³Temple University, Philadelphia, PA; ⁴University of California, San Francisco, San Francisco, CA; ⁵University of California, San Francisco, San Francisco, CA

Background: Access to pre-exposure prophylaxis (PrEP) continues to expand to high HIV risk populations, which includes transgender women. This expansion of services is reflected in the increasing number of healthcare providers who have sought out and/or received formal training for prescribing PrEP and monitoring patients currently prescribed PrEP. However, provider training may not adequately address specific treatment and other related concerns that arise in the context of providing PrEP to transgender women. Lack of transgender competent health care has been shown to contribute to medical mistrust, particularly among transgender women, who may delay or forgo healthcare as a result.

Methods: To evaluate perceptions related to transgender women's healthcare and PrEP, we surveyed 102 healthcare providers who self-identified as prescribers of PrEP. Differences in healthcare and PrEP related perceptions were then assessed by self-reported level of transgender-specific training (1. *have not received training*, 2. *have sought out formal training*, 3. *have received formal training*).

Results: Training status did not differ by age of provider or number of years in practice. However, significant differences in perceptions related to transgender healthcare and PrEP were noted. Specifically, those who had neither sought out or received training reported more agreement with concerns regarding PrEP adherence among transgender women ($F(2,99)=4.95$, $p=.009$); concerns about PrEP leading to drug resistance ($F(2,98)=7.04$, $p=.001$); and discomfort with discussing sexual activity with transgender patients ($F(2,98)=18.8$, $p<.001$).

Conclusion: These results indicate opportunities to enhance the scope and quality of training received by healthcare providers who may prescribe PrEP to transgender patients. Identifying both gaps in provider knowledge and existing concerns about how best to treat this population will help to ensure inclusive healthcare for trans women and more successful promotion of PrEP to patients.

SOCIAL PSYCHOLOGICAL ANTECEDENTS TO RACIAL HOMOPHILY AMONG BLACK MEN WHO HAVE SEX WITH MEN

Andrew Cortopassi, MA¹, Seth Kalichman, PhD¹

¹University of Connecticut, Storrs, CT

Black men who have sex with men (MSM) continue to bear the burden of new HIV infections in the United States. The racial disparity in HIV infection among MSM has been attributed, in part, to high rates of racial homophily within the sexual networks of Black MSM. Within homophilous, closed-off networks, disease propagates easily, increasing the odds of HIV exposure per act of sexual risk behavior. The cause of homophily is unknown, but it is posited that objectification based in race-based sexual stereotypes (e.g., large penis size) by non-Black MSM leads to homophily among Black MSM. In the current vignette-style experimental study with Black MSM recruited from Grindr, we tested the Objectification-Homophily Hypothesis. Specifically, in a 2 (stereotype exposure: racialized versus non-racialized penis size stereotype) x 2 (potential partner race: Black or White) between-subjects design, the interactive effect of stereotype exposure and partner race on partner engagement via state self-objectification (SSO; feeling like a body versus a full self) was examined. Results showed that while stereotype exposure had no unique or interactive effects, White partner race reduced engagement through SSO, an indirect effect moderated by degree of past-year racial homophily, i.e., significant only among those who reported high past-year homophily.

In a second, follow-up study currently being conducted, a stronger contrast between levels of the stereotype exposure variable is used. Initial results are expected to replicate, but a 3-way interaction of stereotype exposure, potential partner race, as well as past-year racial homophily, is predicted instead-leading to decreased engagement via SSO. These projected results would indicate that exposure to race-based sexual stereotypes by non-Black MSM likely leads, in part, to the formation of racially homophilous sexual networks among Black MSM, because such stereotyping is experienced as objectifying. Of particular interest, however, would be the moderation of this indirect effect by past-year homophily. Indeed, results would indicate that such a mechanism is relevant only for those who demonstrate high levels of racially homophilous partnering already. As such, rather than acting as a fundamental cause, it may be that race-based sexual stereotyping and objectification serve to *maintain* racially homophilous sexual networks among Black MSM. Network-level HIV prevention interventions will need to consider the impact of such individual-level psychological processes that perpetuate increased risk for HIV infection among Black MSM.

SEXUAL IDENTITY, RELATIONSHIP PATTERNS, AND HIV RISK BEHAVIORS AMONG CISGENDER MEN WHO PARTNER WITH TRANSGENDER WOMEN

Demetria Cain, PHD MPH¹, Simone J. Skeen, MA², Ruben H. Jimenez, n/a³, Tyrel J. Starks, PhD⁴, H. Jonathon Rendina, PhD, MPH⁵

¹PRIDE Health Research Consortium/Hunter College, New York, NY; ²PRIDE Health Research Consortium, New York, NY; ³Hunter College's PRIDE Health Research Consortium, New York, NY; ⁴Hunter College, New York, NY; ⁵Hunter College and The Graduate Center, CUNY, New York, NY

Background: Cisgender men who partner with transgender women (TW) are often portrayed as an elusive, highly stigmatized population. While these men are pivotal to the dynamics of transmission risk that drive HIV disparities among TW, little is known about their sexual identities, relationship patterns, and sexual health self-management strategies. We present descriptive findings from a first-of-its-kind dataset comprising cis men who describe their main partners as TW.

Methods: Data were taken from a large national online survey recruiting individuals from geo-targeted sexual networking apps from November 2017 to August 2019. Cis men (n=541) were selected and categorized based on sexual orientation identity as gay, queer, heterosexual, and bisexual. Differences in relationship patterns and HIV risk behaviors were examined.

Results: A majority of cis men identified as bisexual (60%), followed by gay (19%), heterosexual (13%), and queer (10%). Heterosexuals were more likely to be in a relationship with TW 3 months or less and gay men were more likely to be in the relationship 1 year or more ($X^2 = 81.67, p = 0.00$). Queer, heterosexual, and bisexual men reported more condomless anal sex with their TW partner ($X^2 = 7.89, p < .05$). A majority of men in all groups reported also having a casual male partner in the past 6 months: 90% of bisexual, 88% of gay and queer, and 66% of heterosexual men. Gay and heterosexual men were less likely to know their HIV status ($X^2 = 26.01, p = 0.00$), with more heterosexual men (12%) never testing for HIV. Queer men were more likely than any other subgroup to have ever been prescribed PrEP, with heterosexual men the least likely among all respondents to have ever been prescribed PrEP ($X^2 = 24.57, p = 0.00$).

Conclusion: These findings are an essential first step toward informing outreach and risk-reduction strategies responsive to the lived experiences of cis men who partner with TW. Effective approaches to HIV prevention must acknowledge the heterogeneity of identity and relational dynamics among these men and their sexual networks.

VIOLENCE, SUBSTANCE ABUSE, DEPRESSION, AND HIV/STI RISK AMONG MEMPHIS-BASED MSM

Meredith Brantley, PhD MPH¹, Jack Marr, MPH², Christopher I. Mathews, MSW, MPH, LMSW³, Randi Rosack, MPH², Sara E. Zellers, MS, RDN, LDN⁴, Latrice C. Pichon, PhD, MPH, CHES⁵

¹TN Department of Health, Nashville, TN; ²Tennessee Department of Health, Nashville, TN; ³Mental and Emotional Resource Center Inc. of Memphis, Memphis, TN; ⁴University of Memphis, Collierville, TN; ⁵The University of Memphis School of Public Health, Memphis, TN

Background: The syndemic impact of intimate partner violence (IPV), substance abuse (SA), and depression on HIV/STI risk is well established globally, particularly among women. Investigating psycho-social dynamics among individuals impacted by the US HIV/STI epidemic, including men who have sex with men (MSM), is critical to curbing transmission via evidence-based prevention and treatment interventions. In 2016, the Tennessee Department of Health joined the CDC National HIV Behavioral Surveillance network to better understand HIV/STI risk behaviors among MSM. The objective of this analysis was to understand the landscape of IPV, SA, and depression, and its association with HIV/STI risk behavior among Memphis-based MSM.

Methods: During August-December 2017, interviewer-administered surveys assessed IPV, SA, depression, and HIV/STI risk behavior among adult MSM recruited at popular venues. We estimated prevalence of recent (past 12 months) IPV, SA, and depressive symptoms and overlapping correlates (e.g., IPV/SA, IPV/SA/depression). Subsequently, bivariate associations between IPV, SA, and depression, and HIV/STI risk behavior (i.e., sex exchange) were examined.

Results: Of 356 participants, 17% reported recent IPV, 41% reported SA, and 16% reported at least sometimes experiencing depressive symptoms; 13% reported recent sex exchange. No significant differences in reported IPV, SA, or MH were observed across age or race/ethnicity categories. Sex exchange was reported more frequently by those who experienced IPV compared to those who did not (34% vs. 9%, $p < 0.001$) and more so among participants who reported all three overlapping correlates (50%).

Conclusion: Our data suggest that MSM in Memphis are largely impacted by a syndemic of violence, SA, and depression, affecting all demographics. Moreover, while IPV alone may be a significant correlate of HIV/STI risk, the combination of IPV, SA, and depression may amplify risk. Findings will inform local partnership efforts in the development of biomedical and psycho-social programs to facilitate HIV/STI prevention efforts among multiple MSM communities.

ENHANCING MENTAL HEALTH CARE IN PRIMARY CARE: ADDING A CLINICAL PHARMACIST TO THE EMBEDDED BEHAVIORAL HEALTH & PRIMARY CARE TEAM

Kathryn Harple, PsyD¹, Corey Haupt, PharmD, RPh¹, Laura Maphis, PhD², Stacey Grassi, Pharm. D.², Gerard A. Greskovic, RPh, CACP, CDE³, David Rolston, MD, FACP¹

¹Geisinger Medical Center, Danville, PA; ²Geisinger Health System, Danville, PA; ³Geisinger, Danville, PA

Primary care (PC) has become the de facto mental health system (Kessler et al., 2005), and the demand for embedded behavioral health (BH) and psychiatric services is great. For instance, the prevalence of depression in PC is 10% (Spitzer et al., 1994), and nearly half of appointments for psychotropic medications are with primary care physicians (PCPs; Pincus et al., 1998). With the increased demand for psychiatric and BH services, systems become strained trying to meet patient demand while adhering to best practices. To navigate these challenges, the authors have embedded a clinical pharmacist with a BH background into an internal medicine team of interdisciplinary providers, including embedded BH, to improve mental health care and address potential care gaps. The pharmacist's primary role is to support PCPs in the medication management of patients with mild-moderate depression and anxiety. Additionally, the pharmacist performs several behaviorally-oriented roles such as: delivering psychoeducation and motivational interviewing, monitoring adherence, administering screeners, and hosting conjoint visits with BH providers. The current study aims to present utilization and satisfaction data from the first 11 months of this pharmacy pilot. A total of 142 (69% female) patients completed 390 visits with the pharmacist. Results show a decrease in average PHQ9 scores across 14 weeks of treatment (13pt - > 4.5pt), indicating remission of depression. Satisfaction surveys (Likert scale of 0-5, 5 being the highest) were administered during the halfway mark of the pilot, which indicate a positive response; patient satisfaction: n=18, average score of 4.85 and provider satisfaction: n=7, average score of 4.52. Moreover, increased adherence to quality metrics of appropriate patient follow-up following medication initiation and best practice guidelines for depression screening were evidenced. Recruiting behaviorally trained clinical pharmacists may alleviate the cost-prohibition and scarcity burden of hiring psychiatrists, particularly for smaller practices, while allowing for more appropriate patient care cases to be escalated to psychiatrists. A paucity of practices have employed embedded BH clinical pharmacists, though published data is largely limited to Veterans Affairs populations or community health centers (Chavez & Kosiog, 2019). This study contributes data from a large private health system in an established integrated primary care model.

PILOT STUDY OF A MULTICOMPONENT INTERVENTION TO INITIATE HEALTH BEHAVIOR CHANGE IN PRIMARY CARE: THE KICKSTART HEALTH PROGRAM

Shannon M. Clark-Sienkiewicz, Ph.D.¹, Annmarie Cano, Ph.D.², Lori Lackman Zeman, PhD, ABPP³, Mark Lumley, n/a⁴, Neha P. Gothe, MA, PhD⁵

¹Arizona State University, Tempe, AZ; ²Wayne State University, Detroit, MI; ³Beaumont Health - Troy, Sterling Heights, MI; ⁴Wayne State University, Novi, MI; ⁵University of Illinois at Urbana Champaign, Urbana, IL

There is a current movement to integrate behavioral health into primary care settings in order to better prevent and manage chronic illness. Group interventions are commonly conducted to provide services to several individuals at once; however, groups are typically tailored to one disease or condition (e.g., chronic pain, diabetes), despite the fact that patients typically present with multimorbidity. Targeting multiple health behaviors (i.e., diet, exercise, and stress) for a multimorbidity population may be ideal for the prevention and treatment of chronic illness in primary care. Few theoretical frameworks and treatment programs incorporate a combination of techniques to address such complex needs, and fewer still have been tested in medical settings, such as primary care. The current study, therefore, describes the development of a novel intervention for multiple health behavior change, The Kickstart Health Program, which integrates components of cognitive, behavioral, acceptance, motivational enhancement, and experiential therapies into a flexibly-delivered group therapy designed for primary care delivery. This program teaches health behaviors in vivo (e.g., group meditation and exercise) and incorporates rolling recruitment to reduce attendance burden. We pilot tested this program in a family medicine clinic. Of 22 patients who expressed interest in the program, 13 attended at least one session and completed measures of self-efficacy, overall perceived health and well-being, physical activity, and mindfulness practice at baseline, 5, and 10 weeks. Some participants reached their individual health goals, and this was reflected in qualitative responses. Patients who attended the program reported increases in overall days practicing mindfulness meditation ($p=.003$, $d=1.24$). Patients also reported clinically significant reliable change in overall perceptions of health and well-being. Significant increases in physical activity and self-efficacy were not detected in this sample; however, clinically relevant improvement occurred among patients who attended multiple sessions. We conclude that The Kickstart Health Program offers a unique approach to health behavior change in primary care and may be useful in teaching mindfulness meditation and influencing overall health and well-being.

UTILIZATION OF THE STANFORD INTEGRATED PSYCHOSOCIAL ASSESSMENT FOR TRANSPLANTATION AS A MEASURE OF LIVER TRANSPLANT CANDIDACY

Benjamin Nissen, MD¹, Jessica L. Hamilton, PhD¹¹University of Kansas, Kansas City, KS

Background: The Stanford Integrated Psychosocial Assessment for Transplantation (SIPAT) is commonly used as a comprehensive screening tool to assess transplant surgery candidacy. This tool has not yet been validated in liver transplant patients but may be useful for evaluating candidacy in this population. The aim of the present study was to assess the association between provider-designated SIPAT scores and psychosocial self-report measure scores (PROMIS 43) to establish concurrent validity.

Methods: Data were collected from 48 liver transplant candidates at the University of Kansas Medical Center during a required pre-surgical psychological evaluation prior to receiving their operation date between December 2017 and March 2019. The sample was split equally by gender. Participants completed PROMIS-43 questionnaires prior to their appointment. PROMIS-43 includes clinical scores for physical function, anxiety, depression, fatigue, sleep disturbance, social role, pain interference, and pain intensity. Providers then assigned a SIPAT score based on the clinical interview. Descriptive analysis using both SIPAT and PROMIS-43 scores was conducted using SPSS.

Results: One-way ANOVAs were run evaluating the relation between the eight PROMIS domains and the SIPAT overall candidacy score. Results indicated that 7 out of the 8 subscales on the PROMIS were significantly related to SIPAT candidacy (i.e., Anxiety and SIPAT candidacy ANOVA was $F(2,44) = 4.602$, $p < .05$), with the sleep disturbance subscale not being significantly related. Additional post hoc analyses were run to evaluate these relations. Overall, minimally acceptable candidates, based off the SIPAT, had lower functional scores across the board.

Discussion: Preliminary analyses examining concurrent validity of the SIPAT in the liver transplant recipient population appear strong with all clinical scales of the PROMIS 43 significantly predicting total SIPAT score, with the exception of sleep disturbance. The SIPAT's total score may be a good overall indicator of a liver transplant recipient's candidacy. Future research assessing other psychosocial predictors as well as other health outcomes are necessary in the validation of the SIPAT as a tool in the liver transplant recipient population.

WHO AM I NOW? POST-TREATMENT IDENTITIES OF BREAST CANCER PATIENTS AND THEIR CORRELATES

Taylor Coats, MA¹, Malwina Tuman, PhD EBD¹, Kailey Roberts, PhD¹, Elizabeth A. Schofield, MPH², Greta Jankauskaite, MA³, Elizabeth Slivjak, BA⁴, Wendy G. Lichtenthal, PhD¹¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Memorial Sloan-Kettering Cancer Center, New York, NY; ³University of Maryland, College Park, MD; ⁴University of Colorado Boulder, Boulder, CO

After cancer treatment, individuals commonly report their sense of identity is challenged as they contend with physical changes and shifts in their goals and priorities. The extent to which they identify as a “cancer survivor” varies and is often dynamic over time. The limited research in this area has suggested that certain identity types may be associated with greater well-being, but few studies have examined how sense of identity and specific psychosocial outcomes are correlated.

As part of an American Cancer Society-funded randomized controlled trial of group interventions for breast cancer survivors (BCS), this study examined psychosocial correlates of self-reported cancer identity types at baseline. Participants included 59 early-stage BCS who were ≥ 3 months post-treatment with at least moderate levels of distress. Adoption of cancer identity types (cancer victim, cancer patient, person who has had cancer, cancer survivor) was evaluated via the Cancer Identity Assessment. Psychosocial outcomes assessed included anxiety, depression, meaning, purpose, post-traumatic growth, and fear of recurrence. Frequencies of the identity types and bivariate correlations between identities and psychosocial outcomes were calculated.

Results showed that participants identified at least ‘somewhat’ with the following: 51% victim, 69% patient, 88% person who has had cancer, and 73% survivor. Notably, 90% of individuals identified at least ‘somewhat’ with more than one identity.

Endorsing a survivor identity was associated with higher levels of meaning ($r=.364$, $p < .01$), purpose ($r=.313$, $p < .05$), and post-traumatic growth ($r=.549$, $p < .01$), and lower levels of depression ($r=-.259$, $p < .05$). In contrast, endorsing a cancer victim identity was associated with higher levels of depression ($r=.306$, $p < .05$). Time spent thinking about the possibility of cancer recurrence was positively correlated with endorsing a cancer victim ($r=.286$, $p < .05$) and cancer patient identity ($r=.265$, $p < .01$).

Results demonstrated that individuals can adopt multiple identities, suggesting the complexity of these constructs. Though findings indicate that identifying as a cancer survivor is linked to more adaptive outcomes as compared to identifying as a cancer victim, data should be interpreted with caution. Further research is needed to understand whether certain identity types are linked to better adjustment, and if so, whether it is clinically beneficial to facilitate adoption of these identity types.

EFFECTS OF REPLAY AND REHEARSAL EXPRESSIVE WRITING WITH MENTAL HEALTH CONCERNS

Wenhui Zhang, Postdoc¹, Mackenzie R. Greenwell, n/a², Jhucin Jhang, n/a³¹Emory University, Atlanta, GA; ²Facebook, Austin, TX; ³N/A, Austin, TX

Background: The expressive writing of replaying previous interactions related to stressors or traumas has been found to be effective while expressive writing in the rehearsal context for expected conversations or interactions has remained unexplored. The purpose of this study was to examine the effects of rehearsal expressive writing compared to the replay and control groups four weeks after writing.

Methods: Eligible participants were recruited mainly from a large university in the southwestern United States. A randomized, three-group (control, rehearsal, and replay) and 3-time (pre-test, post-test, and 4-week follow-up) experimental design was conducted. Psychological adjustment (Mental Health Inventory-18, MHI), self-perceived stress, PROMIS depression and anxiety, social integration, loneliness, and coping (Brief COPE) were measured at baseline (pre-test), after the fourth day of writing (post-test), and four weeks (follow-up). Repeated measures analyses of variance (RMANOVA) were used to examine the time and time by group effects.

Results: 272 out of 384 participants were eligible; 132 were randomly assigned to three groups and 99 completed all 5 tasks (29 control, 32 replay and 38 rehearsal). The 132 study participants were predominantly female (63%) with an average age of 24 years. Fifty-six (42%) were White; 41 (31%) were Asian and 25 (19%) were Hispanic. Fifty-five reported mental health diagnosis with depression as the highest (42, 76%) and followed by anxiety (35, 64%). 3 by 3 RMANOVA showed significant time effects in MHI, self-perceived stress depressive and anxiety symptoms and coping while no significant effects were found in social integration or loneliness, or coping behaviors. No group effects were observed. 2 group by 3 time RMANOVA found significant time by group differences in MHI (control versus replay).

Conclusions: The small and predominantly female sample and short intervention period could explain the results of no significant time by group effects. Future studies should investigate with a larger and more balanced sample. Not only does this study work to theoretically extend a large body of research on expressive writing and methodologically test an existing therapeutic paradigm, but it also has translational research applications for individuals coping with mental illness as well as for clinical therapists and psychologists.

RELATIONSHIP BETWEEN PERCEIVED STRESS AND EXECUTIVE FUNCTIONING: THE MODERATING ROLE OF COMBINED EXERCISE AND THERMOTHERAPY

Madhura Phansikar, MA¹, Brett J. Wong, Ph.D.², Sean P. Mullen, PhD¹¹University of Illinois at Urbana-Champaign, Urbana, IL; ²Georgia State University, Atlanta, GA

Psychosocial stress is typically negatively associated with cognitive functioning yet certain health behavioral stressors that cause physiological and psychological strain can in turn, induce adaptive, therapeutic responses. Specifically, evidence suggests exercise and thermotherapy (sauna, steam-room), independently, can reduce acute and chronic stress and improve executive functioning (EF). The purpose of this analysis was to examine whether aerobic exercise followed by immersive, whole-body heating via sitting in a steam-room (vs. air-conditioned room) moderated the relationship of stress reduction over time with EF. Pre-hypertensive (SBP/DBP $M = 130/87$) adults ($M = 46$ years old; 58.5% female) received 14 weeks of supervised aerobic exercise (50-75% max HR, 50 minutes) sessions, 3x per week, and were randomized to either 10-20 min sessions in a ~90° F steam-room ($n = 21$) or time-matched seated rest in a lobby ($n = 20$). Perceived stress (1-item, 1 = None to 5 = A lot) was measured immediately after exercise at every session and EF components, i.e., inhibition control (flanker task % cost in reaction time [RT]) and working memory (Sternberg task, RT) was assessed at baseline (M0) and month 4 (M4) follow-up. EF at M4, change in post-exercise stress, and group were entered in a moderation analysis (using SPSS and Hayes' PROCESS macro), adjusting for estimated cardiorespiratory fitness, family history of CVD, smoking status, living alone, compliance with hypertension-reduction health behaviors, & respective M0 cognitive performance). No main effect of group was found, yet a significant interaction was found between group and stress over time [b (se) = -3.07 (1.42), $p < .05$] in predicting flanker RT scores. Perceived stress increased over time in the heat therapy group [M s (SD) = 0.48 (1.13) vs. 0.17 (0.99)]. Simple slopes analysis revealed that those in the steam-room group having higher perceptions of stress over time showed better flanker % cost RT [b (se) = -2.82 (.97), $p < .05$]. Concurrently, reduction in heart rate response to exercise over time, for the steam group, appeared to serve as a mediator for group effects on flanker RT. Similar patterns were observed for working memory. Sensitivity analyses to determine impact of contamination (non-steamer trying steam on own, $n = 2$), yielded no contradictory results. Together, results suggest that regular heat therapy (in combination with exercise) may increase perceptions of stress and improve cognitive performance. These data support the growing evidence of thermotherapeutic health benefits, particularly for those with hypertension.

EXAMINING THE PREVALENCE OF MENTAL HEALTH DISORDERS AND RATES OF HELP-SEEKING AMONG UNIVERSITY-ENROLLED, BLACK MEN

Kofoworola Williams, MPH¹, Amy Adkins, Ph. D.¹, Sally Kuo, Ph. D.¹, Jessica G. LaRose, Ph.D.², Shawn O. Utsey, Ph. D.¹, Jeanine D. Guidry, PhD¹, Kellie Carlyle, Ph. D.¹

¹Virginia Commonwealth University, Richmond, VA; ²VCU School of Medicine, Richmond, VA

Background: Black men in college represent a subgroup of emerging adults who are at increased risk of developing mental health disorders (MHDs), such as anxiety and depression. Such risk has been attributed to disproportionate experiences with everyday racial discrimination and high levels of psychological distress. Despite being at higher risk, university-enrolled, Black men are not utilizing mental health or health resources at optimal rates. The current evidence base describing prevalence of MHDs and health services utilization among Black men in college is limited. The present study addresses this by examining mental health prevalence among university-enrolled, Black men and their rates of health services utilization.

Methods: Data were analyzed from the Spit for Science survey, a longitudinal research study at a large, urban, public university. Participants are given surveys in their freshman year and follow-up surveys every spring thereafter. Measures included: mental health disorders (depression and anxiety, as measured by the Symptom Checklist 90) and campus health services utilization (counseling center, health services, wellness center, and recreational sports). We conducted descriptive analyses to determine MHD prevalence and utilization rates. Mann Whitney U tests to compare prevalence rates to White men and Black women; and, Chi-squared tests to compare rates of utilization among groups.

Results: 681 Black men, 2329 White men, and 1679 Black women were included in this analysis. In Year 1, 86.2% of Black men reported experiencing any MHD symptoms compared to 88.1% of White men and 91.8% of Black women. By Year 4, 73.2% of Black men reported experiencing any MHD symptoms compared to 89.2% of White men and 87.9% of Black women. Also, in Year 1, Black men (19.6%) utilized counseling services at lower rates compared to White men (35.7%), $p = .031$. In years 3 and 4, there were significant differences in utilization of health services between Black women and Black men, $p = .007$ (year 3) and $p = .026$ (year 4). Chi-Squared tests also showed significant differences in the utilization of recreational sports between Black men (62.7%) and Black women (41.5%), $p = .009$.

Conclusion: The key findings suggest that Black men report less experiences with anxiety and depression than White men and Black women. Results also show that White men and Black women utilize certain services more than Black men. Implications for future research are discussed.

GENDER AND RACIAL/ETHNIC DISPARITIES IN ASSOCIATIONS BETWEEN WEIGHT MISPERCEPTION AND TRENDS OF SUICIDAL BEHAVIORS

Yunyu Xiao, MPhil¹, Chengbo Zeng, MPH²

¹New York University, JERSEY CITY, NJ; ²University of South Carolina, Columbia, SC

Background: Suicide is the second leading cause of death for adolescents. Previous studies have identified associations of actual and perceived weight with suicidal behaviors. Limited research, however, examined the effect of weight misperception (i.e., mismatched actual-versus-perceived weight categories) on the trends of suicidal behaviors. Furthermore, plausible gender and racial/ethnic disparities in these associations are rarely unknown. Such information is important to guide suicide intervention targeting at-risk adolescents with weight concerns. This study aims to examine gender and racial/ethnic disparities in associations between weight misperception and trends of adolescent suicidal behaviors.

Methods: Data were derived from the 1999-2017 Youth Risk Behavior Survey, a school-based survey of a nationally representative sample of students in grades 9-12 ($n=147,929$, 50.5% female). Weight misperception was constructed by BMI-for-age weight status (i.e., obesity, overweight, normal, underweight) and self-perceived weight (i.e., very underweight, slightly underweight, about-the-right weight, slightly overweight, very overweight). Suicidal behaviors were self-reported ideation, plan, attempts, injury by attempts). Logistic regression analyses were used to examine associations between weight misperception and trends of each suicidal behaviors by sex and racial/ethnic groups. Linear and quadratic trends were examined, controlling for student grade levels.

Results: Male adolescents with weight misperception showed increasing trends of suicidal ideation ($OR=1.03$, $p < .01$), suicide plan ($OR=1.03$, $p < .05$) and injury by suicide attempts ($OR=1.10$, $p < .05$), with slower speed in later periods ($p < .05$). Stratified analyses indicated that with misperceived weight, Asian females ($OR=1.19$) and other-race males ($OR=1.24$) had increasing trends of suicidal ideation; Black males had increasing suicide plan ($OR=1.26$); other-race females had increasing suicide attempts ($OR=1.18$); White females ($OR=1.12$) and males ($OR=1.30$) had increasing injury by attempts ($p < .05$).

Conclusions: Gender and racial/ethnic disparities were uncovered in trends of different suicidal behaviors among adolescents with weight misperception over the past decade. Special attention shall be paid into males, Asian females, other-race females and White females with distorted weight perception. Health practitioners are suggested to screen actual and self-evaluated weight to detect at-risk adolescents. Suicide interventions integrating health education and promotion of body image and weight perception could be more effective.

COGNITIVE IMPAIRMENT FOLLOWING MULTIPLE CONCUSSIONS IN COLLEGE-AGE ATHLETES

Taylor Hanayik, PhD¹, Mitchell Berman, PhD², Chris Rorden, PhD³, Roger Newman-Norlund, PhD³, Michael McCall, PhD³, Richard Nelson, MS²¹University of Oxford, Oxford, England, UK; ²Mississippi State University, Starkville, MS; ³University of South Carolina, Columbia, SC

Among existing concussion and mild traumatic brain injury literature, few studies have examined how having at least one prior concussion affects cognitive performance (Collins et al., 1999). Whereas some previous studies already highlight the negative effects after concussion, many of these studies are five or more years old and dichotomize the participants into groups of 'previously concussed' and 'not previously concussed,' without considering the actual number of previous concussions, which could potentially provide a more nuanced understanding of the role concussions play in cognitive performance. The objective of the present study was to assess whether an association exists between a history of multiple concussions and cognitive performance on tasks addressing multiple aspects of cognition. Data collection included an online self-report survey about participants' health, sports, and concussion history, and a computerized three-part cognitive assessment battery. This assessment included a working memory task, a decision-making task, and a response inhibition task.

Participants included 51 male, club athletes ($M = 19.64$ years old, $SD = 1.22$, range = 18-23) recruited from a university in the southeast United States. Forty-eight of the participants were right-handed and three were left-handed. Exclusion criteria included an existing or prior learning disability diagnosis, ADHD, or other serious neurological issues. Participants received \$10 as compensation. The participants were also informed the highest-performing subjects would receive one of two \$25 gift cards once data analysis was complete. Results revealed that number of concussions was associated with total responses on no-go trials ($r = .364$, $p = .009$), no-go trial accuracy ($r = -.364$, $p = .009$), average reaction time ($r = -.321$, $p = .023$), reaction time on rare-go trials ($r = -.339$, $p = .016$), and number of perseverations ($r = .424$, $p = .002$) on the Go/No-Go response inhibition task. Number of concussions was also associated with accuracy on the working memory task for trials where presented numbers summed to 10 ($r = -.403$, $p = .003$). Results support the notion that multiple concussions impact performance on a range of cognitive tasks, as well as provide evidence for using a continuous index rather than a dichotomous concussion research protocol.

10:30 AM-11:30 AM

TAKE A TIMEOUT: FEMALE STUDENT ATHLETES' MENTAL HEALTH NEEDS, RESOURCE UTILIZATION, AND PRIORITIES FOR PROGRAMMING ON CAMPUS.

Alicia A. Dahl, MS, PhD¹, Abigail F. Coffey, N/A²¹University of North Carolina at Charlotte, Charlotte, NC; ²UNC-Charlotte, Charlotte, NC

Mental health among female collegiate athletes is a public health concern, with 28.1% of female athletes exhibiting clinically-relevant depressive symptoms compared to 17.5% of their male counterparts. Moreover, one-third of female athletes report attitudes and symptoms placing them at increased risk for disordered eating. Concerns around stigma for reporting mental health status combined with the underutilization of mental health services adds another level of complexity for identifying and addressing mental health among National Collegiate Athletic Association (NCAA) members.

Female student athletes ($n=24$) at a southern university were recruited to participate in a 20-minute online needs assessment survey regarding mental health status, resource utilization, and priorities for tailored programming on campus. Measures included the Kessler Psychological Distress scale, health services utilization questions, and feedback on fourteen proposed content topic areas and nine delivery methods being considered for a program tailored to NCAA female student athletes. Descriptive statistics were used to summarize findings of the needs assessment.

A third of respondents ($n=8$, 33.3%) reported a previous medical diagnosis of anxiety. Five respondents (20.8%) reported a clinical diagnosis of depression. General health status was most frequently rated "somewhat good" ($n=10$, 41.7%), while mental health status was rated "average" ($n=9$, 37.5%). The majority of respondents were likely to have moderate mental health disorder ($n=18$, 78.3%), while fewer demonstrated a likelihood of severe ($n=3$, 13.0%) or mild ($n=2$, 8.7%) disorder. Ten students (43.5%) reported receiving psychological services in the past 12 months.

Of the fourteen topics presented for tailored mental health programming, disordered eating was the highest priority to address among female student athletes ($n=20$, 86.9%), followed by signs of mental distress in teammates ($n=19$, 82.6%), managing emotions ($n=17$, 73.9%), managing stress ($n=16$, 70.0%), body image ($n=16$, 70.0%), coping mechanisms ($n=15$, 65.2%), and life balance ($n=14$, 60.9%). Regarding methods for receiving program content, the majority of respondents requested podcasts ($n=16$, 69.6%) or social media ($n=15$, 65.2%). One-on-one approaches were preferred to team-based (78.3% vs. 56.5%) for program delivery.

Findings from this needs assessment informed the development of twelve tailored mental health podcasts using a narrative approach to teach Cognitive Behavioral Therapy skills to female student athletes. The podcasts will be pilot-tested in a group of female student athletes ($n=25$) during fall semester 2019. Qualitative feedback and acceptability data from the pilot study will be included in this presentation. This study aims to provide an innovative solution to address the growing demand for mental health services among female collegiate athletes.

IMPAIRED DRIVING BEHAVIORS, CHARACTERISTICS AND SUICIDE PLANNING: RESULTS FROM THE 2017 YOUTH RISK BEHAVIOR SURVEY.

Ehikowoicho E. Idoko, MS, CHES¹, Idethia Harvey, MPH, DrPH², Ngozi G. Nwosisi, MPH³¹Texas A&M University, College Station, TX; ²Texas A & M University, College Station, TX; ³University of California, Irvine, Irvine, CA

Introduction: Of the many transitions occurring during adolescence, unsupervised operation of a vehicle is notable. While substance-impaired driving is a known risk factor for unintentional injury, it may also bear relevant associations to mental health and suicide outcomes. The objective of this study was to determine the relationship between being an underage impaired driver and suicide risk.

Methods: The 2017 Youth Risk Behavior Survey, which examines U.S. high school students in grades 9 through 12, was utilized (n=14,765). Predictor variables were impaired driving behaviors (e.g., consumption of alcohol or marijuana when driving a vehicle); sadness/hopelessness; cognitive difficulty (item indicated as “because of a physical, mental, or emotional problem, do you have serious difficulty concentrating, remembering, or making decisions?”); education level; race/ethnicity; gender; and sexual orientation. The outcome variable was suicide planning during the last 12 months. Binary logistic regression analyses in SAS 9.4 were utilized to predict suicide risk in survey respondents.

Results: Underage respondents who reported drinking alcohol and driving had higher odds of planning a suicide attempt (OR=0.588; 95% CI=0.426-0.811). Although marijuana-impaired driving behavior had an overall significant relationship to suicide planning (p=0.0273), non-marijuana-using drivers were 1.2 times more likely to have made a suicide plan than marijuana-using drivers (OR=1.170; 95% CI=1.018-1.345). American Indian and Native Hawaiian (p=0.0311); Hispanic (p=0.0004); and multi-race youth (p=0.0075); as well as those who identified as Bisexual (p<.0001) showed a strong likelihood to contemplate and plan suicide. Being sad or hopeless (p<.0001; β =1.0274) and having any cognitive difficulty (p<.0001; β =0.3873) also strongly predicted planning of a suicide attempt.

Conclusion: Previous studies have shown the significant connection between substance abuse and mental health outcomes. The present study further demonstrates that adolescents’ participation in risky, impaired driving behavior is linked to degrees of suicidality such as ideation and planning. Reduction of suicide risk in adolescents and young adults remains a focal point in public health promotion. Therefore, it may be essential to develop interventions that go beyond punitive measures to encourage mental health screenings for adolescents who participate in these risky behaviors. Injury prevention and road safety programs should also consistently include an emphasis on mental health care and help-seeking.

VALIDATION OF THE VALUING QUESTIONNAIRE IN A CARDIOVASCULAR DISEASE SAMPLE

Mindy M. Kibbey, B.A.¹, Angelo M. DiBello, PhD², Jennifer R. Strenger, M.A.¹, Anagha A. Babu, B.A.¹, Samantha G. Farris, Ph.D.³¹Rutgers, The State University of New Jersey, Piscataway, NJ; ²CUNY Brooklyn College, Brooklyn, NY; ³Rutgers, the State University of New Jersey, Piscataway, NJ

Values are characterized as personally selected and constructed guiding principles which intrinsically motivate patterns of behavior (Hayes et al., 2006). The Valuing Questionnaire (VQ; Smout et al., 2014) is a self-report assessment of values-consistent living which includes two subscales measuring *Progress* toward values and *Obstruction* of values. Because engaging in values-consistent positive health behaviors contributes to disease prevention and management, the VQ has been utilized for assessment in behavioral medicine treatment outcome studies (Graham et al., 2016). However, the psychometric properties of the VQ have not been widely validated among chronic disease and at-risk populations. Therefore, the current study aimed to test the psychometric properties of the VQ in a sample of participants (N = 382) with a history of cardiovascular disease (CVD; n = 127, 33.2%) or multiple significant CVD risk factors, a population for whom activation of values-consistent living can support the wholesale health behavior change which is often necessary for meaningful risk reduction. Participants ($M_{age} = 42.2$, $SD = 11.97$; 50.4% female) completed the VQ as part of an anonymous self-report Qualtrics questionnaire via the Amazon Mechanical Turk platform. Confirmatory factor analyses supported the two subscales presented in the measure’s original development and validation study, and both subscales evidenced good internal consistency (Progress: $\alpha = .87$, CI = .80-.86; Obstruction: $\alpha = .83$, CI = .80-.86). The VQ also performed well in terms of known groups validity, convergent validity with related constructs (health-related quality of life; psychiatric symptoms including depressive and anxiety symptoms, stress, and cardiac anxiety; values and psychological flexibility), and concurrent validity with the Values subscale of the Comprehensive Assessment of ACT Processes (CompACT), as well as incremental predictive validity relative to the CompACT Values subscale in terms of health-related quality of life. The current study provides evidence in support of the validity and reliability of the VQ for assessing values-consistent living in behavioral medicine populations and treatment outcome studies.

PSYCHOMETRIC PROPERTIES OF THE ROSENBERG SELF-ESTEEM SCALE AND SOCIAL PHYSIQUE ANXIETY SCALE IN US HISPANIC ADOLESCENTS

Anita M. Reina, MS¹, Eva V. Monsma, PhD², Jennifer L. Gay, PhD¹¹University of Georgia, Athens, GA; ²University of South Carolina, Columbia, SC

Background: Hispanic adolescents in the US may be more likely to experience body image dissatisfaction and decreased self-esteem due to higher weight status relative to their other US non-Hispanic peers. In social physique anxiety (SPA), self-appraisal is dependent upon both perception of one's body as well as the proxy perceptions of others of their physique. Self-esteem can be protective against SPA regardless of weight status. Although SPA is measured among Hispanics, the psychometric properties have not been tested in a non-European Hispanic sample. The aim of the current study is to examine the psychometric properties and factor structure of the Social Physique Anxiety Scale (SPAS) and Rosenberg Self-Esteem Scale (RSES) in a sample of middle school-aged Hispanic adolescents living in the United States.

Methods: A total of 308 middle school students (68.4% female; age $M=12.17$, $SD=1.03$) completed the RSES and the SPAS. A confirmatory factor analyses using the Lavaan statistical software package in R was used to test the factor structure of the SPAS and the RSES. The maximum likelihood estimation was used to evaluate the performance. A multigroup confirmatory factor analysis using configural and metric invariance was used to further examine the measurement invariance between males and females for both scales.

Results and Conclusions: The total reliability for the RSES ($\alpha=.82$) and the SPAS ($\alpha=.86$) were acceptable. The results from the current sample suggests that the RSES was best fit by a two factor model ($X^2(34)=49.34$; $CFI=0.98$; $RMSEA=0.04$). For SPAS, the two-factor model fit the data ($X^2(43)=120.46$; $CFI=0.94$; $RMSEA=0.07$) in alignment with findings from other non-Hispanic samples. Both the two-factor and bifactor SPAS models are further discussed, including previously identified issues with a two-factor model pertaining to method effects of negatively and positively worded items. The use of the bifactor model, a method in item response theory where items load on a primary and secondary dimension, may correct for the method effects of the two factors that affect the model fit of the parsimonious general model. Both the RSEA and SPAS scales were measurement invariant by sex suggesting that the scale performs equally well in male and female Hispanic adolescents. Although the SPAS was invariant by sex, the fit was only marginally acceptable, suggesting there may be some differences in the scale between males and females ($X^2(96)=182.03$; $CFI=0.93$; $RMSEA=0.07$). Overall both scales demonstrated factorial validity and reliability for use in adolescent US Hispanic samples.

PRELIMINARY DEVELOPMENT OF AN INSTRUMENT FOR ASSESSING MOTIVATIONAL INTERVIEWING IN PHYSICAL THERAPY

Eric Kruger, PT, DPT, PhD, MS¹, Rachel Granzow, n/a²¹The University of New Mexico, Albuquerque, NM; ²University of New Mexico, Albuquerque, NM

Motivational interviewing (MI) is a communication strategy for facilitating behavior change and involves the use of communication skills (e.g., use of open-ended questions, reflections, and summaries) and beliefs that influence therapist behavior during therapeutic interactions (the so-called "spirit" of MI). Successful physical therapy (PT) outcomes depend on patients changing their behavior in multiple areas, such as attending appointments, using adaptive equipment, incorporating lifestyle changes, and adopting a new exercise plan. Despite a growing emphasis on MI in the curriculum of PT degree programs, there is limited research on the use of MI in PT practice. This study aimed to assess the construct validity of an instrument evaluating communication skills and beliefs consistent with MI in PT. Therefore, a survey was developed using content experts in both PT and MI: The Motivational Interviewing in Physical Therapy (MIPT) survey. The survey was developed to capture three hypothesized constructs: (1) use of communication skills emphasized in MI (e.g., use of open-ended questions, reflections, and summaries); (2) beliefs consistent with MI spirit (e.g., emphasizing collaboration with the patient, respecting the patient's autonomy in making decisions); and (3) beliefs inconsistent with MI spirit (e.g., emphasizing persuasion or fear as catalysts for patients' behavior change). The MIPT was distributed to practicing physical therapists ($N=802$) and a confirmatory factor analysis (CFA) was used to evaluate the factor structure of the MIPT. Several CFA models were evaluated. Poor fitting items were removed from the model and the best fitting model consisted of two separate constructs: consistent (CON; a combination of MI skills and MI-consistent belief items) and inconsistent (INCON; MI-inconsistent belief items); $\chi^2(188)=656.57$, $p<0.01$, $RMSEA=0.056$ [0.051, 0.06], $CFI=0.94$, $SRMR=0.05$. Preliminary results from this analysis indicate that the MIPT demonstrates a satisfactory factor structure of two unrelated constructs (CON and INCON), $r=0.00$, $p=0.79$. Future work aims to validate the MIPT by evaluating if the survey can predict real-world physical therapist behavior consistent with MI, mediators of behavior change, and patient outcomes.

RECRUITING FOR BEHAVIORAL RESEARCH DURING HEMATOPOIETIC CELL TRANSPLANT: LESSONS LEARNED FROM THE WISE STUDY

Lauren A. Whitmore, MA¹, Taylor Schulte, n/a², Amanda Belanger, B.S.¹, Kristi Graves, PhD³, Christine M. Rini, PhD⁴

¹Cancer Prevention and Control, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ; ²Georgetown Lombardi Comprehensive Cancer Center, Cancer Prevention and Control Program, Washington, DC; ³Georgetown University, Washington, DC; ⁴Northwestern University Feinberg School of Medicine, Chicago, IL

Background: The annual number of hematopoietic cell transplants (HCT) is expected to increase to 100,000 by the year 2030. Physical and psychological symptoms are common and serious in HCT recipients, and these symptoms are highest during treatment. Yet, research on behavioral interventions to reduce symptoms is often conducted post-transplant. Intervening during transplant could reduce symptoms when burden is highest. To promote research during this important period, we describe unique challenges and lessons learned when recruiting HCT patients prior to transplant for an intervention during treatment.

Methods: We are conducting a multisite randomized controlled trial of a behavioral intervention to reduce symptoms in people undergoing HCT. In 6 months, we approached 139, screened 99, and enrolled 73 participants who met our eligibility criteria. We have systematically tracked barriers and facilitators to recruitment and enrollment in the pre-transplant HCT population.

Results: We identified 3 major challenges to enrollment and have implemented multiple solutions. The first major challenge was timing of approach. Initially we tried enrolling patients immediately after transplant was scheduled, but patients reported feeling overwhelmed with pre-transplant responsibilities, leading some to decline. Waiting until hospital admission, or immediately before admission, allowed us to avoid interfering with pre-transplant activities. Second, patients reported experiencing fear related to anticipated physical symptoms and expressed concern about committing to study procedures they may not be able to complete. We developed more flexibility in timing of study procedures. We allowed longer windows for study task completion and expanded our study scripts to more carefully explain the flexibility to accommodate participants' schedules and energy levels. Third, we found that developing clear channels of communication with the clinical team was imperative to recruitment success. These changes reduced the number of patients who declined due to feeling overwhelmed or too busy from 22% at 8 weeks of recruiting to 15% at 6 months.

Conclusions: Recruiting HCT patients prior to transplant is possible when protocols are structured to include support of patient needs, flexible windows, and engagement of the clinical team. Using these strategies, behavioral interventions can be more effectively implemented during this critical time.

PREDICTING BYSTANDER INTERVENTION INTENTIONS IN COLLEGE STUDENTS: A REASONED ACTION APPROACH

Christine L. Hackman, PhD¹, Sarah Rush Griffin, MA, PhD², Paul Branscum, PhD, RD³, Arden Castle, n/a⁴, Marina Katague, n/a⁵

¹California Polytechnic State University, San Luis Obispo, CA; ²Long Island University, New York, NY; ³Miami University, Oxford, OH; ⁴San Jose State University, San Jose, CA; ⁵Yale School of Public Health, New Haven, CT

Background: Considered the gold standard for sexual assault prevention in colleges, bystander intervention (BI) is an approach that teaches individuals to take action in potential sexual assault situations. Increased BI behavior in college populations could drastically reduce sexual assault victimization in young adults. It is important to determine the factors that influence whether a person will engage in BI in order to create relevant and tailored interventions to promote BI and reduce sexual assault. In conjunction, the Reasoned Approach (RAA) and BI can create and evaluate ownership for one's community and capitalize on one's expectation to help.

Purpose: To examine predictors of undergraduate college student intentions to engage in BI using the RAA.

Methods: College students were recruited via an online survey disseminated in general education courses at two separate universities in the US (one in the north-east, and one in the west) measuring intentions, attitudes (including cognitive and affective attitudes), perceived norms (including injunctive and descriptive), and perceived behavioral control (self-efficacy and autonomy). Linear regression models were used to understand how the core constructs of the RAA regressed on intentions.

Results: The sample consisted of 291 undergraduate students between 18 and 24 years old (60.1% women and 80.4% lowerclassmen). Results showed that instrumental attitudes, experiential attitudes, capacity, and autonomy significantly predicted intentions to engage in BI ($R^2=0.55$). Injunctive norms and descriptive norms were not significant predictors.

Discussion: Given the prevalence of sexual assault in college students, it is crucial to identify determinants of BI engagement in college students and explore the interactions among these variables. Results from this study will be used to inform the development of theory-driven, and evidence-based interventions to promote BI. Additionally, study results will provide more in-depth insight into further examining the complex relationships among these predictors.

THE EFFECT OF TEMPORALLY-DENSE SAMPLING ON VARIANCE OF AFFECT IN ECOLOGICAL MOMENTARY ASSESSMENT PROTOCOLS

Eldin Dzubur, PhD¹, Shirlene D. Wang, BA¹, Tyler B. Mason, PhD¹, Bridgette Do, MPH², Donald Hedeker, PhD³, Stephen S. Intille, PhD⁴, Genevieve F. Dunton, PhD, MPH¹

¹University of Southern California, Los Angeles, CA; ²University of Southern California, Santa Monica, CA; ³University of Chicago, Chicago, IL; ⁴Northeastern University, Boston, MA

Introduction: Intensive longitudinal study designs using ecological momentary assessment (EMA) are advantageous for collecting self-report data in real-time and in real-world settings. A novel implementation of EMA is the use of temporally-dense sampling (~every 30 min) with a short survey (~10 items) in order to leverage frequent modern smartphone use. However, less is known about the extent to which such temporally-dense protocols impact compliance rates and capture additional inter- and intra-individual variability beyond relatively sparse EMA sampling schedules (~every 2 h).

Objective: The purpose of the study was to compare temporally dense and sparse EMA sampling protocols in terms of compliance rates and degree of inter-/intra-individual variability of affective variables.

Methods: A sample of 20 women ($M_{age}=42.8$, $SD=6.01$, 60% Hispanic) participated in (1) a temporally-sparse EMA protocol (~20-question surveys randomly prompted every 120 ± 15 min across 7 days, answered in 3.3 ± 0.3 min) and (2) a temporally-dense EMA protocol (15-question surveys prompted every 30 ± 10 min across 2 days, answered in 1 ± 0.5 min). Affect items (happy, angry, sad, stressed) were self-reported during each EMA survey via smartphones. Mixed effects location-scale models were used to estimate between- (BS) and within-subject (WS) variance parameters of affect and test the effect of protocol on BS/WS variance.

Results: Compliance was higher in the temporally-dense (89.8%) than in the temporally-sparse (73.3%) protocol ($p < 0.001$). Happiness and stress showed significantly greater BS variance for the dense vs. sparse protocol ($ps < 0.05$). Anger, stress, and sadness showed significantly greater WS variance for the dense vs. sparse protocol ($ps < 0.05$). The sparse protocol did not yield significant deviation in WS variance between individuals, whereas the dense protocol had significant deviation in WS variance for all measures ($ps < 0.001$).

Discussion: Results indicate that temporally-dense EMA sampling may offer advantages for studying time-varying self-reported constructs. Moreover, there is also evidence to suggest that temporally-dense EMA may improve the ability to detect differences in response patterns between subjects, especially for variables thought to be trait-like (e.g., negative affect). Additional research is needed to determine a good frequency of EMA prompts and protocol length to maximize data collection without overburdening participants.

HOW PRAGMATIC WAS IT? USING PRECIS CRITERIA TO ASSESS A DIGITAL WEIGHT GAIN PREVENTION INTERVENTION IN PRIMARY CARE

Cayla Treadway, B.A.¹, Dori Steinberg, PhD, RD², Miriam Berger, MPH², Sandy Askew, MPH³, Gary Bennett, PhD²

¹Duke University, DURHAM, NC; ²Duke University, Durham, NC; ³Duke University, Ocoee, FL

Background: There is a need for real-world evidence to inform routine practice. Pragmatic trials are designed to offer insight into the implementation of evidence-based interventions within real-world settings among diverse populations. The pragmatic-explanatory continuum indicator summary (PRECIS) tool can help gauge trial correspondence with pragmatic principles.

Objective: To assess Balance, a 12-month pragmatic randomized controlled trial of a digital weight gain prevention intervention among research team members and leaders at a system of Federally Qualified Health Centers (FQHCs), using the PRECIS tool.

Methods: Participants (n=15) involved in the trial were recruited to review the PRECIS tool and trial protocol and to rate the pragmatic level of Balance on 10 PRECIS domains. Each rater independently assessed components of Balance using pragmatic and explanatory examples provided for each domain to score the trial description from 1, “extremely explanatory,” to 5, “extremely pragmatic.” We calculated the mean score and standard deviation for each PRECIS domain and determined inter-rater reliability for all scores using Gwet’s AC2.

Results: All 15 respondents (11 research team members and 4 stakeholders) rated the design of Balance as “mostly pragmatic” or “extremely pragmatic.” PRECIS domains for which the trial was rated as “extremely pragmatic” (defined as mean $> 4.5 \pm SD$) included: follow-up intensity (5 ± 0), comparison intervention (4.8 ± 0.4), primary trial outcomes (4.7 ± 0.4), and experimental intervention flexibility (4.5 ± 0.6). Domains rated as “mostly pragmatic” (defined as mean $> 3.5 \pm SD$) included: participant eligibility criteria (4.1 ± 0.6), practitioner adherence to protocol (4.0 ± 0.7) and participant compliance with intervention (3.7 ± 0.7). Overall inter-rater agreement for research team members and stakeholders at FQHCs showed consensus across PRECIS domains (Gwet’s AC2 = .76, 95% CI: .68 to .84).

Conclusion: Overall, the PRECIS assessment of Balance revealed the trial design to be “mostly” or “extremely” pragmatic. Areas in which the trial was deemed “extremely pragmatic” included utilizing clinic staff/resources and digital health strategies that extend weight gain prevention beyond clinical encounters. Using the PRECIS tool can inform collaborative trial design among research teams and health system leaders, yielding a pragmatic approach and informing evidence-based clinical care practices.

A MOBILE SLEEP AND PHYSICAL ACTIVITY INTERVENTION FOR POST-9/11 VETERANS WITH CHRONIC INSOMNIA

Erin D. Reilly, Ph.D.¹, Beth Ann Petrakis, MPA¹, Stephanie Robinson, Ph.D.¹, Wiener Renda, M.D.¹, Carmen Sceppa, MD, PHD², Karen S. Quigley, Ph.D.¹¹Bedford VA Medical Center, Bedford, MA; ²Northeastern University, Boston, MA

Difficulty falling asleep and staying asleep are common problems that affect over 30 million Americans. Additionally, military personnel and Veterans often have insomnia problems post-deployment. We proposed that insomnia could be improved by behavioral change including increased physical activity, which can be delivered and assessed via mobile health (mHealth) technologies. The goal of this project was to test whether enhancing physical activity (PA group) can improve the impact of a cognitive behavioral therapy (CBT)-based mobile self-management intervention (i.e., CBT-I Coach app) for insomnia, over and above the impact of the CBT-I app alone (CBT-I group). Participants also used a home-based sleep monitor (WatchPAT) to obtain objective sleep data, and a Fitbit to track steps (PA group goal of 10% per week step increase).

Thirty-three post-9/11 Veterans met criteria for insomnia and were enrolled. We compared sleep outcomes for the CBT-I + PA group vs. the CBT-I group over 6-weeks with measures pre- and post-intervention. Of 33 enrolled, 26 participants completed the full intervention (CBT-I + PA group: n=12; CBT-I alone group: n=14). There were no differences between groups (CBT-I + PA vs CBT-I alone) at final visit on WatchPAT recorded total sleep time, subjective sleep measures of the Insomnia Severity Index (ISI), Pittsburgh Sleep Quality Inventory (PSQI), or on Functional Outcomes of Sleep Questionnaire (FOSQ). However, analyses revealed clinically-significant improvements for both groups on the ISI, $t(25) = 5.64, p < .001$, FOSQ, $t(25) = -3.73, p < .01$, and the PSQI, $t(24) = 4.31, p < .001$. WatchPAT sleep data also revealed a significant increase in total time spent asleep between baseline ($m = 79.2, SD = 10.4$) and the last week ($m=83.5, SD=10.1$) of the intervention for both groups, $t(22) = -2.285, p = .03$.

There was no significant difference between the two groups on self-reported or total sleep time as measured by the WatchPAT. However, across both groups, we found an increase in both objective sleep time and subjective sleep quality. This study demonstrates that cognitive behavioral-based mobile apps for self-management of insomnia can improve sleep quality and quantity.

COGNITIVE BEHAVIORAL THERAPY FOR CHRONIC PAIN IN PRIMARY CARE: IMPLEMENTATION AND OPIOID PRESCRIPTIONS AMONG VETERANS

Jenna Gress Smith, PhD¹, Dominika Borowa, PhD², Yen Tran, PharmD, BCPS¹, Brian Arizmendi, PhD¹, Angela Rossetto, MS¹, Stephanie Miller, BA³, Shannon Patterson, PhD⁴, Nicole A. Roberts, PhD³¹Phoenix VA Healthcare System, Gilbert, AZ; ²Rocky Mountain Regional VAMC, Aurora, CO; ³Arizona State University West Campus, Glendale, AZ; ⁴Phoenix VA Healthcare System, Phoenix, AZ

Over 50% of Veterans in primary care settings report chronic pain (i.e., chronic non-cancer pain [CNCP] that persists 3 months past expected healing time), 57% of whom are prescribed chronic opioid therapy (Edlund et al., 2014). Further, Veterans with mental health diagnoses are more likely to receive higher doses of opiate medication than Veterans without mental health diagnoses (Edlund et al., 2014; Seal et al., 2012). Given the health costs of prolonged opiate use for CNCP, including cognitive deficits, depression, higher accident risk, and death (Baldacchino, Balfour, Passetti, Humphris, & Matthews, 2012), there is a pressing need for research about non-pharmacological treatment options. The present study examined the feasibility and preliminary effectiveness of a six-week Cognitive Behavioral Therapy for Chronic Pain (CBT-CP) group treatment adapted for Veterans and implemented in a VA primary care setting. We studied 403 Veterans (86% male, 83% Caucasian) referred to CBT-CP over a 2.5 year period. Patient characteristics and opiate prescriptions (measured in morphine milligram equivalent [MME]) were compared between those who were referred and attended treatment (n=179) versus those referred but who did not attend (n=220). Chart history of mental health diagnoses revealed 63.1% of the sample had a history of depression; 39.8% traumatic stress symptoms; 35.0% anxiety symptoms; and 24.1% insomnia. There were no significant differences in prevalence of mental health diagnoses between Veterans who did versus did not attend treatment once referred. There also were no differences between those who did versus did not attend treatment and initial overall MME prescription amounts. We categorized Veterans as low (0-20 MME; n=251, 62.6%), moderate (21-50 MME; n=76, 19.0%), high (51-90 MME; n=39, 9.7%), and very high (91+ MME; n=35, 8.7%) in initial MME prescription amounts. Among the low MME group, those who and attended the intervention showed a significant decrease in opioid use 12 months post-referral ($M=-2.90, SD= 6.47$) compared to those who did not attend ($M=.14, SD=11.79$), $t(220)=2.53, p < .05$. There were no differences in the other three groups. These preliminary results suggest CBT-CP may promote decreases in opioid prescriptions in those with lower levels of initial use. Findings support the use of a stepped model of integrative care for pain management that considers levels of opioid prescriptions in Veterans.

MULTIPLE HEALTH BEHAVIOR CHANGE INTERVENTION TARGETING PHYSICAL ACTIVITY AND DIET IMPROVES STRESS, NOT SLEEP

Sandra Bajc-Dimitrov, B.S.¹, Samuel Battalio, B.S.¹, Donald Hedeker, PhD², Bonnie Spring, PhD³¹Northwestern University, Chicago, IL; ²University of Chicago, Chicago, IL; ³Northwestern University Feinberg School of Medicine, CHICAGO, IL

Physical inactivity, unhealthy diet, chronic elevated stress, and poor sleep quality are prevalent lifestyle risk factors for chronic disease. Given that risk behaviors are interconnected and lifestyle risk factors often co-occur, research should examine whether multiple behavior change interventions targeting one or more of these domains may also impact adjacent domains. We examined whether interventions targeting physical activity (PA), sedentary behavior, and diet also improved stress and sleep, and whether these improvements were comparable to an intervention targeting stress and sleep directly. Participants (n=212) were Chicago area adults (76.4% female, 59% non-white minority, mean age = 40.8 years) with low PA, high sedentary time, and poor quality diet who took part in the Make Better Choices 2 (MBC2) trial between 2012-2014. MBC2 aimed to improve diet and PA through a multicomponent intervention incorporating telephone-based health coaching, monetary incentives, and self-monitoring in a custom smartphone application. We randomly assigned participants to one of three conditions: 1) targeting PA simultaneously with other diet and activity goals, 2) targeting PA sequentially after mastering other goals, or 3) a stress management control group targeting stress, sleep, and relaxation. At baseline, 3, 6, and 9 months, participants completed daily smartphone surveys evaluating all study domains for 7 days. Participants rated perceived stress on an 11-point scale ranging from 0 (no stress) to 10 (high stress). We computed a sleep health composite score by norming three sleep domains (duration, quality, and efficiency) onto a Z-score metric and taking the mean of normed domain scores at each daily evaluation. Mixed growth models demonstrated that all three conditions produced comparable ($\chi^2[2] = 0.87, p = .65$) reductions in stress across the trial (mean reduction in predicted values = 1.81). Models evaluating composite sleep health demonstrated greater improvements in the stress and sleep condition relative to the diet and PA conditions ($\chi^2[2] = 18.58, p < .001$). These findings suggest a behavior change intervention to improve diet and physical activity can cause collateral improvements in stress but not sleep. Research should evaluate how sleep can be efficiently targeted in multiple health behavior change interventions.

SELF-DETERMINATION THEORY INTERVENTIONS IN THE HEALTH DOMAIN: A META-ANALYSIS

Nikos Ntoumanis, Prof¹, Johan Ng, PhD², Andrew Prestwich, PhD³, Eleanor Quested, PhD¹, Jennie Hancox, PhD⁴, Cecilie Thøgersen-Ntoumani, Prof¹, Edward Deci, Professor⁵, Richard Ryan, Professor⁶, Chris Lonsdale, Professor⁶, Geoffrey C. Williams, MD, PhD⁵¹Curtin University, Perth, Western Australia, Australia; ²Chinese University of Hong Kong, Hong Kong, N/A, Hong Kong; ³University of Leeds, Leeds, England, UK; ⁴University of Nottingham, Nottingham, England, UK; ⁵University of Rochester, Rochester, NY; ⁶Catholic University, Sydney, New South Wales, Australia

Ng et al. (2012) meta-analysis of applications of self-determination theory (SDT; Ryan & Deci, 2017) in the health domain included many non-experimental studies. A more recent meta-analysis by Gillison et al. (2019) of intervention studies in this area did not calculate changes in indices of physical or mental health. Advancing the SDT literature in the health domain, we present a meta-analysis of experimental studies that tested changes in at least one SDT variable and at least one health-behavior, physical-health outcome, or psychological-health outcome.

73 studies (N=30,088) met our inclusion criteria and provided sufficient data for the purposes of the review. The behaviour change techniques (BCTs) and SDT-based need supportive techniques used in the studies were also coded. Risk of bias was assessed using an adapted version of the Cochrane Risk of Bias Tool. To test whether changes in SDT-related constructs engender changes in other SDT-related constructs, health behavior, physical health and psychological health, a set of meta-regressions were conducted. Sensitivity analyses were applied to examine the robustness of the synthesized results by removing outliers and by examining whether any of the BCTs were associated with the effect sizes from individual studies.

A random-effects meta-analytic model (using Stata, v. 15) showed that the interventions produced small-to-medium changes in most SDT constructs at the end of the intervention period, and in health behaviors at the end of the intervention period and at the follow-up. Small positive changes in physical and psychological health outcomes were also observed at the end of the interventions. Increases in need support and autonomous motivation (but not controlled motivation or amotivation) were associated with positive changes in health behavior.

Interventions in the health domain based on SDT produce modest (in the region of $g = .30$ to $.60$) but sustained increases in health behaviors and improvements in physical health, and short-term changes in psychological health. These effects are partly due to increases in self-endorsed motivation for change and support from social agents.

SUSTAINABILITY OF MHEALTH MEDICATION REGIMEN SELF-MANAGEMENT PROGRAM FOR KIDNEY TRANSPLANT RECIPIENTS

Luke Sox, B.S.¹, Jessica Chandler, PhD¹, Kinsey N. Kellam, Bachelor of Arts, Biology¹, Lauren I. Feder, B.S.¹, Frank Treiber, PhD¹, John McGillicuddy, M.D.¹

¹Medical University of South Carolina, Charleston, SC

Background: Despite advances in medical care of kidney transplant recipients (KTRs), three-year graft survival is ~81% and graft half-life ~9yrs. Medication nonadherence and uncontrolled hypertension (HTN) are two primary risk factors for graft damage, loss, and death. A patient/provider user centered, theory guided, iterative design resulted in an mHealth technology enabled solution providing real-time monitoring of medication adherence (MA) and blood pressure (BP), and timely patient provider communication including, reinforcement/motivational SMS feedback to patients and quicker med changes by providers. Objective of the study was to determine the Smartphone MA Saves Kidneys: SMASK program's effects on MA and BP in KTRs with uncontrolled HTN.

Methods: The research design was a 6-month, two-arm efficacy trial followed by a 6-month follow-up evaluation. The SMASK experimental arm utilized an electronic medication tray, Bluetooth enabled, BP monitor and the SMASK app to monitor home-based adherence to their regimen, receive reminder alerts and tailored social reinforcement/motivational SMS based upon levels of adherence. The attention control standard care (SC) arm received text messages including links to PDFs and brief video clips containing healthy lifestyle tips.

Results: Participants were 80 adult KTRs (mean age: 54.2 yrs) with verified MNA and uncontrolled HTN. They were randomly assigned to either SMASK (n=40) or SC (n= 40) arms. At baseline, no participants had controlled systolic BP (SBP). MA scores during a 1-month screening phase were not different (53.9 vs. 47.3%; p=0.16) nor did SBP baseline values differ (141.4 and 144.8 mmHg, p =.16) between SC and SMASK groups, respectively. Average MA, as indicated by timestamped pill compartment use, was significantly higher (all p's < 0.001) for SMASK arm at each evaluation across the active 6-month trial (M1: 85.9 vs 45.3, M3: 97.5 vs. 38.5, and M6: 97.5 vs. 48.0% for SMASK and SC groups, respectively. At the 1, 3, 6 and 12- month time points, SBP averages were significantly lower in SMASK versus SC arms, respectively (M1: 130.9 vs 140.9; M3: 127.4 vs 139.3, M6: 124.3 vs 140.6, M12:128.3 vs 139.3; all p-values < .01). At months 3, 6, and 12 there were significant differences between the % meeting KDIGO cutoffs for SBP control (M3: 84.0 vs 37.5, M6: 75.8 vs 31.6 and M12: 58.6 vs 34.3%, all p's< .01) for SMASK and SC groups, respectively.

Conclusion: Our findings indicate the smartphone enabled medical regimen program is efficacious and sustainable after cessation of the formal program. A multi-site effectiveness RCT with longer follow-up and booster sessions post trial is needed to determine whether MA and BP control are maintained and improvements are gleaned in clinical outcomes (e.g., reduced rejection episodes, graft loss, improved GFRs, TAC variability).

PATTERNS OF EARLY ADHERENCE TO PHYSICAL ACTIVITY GOALS IN BEHAVIORAL WEIGHT CONTROL

Melissa L. Stansbury, M.S., EP-C¹, Jean Harvey, PhD, RDN², Rebecca Krukowski, PhD³, Andrew Ortaglia, MSPH, Ph.D.⁴, Christine Pellegrini, PhD⁴, Xuewen Wang, PhD, FAHA⁴, Delia West, PhD⁴

¹University of South Carolina, West Columbia, SC; ²University of Vermont, Burlington, VT; ³University of Tennessee Health Science Center, College of Medicine, Memphis, TN; ⁴University of South Carolina, Columbia, SC

Introduction: Weight loss response and adherence to behavioral recommendations, particularly physical activity (PA), vary substantially across individuals in lifestyle programs. While weight loss in the initial 4-8 weeks is shown to predict future weight loss, it is unclear what distinguishes responders from non-responders. Detecting early response indicators, such as poor adherence to PA, may provide targets for treatment tailoring. This study characterized patterns of adherence to prescribed step- and minutes-based PA goals during the first 8 weeks of an online group behavioral weight control program and identified associations with early weight loss.

Methods: Patterns of adherence to weekly goals for steps and minutes of moderate-to-vigorous physical activity (MVPA) were examined using latent class analysis. For each week, participants were considered adherent if the goal was met ($\geq 100\%$) or nonadherent if the goal was unmet ($< 100\%$) from self-reported PA. Step and minute goals were considered separately. Body weight was objectively measured at baseline and 8 weeks. Attendance, self-monitoring, and meeting calories goals were measured daily/weekly.

Results: PA goal adherence among participants (N=212; 91.5% female, 31.6% racial minority, M age of 47.9 years, M BMI of 35.8 kg/m²) revealed three unique subgroups: 27.3% had a high probability of consistently meeting both weekly PA goals (Adherent class), 28.4% were estimated to meet the MVPA goal until it progressed to 150 minutes while never meeting the step goal (Partially Adherent class), and the majority (44.3%) had the lowest probability of meeting either goal at any time (Nonadherent class). Adherent individuals had significantly greater weight loss at 8 weeks (estimated weight loss M [95% CI]: -5.5% [-4.5, -6.4]) compared to Partially Adherent (-3.4% [-2.8, -4.0]) and Nonadherent (-1.6% [-1.0, -2.1]). The Nonadherent class was least likely to attend group sessions, self-monitor their weight, dietary intake, or PA, or meet their calorie goal. The Partially Adherent class self-monitored significantly less than the Adherent class but was similar in attendance and meeting calorie goals.

Conclusions: Distinct patterns of adherence to weekly PA goals are associated with early response to weight loss and overall engagement, suggesting potential targets for optimizing adaptive interventions. Future research should investigate whether these early behavioral trajectories are predictive of long-term outcomes.

THE ADDITION OF FINANCIAL INCENTIVES TO AN ONLINE GROUP-BASED BEHAVIORAL WEIGHT CONTROL PROGRAM: A RANDOMIZED CONTROLLED TRIAL

Delia West, PhD¹, Rebecca Krukowski, PhD², Eric Finkelstein, PhD³, Melissa L. Stansbury, M.S., EP-C⁴, Courtney Monroe, PhD, EP-C¹, Doris E. Ogden, MS, LCMHC⁵, Chelsea Larsen, MPH¹, Shelly Naud, PhD⁵, Jean Harvey, PhD, RDN⁵

¹University of South Carolina, Columbia, SC; ²University of Tennessee Health Science Center, College of Medicine, Memphis, TN; ³Duke-NUS Medical School, Singapore, N/A, Singapore; ⁴University of South Carolina, West Columbia, SC; ⁵University of Vermont, Burlington, VT

Internet-delivered behavioral weight control is promising for expanding the reach and availability of weight management, but online programs produce lower weight losses than are typically achieved in-person. Financial incentives have been shown to increase weight losses but have not been examined in a synchronous online program. The current study examined whether adding financial incentives for both self-monitoring (process incentives) and achieving target weight losses (outcome incentives) increases weight losses achieved in a fully online, group-based behavioral weight management program compared with the same program without incentives. Adults with overweight and obesity (N=418; 91% female; 28% minority) recruited from 2 clinical centers were randomized to either a 24-session online group-based behavioral weight control program with weekly synchronous chat sessions (Internet-only) or the same program with weekly financial incentives for daily body weight and dietary self-monitoring and for achieving target weight losses at 2- and 6-months (Internet+Incentives). Primary outcomes included weight loss at 6 months and treatment engagement (attendance, self-monitoring of body weight, dietary intake, physical activity). Participants randomized to Internet+Incentives lost more weight (-6.1 + 5.5 kg) than those in Internet-only (-4.3 + 6.2 kg; $p < .01$). Further, a higher proportion of the Internet+Incentives group achieved $\geq 5\%$ weight loss (55%) compared with those in the Internet-only group (40%; $p < .05$). Treatment engagement was higher in the Internet+Incentives condition, with greater self-monitoring of behaviors targeted by incentives as well as higher rates of self-monitoring of behaviors not targeted (i.e., a spillover effect) and higher self-reported physical activity. Study retention was also higher among those in the Internet+Incentives condition (91%) than those in the Internet-only condition (81%; $p = .003$). Thus, it appears that adding financial incentives to a behavioral program delivered fully online can achieve higher weight losses than the online program alone; indeed, the weight losses approach those achieved by in-person weight control programs, offering potential for effective weight management with substantial geographic reach because the program is delivered without in-person contact.

MINDFULNESS-BASED APPROACHES REDUCE HEALTH DISPARITIES BY IMPROVING WEIGHT LOSS MAINTENANCE AMONG RACIAL/ETHNIC MINORITIES

Jennifer Daubenmier, PhD¹, Maria T. Chao, DrPH², Patricia Moran, PhD², Elissa S. Epel, PhD³, Wendy Hartogensis, PhD², Aundria De La Fuente, AA¹, Daniel Ramirez, n/a⁴, Frederick M. Hecht, MD²

¹San Francisco State University, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA; ³University of California, San Francisco, San Francisco, CA; ⁴San Francisco State University, San Pablo, CA

Racial/ethnic minorities have a higher prevalence of obesity compared to non-Hispanic Whites and are underrepresented in research on weight loss interventions. Furthermore, existing studies indicate less initial weight loss and greater likelihood of weight regain among racial/ethnic minorities compared with non-Hispanic Whites. We examined whether mindfulness-based approaches can reduce racial/ethnic disparities in weight loss interventions. We analyzed data from a randomized clinical trial comparing 5.5-month diet/exercise weight loss interventions with or without mindfulness meditation and mindful eating training among 194 adults with obesity (82% female; 41% racial/ethnic minorities; and 36% without a college degree). Weight was measured at 3 month intervals. We assessed racial/ethnic differences in initial weight loss and weight loss maintenance using a linear mixed effects model including a linear spline of time with a single knot at 6 months, allowing the slope of weight change to differ from the period of active intervention (0-6 months) to the subsequent maintenance phase (6-18 months), adjusting for baseline body mass index and education level. During the initial intervention period of 0-6 months, non-Hispanic Whites in the mindfulness arm lost significantly more weight than all other groups, (0.37 more kg/month compared to Whites in the control arm, $p = .02$; and .42 kg/month compared to racial/ethnic minorities in the mindfulness arm, $p = .02$). During the one-year maintenance phase from 6-18 months, we found a significant interaction of intervention arm, race/ethnicity, and time (a joint chi-square test of all paired comparisons of slopes of weight change for each category of intervention arm and race/ethnicity was $p = .03$). In the active control arm, racial/ethnic minorities regained more weight per month during maintenance compared to Whites (0.34 kg/month; $p = 0.004$). However, in the mindfulness arm, minorities and Whites had similar rates of weight regain (0.05 kg/month difference; $p = .68$). Furthermore, minorities in the mindfulness arm tended to maintain greater weight loss compared to minorities in the control group (-0.23 kg/month, $p = .07$). For Whites, there was no significant difference in weight loss maintenance between those in the mindfulness vs control groups (0.06 kg/month; $p = .58$). Of note, Whites lost more weight compared to racial/ethnic minorities across both intervention arms at 18 months (-5.54 vs -2.09 kg, $p = .006$). The integration of mindfulness meditation and mindful eating training into diet/exercise weight loss programs may improve weight loss maintenance among racial/ethnic minorities compared to standard of care diet/exercise weight loss interventions. Optimizing mindfulness interventions to address disparities in absolute weight loss and weight regain deserves further research.

RURAL-URBAN WEIGHT-LOSS OUTCOMES FOLLOWING BARIATRIC SURGERY

Thomas Parkman, M.A., M.B.A.¹, Vivian Bauman, MS², Andreana N. Apostolopoulos, BPH², Gwendolyn Crispell, RN MSN CBN³, Kathryn M. Ross, Ph.D., M.P.H.²

¹University of Florida, Celebration, FL; ²University of Florida, Gainesville, FL; ³UF Health Shands, Gainesville, FL

Introduction: Bariatric surgery is an effective treatment for obesity. Although obesity disproportionately affects rural populations, there is limited data on whether surgical outcomes differ between rural/urban residents. The present study aims to describe characteristics of and explore potential differences in postoperative weight loss outcomes in patients who completed bariatric surgery residing in rural vs. urban areas.

Methods: The study included 170 patients who underwent Roux-en-Y gastric bypass or vertical sleeve gastrectomy from rural (n=52) and urban (n=118) counties. Retrospective chart review was used to collect data on age, race, gender, insurance status, surgery type, preoperative height and weight, and 3- and 6-month postoperative weights. Patients' county of residence was coded as "rural" or "urban" using the US Census Bureau's classification of counties. Weight outcomes included change in BMI (Δ BMI), percent excess BMI lost (%EBMIL), and percent total weight loss (%TWL). Chi-square and t-tests were used to investigate group differences in demographic characteristics, and t-tests were used to investigate differences in 3- and 6-month post-operative weights.

Results: Compared to urban patients, patients from rural counties had lower pre-operative BMIs, were more likely to identify as either White or Hispanic/Latino, and were more likely to undergo sleeve gastrectomy vs. Roux-en-Y procedures, all $ps < .05$. Across all participants, average ($M \pm SE$) Δ BMI was 7.8 ± 0.2 at month 3 and 10.7 ± 0.3 at month 6. %EBMIL was $37.5\% \pm 1.0\%$ at month 3 and $50.9\% \pm 1.4\%$ at month 6, and %TWL was $16.5\% \pm 0.3$ at month 3 and $22.5\% \pm 0.6$ at month 6. At month 3, patients from rural areas demonstrated larger weight losses (across Δ BMI, %EBMIL, and %TWL) patients from urban counties, all $ps < .05$; however, there was no significant difference in 6-month weight outcomes on any of the weight outcome measures, all $ps > .05$.

Discussion: Results demonstrated some demographic differences between urban and rural patients undergoing bariatric surgery. While rural patients demonstrated greater weight losses at 3-month follow-up appointments, there was no difference observed between groups at 6-month visits. Taken together, results demonstrate that, when provided access and opportunity to pursue surgical weight-loss treatment, patients from rural counties have potential to realize weight loss outcomes comparable to those of their urban counterparts.

THE FOOD EMBARRASSMENT QUESTIONNAIRE INITIAL CONCEPTUAL DEVELOPMENT AND FACTOR ANALYSIS

Jacob Burmeister, PhD¹, Emma Studer, n/a², Robert A. Carels, PhD, MBA, ABPP³

¹University of Findlay, Findlay, OH; ²The University of Findlay, Bloomville, OH; ³East Carolina University, Greenville, NC

The current study reports on the initial development of the Food Embarrassment Questionnaire (FEQ)—an instrument for assessing embarrassment and hindrance in the healthy eating behaviors of people who are attempting to lose weight. Obesity is a commonly stigmatized health condition with well-studied negative psychological and social consequences for individuals including being the targets of blame, shame, and embarrassment (Tomiya, 2014). For example, a common component of eating disorders involves shame and resulting secrecy (Bennett & Dodge, 2007). Other research has examined embarrassment in the context of purchasing behavior. One study found that purchases of unhealthy snacks were higher at grocery self-checkouts (Olden, 2018). In sum, surprisingly little is known about the impact of these types of experiences on the eating behaviors of individuals attempting to lose weight. And no reliable and valid instrument exists to measure the magnitude of such experiences.

The intended purpose of the FEQ is to measure the degree to which people feel embarrassed and hindered when purchasing or consuming both "diet" and "unhealthy" food in a variety of contexts (e.g., at restaurants, grocery stores, and social settings). Twenty questionnaire items (e.g., *I'd rather not eat healthy "diet" foods that my family members might notice*) were created with input from various health professionals experienced in behavioral weight loss treatment and piloted with a sample of 40 weight loss participants. Principal components analysis suggests a coherent and statistically strong two-factor structure. The KMO measure of sampling adequacy was .69, indicating sufficiently large effect sizes for associations between scale items (Kaiser, 1974). Also, Bartlett's test of sphericity was significant ($\chi^2(190) 565.46, p < .001$), confirming that the correlation matrix for the items is not an identity matrix. All communalities were above .30, indicating a shared common variance between each item (Gorsuch, 1997). Analysis of the eigenvalues for this initial iteration of the FEQ indicated that two factors had values of 6.99 and 3.99 and they explained 34.98% and 19.93% of the variance, whereas all other components had eigenvalues of approximately 1.00 and explained less than 4% of the variance on average.

Next steps in the development of the Food Embarrassment Questionnaire include determining divergent, convergent, and criterion validity in a larger sample of adults attempting to lose weight. For example, convergent validity would be supported by confirming that scores on the FEQ are associated with measures of disordered eating and inversely with measures of eating self-efficacy. It will also be important to determine whether scores on the FEQ predict difficulty in weight loss.

ASSOCIATIONS BETWEEN IMPULSIVITY, IMPLICIT FOOD ATTITUDES, AND BEHAVIORAL WEIGHT MANAGEMENT PROGRAM OUTCOMES

Umelo A. Ugwoaba, Bachelor of Science¹, Brittney N. Dixon, M.P.H.¹, Abraham J. Eastman, M.S.¹, Andrea N. Brockmann, M.A.¹, Charlayne A. Scarlett, M.P.H.¹, Vivian Bauman, M.S.¹, Meena N. Shankar, MS, RD, CCRC¹, Michael Perri, PhD², Kathryn M. Ross, Ph.D., M.P.H.¹

¹University of Florida, Gainesville, FL; ²University of Florida, College of Public Health and Health Professions, Gainesville, FL

Background: An interaction between behavioral impulsivity and food-related implicit attitudes has been shown to predict weight gain in normal weight adults, such that individuals with lower response inhibition and greater implicit preference for snack foods may be at highest risk for weight gain. To date, no studies have investigated this interaction in the context of weight loss. To fill this gap, the current study investigated associations between response inhibition and implicit food preferences and both caloric intake and weight change during a behavioral weight loss program.

Methods: Participants were 74 adults with overweight/obesity (mean±SD, age = 50.7±10.4 years, BMI = 31.2±4.4 kg/m², 84% White, 69% Female) who took part in a 12-week Internet-based behavioral weight loss program. At baseline, participants used a study computer to complete a Go/No-Go (GNG) response inhibition task and a food-related Implicit Association Test (IAT) that assessed implicit attitudes towards calorie dense (e.g., cheese pizza, chocolate cake, ice cream) vs. healthier foods (e.g., fresh fruit, green beans, baby carrots). Participants were asked to report daily caloric intake on a study website throughout the intervention, and weight was assessed at baseline and Month 3. Multilevel models were used to assess associations between baseline GNG, IAT, and caloric intake during the intervention, and regression models were used to assess associations between baseline GNG, IAT, and weight change.

Results: Participants lost an average (mean±SD) of 5.8±4.9 kg during the intervention. There were no associations between baseline GNG and IAT and caloric intake during the intervention, and no significant interaction between GNG and IAT, all *ps* >.05. There were also no associations between baseline GNG and IAT scores and weight at baseline or weight change over the course of the intervention, all *ps* >.05. Contrary to hypotheses, there was also not a significant interaction between GNG and IAT for either initial weight or weight change over time, *ps* >.05.

Conclusion: Results demonstrated no significant associations between response inhibition, implicit food preferences, and either caloric intake or weight loss during a behavioral weight management program. Future studies should replicate the previous study conducted in normal weight adults, and investigate the potential mechanisms by which response inhibition or implicit food preferences may impact eating behavior and weight change over time.

ASSOCIATION BETWEEN DISCRIMINATION AND WEIGHT LOSS OUTCOMES AMONG NON-HISPANIC BLACK EMERGING ADULT WOMEN

Kristal L. Brown, MSPH¹, Jessica G. LaRose, Ph.D.²

¹Virginia Commonwealth University, Richmond, VA; ²VCU School of Medicine, Richmond, VA

Background: Over half of non-Hispanic Black (NHB) emerging adult (EA) women meet criteria for overweight or obesity, yet they fare the worst in behavioral weight loss (BWL) trials. Further, tremendous variability in treatment response has been observed among NHB EA women, but little is known about the drivers of this variability, making it difficult to optimize treatment programs for this vulnerable population. Discrimination—perhaps due to the intersection of race, gender and body size—might be a unique stressor that contributes to poorer outcomes for some NHB EA women. Thus, the goal of the present study was to examine the relationship between discrimination and BWL treatment outcomes among NHB EA women.

Methods: Data were drawn from a randomized controlled trial targeting EA; for the purposes of this ancillary study, we extracted data for two waves of participants, limiting analyses to NHB women. Participants (N=52; ages 18-25; BMI=34.2 + 4.2kg/m²) all received a 6-month technology mediated program. At baseline (BL), discrimination was assessed using the everyday discrimination scale (EDS) short version. Similar to other studies, total scores were used to classify into groups: never (<=5), low (6-12), medium to high (13-20+). Physical outcomes (blood pressure (BP), weight, and waist circumference) were taken at 0 and 3 months. ANOVA was used to determine whether baseline physical measures varied by EDS category, and ANCOVA was used to examine treatment outcomes, controlling for arm.

Results: At BL, 76.9% of NHB women reported experiencing discrimination; the most common attributions for the discrimination were race (62.5%), gender (12.5%), ancestry / national origin, education or income, and other (all 6.3%), and other aspects of their physical appearance and religion (each 3.1%). At BL, SBP differed by EDS group [never vs. low (105 vs. 113, *p*=.009); never vs. medium/high (105 vs. 113, *p*=.03)] but no other differences were observed. EDS did not predict change in weight (*p*=.37), waist (*p*=.83), systolic BP (*p*=.40) or diastolic BP (*p*=.63) at 3 months.

Conclusion: Experiences of discrimination were associated with higher systolic BP, but were not associated with changes in BP or adiposity at 3 months. More research is needed to determine the long-term impact of discrimination on treatment outcomes in this vulnerable population, and to identify potential protective factors which could be targeted in future interventions to improve cardiovascular health.

10:30 AM–11:30 AM

EFFICACY OF A BRIEF SELF-COMPASSION INTERVENTION FOR REDUCING INTERNALIZED WEIGHT BIAS AND ASSOCIATED OUTCOMES

Erin Haley, M.Ed.¹, Christyn Dolbier, Ph.D.¹¹East Carolina University, Greenville, NC

Introduction: Internalization of weight bias (IWB) occurs when one believes negative weight-related stereotypes to be true of themselves. IWB is strongly associated with a range of negative consequences, such as maladaptive eating patterns (e.g., binge eating), body image concerns, and greater psychopathology, above and beyond other risk factors such as BMI (Durso & Latner, 2008). While effective and accessible interventions for reducing IWB are limited, self-compassion represents a valuable psychological resource that may help reduce IWB and associated consequences (Tylka et al., 2014). Therefore, the purpose of this study is to examine the impacts of a brief, 3-session self-compassion intervention for women who are overweight/obese with IWB.

Method: A single group, within-participant, pre-post design was used. The sample consisted of female university students and faculty/staff with BMIs of 25+ and moderate-high IWB ($N = 13$); 69% Caucasian, aged 18–59 years old ($M = 34.7$). Surveys assessed self-compassion (Self-Compassion Scale-Short Form), IWB (Weight Bias Internalization Scale), body appreciation (Body Appreciation Scale 2), body image shame (Body Image Shame Scale), intuitive eating (Intuitive Eating Scale 2), uncontrolled and emotional eating (Three Factor Eating Questionnaire), and psychological symptomology (Depression Anxiety Stress Scales-21). A modified version of Smeets and colleagues' (2014) 3-session self-compassion intervention was implemented. The intervention consisted of discussion, introduction to self-compassion practices, and assigned application of skills between sessions.

Results: Intuitive eating significantly increased pre- to post-intervention, $t(12) = 3.65, p = .003$ ($M_{pre} = 2.75, M_{post} = 2.99$, Cohen's $D = 1.02$), as did body appreciation, $t(12) = 2.88, p = .014$ ($M_{pre} = 2.55, M_{post} = 2.87, D = .80$). While not statistically significant, small to moderate changes were observed for other variables in the expected direction: self-compassion increased ($D = .28$), uncontrolled eating decreased ($D = .49$), and emotional eating decreased ($D = .46$). Further, 100% of participants said they would recommend the program.

Conclusions: Findings from this pilot intervention study demonstrated women with overweight/obesity and IWB showed increases in self-compassion, body appreciation, and intuitive eating after participation in a brief self-compassion intervention. Results suggest that self-compassion practices may hold promise for improving body image and eating behavior in this population. Future studies with active control designs and larger sample sizes are warranted.

ASSOCIATIONS BETWEEN SELF-REGULATION AND ATTENDANCE: TOWARDS IMPROVING OUTCOMES FOR WEIGHT LOSS TREATMENTS

Adam Payne-Reichert, B.S.¹, Stephanie Manasse, Ph.D.², Evan M. Forman, PhD²¹Drexel University, Newtown, PA; ²Drexel University, Philadelphia, PA

Although outcomes from behavioral weight loss treatments (BWLts) are highly variable, one consistent finding is the association between participant attendance and below-average weight loss (WL). Although a large body of research has examined predictors of attrition from BWLT, few studies have identified predictors of attendance in BWLT. One construct which is understudied but plausibly related to attendance is self-regulation, as deficits in this capacity are thought to impede long-term goal-directed behavior (e.g., participation in treatment). To test this potential relationship, the present study analyzed whether executive functioning (EF; i.e., the cognitive capacities such as planning and emotional control which underlie behavioral regulation) and impulsivity (i.e., the tendency to act rashly without forethought for future consequences)—two central domains of self-regulation—predict attendance in a BWLT program.

This study represents secondary data analysis from a randomized trial comparing standard and acceptance-based BWLTs (Forman et al., 2016, 2019). Participants with overweight and obesity ($n=190$), with a mean age of 51.61 ± 9.97 years and initial BMI of $36.50 \pm 5.41 \text{ kg/m}^2$, participated in the 25-session manualized trial. Treatment occurred over the course of 50 weeks, and self-report measures of impulsivity (UPPS) and executive functioning (BRIEF-A) were administered at baseline.

Regressions controlling for baseline participant age and weight demonstrated a significant association between baseline scores on the UPPS (Lack of) Perseverance subscale and total session attendance ($\beta = -.022, p = 0.03$). Other UPPS subscales, BRIEF-A subscales, and BRIEF-A composite scales demonstrated non-significant associations with attendance (β s = -0.15 to $0.16, ps = 0.11$ to 0.97).

This study presents evidence that a low ability to persist in boring or difficult projects is predictive of low attendance in a BWLT. Consistent with previous research showing superior predictive validity of objective EF measures, these results also further call into question the legitimacy of self-report measures of EF. Future research may benefit from using these findings to inform BWLT design so that high-likelihood dropouts are identified and individually treated.

EXECUTIVE FUNCTIONING AND FOODS IN THE HOME BEFORE AND DURING AN ONLINE BEHAVIORAL WEIGHT-LOSS PROGRAM.

Maya Benson, n/a¹, Emily P. Wyckoff, M.S.¹, Zeely A. Denmat, B.S.², Christiana M. Field, B.A.³, Amy A. Gorin, Ph.D.¹, Jessica G. LaRose, Ph.D.⁴, Tricia M. Leahey, Ph.D.¹

¹University of Connecticut, Storrs, CT; ²UConn Weight Management Research Group, Hartford, CT; ³University of Connecticut, Hartford, CT; ⁴VCU School of Medicine, Richmond, VA

Executive functioning (EF) has been linked to obesity and weight loss (WL). In behavioral interventions, targeting EF with behavioral strategies (e.g., action planning) has resulted in improvements in eating choices (e.g. reducing snacking). Behavioral WL programs also target foods in the home (FH), as FH are associated with one's diet. No one has yet examined how EF relates to FH in a WL intervention. This study examined EF, FH, and WL outcomes in an online behavioral WL program. It was hypothesized that: 1) higher baseline EF would be associated with more fruits and vegetables and fewer high-fat FH; 2) Higher baseline EF and an improvement in EF would predict an increase in fruits and vegetables and a decrease in high-fat FH; 3) Healthy changes in FH and improvement in EF would predict greater WL.

248 adults (34% minority; 22% male; BMI 35.1 +/- 5.7) enrolled in a 2-phase trial consisting of a 4-month online WL program and an 18-month maintenance phase for those who lost at least 5% of their initial body weight. Participants completed the adult Behavior Rating Inventory of Executive Function (BRIEF-A), a household food inventory, and an objective measurement of weight at baseline. The 4-month online program, based on the Diabetes Prevention Program, included calorie and exercise goals, self-monitoring, and weekly lessons and feedback. After 4-months, participants (n=122) eligible for the maintenance trial repeated baseline measures. The current study used BRIEF subscales Inhibit and Plan/Organize.

At baseline, controlling for demographic variables, poorer inhibition was related to fewer fruits and vegetables in the home ($p < .02$); no relationship was found between high-fat foods and BRIEF-A scores. At 4-months, improvements in Plan/Organize was associated with an increase of fruits and vegetables in the home ($p < .05$). Contrary to our hypothesis, better inhibition at baseline and greater improvement in inhibition at 4-months was associated with an increase in high-fat FH post-treatment ($p < .02$). Controlling for demographic variables and baseline BMI, neither BRIEF-A scores nor FH (at baseline or post-treatment) were predictive of WL.

Overall, results support a link between EF, food environment, and one's ability to change that environment. The finding that high-fat FH increase with greater improvement in inhibition and better baseline inhibition may reflect that those with better inhibition may not feel the need to decrease tempting FH to decrease caloric intake. The result that neither BRIEF-A scores nor FH predicted WL highlights that WL is influenced by many more factors than FH (e.g. exercise, portion control). Given the mixed findings and limitations of this study (i.e. self-report EF and decreased sample size at end of treatment), further research on EF and home environment in behavioral interventions can clarify the role of these factors to guide development of targeted interventions.

A HUMAN CENTERED DESIGN APPROACH TO BARIATRIC SURGERY PREPARATION & SUPPORT AT KAISER PERMANENTE

Kelly Dumke, MS, DrPH (c)¹, Angela Shumaker, RD¹, Amy Wong, MPH¹, James Wannares, MPH¹, Sameer Murali, MD¹

¹Kaiser Permanente, Pasadena, CA

Bariatric surgery is a powerful tool with the potential to improve long-term health status, improve quality of life, and even reverse chronic disease. Often, the majority of research and attention is focused on the surgery itself with limited emphasis on the actual lifestyle factors that have profound influence over surgery outcomes.

As one of the largest bariatric surgery providers worldwide with over 40,000 surgeries completed, Kaiser Permanente's Southern California (KP Scal) region has long been committed to supporting the health of its members undergoing bariatric surgery. In 2018, KP Scal's Center for Healthy Living began to reimagine and redesign the bariatric surgery experience for its members. Guided by the principles of human centered design, KP Scal engaged with over 100 bariatric surgery candidates and post-op members to design a new framework for the bariatric surgery education experience that puts members need at the core.

By using human centered design to design WITH bariatric members and not simply FOR them, KP Scal has created a new framework for how it prepares and supports its bariatric members, which includes a trauma-informed approach with four components: 1.) pre-surgery skill building program, 2.) post-surgery long-term engagement program, 3.) comprehensive member-centric website, and 4.) wellness coaching program.

This presentation will share key insights and findings from focus groups, interviews, and codesign sessions with over 100 pre and post-op members; highlight the framework of KP Scal's new approach to bariatric surgery education, and long-term support; and highlight an innovative approach using human-centered design to truly put patient needs at the core of all solutions.

ECONOMIC POSITION AND REINFORCEMENT PATHOLOGY: AN ANALYSIS OF ADOLESCENTS

Amanda Crandall, MS¹, Amanda Ziegler, BSN, BS, MPH¹, Tegan Mansouri, RD MS¹, Emily Isenhardt, n/a¹, Jalen Matteson, n/a¹, Autum Carter, n/a¹, Katherine N. Balantekin, PhD, RD¹, Jennifer Temple, PhD¹

¹University at Buffalo, Buffalo, NY

Objective: Poverty and obesity are strongly and inversely associated in the United States. Emerging evidence suggests that living under conditions of economic disadvantage may increase one's risk for reinforcement pathology, which is state of having high reinforcing value (RRV) of food and high delay discounting (DD). We sought to examine the relationships among multiple measures of household economic position, RRV of food, DD, and body mass index (zBMI) in adolescents.

Methods: These data were collected as part of ongoing longitudinal study of risk factors for obesity in 244 adolescents. Participants and one parent had height and weight measured, filled out surveys, and completed an adjusting amount DD task. RRV was measured using a computer task that measures mouse clicks for food or an alternative activity on a progressive ratio schedule. Analyses consisted of correlations among measures of economic position (i.e. income, socioeconomic status (SES), and food insecurity) and RRV, DD, and BMI z-scores. In the case of significant associations, multiple regression models were created with theoretically informed covariates.

Results: As expected, household income, SES, and food insecurity were related to one another (all $p < .05$). Household income was the only measure of economic position associated with RRV ($r(224) = -0.16$, $p < .05$). This relationship remained significant after controlling for participant hunger, food liking, dietary restraint, and RRV of the alternative activity ($\beta = -4.87e-6$, $p < .05$). SES was associated with DD ($r(230) = -0.13$, $p < .05$), and this remained significant after controlling for adolescent age and sex ($\beta = -0.06$, $p < .05$). Finally, adolescent zBMI was positively associated with household food insecurity ($r(230)=0.13$, $p < .05$). This relationship remained significant after controlling for age, sex, dietary restraint, and sensitization score ($\beta = 0.09$, $p < .01$).

Conclusion: Our results suggest that household income, SES, and food insecurity are interrelated, but separate constructs, that may exert differential effects on behavior and obesity risk. When low income and low SES occur together, there may be an increased risk of reinforcement pathology. Further, in the most severe cases, those with food insecurity, the adolescents had higher zBMIs. Future research should replicate and confirm the effects of low income and low SES on reinforcement pathology by examining them in an experimental context.

ADHERENCE TO SIMPLIFIED DIETARY “RED FOOD” MONITORING AMONG YOUNG ADULTS USING A MOBILE-BASED BEHAVIORAL WEIGHT LOSS APP

Brooke T. Nezami, PhD, MA¹, Carmina G. Valle, PhD, MPH¹, Julianne M. Power, MS¹, Karen E. Hatley, MPH², Deborah F. Tate, PhD³

¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²UNC Chapel Hill, Chapel Hill, NC; ³University of North Carolina, Chapel Hill, NC

Background: Self-monitoring of diet is associated with weight loss success in behavioral weight control interventions for adults, but young adults, in particular, have poorer adherence to diet monitoring than older adults. The goal of this study was to examine adherence to a simplified form of dietary tracking in a mobile-delivered intervention for young adults and its association with immediate and long-term weight changes.

Methods: Data were drawn from the Nudge study, a 12-week micro-randomized trial that tested the effect of intervention messages delivered through a smartphone application on achievement of daily dietary, activity, and weighing goals. This sample includes 50 participants (out of N=52) with a follow-up weight measurement ($M_{age} = 29.4 \pm 3.8$ years; $M_{BMI} = 31.8 \pm 4.2$ kg/m², 80% female, 32% minority). Nudge used a simplified tracking approach in which participants tracked “red” foods (RF; high-calorie, high-fat foods) in the study smartphone app. Participants also weighed daily on a WiFi-enabled scale, used a Fitbit to track their physical activity, had a personalized daily RF limit and activity goal, received weekly personalized, automated feedback, and received messages in the app each day. Linear regression evaluated the association between complete RF tracking days and 12-week weight change, controlling for baseline weight. T-tests compared 12-week weight change between participants who tracked an average of 5+ days a week and those who did not. The effect of lapses in RF tracking on immediate weight changes was examined using a generalized estimating equation controlling for repeated measurements within individuals that evaluated the effect of lapse length (number of consecutive days without RF tracking) on concurrent weight change during the time of the lapse.

Results: Participants averaged 55.5 ± 22.9 complete RF tracking days (66% of 84 study days) and 62.1 ± 21.5 days with any tracking (74%). In Week 1, 92% of participants tracked 5+ complete days, compared to 42% in Week 12. Participants who tracked an average of 5+ complete days per week ($M = 6.1 \pm 1.4$ days/week; $n=26$) lost 4.7 kg (± 3.5) at 12 weeks compared to a loss of 0.4 kg (± 2.3) among those who tracked less often ($M = 3.0 \pm 0.7$ days/week; $n=24$; $p < .0001$). For every 1-day increase in RF tracking, weight loss increased by 0.10 kg ($p < .0001$). Lapses in RF tracking averaged 3.2 ± 6.7 days in length, and each 1-day increase in lapse length was associated with a weight gain of 0.44 kg (95%CI: 0.24, 0.64). All results were similar in analyses that also included partial RF tracking days.

Conclusion: The comparative effectiveness of red food tracking vs. traditional calorie monitoring is not yet known, but the results suggest a potentially viable alternative monitoring method. Future research should examine whether simplified monitoring can lead to increased adherence to dietary monitoring and weight loss.

ACCEPTANCE-BASED BEHAVIORAL TREATMENTS FOR WEIGHT MANAGEMENT: A SYSTEMATIC REVIEW

Abraham J. Eastman, M.S.¹, Vivian Bauman, MS¹, Brittney N. Dixon, M.P.H.¹, Umelo A. Ugwoaba, Bachelor of Science¹, Andrea N. Brockmann, M.A.¹, Charlayne A. Scarlett, M.P.H.¹, Meena Shankar, M.S., R.D.¹, Michael Perri, PhD², Kathryn M. Ross, Ph.D., M.P.H.¹

¹University of Florida, Gainesville, FL; ²University of Florida, College of Public Health and Health Professions, Gainesville, FL

Background: Standard behavioral weight loss interventions (SBTs) have been shown to produce clinically significant weight losses of 8-10%; however, participants often regain weight following treatment. Novel treatment methods, such as acceptance-based behavioral treatment (ABT), have been suggested as a way to improve long-term outcomes. We conducted a systematic review to examine whether, compared to SBT, ABT interventions produced 1) greater initial weight losses and 2) improved weight loss maintenance.

Methods: A systematic review of the literature on ABT for weight management (using PubMed, Web of Science, and PsychINFO) was completed following PRISMA guidelines. Inclusion criteria included: 1) use of a comprehensive behavioral weight loss intervention with components based in acceptance and commitment therapy and 2) publication in a peer-reviewed journal. Exclusion criteria included: 1) use of medication or surgery to promote weight loss, 2) no report of weight change outcomes, and 3) secondary data analyses of a trial already included in the review.

Results: A total of 233 studies were identified. Following title, abstract, and full paper review, 6 articles, representing outcomes from 5 randomized controlled trials (RCTs) conducted by 3 research groups, met the eligibility criteria and were included. The Delphi list method suggested the included studies were of good quality (median 7 out of 9) with one study of lower quality. While 3 of the 5 trials found no significant difference between initial weight losses for ABT and SBT, one found greater weight loss for ABT and another found significant differences only when experts delivered ABT. Four studies included results on weight loss maintenance from 6-months after the end of initial intervention; 2 reported superior weight loss maintenance in ABT versus SBT and 2 did not. Additionally, 2 studies reported outcomes at 12 months with one finding significant differences between groups and the other finding no differences at 12 or 24 months.

Discussion: The current review found preliminary support for the effectiveness of ABT over SBT for initial weight loss and weight loss maintenance; however, additional research should be conducted to examine whether ABT can be disseminated into real-world settings and administered by clinicians not affiliated with the initial intervention design. Moreover, additional studies are needed to clarify active processes of ABT in order to improve treatment effectiveness.

COMPARING THE EFFECT OF HEALTH GOAL VS GENERAL FUTURE THINKING ON HEALTH BEHAVIORS AMONG CIGARETTE SMOKERS AND OBESE INDIVIDUALS

Liqia Athamneh, MA¹, Madison Stein, n/a¹, Warren K. Bickel, Ph.D.²

¹Virginia Tech, Roanoke, VA; ²Fralin Biomedical Research Institute at VTC, ROANOKE, VA

Episodic Future Thinking (EFT; vividly imagining realistic future events) reduces delay discounting (DD; preference for smaller, immediate rewards) and various maladaptive behaviors. Exploring potential personalization of EFT to optimize its ability to alter DD and demand for unhealthy reinforcers is important for the development of interventions targeting long-term improvement and maintenance of health. In this investigation, using two separate studies, we examined the effects of EFT with and without a health goal on rates of discounting, demand, and craving for cigarettes and fast food among cigarette smokers and obese individuals, respectively. Using data collected from Amazon Mechanical Turk (MTurk; a crowdsourcing platform), Study 1 (N=189) examined the effect of EFT on DD and measures of cigarette demand and craving in cigarette smokers who were randomly assigned to one of three conditions: EFT-health goal, EFT-general, or EFT-general. Study 2 (N=255), using a 2x2 factorial design, examined the effects of health goals and general EFT on DD and measures of fast food demand and craving in obese individuals who were randomly assigned to one of four conditions: EFT-health goal, EFT-general, EFT-health goal or EFT-general. Health-goal EFT was not more effective than general EFT in reducing monetary discounting. However, the addition of a health goal to general EFT significantly increased its effect on intensity and elasticity of demand for cigarettes and fast food. These findings suggest that the amplification of future thinking through the inclusion of a health goal may promote healthy decisions and result in positive behavior changes.

CLARIFYING THE ROLE OF VALUES IN WEIGHT CONTROL:
A PILOT STUDY OF A VALUES-BASED INTERVENTION TO PROMOTE WEIGHT LOSSDiane H. Dallal, BA¹, Evan M. Forman, PhD¹¹Drexel University, Philadelphia, PA

Autonomous motivation is implicated in initiating and sustaining weight control efforts over time. Two acceptance-based strategies thought to enhance autonomous motivation are *values clarification* (identifying one's valued domains of life) and *values awareness* (enhancing salience of clarified values during decision-making). When clarification (VC) and awareness (VA) strategies are utilized, extrinsic factors that may motivate weight control efforts (e.g., social pressure, body dissatisfaction) are posited to be outweighed by newly salient, autonomous motivators for change (e.g., enhancing health, quality of life). However, minimal research has been conducted to evaluate these components in isolation. Namely, VC and VA have only been deployed within larger acceptance-based treatment packages (ABTs). Moreover, because measures of VC and VA have not previously been developed, no data are available to evaluate the constructs as mechanisms of action. As a result, their efficacy in treatment warrants further investigation.

The present study piloted a values-based intervention for weight control. Over 3 weeks, participants with overweight/obesity ($N=18$) received 3 sessions of an analog weight loss intervention, infused with techniques to clarify health-promoting values and elicit awareness of those values during dietary decision-making. Assessments were conducted at baseline and post-treatment (1 month). A newly developed measure by our team was used to evaluate whether the intervention could achieve target engagement of VC and VA.

Results revealed modest improvements in VC at trend-level ($M_d=.51$, $SD_d=1.11$, range: 0-3; $t(17)=1.96$, $p=.07$, $d=.46$) and large, statistically significant improvements in VA ($M_d=1.50$, $SD_d=1.38$, range: 0-4; $t(17)=4.61$, $p<.001$, $d=1.08$). Participants also experienced moderate, significant increases in values-congruent behaviors on the Valued Living Questionnaire ($M_d=14.58$, $SD_d=23.00$; $t(17)=2.69$, $p=.02$, $d=.63$). In addition, the sample exhibited an average weight loss of 1.3% ($SD=1.17$, $d=1.12$) over 3 weeks (consistent with 3-week weight losses in longer-term trials conducted by our team). Results suggest that the analog treatment was able to engage the targets of VC and VA, produce meaningful improvements in VA during dietary decision-making, and increase values-congruent behaviors consistent with weight control. Future work should evaluate whether a longer term, values-based weight loss program may drive effects on weight change over and above gold standard behavioral weight loss.

POOR SLEEP QUALITY AS A RISK FACTOR FOR WEIGHT GAIN IN
FIRST YEAR COLLEGE STUDENTSHannah Peach, PhD¹, Christina Lambros, n/a¹, Conner Clarken, n/a¹, Katerina Lantz, n/a¹, Malaysia Wilcox, n/a¹¹University of North Carolina at Charlotte, Charlotte, NC

Introduction: College students – particularly first year students – experience a high risk for weight gain, sometimes referred to as the “freshman fifteen.” This raises a significant health concern, as obesity earlier in life tracks into later adulthood, contributing to nearly 40% of the U.S. adult population meeting criteria for obesity. While poor nutrition and physical inactivity are widely known risk factors for weight gain, sleep is slowly gaining recognition as an important predictor of obesity. Yet, the impact of sleep patterns on weight gain during college is understudied. A recent study found that sleep duration predicted weight gain among first year students (Ludy et al., 2018), but little research has examined if sleep quality also plays a role. Therefore, the present study predicted that sleep quality during the first semester of college would predict weight gain in first year students, above and beyond the influence of established risk factors.

Method: First year university students ($N=34$) completed a series of self-report questionnaires and a Dual-energy X-ray absorptiometry (DEXA) scan during their first semester (Time 1) and second semester (Time 2) of college. Sleep quality was measured using the Pittsburgh Sleep Quality Index. The DEXA scan generated reports of body composition, including lean and fat pounds. Weight gain was calculated as fat pounds at Time 1 subtracted from fat pounds at Time 2.

Results: On average, participants gained nearly 2 pounds of fat across their first year of college ($M=1.83$, $SD=5.17$, Range = $-8.20-14.77$). A hierarchical regression was analyzed, with age, gender, socioeconomic status, and Time 1 stress entered in Block 1, Time 1 eating habits and physical activity entered in Block 2, Time 2 sleep quality entered in Block 3, and Time 1 sleep quality entered in Block 4. After controlling for all covariates, Time 1 sleep quality significantly predicted fat pound weight gain ($\Delta R^2=.28$, $b=1.42$, $p<.001$).

Discussion: Sleep quality served as an independent risk factor for weight gain among first year college students. While the sample size in the present study was relatively small, findings yield strong, longitudinal associations with self-reported sleep quality and gold-standard measures of fat pound weight gain. Targeting sleep hygiene education and intervention programs among first semester college students may serve as an innovative approach to preventing weight gain during this transitional period.

TEST-RETEST PERFORMANCE OF A BRIEF INTEGRATED QUANTITATIVE
SENSORY TESTING PROTOCOL IN HEALTHY ADULTSChristina E. Gilmour, n/a¹, Martin De Vita, MS², Katherine Buckheit, MS², Dezarie Moskal, MS², Stephen Maisto, PhD²¹Syracuse University, Mohegan Lake, NY; ²Syracuse University, Syracuse, NY

Quantitative sensory testing (QST) is a rapidly expanding domain of pain reactivity research that involves measuring psychophysiological responses to standardized experimental stimuli. QST has numerous clinical and research applications and is frequently used for assessing pain pathophysiology, analgesic effects of substances, and sensory function. Given the increasingly variable procedures employed by QST researchers, there is a recognized need for reliable brief QST assessments. Extant protocols are characterized by lengthy procedures and varying combinations of specialized equipment. By contrast, we integrated static and dynamic pain reactivity measures into a brief 20-minute QST protocol that uses a single thermal QST device. Test-retest performance was evaluated by administering the protocol among 33 healthy young adults on 2 occasions separated by exactly one week. Static measures of pain threshold (ICC = 0.80), tolerance (ICC = 0.81), and suprathreshold (ICC = 0.83) exhibited excellent reliability. Dynamic measures of conditioned pain modulation (ICC = 0.66), offset analgesia (ICC = 0.69), temporal summation (ICC = 0.71) scored using a ‘percent change’ method yielded optimal reliability in the good to excellent range. Alternative dynamic scoring methods demonstrated poorer reliability and/or agreement. Our findings indicated that this brief integrated QST protocol can reliably monitor human pain reactivity over brief periods.

RACE AS MODERATOR OF THE RELATIONSHIP BETWEEN RESILIENCE AND PAIN-RELATED OUTCOMES AMONG OLDER ADULTS WITH LOW-BACK PAIN

Calia A. Morais, PhD¹, Shreela Palit, PhD¹, Michael E. Robinson, PhD¹, Roger Fillingim, PhD², Emily Bartley, PhD¹

¹University of Florida, Gainesville, FL; ²Pain Research and Intervention Center of Excellence, University of Florida, Gainesville, Gainesville, FL

Background: Racial/ethnic disparities are well documented in clinical and experimental pain. Across studies, non-Hispanic blacks (NHBs) report greater pain intensity, pain interference, and poorer pain-related outcomes, including negative psychological functioning (i.e., depression, anxiety), compared to non-Hispanic whites (NHWs). While risk factors have been implicated in these disparities, little is known regarding how sources of resilience contribute to these differences, despite the growing body of research supporting the protective role of resilience in clinical pain and disability among adults with chronic pain. To address this gap, the current study sought to examine the association between psychological resilience and pain outcomes, and the moderating role of race across these relationships.

Methods: In this secondary data analysis, 60 adults over the age of 60 (NHWs=42, NHBs=18) with chronic low-back pain completed a battery of psychological and pain-specific questionnaires assessing pain resilience (Pain Resilience Scale), positive affect (Positive and Negative Affect Schedule), and PROMIS pain intensity and physical functioning. The Back Performance Scale was administered as a measure of back-related physical functioning and movement-evoked pain. Bivariate correlations assessed the association between each independent variable (race, pain resilience, positive affect) and pain symptoms, while the interaction of race and resilience was examined via linear regression.

Results: In bivariate analyses, race was a significant correlate of pain outcomes, with NHBs demonstrating greater pain intensity ($r=.42$, $p=.001$), poorer physical function ($r=-.32$, $p=.01$), and greater movement-evoked pain ($r=.28$, $p=.03$) than NHWs. There were no associations between measures of resilience with pain outcomes. Moderation analysis revealed that higher levels of positive affect were protective against movement-evoked pain ($b=-1.09$, $p=0.01$), while greater pain resilience was associated with lower pain intensity ($b=-0.06$, $p=0.03$), but only in NHWs.

Conclusion: These results bring attention to racial differences in how resilience factors influence pain and functioning. Based on these results, future studies should examine the potential benefits of targeted interventions to improve resilience and help ameliorate pain disparities among racial and ethnic minorities.

PSYCHOLOGICAL RISK FACTORS AND THEIR RELATION TO KNEE PAIN SEVERITY IN ADULTS WITH OR AT RISK FOR KNEE OSTEO-ARTHRITIS

Daniel A. Kusko, BA¹, Cesar Gonzalez, M.A.¹, Tyler Huang, n/a¹, Kimberly Sibille, PhD², Roger Fillingim, PhD², Burel R. Goodin, PhD¹

¹The University of Alabama at Birmingham (UAB), Department of Psychology, Birmingham, AL; ²Pain Research and Intervention Center of Excellence, University of Florida, Gainesville, Gainesville, FL

Background: Knee pain is a widespread clinical problem, with almost half of those aged 50 and over reporting pain at the knee and 25% of these experiencing symptoms of a chronic nature. Considerable evidence demonstrates that radiographic findings (e.g., osteophytes) are only modestly associated with the severity of knee pain, signaling that factors beyond disease severity influence symptom severity. Psychological risk factors such as pain catastrophizing, anxiety, depression and negative affect may play a significant role in explaining knee pain severity, beyond radiographic evidence of knee OA. This study had two aims: 1) to examine differences in psychological risk factors between pain-free controls and people with knee pain, and 2) to examine the relationships among psychological risk factors and knee pain severity.

Methods: We collected survey data from pain-free controls ($N = 65$) and individuals with knee pain who either had, or were at risk of having, knee OA ($N = 187$). Participants self-reported psychological and health related constructs including: clinical pain severity on the Western Ontario & McMaster Universities Osteoarthritis Index (WOMAC), Positive and Negative Affect Schedule (PANAS), pain catastrophizing on the Coping Strategies Questionnaire-Revised (CSQ-R), and PROMIS-Anxiety and Depression.

Results: The knee pain group reported significantly greater depression ($p < .001$), anxiety ($p = .006$), negative affect ($p = .004$), and pain catastrophizing ($p < .001$) relative to pain-free controls. Within the knee pain group, we found that greater severity of knee pain was significantly correlated with depression ($r(184) = .365$, $p < .001$), anxiety ($r(183) = .300$, $p < .001$), negative affect ($r(182) = .410$, $p < .001$), and pain catastrophizing ($r(186) = .552$, $p < .001$).

Discussion: Prior research has demonstrated that psychological risk factors play a significant role in explaining increased pain severity across various chronic pain conditions. These results specifically suggest that depression, anxiety, negative affect, and higher pain catastrophizing represent psychological risk factors for greater knee pain severity in individuals with or at risk for knee OA. This research points toward a need for evidence based psychotherapeutic treatments addressing these psychological risk factors for those with knee pain.

RESILIENCE PHENOTYPES PREDICT PHYSICAL AND COGNITIVE FUNCTIONING IN OLDER ADULTS WITH CHRONIC LOW BACK PAIN

Emily J. Bartley, PhD¹, Shreela Palit, PhD¹, Calia A. Morais, PhD¹, Michael E. Robinson, PhD¹, Roger Fillingim, PhD²¹University of Florida, Gainesville, FL; ²Pain Research and Intervention Center of Excellence, University of Florida, Gainesville, Gainesville, FL

Introduction: Chronic pain has emerged as a public health priority, resulting in a number of negative psychological, physical, and health-related sequelae. Despite its associated burden, it is recognized that individuals differ in their experience of and ability to cope with pain. While some are adversely impacted, others maintain adaptive physical and psychological functioning even in the context of severe pain, suggesting a high degree of resilience in this population. However, limited research has considered the role of positive resources in promoting pain resilience as efforts have traditionally focused on psychosocial and behavioral vulnerabilities associated with chronic pain, particularly among older adults. Likewise, the factors that promote adaptive functioning in individuals with pain have largely been examined independently. Combining these factors to conceptualize resilience from a broader biopsychosocial perspective may have greater clinical relevance than examining them in isolation.

Methods: Sixty adults (ages 60–93) with chronic low back pain (cLBP) completed measures of psychological (positive affect, hope, wellbeing, optimism), health (waist–hip ratio, body mass index, medical comorbidities), and social (emotional, instrumental, informational support) functioning. Principal components analysis was conducted to create composite domains for these measures, followed by cluster analysis to identify phenotypic subgroups based upon composites.

Results: Four resiliency profiles emerged from the cluster analysis: Cluster 1 (41.7%; high levels of psychosocial and health-related functioning); Cluster 2 (21.7%; optimal health, low psychosocial functioning); Cluster 3 (25.0%; high psychosocial function, poorer health); and Cluster 4 (11.7%; low levels of functioning across the three composites). In a subsequent step, cluster group differences across symptoms found to be prevalent in cLBP were examined: sleep disturbance, fatigue, and cognitive impairment. After controlling for demographic and clinical factors (age, race, income, marital status, pain severity), individuals with the highest levels of resiliency (Cluster 1) demonstrated more optimal outcomes in sleep and fatigue ($p < .001$), when compared to individuals with a less resilient phenotype (Cluster 4). Further, the High Resilience (Cluster 1) and High Psychosocial/Low Health (Cluster 3) clusters had lower cognitive impairment than the High Health/Low Psychosocial (Cluster 2) and Low Resilience (Cluster 4) groups (all $p \leq .001$).

Conclusions: Results signify that a higher array of protective resources may buffer against the negative sequelae associated with chronic pain. Importantly, findings support the multidimensional nature of resilience and suggest that targeting resiliency from a multisystem perspective may optimize interventions for older adults with chronic pain.

PSYCHOSOCIAL AND BEHAVIORAL CORRELATES OF PAIN-RELATED SMOKING EXPECTANCIES AMONG SMOKERS WITH CHRONIC PAIN

Romano Endrighi, Ph.D.¹, Belinda Borrelli, PhD²¹Boston University, Boston, MA; ²Boston University, Henry M Goldman School of Dental Medicine, Boston, MA

Expectancies that smoking helps to cope with chronic pain (CP) reinforce smoking behavior and may act as a barrier to quitting. The extent to which pain-coping expectancies relate to risk factors that are common in CP populations is unknown. Our study examines associations between pain-coping expectancies and risk factors for smoking maintenance among smokers with CP.

Smokers with CP ($n=504$; M age= 46 ± 13 yrs; 58% female; 24% minority race; 74% < college degree) were recruited online in the US and completed a survey about pain and tobacco smoking. We assessed several factors thought to be important in maintaining smoking and hindering cessation. Pain measures included the bodily pain and the physical functioning scales from the SF-12 health survey (score range 0–100), and current use of pain medications (yes/no). Psychosocial measures included psychological distress (Kessler Scale; 0–24), major depression (Patient Health Questionnaire), and trait pessimism (Life Orientation Test; 0–12). Behavioral measures included the number of past-year quit attempts, number of cigarettes per day, Fagerstrom scale for nicotine dependence (0–10), lifetime use of pharmacologic evidence-based treatment for smoking cessation (EBT; yes/no), lifetime use of non-pharmacologic EBT for cessation (counseling, quitline, or text message; yes/no), motivation to quit smoking (Motivation to Stop Scale; 1=“I don’t want to stop smoking” to 7=“I really want to stop and intend to in the next month”), pain-smoking self-efficacy (1–7), and perceived difficulty quitting (1–10). Pain-coping expectancies were measured with the pain and smoking inventory (e.g., “smoking helps me think about something other than my pain”; 0=“not true at all” to 6=“extremely true”). Higher scores reflect greater use of smoking to cope with pain. Data were analyzed with multiple linear regressions. All factors were entered simultaneously along with demographics.

The model explained 33% of the variance ($F(16, 487) = 15.4, p < .001$). Higher expectancies scores were associated with younger age ($\beta = -.16, p < .001$), college education or higher ($\beta = .13, p = .001$), lower physical functioning ($\beta = -.11, p = .01$), greater distress ($\beta = .20, p < .001$), smoking fewer cigarettes per day ($\beta = -.15, p = .002$), higher nicotine dependence ($\beta = .19, p < .001$), lower self-efficacy to resist smoking with worsening pain ($\beta = -.20, p < .001$), and greater perceived difficulty quitting ($\beta = .10, p = .02$). Greater expectancies scores were also observed among those using pain medications ($\beta = .09, p = .02$), those who never used pharmacologic EBT ($\beta = -.01, p = .02$), and in those who have used non-pharmacologic EBT ($\beta = .14, p < .001$).

We have identified several risk factors for smoking maintenance that are associated with pain-coping expectancies among smokers with CP. This is the first step in identifying potential targets for smoking cessation approaches tailored to this population.

PRESCRIPTION OPIOID USE IN MOTHERS WITH PAIN: RELATIONS WITH MEDICATION BELIEFS AND CHILD PERCEPTIONS OF HARM

Simone Mendes, BA¹, Amanda L. Stone, PhD², Kira Beck, n/a¹, Anna Wilson, PhD¹¹Oregon Health and Science University, Portland, OR; ²Vanderbilt University Medical Center, Nashville, TN

Objective: For mothers with chronic pain, opioid therapy presents as a lifeline for managing pain and activities of daily living, such as parenting. For children of mothers with chronic pain, exposure to maternal medication beliefs and opioid use patterns may influence children's perceptions of harm from opioids. The current study aimed to evaluate the association between maternal opioid use patterns, mothers' own medication beliefs, and perceptions of harm of opioid use in their children. We hypothesized that chronicity of maternal opioid therapy would predict favorable beliefs about the benefits of opioids in mothers, and lower perceptions of harm from opioid use in their children.

Methods: Mothers with chronic pain and one child 8-12 years old (n=165 dyads, 52.7% F) were recruited as part of a larger longitudinal study examining the impact of maternal chronic pain on children. Mothers completed an annual survey for 3 years and reported on current opioid use. In Year 3, mothers reported on medication beliefs and children (M age 12.3) completed the Perceived Harm of Opioid Use scale. Mothers were categorized into 3 groups: 1) *No opioid use* (consistent across all 3 years), 2) *Shorter term/PRN users* (1 year daily use or 1-3 years PRN use), and 3) *Long-term daily users* (3 years of use and daily use endorsement). Analysis of variance (ANOVAs) and posthoc tests examined differences in mother and child beliefs by maternal opioid group.

Results: Mothers with long-term daily use (n=29) and short-term use (n=48) reported significantly greater beliefs in medication necessity ($p=.001$), better functioning with free access to medication ($p<.05$), and improved mood with pain medication ($p<.05$) compared to mothers with no opioid use (n=88). Long-term daily users reported a greater need for more pain medication compared to short-term and no use groups ($p's<.01$), as well as improved pain control from medications ($p<.02$) compared with the no opioid use group only. Children's beliefs about potential harm from prescription opioid use did not differ by maternal opioid use pattern.

Conclusion: Chronicity of maternal opioid therapy predicted favorable beliefs about the necessity of opioids and access to opioids as key to managing mood, pain, and daily function. Unexpectedly, children's perception of the risk of harm from opioids was not related to mother use patterns, suggesting this aspect of child risk for later substance use is not impacted by maternal prescription opioid use.

PAIN AS A PREDICTOR OF EXERCISE GROUP ATTENDANCE AMONG SMOKERS ENROLLED IN A CESSATION TRIAL

Lisa A. Uebelacker, PhD¹, Bailey O'Keeffe, BA², Sage Feltus, BA², Eliza Marsh, BA², Summer Peterson, BA², Ana M. Abrantes, PhD³¹Brown University and Butler Hospital, Providence, RI; ²Butler Hospital, Providence, RI; ³Brown University / Butler Hospital, Providence, RI

Background: Exercise has been purported to serve as a strategy to aid cessation among smokers engaged in a quit attempt. However, smokers have high rates of chronic pain that may interfere with engaging in exercise. Indeed, individuals with chronic pain often avoid engaging in exercise due to concerns about exacerbating pain. In the context of an RCT designed to test the efficacy of moderate-intensity aerobic exercise (AE) relative to health education contact (HEC) control among smokers initiating a quit attempt, we examined whether chronic pain was associated with exercise group attendance.

Method: Two-hundred and thirty-one (70.1% female; mean age= 45.3 years) low-active smokers with depressive symptoms were randomized to either AE (n = 119) or HEC (n = 112). Each condition consisted of 12 weekly, in-person group sessions. In addition, all participants received 6 sessions of individual standard smoking cessation telephone counseling plus 8 weeks of nicotine patches. Quit day for all participants was the beginning of week 5. Attendance was taken at each of the 12-week in-person group sessions. Participants were considered to have chronic pain if they endorsed past AND current pain of any of the following: arthritis, joint, muscle, and back pain.

Results: Approximately 40% of the randomized sample reported chronic pain and rates were similar in the AE and HEC conditions. While n = 30 participants never initiated the intervention after being randomized, there was no difference in rates of chronic pain between those who did and did not initiate the intervention. Rates of chronic pain were higher among women than men (44.6% vs. 30.6%, respectively; $c^2 = 3.47$, $df = 1$; $p = .06$). A general linear model was constructed with number of intervention groups attended as the dependent variable and condition, chronic pain, and a condition X chronic pain interaction term as independent variables and gender and age as covariates. Results revealed a significant condition X chronic pain interaction in predicting group attendance ($F(1, 2.7) = 34.4$, $p = .01$). Participants with chronic pain attended an average of 8.4 (SD = 3.2) HEC sessions and 7.5 (SD = 3.2) AE sessions. In contrast, participants without chronic pain, attended an average of 7.9 (SD = 3.7) HEC sessions and 8.5 (SD = 3.4) AE sessions.

Conclusion: High rates of chronic pain were observed among smokers engaging in a quit attempt. People with chronic pain had decreased attendance at exercise sessions, relative to attendance at health education sessions, whereas the opposite was true for those without chronic pain. It is possible that chronic pain may interfere with engagement in exercise even among smokers interested in physical activity as a smoking cessation strategy. Future studies implementing exercise as an intervention for smoking cessation or mental health symptom reduction, more broadly, may need to consider the role of chronic pain on adherence.

THE EFFECTIVENESS OF A BRIEF AVATAR-GUIDED ACCEPTANCE AND COMMITMENT THERAPY DIGITAL INTERVENTION (ALGEAPP) FOR CHRONIC PAIN

Maria Karekla, PhD¹, Orestis Kasinopoulos, n/a²¹University of Cyprus, Nicosia, Nicosia, Cyprus; ²University of Cyprus, NICOSIA, Northern Cyprus, Cyprus

Acceptance and Commitment Therapy is an empirically supported intervention for the management of Chronic Pain. Increasing demands for cost reduction in healthcare services in addition to obstacles regarding physical access to treatment, highlight the need for innovative, cost-reducing, digital self-management interventions. Low adherence, nonetheless, is a significant challenge often faced in digital interventions, which may impact treatment effectiveness and result in high dropout rates (Kelders et al., 2012). Very few digital interventions appear to be planned for adherence a-priori, when designing an intervention. In addition, there is a lack of brief digital interventions with minimum human contact, in the field of CP. The main purpose of this study was to design an engagement-focused, brief, Avatar-led intervention for CP management and evaluate its effectiveness. Sixty-four participants were randomly allocated to the intervention group (ALGEApp) or an active control group (relaxation techniques). Both groups significantly contributed to improvements in the short-term on primary treatment outcomes of pain daily interference and quality of life; secondary outcomes of mood; and proposed processes of change outcomes of acceptance and psychological flexibility. ALGEApp demonstrated improvements in acceptance to a greater extent than the control. Satisfactory adherence and completion rates favored the ALGEApp group. Findings highlight the potential of brief, planned-for-engagement digital interventions, on reaching and engaging users who may not have easy access to treatment, while providing a set of skills to help them manage their pain through a home-based self-care approach.

A BRIEF 10-ITEM MEASURE FOR RAPID IDENTIFICATION OF PAIN-RELATED FEAR-AVOIDANCE IN YOUTH WITH CHRONIC PAIN

Gillian Rush, n/a¹, Lauren C. Heathcote, PhD², Rashmi Bhandari, PhD³, Inge Timmers, PhD⁴, Lauren Harrison, PhD⁵, Laura E. Simons, PhD⁵¹Stanford University School of Medicine, Concord, CA; ²Stanford University Medical School, Palo Alto, CA; ³Stanford Children's Health, Palo Alto, CA; ⁴Stanford University, Palo Alto, CA; ⁵Stanford University School of Medicine, Palo Alto, CA

Background: Pain-related fear and avoidance are increasingly shown to influence adult and childhood chronic pain. This series of two studies describes the development and psychometric examination of a short version of the Fear of Pain Questionnaire for Children (FOPQC-SF) to enable rapid identification of fear-avoidance in youth. We also assessed clinical indices of the FOPQC-SF to promote its use in clinical practice.

Methods:

Study 1 – Item selection: 613 youth with mixed etiology chronic pain (80.3% female; *Age* = 14.7 years, *SD* = 3.16) completed the FOPQC long form at the Chronic Pain Clinic at Boston Children's Hospital. Data were entered into SPSS for exploratory factor analysis to select the most appropriate items for the FOPQC-SF based on their factor loadings, with the goal of maintaining a two-subscale structure with 5 items each on the fear and avoidance subscales.

Study 2 – Preliminary reliability, validity, and clinical cutoffs: 526 youth (70.1% female; *Age* = 14.7 years; *SD* = 2.58) completed the FOPQC-SF at the Pediatric Chronic Pain Clinic at Stanford Children's Hospital. They also completed the Pain Catastrophizing Scale - child version (PCS-C), a pain severity index, and Patient Reported Outcomes Measurement Information System (PROMIS) measures. We performed a confirmatory factor analysis and calculated clinical reference points and a reliable change criterion.

Results: The FOPQC (long form) and FOPQC-SF (short form) total scores correlated very highly ($r = .96, p < .001$). The subscales also correlated highly across the long and short forms (Fear: $r = .92, p < .001$; Avoidance: $r = .95, p < .001$). A CFA revealed one item previously on the avoidance subscale was better suited to the fear subscale. After making this modification, our second CFA showed acceptable to excellent model fit ($\chi^2 = 133.25, p < .001$; $\chi^2/df = 3.92$; CFI = 0.95; RMSEA = 0.08 [90% CI = .06 - .09]). The FOPQC-SF demonstrates excellent construct validity, with total scores correlating with the PCS-C ($r = .64, p < .001$) and PROMIS anxiety measures ($r = .59, p < .001$). 94 participants completed the FOPQC-SF a second time, three months after their baseline clinic visit. Test-retest correlations suggest adequate internal consistency ($r = .635, p < .001$). We calculated the scores for clinical reference groupings as follows: low < 20; moderate = 20-25; high ≥ 26 , and the reliable change criterion as $> \pm 8.6$ points.

Conclusions: This short form retains similar reliability and validity as the long form, and is suited for rapid identification of pain-related fear and avoidance in youth during clinic evaluations and for clinical registries. To aid integration into clinical practice and intervention trials, we provide clinical reference points to classify patients, and a criterion to assess treatment response longitudinally.

PAINFULLY MISSING SPORTS: THE ROLE OF SPORTS PARTICIPATION AND ATHLETIC IDENTITY IN PEDIATRIC CHRONIC PAIN

Nele Loecher, Bachelor of Arts¹, Laura E. Simons, PhD², Lauren C. Heathcote, PhD³¹Stanford University School of Medicine, east palo alto, CA; ²Stanford University School of Medicine, Palo Alto, CA; ³Stanford University Medical School, Palo Alto, CA

Background: Chronic pain in childhood is often disruptive to children's everyday lives, restricting their participation in sports, school, and other activities. Restriction in sports may be especially difficult for children who strongly identify with their athletic identity (AI) and cause worse behavioral and emotional outcomes. Therefore, we expect children higher in AI to have higher depression, anxiety, functional disability and fear of pain, moderated by whether they're currently participating in sports.

Methods: Youth aged 8 to 21 were recruited from the pain program at Boston Children's Hospital (n = 330). One hundred of these patients reported current participation in a sport, and 136 were not currently in a sport but were planning to return. The remaining youth were excluded due to never being involved in a sport or no intent to return (n=69) or were missing responses to AI questions (n=25). Participants completed the Athletic Identity Measures Scale (AIMS), the Children's Depression Index (CDI), Fear of Pain Questionnaire (FOPQ), Functional Disability Index (FDI) and either the Multidimensional Anxiety Scale for Children (MASC) or the Revised Children's Manifest Anxiety Scale (RCMAS) which were then converted to standardized scores and combined into one measure of anxiety.

Results: Pain duration, age, and gender did not significantly differ based on whether or not children were currently in sports. ANOVA tests revealed that those involved in sport had significantly higher AI ($F(1, 232) = 1.106, p = .002$), lower FDI scores ($F(1, 232) = 10.717, p = .001$), and marginally lower FOPQ scores ($F(1, 232) = 3.763, p = .054$) but did not differ on other measures. Higher AI was significantly correlated with increased anxiety ($p < 0.05, R^2 = .177$). Moderation analyses were non-significant.

Conclusions: Unsurprisingly, children still in sports had lower functional disability. However participants did not differ in fear, anxiety, or depression, indicating that sports participation may not be a strong indicator of well-being, even among athletes. AI may be a slightly better indicator as it correlated with higher levels of anxiety. Future research should investigate whether this correlation indicates a clinical use for addressing AI in chronic pediatric pain patients.

DIAGNOSTIC UNCERTAINTY IN PARENTS OF CHILDREN WITH CHRONIC PAIN

Marissa Heirich, n/a¹, Lauren C. Heathcote, PhD², Vivek Tanna, n/a¹, Laura E. Simons, PhD³¹Stanford School of Medicine, Palo Alto, CA; ²Stanford University Medical School, Palo Alto, CA; ³Stanford University School of Medicine, Palo Alto, CA

Introduction: For families of children with chronic pain, a formal diagnosis provides needed validation and buy-in for an actionable intervention. Unfortunately, many families express uncertainty around their child's pain diagnosis, which has negative implications for pain-related distress and treatment adherence. As of yet, there are no validated measures of diagnostic uncertainty (DU) in children with chronic pain or their parents. This study examined the utility of three items to measure DU in parents of children presenting to a multidisciplinary pain clinic at Stanford Children's Health (SCH).

Methods: There were 66 patient families who completed an electronic survey on parent DU, distress and behavior. DU was measured based on parent responses (yes/no) to the following statements: I have been given a clear label/diagnosis for my child's chronic pain (DU1); I have been given a clear explanation about why my child has chronic pain (DU2); I think there is something else happening with my child's chronic pain which the doctors have not found out about yet (DU3). For those who answered "yes" to DU2, a follow-up statement was presented: Generally speaking, I agree with this label/diagnosis (DU2a).

Parents also completed the following validated measures: Parent Risk and Impact Screening Measure (PRISM), Parent Psychological Flexibility Questionnaire (PPFQ), Parent Pain Catastrophizing Scale (PPCS), and Adult Responses to Child Symptoms (ARCS).

Results: About 50% of parents indicated DU of their child's chronic pain (DU1 range = 43.1-54.5%). For parents prompted with DU2a (N=33), 97% agreed with the label/diagnosis their child was given. All DU items were significantly associated with each other ($\chi^2 = 7.70 - 24.44, p < .01$), suggesting they tap into one underlying construct. Diagnostic certainty vs. uncertainty did not differ by parent cognitive and behavioral responses to their child's pain.

Discussion: About half of parents of children with chronic pain reported uncertainty regarding their child's diagnosis. A 3-item measure was sensitive in detecting differences in DU among parents, but a multidimensional tool might be necessary to detect differences in parent factors by DU. Further analyses are needed to explore how parent DU interacts with child DU, and how this relationship might influence child outcomes.

PREDICTING THE FREQUENCY OF MIGRAINES: RISK FACTORS AND TARGETS FOR TREATMENT

Dallas Robinson, M.S.¹, Amrita Bhowmick, MBA, MPH², Amy Wachholtz, PhD, MDiv, MS³, Sarah Martin, MS⁴¹University of Colorado Denver, Wheat Ridge, CO; ²Health Union, LLC, Chapel Hill, NC; ³University of Colorado Denver, Denver, CO; ⁴University of Colorado Denver, Centennial, CO

Introduction: Migraines are a common headache disorder with a lifetime prevalence rate of over 20%. They interfere with sufferer's ability to work or function normally. Research has shown a significant association between chronic pain, depression, smoking, and migraines, as well as environmental and individual migraine triggers. Understanding common migraine triggers may allow for the identification of clear treatment goals aiming at migraine reduction.

Method: A national study examined migraine frequency in 4,502 adult migraine sufferers ($M_{age} = 45.72$, 95.5% female, 91.2% Caucasian) diagnosed by a physician in the 2015 Migraine.com survey in relation to comorbid conditions and potential triggers. Multiple linear regressions assessed the predictive strength of triggers and comorbid psychiatric disorders on migraine frequency.

Results: The majority of participants suffered from 3–7 migraines per month (30.8%) or 15+ migraines per month (32.6%). The regression established that the comorbid conditions of chronic (non-migraine) pain ($\beta = 0.110$) and depression ($\beta = 0.067$), as well as the triggers of bright lights ($\beta = 0.102$), cigarette smoke ($\beta = 0.071$), loud noises ($\beta = 0.145$), alcohol/drugs ($\beta = 0.052$), and using nicotine to cope ($\beta = 0.076$) statistically significantly predict frequency of migraines ($F(7, 4494) = 76.417$, $p < .001$), accounting for 10.6% of the variance. These findings support previous research on migraines, showing that certain conditions and variables can lead to increased frequency of migraines.

Discussion: Those with comorbid conditions and the specific triggers examined in this large population study experienced a significantly higher frequency of migraines. A causal relationship remains unclear, and future research is needed to determine if migraines lead to comorbid conditions, if living with comorbid conditions leads to migraines, or if there is another contributing variable yet to be explored. Regardless of causality, treatment options working with patients suffering from comorbid conditions like depression and chronic pain in addition to migraines should be utilized, as well as ensuring patients receive psychoeducation on migraine triggers, to provide the best possible care.

OPIOID TAPERING IN PAIN REHABILITATION PROGRAM ELIMINATES OPIOID-RELATED DEPRESSION DISPARITY FOR PATIENTS WITH CHRONIC PAIN

Taylor B. Crouch, PhD¹, Sharlene Wedin, PsyD, ABPP¹, Rebecca L. Kilpatrick, PhD¹, Lillian Christon, PhD, Licensed Psychologist², Jeffrey Borckardt, Ph.D.¹, Kelly Barth, DO²¹Medical University of South Carolina, Charleston, SC; ²MUSC, Charleston, SC

Background: This study evaluated pre- to post-treatment changes in depression symptoms among patients in an intensive outpatient Pain Rehabilitation Program (PRP), taking into account whether patients were using prescription opioids at program entry. Research has found chronic pain patients taking opioids report higher levels of depression, perhaps related to depression predicting initiation of chronic opioid therapy and/or due to depressogenic effects of opioids themselves. However, there is limited research examining whether tapering off opioids in a PRP significantly improves depression, as compared to patients not on opioids.

Methods: Patients ($N=45$) enrolled in a 3-week, interdisciplinary PRP for chronic pain, including group-based treatment from psychology, physical therapy, occupational therapy, nursing, and physicians. Patients were aided opioid tapering, if entering on opioids. All patients discontinued opioids by discharge. During initial assessment (baseline) and discharge (post-treatment), patients completed measures of physical and emotional symptoms and functioning. The depression subscale of the Brief Symptom Inventory (BSI) measured depression. Opioid use was via patient report, confirmed via electronic Prescription Drug Monitoring Program. Data was analyzed using independent samples t-tests and regression/ANOVA.

Results: At baseline, patients on opioids ($n=32$) endorsed more depression symptoms ($M=11.16$, $SD=5.90$) than those not on opioids ($n=15$; $M=6.60$, $SD=5.60$), $t(45)=-2.51$, $p < .05$. All patients had a significant reduction in depression across the program; baseline opioid use was a significant predictor of change in depression scores from pre- to post-treatment ($F(1,45)=4.23$, $p < .05$), with patients on opioids experiencing greater reduction in depression. At post-treatment, there was no longer a significant difference in depression between those who entered on ($M=3.59$, $SD=4.05$) or off opioids ($M=2.53$, $SD=3.42$, $p > .05$).

Conclusions: Among patients with chronic pain enrolled in PRP, those taking prescription opioids report higher levels of depression prior to the program. Results suggest that PRP is an effective treatment not only for weaning patients from opioids, but also for depression for both opioid patients and non-opioid patients. Further, patients taking opioids at baseline experienced a greater reduction in depression and by the end of the program, reported similar levels of depression as non-opioid patients. These results suggest that tapering off opioids through a PRP can mitigate the increased depression risk among patients with chronic pain taking opioids. Comorbid opioid use and depression risk remains a public health concern in the context of the larger opioid epidemic, and PRP may be a viable means to dually target both concerns.

DEVELOPMENT AND VALIDATION OF A DAILY INJUSTICE EXPERIENCE QUESTIONNAIRE

Joshua Seward, n/a¹, John A. Sturgeon, PhD², Deanna D. Rumble, PhD³, Zina Trost, PhD⁴¹University of Alabama at Birmingham, Moody, AL; ²University of Washington School of Medicine, Seattle, WA; ³The University of Alabama at Birmingham (UAB), Department of Psychology, Birmingham, AL; ⁴Virginia Commonwealth University, New York, NY

The Injustice Experience Questionnaire (IEQ) is a validated measure assessing injustice appraisals related to the experience of pain, injury, and disability. This measure is comprised of a 2-factor structure reflecting irreparability of loss related to pain or injury, as well as attributions of blame and unfairness. Although the IEQ has demonstrated value as a significant predictor of maladjustment and psychosocial difficulties in a variety of cross-sectional studies, recent evidence has suggested that patterns of cognitive appraisal may manifest differentially across time due to a variety of factors, including severity of medical symptoms and social and contextual factors. To date, there has been limited inquiry in the variability of injustice appraisals across time. The current study details the development and validation of a brief, daily version of the IEQ for use in daily diary studies. IEQ items were adapted for daily use and were evaluated using 3 rounds of cognitive interviews with 30 adults with chronic low back pain (CLBP). The resulting measure was administered to 2 online, cross-sectional studies each conducted over a 10-day period with a combined total of 317 US adults with CLBP. Study 1 (N = 186) refined the 12-item IEQ measure into a 6-item short-form; exploratory factor analyses suggested optimal model fit for the 2-factor model established in the original IEQ. Study 2 (N = 131) replicated the factor structure using confirmatory factor analysis and demonstrated significant correlations of the daily IEQ with other indices relevant to chronic pain, such as pain catastrophizing, pain intensity, pain-related activity and social interference, depressed mood, and anxiety. In both studies, items from the Daily IEQ showed a significant degree of clustering (intraclass correlations ranging from .577 to .735) but demonstrated sufficient variability at the daily level to allow for daily-level analysis. Our results indicate that, despite a notable degree of stability across the study period, injustice appraisals show a significant degree of stability across time that would warrant their measurement as a time-varying construct. Further examination of antecedents and correlates related to daily injustice appraisals, as well as their potential role as mechanisms of effect, may better explain the dynamics of mood and adaptive behavior in chronic pain populations.

DAILY PAIN APPRAISALS AND ANGER AND THEIR ROLE IN PAIN-RELATED ACTIVITY AND SOCIAL INTERFERENCE

John A. Sturgeon, PhD¹, Joshua Seward, n/a², Deanna D. Rumble, PhD³, Zina Trost, PhD⁴¹University of Washington School of Medicine, Seattle, WA; ²University of Alabama at Birmingham, Moody, AL; ³The University of Alabama at Birmingham (UAB), Department of Psychology, Birmingham, AL; ⁴Virginia Commonwealth University, New York, NY

Cognitive appraisals have long been highlighted as a key factor in patterns of psychosocial adjustment to chronic pain. Among the appraisal patterns most commonly studied in chronic pain in recent years are pain catastrophizing and injustice perception related to pain. However, more recent evidence has suggested that these appraisal patterns may be better characterized as dynamic rather than static processes, such that the intensity and frequency of these cognitions may vary across time and according to context. Accordingly, there remains a need to articulate the role of cognitive appraisal variables in contexts beyond single-time point, cross-sectional studies. The current project utilized data from 131 participants with chronic low back pain captured in a daily diary format across a 10-day period, and examined the direct relationships of daily levels of pain catastrophizing and injustice perception with pain-related daily activity interference and social role interference. Further, we examined the potential intervening role for anger states, commonly highlighted as a potential mechanism of effect in prior studies of injustice perception, in these relationships. Results indicated that higher daily levels of both pain catastrophizing and injustice perception were found to predict greater daily levels of both activity interference and social interference, above and beyond the effects of daily pain intensity. Higher levels of daily anger mediated only the relationship between injustice perceptions and daily social interference, however. These findings replicate prior cross-sectional findings and highlight the potentially dynamic nature of cognitive appraisal, affective states, and social activity in chronic pain. Future research may benefit from articulating other potential antecedents to injustice perception and pain catastrophizing, as well as implementation of study methodologies that allow for a greater degree of inference regarding temporal precedence (e.g., within-day or electronic momentary assessment studies).

CHRONIC PAIN EXPERIENCE IN PEDIATRIC SICKLE CELL DISEASE: A QUALITATIVE EXAMINATION

Soumitri Sil, PhD¹, Lindsey L. Cohen, PhD², Carlton Dampier, MD³¹Emory + Children's Pediatric Institute, Atlanta, GA; ²Georgia State University, Atlanta, GA; ³Emory University School of Medicine, ATLANTA, GA

Introduction: Chronic pain in sickle cell disease (SCD), that is pain that is present on most days per month and persists for at least 6 months, can begin in childhood and persist through adulthood. Children and adolescents with chronic SCD pain report high levels of functional disability, elevated depressive and anxiety symptoms, and reduced quality of life relative to youth with SCD without chronic pain. However, the course of chronic SCD pain as experienced by youth and their parents is not well-understood. This study aimed to examine the perceptions of youth with SCD and their parents regarding their experience of chronic SCD pain and its management.

Method: Purposive sample was used to recruit youth with chronic SCD pain (ages 10-18) and their parents receiving care at comprehensive outpatient pediatric SCD clinics at a large southeastern children's hospital. Patients and parents separately completed face-to-face individual semi-structured interviews lasting 60-75 minutes. Interviews were recorded and transcribed; memoing was used to develop a working codebook. Content was coded using thematic analysis.

Results: Participants included 11 youth (average age 12.6) with chronic SCD pain and their parents. Patients were primarily female (60%), parents were mostly mothers (91%), and all were Black or African American. Eight codes emerged from analysis, which informed 3 major themes: 1) chronic pain experience, 2) impact on parent and family functioning, and 3) preferences for treatment and intervention components. Patients and parents described the transition from acute to chronic pain in terms of increased pain frequency, changes in pain quality, and healthcare utilization; changes in perceived sense of control over pain; the impact of chronic pain on daily life; and social comparison with peers and difficulties communicating their limitations in activity engagement. Parents and their children also described efforts to protect each other from pain and the challenges of managing chronic pain. Parental behaviors in response to pain, such as coddling or limiting responsibilities, were noted to change as chronic pain persisted over time. Patient experiences with various treatments and preferences for behavioral treatment components, such as preparation for real-life, effective communication about pain, and engagement in daily activities, also emerged.

Discussion: Youth with chronic pain related to SCD experience daily challenges that can affect their quality of life. Tailoring interventions to address the unique individual and family experiences and needs may enhance behavioral pain interventions and optimize the health of youth with chronic SCD pain.

VALIDATION OF THE MODIFIED EXERCISE AND SELF-ESTEEM MODEL IN ENDURANCE ATHLETES

James F. Konopack, PhD¹¹New Jersey City University, Jersey City, NJ

The research literature supports the capacity of endurance sport participation to improve people's self-esteem and overall well-being in humans. The Exercise and Self Esteem Model, first articulated by Sonstroem and Morgan (1984) and subsequently refined and modified by others (e.g., McAuley et al., 2005), posits a hierarchical model in which physical activity and self-efficacy positively influence general self-esteem via mediation by sub-domains of physical self-worth. However, the extent to which this model holds true for highly active endurance athletes remains untested. The current study tested a Modified Exercise and Self-Esteem Model among participants ($N=584$) who had run at least one marathon in the past year, using psychosocial measures central to the Exercise and Self-Esteem Model. Using SPSS and structural equation modeling, data analysis yielded significant relationships among constructs in the hypothesized model, which provided good fit to the data ($\chi^2 = 15.32$, $df=10$, $p=0.12$; CFI=0.99; SRMR=0.03, RMSEA=0.03). Notably, physical activity and exercise self-efficacy showed a strong, positive relationship ($\beta = 0.31$), and exercise self-efficacy showed significant positive relationships with the subscales of physical condition ($\beta = 0.48$), body attractiveness ($\beta = 0.32$), and strength esteem ($\beta = 0.30$). These results lend support to the robustness of the Modified Exercise and Self-Esteem Model even among highly active marathon runners whose high-volume exercise patterns are often misconstrued as pathological.

THE IMPACT OF FINANCIAL INCENTIVES ON PHYSICAL ACTIVITY: A SYSTEMATIC REVIEW AND META-ANALYSIS

My-Linh N. Luong, MSPH¹, Michelle Hall, PhD², Kim Bennell, PhD³, Jessica Kasza, PhD⁴, Anthony Harris, PhD⁵, Rana Hinman, n/a⁶

¹Centre for Health, Exercise and Sports Medicine at the University of Melbourne, Los Alamos, NC; ²University of Melbourne, Carlton, Victoria, Australia; ³Centre for Health Exercise and Sports Medicine | Department of Physiotherapy, Melbourne School of Health Sciences, Melbourne, Victoria, Australia; ⁴Monash University, Melbourne, Victoria, Australia; ⁵Monash Business School, Centre for Health Economics, Caulfield East, Victoria, Australia; ⁶University of Melbourne, Melbourne, Victoria, Australia

Objective: Evaluate effects of financial incentives on physical activity for adults.

Eligibility criteria for selecting studies: Randomised controlled trials with adults aged ≥ 18 years that assessed the effect of financial incentives on physical activity.

Data sources: MEDLINE, Embase, seven other databases and two trial registries from inception to 17 July 2019.

Design: Data were pooled across five physical activity domains using random-effects models.

Results: Of 5,765 records identified, 51 individual trials ($n=17,773$ participants) were included. Financial incentives increase leisure-time physical activity (standardized mean difference [95% CI], 0.46[0.28,0.63], $k=15$ trials, $n=5,057$) and walking behaviour (0.25[0.13,0.36], $k=20$, $n=3,254$). No change in total minutes of physical activity (0.52 [-0.09,1.12], $k=6$, $n=968$), kilocalories expended (0.19[-0.06,0.44], $k=3$, $n=247$), or the proportion of participants meeting physical activity guidelines (risk ratio [95% CI] 1.53[0.53,4.44], $k=2$, $n=650$) post-intervention was observed. Financial incentives sustain a slight increase in leisure time physical activity (0.10[0.02,0.18], $k=6$, $n=2678$), and they might sustain a slight increase in walking behaviour (0.11[0.00,0.22], $k=14$, $n=2425$), at longest follow-up after intervention has ceased (range: 2–104 weeks).

Summary/Conclusion: Financial incentives probably improve leisure-time physical activity and probably slightly improve walking behaviour but may lead to little or no difference in kilocalories expended or minutes of physical activity at the end intervention. It is uncertain whether incentives change the likelihood of meeting physical activity guidelines because the certainty of the evidence is low. Small improvements in leisure time physical activity and walking behaviour may be sustained over time once incentives have ceased.

THE ROLE OF BODY COMPOSITION AND INTERNALIZED WEIGHT BIAS IN EXERCISE MOTIVATIONS

Alexis Mitchell, B.S.¹, Sara J. Sagui-Henson, PhD², Sara M. Levens, PhD³

¹University of North Carolina at Charlotte, Concord, NC; ²University of California, San Francisco, San Francisco, CA; ³University of North Carolina at Charlotte, Charlotte, NC

Introduction: Individuals with a higher weight status are vulnerable to negative health outcomes, potentially due to dysregulated motivation for healthy behaviors. Derogative attitudes and norms about weight are pervasive in society and when internalized, may independently affect health-related motivation or exacerbate the effects of higher weight status. To examine this, we explored associations among body fat composition, internalized weight bias, and exercise motivations, as well as potential synergistic effects of higher body fat and greater weight bias on motivation.

Method: Participants ($n=114$; 56.5% female; M age=27 years; M body fat=33%) completed a measure of weight bias internalization and a measure of exercise motivation for enjoyment, competency, appearance, physical fitness, and social reasons. We assessed total body fat composition with a full body dual-energy x-ray absorptiometry scan. Controlling for age and gender, linear regressions tested associations among body fat, weight bias, and each exercise motive, and moderated regressions tested the interactions between body fat and weight bias.

Results: Higher body fat was associated with higher internalized weight bias ($\beta=.50$, $p<.001$) and lower exercise motives for enjoyment ($\beta=-.22$, $p<.05$), competency ($\beta=-.26$, $p<.05$), and fitness ($\beta=-.26$, $p<.05$), but not appearance or social motives. Higher weight bias was only associated with higher appearance motivation ($\beta=.40$, $p<.001$). A marginally significant interaction between body fat and weight bias predicted appearance motivation ($\beta=.17$, $\Delta R^2=.02$, $p=.06$). Among individuals with higher body fat, those who had great internalized weight bias had greater appearance motivation than those with lower weight bias.

Conclusions: Although higher body fat was associated with less exercise motivation across several domains, higher internalized weight bias was associated with greater motivation to exercise for appearance reasons. This indicates that weight bias may relate to more extrinsic motivation for exercise. The interaction between body fat and weight bias also suggests that weight bias may promote this type of motivation specifically among individuals of a higher weight. Strategies to mitigate internalized weight bias, such as acceptance-based techniques, may be beneficial for promoting more intrinsic exercise motivation among individuals with higher body fat.

ARE ALL STEPS EQUAL WHEN IT COMES TO HAPPINESS AND WELL-BEING? THE IMPORTANCE OF EXERCISE MOTIVATIONS

Stefanie Ciszewski, M.A.¹, Brooke Dudley, BSc², Ali Caldwell, n/a³, Carmela A. White, M.A.,⁴ Lesley Lutes, Ph.D.⁵¹University of British Columbia - Okanagan, Kelowna, BC, Canada; ²UBC Okanagan, Kelowna, BC, Canada; ³University of British Columbia Okanagan, Kelowna, BC, Canada; ⁴University of British Columbia - Okanagan, Calgary, AB, Canada; ⁵University of British Columbia - Okanagan, Kelowna, BC, Canada

Physical activity has been recognized as an important predictor of health-related quality of life and positive mood states. Recently, exercise has been suggested to be positively related to subjective well-being (i.e., high life satisfaction and positive affect with low negative affect). However, reasons for engaging in exercise and physical activity may differ across individuals. That is, motivations that are more intrinsically-based (e.g., positive health, enjoyment) may have a stronger relationship with well-being and happiness than motivations that are more extrinsically-based (e.g., competition, recognition, appearance). To date, little is known about the relationship between different types of exercise motivations and subjective well-being. The present study examined the relationship between exercise motivations, life satisfaction, and happiness. Participants included male (34%) and female (66%) undergraduate students ($N = 202$; $M_{age} = 20.45$; $M_{BMI} = 23.21$) who completed a battery of psychosocial measures including the Exercise Motivations Inventory (EMI), the Satisfaction with Life Scale (SWLS), and the Subjective Happiness Scale (SHS). Exploratory factor analysis was used to reduce the nine EMI scales to three latent factors: Internal, External, and Body Motivations. A series of two multiple regressions were performed with the latent EMI factors entered as predictors with life satisfaction (SWLS) and subjective happiness (SHS) as outcome variables. Both models were statistically significant in predicting life satisfaction, $F(3, 185) = 3.25, p < .05$, and subjective happiness, $F(3, 185) = 2.91, p < .05$. Intrinsic motivation was the strongest individual predictor in both models, where greater levels of intrinsic motivation was the strongest predictor of life satisfaction, $t = 2.59, p < .05$, and subjective happiness, $t = 2.81, p < .05$. Body motivation was also a significant predictor of subjective happiness where greater body motivation was negatively related to subjective happiness, $t = -2.10, p < .05$. These findings suggest that motivation type may be an important predictor of happiness and life satisfaction benefits that are gained from physical activity and exercise. Practical implications suggest that restructuring goals to be more intrinsic and less extrinsic or body-focused may yield greater well-being benefits.

DAY-LEVEL COUPLING OF ACCELEROMETRY-BASED MOVEMENT BEHAVIORS IN MOTHER-CHILD DYADS

Chih-Hsiang "Jason" Yang, PhD¹¹University of South Carolina, Columbia, SC

Background: Physically-active parents tend to have more physically-active children. Many studies in this area have identified mother-child activity associations because mothers are usually the main caregivers who spend more time with their children. However, it is unclear whether this association occur on a daily basis (i.e., are children more active on days when their mothers are more active than usual?) and whether it is more prominent on weekend days or when children are younger (i.e., Is the association stronger on weekend days versus on weekdays, or when children are younger than older?).

Methods: This study examined to what extent mothers and their children's device-based moderate-to-vigorous physical activity (MVPA) and sedentary time (ST) were associated with each other at the day level. Mother-child dyads ($N=193$; Mean age= 11.48, $SD=1.28$) provided 3,614 paired days of waist-worn accelerometry data from six bi-annual waves across three years. Each wave consisted of up to seven days of accelerometry data. Multilevel models tested (1) whether mother's mean levels and daily deviations in MVPA and ST predicted children's corresponding day-level MVPA and ST, and (2) whether these associations were moderated by children's age at each wave or weekend day (versus weekday). Both models controlled for mothers' and children's demographics, daily valid accelerometer wear time, children's age (baseline and at each wave) and BMI-z score.

Results: Significant interactions between weekend day and mothers' deviations in day-level activity levels were identified for models predicting children's daily MVPA ($b=0.28, p < .001$) and sedentary time ($b=0.11, p < .001$). Compared to weekdays, mothers' daily deviations in MVPA and sedentary time had stronger and positive predictivity on children's corresponding day-level activities on weekend days.

Conclusions: Results indicate that mothers and their children's physical activity and sedentary time are coupled at the day level, especially on weekend days. Different intervention strategies are needed to target MVPA and ST during different days of the week. Weekend days may be promising times to encourage physical activity and limit sedentary time for both mothers and children.

AN ECOLOGICAL FRAMEWORK AND INTERVENTION FOR PHYSICAL LITERACY PARENTING IN EARLY CHILDHOOD

Nan Zeng, n/a¹, Susan Johnson, n/a², Laura Bellows, n/a¹¹Colorado State University, Fort Collins, CO; ²University of Colorado Anschutz Medical Campus, Aurora, CO

Background: Physical literacy (PL) is a multidimensional concept that includes confidence, motivation, and competence in fundamental movement skills (FMS) leading to lifelong physical activity (PA) engagement. Parents play a central role in shaping PL during early childhood, as they help develop PA and FMS for their young children. While PL has stimulated increased research in recent years, the concept is limited in its translation into effective behavior change interventions in the U.S. The HEROs (HEalthy ENviRONments) study aims to develop a technology-based, interactive intervention to promote healthy eating and PA behaviors for young children in family settings. This study outlines the development of an ecological framework, educational model and intervention materials to promote PL in preschool-aged children living in low-income, rural Colorado communities.

Methods: Intervention development included three core components: 1) a conceptual framework of PL in early childhood informed by HEROs formative research with parents and research literature; 2) an educational model for parents outlining key PL concepts; and 3) theoretically-based intervention materials for parents (Adult Learning Theory, Social Cognitive Theory (SCT)) and preschoolers (SCT) to promote PL.

Results: First, the conceptual framework, *An Ecological Model of Physical Literacy Parenting in Early Childhood*, was driven by the social-ecological model and underlines the contexts in which environmental (e.g. childcare, home, and community) and social (e.g. parent attributes, parent-child interactions, parent perception of child attributes, and parenting practices) variables operate to influence a child's PL. Second, a parent PL model, *Physical Literacy: Learning to Move*, was developed to graphically depict key PL concepts (FMS, competence, and motivation) and PA opportunities focused on the child, parent, and environment. Third, six, 90-minute weekly workshops were developed for parents and children to promote PA, FMS, and PL. Supporting materials included custom mobile apps (3 focused on PA and FMS), activity cards, educational enhancers, and website materials.

Conclusions: The ecological framework and PL educational model highlight the importance of parents in the development of young children's PA and FMS. Intervention materials serve to promote PA and FMS parenting and provide strategies targeting young children's PL.

THE EFFECTS OF EXERCISE DURATION AND INTENSITY ON BREAST CANCER-RELATED DNA METHYLATION

Arielle S. Gillman, PhD, MPH¹, Kent E. Hutchison, PhD², Angela Bryan, PhD³¹National Cancer Institute, Rockville, MD; ²University of Colorado Boulder, Boulder, CO; ³University of Colorado Boulder, BOULDER, CO

Background: Across numerous studies, physical activity has been associated with reduced risk of developing breast cancer, yet the biological mechanisms through which exercise may reduce cancer risk are still being explored. Emerging evidence suggests that physical activity may decrease cancer risk via its influence on the methylation of genes associated with cancer.

Objective: The purpose of the current study was to prospectively test in a rigorous experimental design whether aerobic exercise influences DNA methylation in genes associated with breast cancer, and whether a dose-response relationship exists between exercise volume and the degree of change in DNA methylation. We hypothesized that we would observe a dose-response relationship between volume of aerobic exercise and changes in DNA methylation over four months.

Methods: The Genetics, Exercise, and Methylation (GEM) study was a randomized controlled trial in which participants were randomly assigned to one of four supervised aerobic exercise programs that varied in a fully crossed design by intensity (55%-65% versus 75%-85% of VO₂max) and duration (40 versus 20 minutes per session). Participants provided blood samples for assessment of DNA methylation at baseline and immediately after completing the 16-week supervised exercise intervention. Change in percent methylation of 12 candidate genes associated with breast cancer was assessed.

Participants: 276 women (*M* age = 37.25, *SD* = 4.64) were recruited from the Denver metro area to participate in the study. Women were eligible to participate if they were between the ages of 30-45, sedentary (< 60 minutes of moderate intensity exercise per week), and met a list of inclusion and exclusion criteria related to safety for exercise and lack of personal history of breast cancer.

Results: Contrary to hypotheses, we did not observe significant relationships between total volume of exercise completed and methylation for any of the genes of interest. However, longer exercise duration was associated with decreased methylation of RUNX3, *p* = .03, and there was a trend for an association between duration and increased TLR4 methylation in the expected direction, *p* = .07. Moreover, change in VO₂max was associated with decreased methylation of BRCA1, *p* = .02, arguably the most well-known gene for breast cancer risk.

Conclusion: While results were mixed, this study provides initial evidence that increased exercise behavior might affect methylation of genes associated with breast cancer.

THE ROLE OF PHYSICAL ACTIVITY ON HEALTH-RELATED QUALITY OF LIFE AMONG YOUTH LIVING IN URBAN POVERTY

Jesse Mala, Ph.D.¹¹University of Connecticut, Storrs, CT

Researchers have demonstrated the positive benefits of physical activity among youth including improved self-esteem, and higher perceptions of quality of life (Marker, Steele & Noser, 2018; Wretman, 2017). However, there is a limited amount of studies assessing physical activity, and health-related quality of life among Black and Latinx youth living in urban poverty. Race and ethnicity are widely considered a crucial social determinant of health, due to its association with poverty, residential segregation, and unequal access to health care (Mehta, Lee & Ylitalo, 2013; Williams & Jackson, 2005). Therefore the purpose of this research was to examine physical activity and health-related quality of life among Black and Latinx youth living in urban poverty.

A physical activity questionnaire (PAQ-C) and a health-related quality of life inventory (PedsQL 4.0) was administered in the spring of 2018, to 5th-8th grade students in three schools in urban poverty. A one-way analysis of covariance (ANCOVA) was used to assess if PedsQL scores were different among reported physical activity rates. Additionally, a hierarchical multiple regression was performed to see if physical activity rates improved prediction of PedsQL scores, above and beyond grade and sex. The ANCOVA revealed no statistically significant differences in PedsQL scores between physical activity rates $F(1, 146) = 2.17, p = .08$, partial $\eta^2 = .06$, after controlling for sex. The hierarchical multiple regression revealed the full model of sex, grade, and physical activity levels was not statistically significant, $R^2 = .10, F(8, 140) = 1.94, p = .06$, adjusted $R^2 = .05$. Model 1 including sex, did not lead to a statistically significant increase in R^2 of .02, $F(1, 147) = 2.22, p = .14$. The addition of grade did not lead to a statistically significant increase in R^2 of .03, $F(3, 144) = 1.70, p = .17$, and the addition of physical activity did not lead to a statistically significant increase in R^2 of .05, $F(4, 140) = 1.99, p = .10$. The findings reveal the role of physical activity on perceptions of quality of life among Black and Latinx youth in urban poverty. These findings grant insight into the adversity experienced by Black and Latinx youth in urban poverty, and the effects of systemic oppression in the US. More research must also be done to examine the contextual factors of physical activity (peer climate, bullying), since not all physical activity is beneficial to physical, and socio-emotional health.

TIME-VARYING ASSOCIATIONS BETWEEN FEELING STATES AND ACTIVITY-RELATED BEHAVIORS IN OLDER ADULTS: AN EMA STUDY

Derek J. Hevel, M.S.¹, Genevieve F. Dunton, PhD, MPH², Jaclyn P. Maher, Ph.D.¹¹University of North Carolina at Greensboro, Greensboro, NC; ²University of Southern California, Los Angeles, CA

Introduction: Hedonic theory posits that individuals are more likely to engage in behaviors that make them feel good (e.g., increased positive affect). Despite evidence that a bout of physical activity leads to acute changes in feeling states (i.e., affect, arousal), little is known about the strength and direction of these associations between physical activity and subsequent feeling states change over the course of the day. Ecological Momentary Assessment (EMA) is an intensive data capture strategy which examines moment-to-moment changes in constructs of interest such as behavior and feeling states in the context of everyday life. This study utilized EMA and time-varying effect modeling to determine the extent to which affective response to physical activity changes over the course of the day in older adults.

Methods: Older adults ($N=104$, age $M=72.3$) participated in a 10-day study and completed 6 random EMA prompts/day via a smartphone. At each EMA prompt, participants reported positive affect (e.g., happy), negative affect (e.g., sad), and arousal (i.e., energy). Participants wore an *activPAL* accelerometer as a device-based measure of time spent stepping in the 15-min before the EMA prompt. Time-varying effect models regressed feeling states on time spent stepping in the 15-min before the prompt. Models were run separately for weekdays and weekend days. Results are rounded to the 5-min interval.

Results: On weekdays, the time spent stepping in the 15-min before the prompt positively predicted feelings of energy from 8:00-11:40am ($b_{\text{range}} = 0.02-0.05$) and 4:00-6:45pm ($b_{\text{range}} = 0.02-0.03$). Time spent stepping in the 15-min before the prompt positively predicted positive affect from 8:00-9:00am ($b_{\text{range}} = 0.02-0.03$) and negatively predicted negative affect from 9:25am-12:50pm ($b_{\text{range}} = -0.005$ to -0.006) on weekdays. On weekend days, the time spent stepping in the 15-min before the prompt positively predicted feelings of energy from 8:00-9:40am ($b_{\text{range}} = 0.02-0.10$). Time spent stepping in the 15-min before the prompt did not predict positive or negative affect on weekend days.

Conclusions: Time spent stepping predicted feelings of energy in the mornings across all days and in the early evening on weekdays. Positive and negative affect responses to stepping were significant on weekdays but for shortened periods of time compared to feelings of energy. Implications for the timing of intervention content delivery in just-in-time adaptive interventions will be discussed.

THE EFFECT OF WORK FACTORS ON NURSES' OCCUPATIONAL PATTERNS OF PHYSICAL ACTIVITY, SEDENTARY BEHAVIOR, AND FATIGUE

Roberto M. Benzo, M.S.¹, Lucas Carr, Ph.D.², Qian Xiao, Ph.D.², Kara M. Whitaker, Ph.D.², Amany Farag, Ph.D.²¹Well Living Lab - Mayo Clinic, Delos LLC, Rochester, MN; ²University of Iowa, Iowa City, IA

Introduction: Nurses have a psychologically and physically demanding occupation and are the largest professional group within healthcare settings. The physical behaviors of nursing work (e.g. occupational physical activity and sedentary behavior) and specific work factors (e.g. total working hours, shift length, day/night shift) are linked to fatigue. However, it is not fully understood how these factors impact fatigue among nurses. We conducted a study to examine the relations between work schedule characteristics (shift type: day vs. night), occupational physical activity and sedentary behaviors, and momentary levels of fatigue among a sample of nurses working 12-hour shifts. We hypothesized that nurses working day shifts are more active, less sedentary, and experience an attenuated rise in fatigue while at work compared to nurses working night shifts.

Methods: A total of 80 registered nurses working 12-hour day and night shifts participated in this study. Occupational physical activity and sedentary behaviors (e.g., step count, time spent sitting, standing, and walking) were measured for 14 continuous days using an ActivPAL™. Momentary fatigue levels (0=no fatigue to 10=worst imaginable) were measured four times per day via a text message that was sent to nurses' personal cell phone over a 14-day period. Mixed models were used to examine the effect of work factors on occupational physical activity, sedentary behavior, and fatigue. Generalized estimating equations (GEEs) were used to explore the impact of sedentary behavior and physical activity on changes in fatigue during a shift.

Results: Day shift nurses spent significantly more minutes/hour standing (30.2; SD: ± 11.8) and walking (9.1; SD: ± 4.3) and less sitting (20.7; SD: ± 14.0) at work compared to night shift nurses (stand: 27.0 ± 12.5 ; walk: 8.3 ± 4.2 ; and sit: 24.6 ± 15.0). Fatigue increased over the course of a shift for both day and night shift nurses. However, the rise in fatigue was significantly greater during night shifts, compared to day shifts. The relationship between occupational walking and change in fatigue was positive for day shift nurses but negative for night shift nurses.

Conclusion: Our findings suggest day shift nurses are subject to higher levels of occupational physical activity which is positively associated with fatigue. Collectively, this work supports future research that tests whether opportunities for recovery is effective for reducing within shift rises in fatigue among nurses working 12-hour day shifts.

ASSOCIATIONS OF LIGHT VS. MODERATE TO VIGOROUS PHYSICAL ACTIVITY WITH FATIGUE AND STRESS IN CANCER SURVIVORS

Samuel Streeter, BS¹, Neha P. Gothe, MA, PhD¹¹University of Illinois at Urbana Champaign, Urbana, IL

Background: Cancer and cancer related treatments have been shown to have negative side effects on many psychosocial health outcomes, including fatigue and stress. Exercise, specifically moderate to vigorous physical activity (MVPA) has been shown to improve a variety of health outcomes among cancer survivors. However, regular participation in MVPA can be challenging for this population given the high levels of fatigue and negative side effects of cancer therapies and treatments. The purpose of this pilot study was to examine the associations between objectively assessed sedentary time, light PA, and MPVA with affect among adult cancer survivors.

Methods: Adult cancer survivors (n=37, mean age 50.24 years, female=30, average time since diagnosis=8.5 years) completed the Functional Assessment of Chronic Illness Therapy – Fatigue (FACIT-F) subscale and the Perceived Stress Scale (PSS). MVPA, light PA, and sedentary time were measured objectively using an accelerometer (GT3X-BT) which the participants wore for seven days on their non-dominant hip. Accelerometer data were scored using the NHANES cut-points for sedentary (0-99), light PA (100-2019) and MVPA (2020 or higher).

Results: Only 30 of the 37 participants wore the accelerometer per protocol. On average, participants reported spending 666.55 mins/day in sedentary time, 142.63 mins/day in light PA and 38.31 mins/day in MVPA. After controlling for age and years since diagnosis, light PA was significantly negatively correlated with the fatigue subscale of the FACIT (r = -0.45) and the PSS scale (r = -0.38). MVPA and sedentary time showed no correlations with FACIT-F and PSS measures.

Conclusions: Our results showed that light PA and not MVPA was associated with affect, specifically fatigue and stress in this sample of cancer survivors. There is growing evidence for health benefits of engaging in light PA, which can be particularly beneficial and suitable for cancer survivors given their long-lasting symptoms and side-effects. Future studies should examine the efficacy and effectiveness of interventions that incorporate light PA in comparison with the widely recommended MVPA for cancer survivors.

MOTIVATIONAL ORIENTATION AND MESSAGE CONTENT: TESTING THE CONGRUENCY HYPOTHESIS IN A BRIEF PHYSICAL ACTIVITY TRIAL

Kathryn Wilson, PhD¹, Paul Estabrooks, PhD²¹Georgia State University, Powder Springs, GA; ²University of Nebraska Medical Center, Omaha, NE

Health promotion messages are a fundamental component of behavioral interventions. According to the “congruency hypothesis,” gain-framed messages should be more effective for people who are approach oriented, and loss-framed messages more effective for those who are avoidance oriented. This effect is supported for a variety of health behaviors, but little evidence exists with specific regard to physical (PA).

Purpose: To test the interaction between motivational orientation (MO) and message frame on change in PA after a brief, minimal-contact messaging trial. We expected the MO would interact with message frame to influence change in PA in a manner that is consistent with the congruency hypothesis.

Methods: All methods were approved by the appropriate IRB. Participants were recruited in a primary care clinic waiting room. MO was measured using a validated survey. Participants could volunteer for a brief, low burden PA intervention by providing their contact information to a researcher on-site at the clinic. Of the 110 people who provided contact information, 18% (N=20; 65% female; m(sd) age= 60.3(11.3) yrs) consented to participate upon follow-up. Percent time spent in light (LPA) and moderate-to-vigorous (MVPA) intensity PA was measured by wrist accelerometry for one week at baseline, then again following an 8-week message intervention. Valid accelerometer wear time required at minimum 3 weekdays and 1 weekend day of 10 hours of wear or more. Participants were randomly assigned to one of three message conditions (gain-framed, loss-framed, or neutral/control), and received one PA promotion message per week for 8 weeks. A blinded PA counselor administered two PA counseling sessions (baseline and week 4), using the five A's behavioral counseling framework.

Results: Percent time spent in LPA and MVPA dropped from 62% to 60% (F(df)=2.5(1); p=.13), and from 10% to 8% (F(df)=10.7(1); p<.01), respectively. RM-ANOVA indicated no effect of message condition on change in LPA or MVPA (F(df)< 1.6722(2); p>.21). Further, MO did not effect changes in PA.

Conclusions: The congruency hypothesis was not supported in this brief trial. Results reported here suggest that a low burden counseling and text-messaging protocol is insufficient to improve PA among older adults. Efforts to understand factors that influence intervention reach in the clinic setting are needed.

DISEASE PREVENTION AND ENVIRONMENTAL SUPPORT VIA BIKE USE ON COLLEGE CAMPUSES.

Karly S. Geller, Ph.D.¹¹Miami University, Oxford, OH

Background: Physical activity has positive effects on humans' physical and mental health. In addition to personal health, physical activity also provides significant benefits to the environment. Substituting our reliance on gas powered transportation with active commute (e.g., bicycling) will reduce the risk of chronic disease and sustain the environment needed for human existence.

Purpose: The purpose of this research was to describe the most salient environmental and cognitive indicators relative to bicycle use among college-aged adults attending a midwestern liberal arts university. The ultimate goal is to support human and environmental health.

Methods: A cross-sectional study design was used, asking participants to report their perceived barriers, self-efficacy, social norms, beliefs, safety, and community support relative to bicycle use on-campus. Observational data were also collected regarding the accessibility and use of bike racks on campus.

Results: Self-report data included 315 college-aged adults (69% female; 31% male; 85% Caucasian). Sixty-six percent of participants currently owned a bicycle. On a scale of 1 (strong disagree) to 5 (strongly agree), participants reported their barriers to bicycle use was 3.07 (SD=0.53). Using the same scale, participants reported their supportive environment for bicycle use was 3.09 (SD=0.53), self-efficacy was 3.29 (SD=0.59), perceived safety was 2.97 (SD=0.43), social norms was 3.23 (SD=0.44), and relative beliefs was 3.31 (SD=0.37). Observational data demonstrated a total of 689 bicycles present on bicycle racks on campus. Among those observations 83.3% of the bikes were rideable (i.e., tires and chains in working condition).

Conclusion: Increased bicycle use on similar campuses could result in benefits to both human and environmental health. Study results support an understanding of the current active commute on similar campuses. Future research needs to examine how active commute could improve both human and environmental health.

ASSESSING THE INTERPLAY BETWEEN INDIVIDUAL EXERCISE IDENTITY, GROUP EXERCISE IDENTITY, AND PHYSICAL ACTIVITY BEHAVIORS

Natalie M. Golaszewski, PhD¹, Guillaume Cheavance, PhD², Eric Hekler, PhD³, John B. Bartholomew, PhD⁴¹University of California, San Diego, SAN DIEGO, CA; ²University of California, San Diego, San Diego, CA; ³UC San Diego, San Diego, CA; ⁴The University of Texas at Austin, Austin, TX

Introduction: Identities provide standards for behavioral regulation as well as personally relevant behavioral goals. The concept of individual exercise identity (EI) implies that the stronger an individual identifies as an exerciser, the more likely they are to behave within the normative behaviors that are associated with that identity. Additionally, individuals may adopt a group EI (e.g. cycling or running group) and behave in accordance with the norms, endorse attitudes, beliefs, and/or feelings for the group. It is unclear how these concepts interact and whether they have unique contributions to physical activity behaviors. The purpose of this study was to examine the interplay between individual EI, group EI, and physical activity per week, and whether exercise group membership was a moderator between these associations among a large sample of active adults.

Methods: Participants included 546 adults (70% female; 82% White; M age = 34.3(13.2)) who engaged in physical activity at least two times/wk. They completed a 235-item questionnaire assessing physical activity behaviors, individual EI, group EI, and other psychosocial determinants of physical activity. Hierarchical linear regressions determined the associations between individual EI, group EI, and metabolic equivalent (MET) minutes/wk. Exercise group membership was tested as a moderator. The interaction between individual EI and group EI was also tested. Bayesian linear regressions were conducted with null findings.

Results: Individual EI ($B = 0.4$, $p < 0.01$) and group EI ($B = 0.12$, $p < 0.05$) were associated with MET mins/wk. Only individual EI ($B = 0.43$, $p < 0.01$) was associated with MET mins/wk when both EI constructs were in the model. Exercise group membership did not change the associations between individual EI ($B = 0.10$, $p = 0.051$) or group EI ($B = 0.07$, $p = 0.23$) and MET mins/wk. The interaction between individual EI and group EI was not significant ($B = 0.05$, $p = 0.27$). Bayesian linear regressions confirmed moderate evidence for null hypotheses ($BF_{01} = 2.71 - 4.39$).

Conclusions: Findings suggest that individual EI and group EI are associated with amount of physical activity per week. They also suggest that the strength of the individual EI is a stronger predictor of the amount of physical activity per week over and above group EI. Lastly, participating in an exercise group did not change the associations between individual EI or group EI and amount of physical activity per week.

INTENTION TO MEET THE RECOMMENDED ADULT PHYSICAL ACTIVITY LEVELS IN JUNIOR HIGH SCHOOL TEACHERS: A THEORY-DRIVEN EXPLORATION

Jiun-Hau Huang, S.M., Sc.D.¹, Pei-Chun Kuo, M.S.¹¹National Taiwan University College of Public Health, Taipei, Taipei, Taiwan (Republic of China)

Background: According to the World Health Organization, lack of physical activity (PA) is the fourth leading risk factor globally for attributable deaths. Alarming, survey data in Taiwan have shown that a relatively large proportion of junior high school teachers are physically inactive. Yet, they serve as a role model for students not only in learning, but also in their lifestyle. In addition, prior research has found that increased PA levels contribute to enhanced performance among teachers. However, their intention to meet the recommended adult PA levels remains largely unknown in Taiwan. Therefore, this study aimed to compare male and female junior high school teachers in their intention to meet the recommended PA levels and their associated factors using the Theory of Planned Behavior (TPB).

Methods: A TPB-based quantitative questionnaire was developed, including items measuring the three main TPB constructs—namely, Attitude toward the Behavior (ATB), Subjective Norm (SN), and Perceived Behavioral Control (PBC). A total of 49 individual TPB items were factor-analyzed to form 5 multiple-item scales (i.e., ATB about positive and negative outcomes, general SN, and PBC under facilitating and constraining conditions), which demonstrated satisfactory psychometric properties. In addition, cross-loading on two factors, five items were removed from the factor but included in the multivariate analysis. Survey responses from 146 junior high school teachers were analyzed using multivariate logistic regression to explore the TPB-based factors associated with their intention to meet the recommended adult PA levels, separately by gender.

Results: The theory-driven analysis revealed that high intention to meet the recommended adult PA levels was related to: (1) in male teachers: perceiving supportive SN (AOR=35.32) and intermediate PBC under facilitating conditions (AOR=39.38); (2) in female teachers: perceiving high PBC under facilitating conditions (AOR=6.15), and intermediate (AOR=8.42) and high (AOR=5.46) PBC under constraining conditions. In addition, female teachers who perceived low PBC owing to lack of PA-related knowledge (AOR=0.08) were less inclined to meet the recommended adult PA levels.

Conclusions: Male and female teachers' intention to meet the recommended adult PA levels was differentially associated with different TPB-based factors. Notably, male teachers were strongly influenced by supportive norms and PBC under facilitating conditions. By contrast, female teachers' intention to meet the recommended adult PA levels was mainly driven by their PBC under facilitating and under constraining conditions, as well as PA-related knowledge. These findings could inform future programs tailored for junior high school teachers of different genders to increase their intention to meet the recommended adult PA levels.

DOES MINDFULNESS PREDICT HOW AN EXERCISE BOUT IS REMEMBERED? ASSOCIATIONS BETWEEN TRAIT MINDFULNESS AND REMEMBERED AFFECT

Bree Geary, MPH¹, Austin S. Baldwin, PhD¹¹Southern Methodist University, Dallas, TX

Objective: How pleasantly an exercise bout is remembered is associated with subsequent physical activity (Kwan et al., 2017). Due to the inherent unpleasant sensations of vigorous physical activity, components of trait mindfulness, including present-focused nonjudgmental observation and emotional regulation, may be positively associated with how pleasantly an exercise bout is remembered. However, the association between trait mindfulness and remembered exercise affect has not been examined.

Methods: In a secondary analysis from an intervention study, healthy young adults (N=94) completed a 15-minute vigorous intensity exercise bout on a treadmill. At baseline, participants self-reported past seven days of physical activity levels (MVPA) and trait mindfulness, measured by the Five Facet Mindfulness Questionnaire (FFMQ). Remembered affect was assessed on a visual analog scale (VAS) from '+100' (*very pleasant*) to '-100' (*very unpleasant*) 15 minutes after the exercise session, at the end of the day, and one week later. Multi-level modeling was used to test the prospective association between trait mindfulness and remembered affect using all three assessment points, while controlling for baseline MVPA. Intervention condition was also included as a covariate because the intervention was designed to target remembered affect.

Results: Overall, the sample was 66% female, 71% White or Caucasian with a mean age of 20.0 years, and a mean BMI of 22.9. The average trait mindfulness score was 3.25 (SD=.42; range: 1-5) and the average baseline MVPA was 209 minutes (SD=294). Trait mindfulness significantly predicted remembered affect, while controlling for baseline MVPA, $b=20.87$, $t(89) = 2.43$, $p = .02$. The strength of the association did not differ across the three assessment points ($p=.91$).

Conclusion: These findings are the first to demonstrate an association between trait mindfulness and how pleasantly an exercise bout is remembered. At this point, it is unclear whether the association reflects shared dispositional tendencies to interpret experiences more positively or if mindfulness is a modifiable intervention target to positively influence affective experiences with exercise. Future research could address this issue.

CLINICAL EXERCISE COMMUNICATION FOR PANCREATIC CANCER SURVIVORS: A MIXED-METHODS ANALYSIS

Nathan H. Parker, MPH, PhD¹, Karen Basen-Engquist, PhD²¹The University of Texas MD Anderson Cancer Center, Houston, TX;²University of Texas MD Anderson Cancer Center, Houston, TX

Background: Clinical cancer care provides opportunities for exercise assessment and advice to improve survivorship. Exercise is understudied in pancreatic cancer (PC) despite potential to improve survivorship outcomes. Recommendations for cancer survivors include ≥ 150 min/wk moderate-to-vigorous aerobic and ≥ 2 x/wk muscle strengthening exercise. We aimed to characterize the frequency and nature of clinical exercise communication among PC survivors and examine its associations with meeting exercise guidelines and perceptions of receiving advice.

Methods: We performed retrospective chart review among PC survivors who underwent tumor resection and participated in a previous survey study (N=146). Surveys assessed aerobic and strengthening exercise and perception of receiving exercise advice from providers. Charts were searched systematically for the keywords "exercise," "physical activity," and "activity" (and variants) from diagnosis through survey date. Two coders analyzed exercise-related passages using an iterative, general inductive approach.

Results: Participants were 45% female with mean age 66 (SD=11) and 74 months since surgery (SD=50). Self-reported adherence to aerobic, strengthening, and both exercise guidelines was 38%, 40%, and 23%, respectively. 66% of participants reported receiving exercise advice from providers. Participants had, on average, 10 exercise communications (SD=8) and 1 communication per restaging visit (SD=.8). Few notes addressed exercise frequency (35%), intensity (6%), or duration (16%) or discerned between aerobic (31%) and strengthening exercise (15%). There were no significant associations among exercise communication frequency and odds of meeting aerobic, strengthening, or both guidelines (all $p > .05$). Number of exercise communications was associated with increased odds of perceiving exercise advice from cancer care providers (OR=1.1, 95%CI 1.01-1.13). Qualitative themes included assessment, advice, facilitators, barriers, and outcomes.

Conclusion: PC survivors generally receive clinical exercise communication, but there are important opportunities to improve assessment and prescription of details including frequency, intensity, duration, and mode. Although more communication may increase survivors' perceptions of receiving exercise advice, it may be insufficient to elicit guideline-concordant behavior. This highlights the importance of integrating formal exercise programming and referral pathways into PC care and survivorship.

REACHING PHYSICAL ACTIVITY GUIDELINES THROUGH SEAMOS ACTIVAS, A THEORY AND TECHNOLOGY ENHANCED INTERVENTION FOR LATINAS

Tanya Benitez, PhD, MSW¹, Dorothy Pekmezi, Ph.D.², Shira Dunsiger, PhD³, Sheri J. Hartman, PhD⁴, Andrea S. Mendoza-Vasconez, MPH, PhD⁵, Britta Larsen, PhD⁶, Bess H. Marcus, Ph.D.⁷

¹Brown University, Providence, RI; ²University of Alabama at Birmingham, Birmingham, AL; ³Brown University, Portsmouth, RI; ⁴University of San Diego, California, La Jolla, CA; ⁵UC San Diego/San Diego State University, San Diego, CA; ⁶University of California, San Diego, San Diego, CA; ⁷Brown University, Sharon, MA

Introduction: Latina women report disproportionately high rates of physical inactivity and related chronic health conditions (obesity, diabetes). Physical activity (PA) efforts to date have shown modest success in this at-risk population. A culturally and linguistically adapted, print-based physical activity intervention (*Seamos Saludables*) produced significant increases in moderate to vigorous physical activity (MVPA) from baseline to 6 months (+71.49 min/week) compared to control (+29.96 min/week). However, only 11% of intervention participants reached the national PA guidelines of ≥ 150 min/week of MVPA. Thus, we enhanced the original intervention to achieve larger, more health enhancing PA increases in Latinas. Intervention refinements involved further targeting key constructs of the Social Cognitive Theory (via additional print materials and more in-depth tailored reports), and incorporating interactive text-message-based self-monitoring strategies. The current study tests the original print-based *Seamos Saludables* PA intervention against a theory and technology enhanced iteration (*Seamos Activas*). Study aims and intervention refinements focus on increasing the percentage of Latinas meeting national PA guidelines.

Methods: A randomized controlled trial (N = 199) of two (original vs. enhanced) tailored PA interventions was conducted. Self-reported PA was assessed at baseline and 6 months using the 7-Day PA Recall.

Results: Participants were primarily overweight/obese (mean BMI = 30.6, SD = 7.56) Mexican/Mexican-American (89%) women. Mean age at baseline was 43.8 (SD=10.11). Fifty seven percent of enhanced arm participants (n = 102) met national PA guidelines at 6 months compared to 44% of original arm participants (n = 97), with a significant difference in the odds of meeting criteria, favoring the enhanced arm, OR = 1.66, 95% CI: 1.09–2.89. The enhanced arm reported increasing MVPA from 14.3 min/week (SD = 25.06) at baseline to 127.9 min/week (SD = 98.91) at 6 months, $p < .01$. Similar significant within group changes in MVPA were reported by the original arm, with no significant between group differences in MVPA total min/week at 6 months ($p = .73$).

Conclusion: Addressing interactivity and accountability through text-messaging, and more rigorously targeting theoretical constructs may be key to helping Latinas achieve nationally recommended, health enhancing PA levels.

APPLYING SELF-DETERMINATION THEORY TO PARTICIPANTS' EXPERIENCES IN FOR-CAUSE PHYSICAL ACTIVITY EVENTS: A QUALITATIVE STUDY

Bernhart John, MPH, PhD¹, Sara Wilcox, PhD¹, Lindsay M. Decker, MPH¹, Diane K. Ehlers, PhD², Jennifer O'Neill, MPH, PhD¹, Brooke W. McKeever, Ph.D.¹

¹University of South Carolina, Columbia, SC; ²University of Nebraska Medical Center, Omaha, NE

Introduction: Self-determination theory has recently been applied to understanding physical activity behavior and motivation. For-cause physical activity events reach many people providing them with an opportunity to support a cause while also engaging in physical activity. To date, little existing research has incorporated established physical activity behavior theories to explain participants' experiences in these events.

Purpose: The purpose of this study was to qualitatively explore participants' motivations and experiences related to completing a for-cause physical activity event. We also studied intention to participate in future physical activity and for-cause events.

Methods: Semi-structured interviews founded in a Self-Determination Theory (SDT) and altruism framework were conducted with participants (n=18) of 5K for-cause events. The interview guide and coding structure were guided by SDT as well as grounded theory for emerging themes.

Results: The average age of interview participants was 40.22 years (SD = 10.09). Most participants were women (78%) and white (83.33%). Half of participants had not completed a for-cause event in the past 12 months. Most participants discussed their experiences consistent with SDT constructs. The themes of competence (e.g., feelings of accomplishment completing the event) and relatedness (e.g., shared experiences with friends, family and the community) were most common, followed by autonomy (e.g., personal decision to select and sign up for event). Responses also reflected the importance of identified (e.g., participating in event to stay in shape) and intrinsic motivation (e.g., doing physical activity for pleasure of doing behavior) and altruism (e.g., desire to help others and support charity). In addition, the participants' descriptions of the unique creation of a strong community at the event and continued interest for supporting the cause explained intention to participate in future for-cause events and engage in physical activity.

Discussion: SDT was useful for understanding and explaining participants' motivations and behaviors related to PA in for-cause events. Altruism, while not a core construct of SDT, may be useful to include in future applications of SDT on physical activity behaviors and motivations within the context of for-cause events. Participants' descriptions of intention for future event participation suggest for-cause events may be a unique leveraging point for promoting physical activity.

ACTIVE-AGEING IN PLACE: A COMMUNITY-BASED PARTICIPATORY PHYSICAL ACTIVITY INTERVENTION FOR OLDER ADULTS IN HONG KONG

Lok Chun Janet Lee, MPhil¹, Rainbow T.H. Ho, PhD, REAT, BC-DMT, AThR, RSMT/E, CGP, CMA²¹The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong**Aims and Objectives:** The purpose of this study was to evaluate Active-Ageing in Place, a neighbourhood environment tailored physical activity (PA) education intervention for community-dwelling older adults to increase PA level.**Background:** The World Health Organization (WHO) has made PA recommendations for older adults in terms of type, intensity and frequency. However, the number of older adults attained the recommended level of PA recommended by WHO has remained low in Hong Kong. In the last decade, community-based participatory research (CBPR) methodology was commonly used to develop physical activity (PA) behavioural change intervention, especially for participants from low socioeconomic status group.**Methods:** Forty-seven community-dwelling older adults over 60 years old participated in the 5-week PA education intervention. Participants received a towel and pedometer as participation incentive. Primary outcome was PA level (as measured by WHO criteria and RAPA). Secondary outcomes were measured at individual (exercise self-efficacy, blood pressure, lower body strength, balance), social (perceived neighbourhood cohesion) and environmental (Perceptions of physical activity support in physical environment) levels.**Results:** Following the intervention, twenty participants (43%) were able to fulfill PA recommendations suggested by WHO. For acute intervention effects on aerobic PA level measured by RAPA, RAPA score on aerobic physical activity at post-intervention (Mdn = 6.0) was statistically significantly higher than pre-intervention (Mdn = 3.0), $Z = -5.452$, $p < 0.001$. For acute intervention effects on anaerobic PA level measured by RAPA, RAPA2 score on anaerobic physical activity at post-intervention (Mdn = 3.0) was statistically significantly higher than pre-intervention (Mdn = 2.0), $Z = -5.082$, $p < 0.001$. In terms of attitude at post-intervention, there were significant increase in exercise self-efficacy and decrease in exercise barriers. In terms of changes in physiological parameter and physical ability, there were significant reduction in blood pressure and improvement in balance. The effect ranged from small to medium (Cohen's d : 0.30-0.53, all $p < 0.01$).**Conclusion:** The results suggest that a 5-week PA educational intervention developed by CBPR can promote PA behaviours among community-dwelling older adults that attained WHO recommendations, improve exercise attitude, blood pressure level and balance. PA intervention developed by CBPR may also be relevant to other neighbourhoods aiming to promote PA among community-dwelling older adults.**CORRESPONDING AUTHOR:** Rainbow T.H. Ho, PhD, REAT, BC-DMT, AThR, RSMT/E, CGP, CMA, Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong; tinho@hku.hk

THEORY-BASED GENDER COMPARISONS OF PHYSICIANS' INTENTION TO PROVIDE PATIENT COUNSELING ON RECREATIONAL SPORTS AND STRETCHING

Jiun-Hau Huang, S.M., Sc.D.¹, Pei-Chun Kuo, M.S.¹, An-Min Lynn, M.D., M.P.H.¹¹National Taiwan University College of Public Health, Taipei, Taipei, Taiwan (Republic of China)**Background:** Insufficient physical activity (PA) is a key risk factor for overweight/obesity and chronic diseases. Accordingly, more clinical guidelines have recommended that physicians provide patients with exercise counseling (EC) to help increase their PA, including recreational sports and stretching/flexibility training. However, little is known about the intention to provide such EC among male and female physicians in Taiwan. Therefore, this study aimed to compare physicians' intention to provide recreational sports and stretching/flexibility EC, by gender, and their associated factors using the Theory of Planned Behavior (TPB).**Methods:** Based on the TPB constructs—Attitude Toward the Behavior (ATB), Subjective Norm (SN), and Perceived Behavioral Control (PBC), a quantitative survey was developed, including 27 individual TPB items, which were subsequently factor-analyzed to form 5 multiple-item scales (i.e., ATB about positive and negative outcomes, general SN, and PBC under facilitating and constraining conditions), which demonstrated satisfactory psychometric properties. Survey responses from 1,006 physicians were analyzed using multivariate logistic regression to examine the TPB-based factors related to high recreational sports and stretching/flexibility EC intention, respectively and separately by gender.**Results:** This study found that high intention to provide recreational sports EC was related to: (1) in male physicians: perceiving supportive SN (AOR=1.72), intermediate (AOR=1.55) and high (AOR=2.23) PBC under facilitating conditions, and high PBC under constraining conditions (AOR=1.65); (2) in female physicians: perceiving neutral (AOR=2.53) and supportive (AOR=2.92) SN. By contrast, high intention to provide stretching/flexibility EC was related to: (1) in male physicians: perceiving neutral (AOR=1.61) and positive (AOR=1.68) ATB about positive outcomes, neutral (AOR=1.67) and supportive (AOR=3.38) SN, and high PBC under facilitating conditions (AOR=2.02); (2) in female physicians: perceiving high PBC under facilitating conditions (AOR=2.65).**Conclusions:** Male and female physicians' intention to provide recreational sports and stretching/flexibility EC, respectively, was influenced by different TPB-based factors. Also, female physicians appeared to have a higher threshold to provide either type of EC than male physicians. These findings could inform the development of gender-specific programs to increase physicians' intention to provide recreational sports and stretching/flexibility EC.**CORRESPONDING AUTHOR:** Jiun-Hau Huang, S.M., Sc.D., National Taiwan University College of Public Health, Taipei, Taipei, Taiwan (Republic of China); jhuang@ntu.edu.tw

BREAKFAST INTAKE INFLUENCES FEELINGS OF ENERGY BUT IS NOT INFLUENCED BY OBJECTIVE PHYSICAL ACTIVITY IN LGBTQ COLLEGE STUDENTS

Isaura M. Castillo-Hernández, M.Sc.¹, Ginny M. Frederick, M.S.¹, Ewan R. Williams, MSc, MPT¹, Anneliese A. Singh, PhD¹, Ellen M. Evans, PhD¹¹University of Georgia, Athens, GA

Introduction: Habitual breakfast (BF) consumption is associated with numerous health outcomes and feelings of well-being across the lifespan. The literature also suggests that regular BF behaviors may be a proxy for other modifiable health-related behaviors such as physical activity (PA). Emerging adulthood is a critical life stage for establishing positive behaviors, including both BF intake and adequate PA. Moreover, evidence suggests the existence of health behavior disparities among lesbian, gay, bisexual, transgender, and queer (LGBTQ) college students that may impact feelings of well-being. Thus, the aim of this study was to examine whether BF eating frequency impacts feelings of vigor and fatigue and objectively measured PA in LGBTQ college students.

Methods: Self-identified LGBTQ college students ($n = 41$) were assessed for BF consumption patterns using a web-based 3-day food record tool (ASA24; 1-weekend (WKN), 2-weekdays (WKD)). BF was characterized as an eating occasion that occurred between 5-10AM on WKD and 5-11AM on WKN. Participants were classified as BF skippers (SKIP-BF, omitted BF on at least 1-d of the dietary recall) or BF consumers (EAT-BF, consumed BF on 3-d of the recall). Vigor and Fatigue were assessed using the Profile of Mood States 2-Brief (POMS2). Moderate-vigorous PA (MVPA) was obtained via accelerometer (GT3-X+ ActiLife; minimum of 4-valid d, 10-hr/d). Independent-groups t-tests and Pearson's r for overall bivariate relationships were utilized for data analysis.

Results: SKIP-BF ($n = 20$) and EAT-BF ($n = 21$) were similar in age and weight status (22.4 ± 4.5 vs 22.9 ± 6.0 yo; 24.6 ± 3.5 vs 25.3 ± 8.0 kg/m², respectively; all $p > .05$). No differences were observed between groups in MVPA (EAT-BF = $48.5 \pm 19.18.0$ vs SKIP-BF = $51.25.8 \pm 24.48.6$ min/day; $t = .38$, $p = .71$). EAT-BF reported significantly higher Vigor scores compared to SKIP-BF (8.3 ± 3.7 vs 5.7 ± 4.3 ; $t = -2.1$, $p = .04$) whereas no differences in Fatigue were detected (7.1 ± 5.3 vs 8.4 ± 5.4 , $p = .46$). In the total group, MVPA was not correlated with Vigor or Fatigue ($r = -.15$ and $-.25$, both $p > .05$).

Conclusion: Feelings of vigor are greater in LGBTQ college students whom consume BF compared to those who do not irrespective of MVPA behaviors. Causal research designs are warranted to better elucidate the impact of BF intake on feelings of vigor and fatigue in emerging adults, especially in the LGBTQ population known to have health disparities in feelings of well-being.

EXPLORING SOCIAL MOTIVATION FOR PA AMONG LATINAS WITH OSTEOARTHRITIS AND A MEMBER OF THEIR SOCIAL NETWORK

Sandra H. Soto, PhD, MPH, BSN¹, Diane Berry, PHD, ANP-BC, FAANP, FAAN¹, Leigh F. Callahan, PhD¹¹University of North Carolina at Chapel Hill, Chapel Hill, NC

Purpose: The social environment (e.g., social support, modeling) influences the physical activity (PA) of Latinas and other minorities. There is a dearth of evidence on the impact of the social environment on the PA of Latinas with osteoarthritis (OA), who may experience PA-limiting symptoms (e.g. pain and stiffness). The purpose of this study was to qualitatively explore how Latinas with OA and a self-selected supporter of their PA motivate each other's PA.

Methods: Separate semi-structured dyadic interviews were conducted with 14 Latinas with OA and a member of their social network who supports their PA efforts ("supporters"; daughter=5; spouse=4; son=2; granddaughter=1; nephew=1; friend=1). Supporters were ≤ 18 years old. Interviews were digitally recorded in the preferred language of participants and transcribed verbatim in their original language. We used framework analysis to reduce qualitative data to themes and subthemes in Atlas.ti.

Results: Latinas with OA were on average 66 years old (SD 18), 50% married, 50% \geq high school education, 65% retired or homemakers, 36% with a monthly household income $< \$1500$, and 93% born outside the US. Supporters were 50% female, on average 48 years old (SD=23), 71% married/partnered, 93% \geq high school education, 36% retired, 23% with a monthly household income $< \$1500$, and 36% born in the US. Latinas and supporters said that supporters often motivated Latinas' PA by creating opportunities for them to engage in PA together. Other ways of receiving PA motivation included having supporters a) nudge/tell Latinas to engage in PA, b) model PA behaviors, c) talk to Latinas about PA, and d) help them with household responsibilities so that they could be active. In many cases, dyads said motivation to engage in PA was reciprocated between each other rather than focused solely on Latinas with OA. Although most supporters agreed that PA has a positive effect on OA symptoms, many said they did not encourage PA when Latinas experienced symptoms. Several supporters indicated that Latinas' OA was a motivator of their own PA, especially adult children who believed their mothers' OA increased their risk for developing OA in the future.

Discussion: Findings suggest opportunities for dyadic PA interventions among Latinas with OA. Dyadic strategies for promoting Latinas' PA and how motivation may be reciprocated were identified. Further investigation using quantitative methods may help generalize findings to other Latinas with OA.

PREDICTING PHYSICAL ACTIVITY MAINTENANCE AFTER BEHAVIORAL WEIGHT LOSS TREATMENT

Laura D'Adamo, B.A.¹, Christine C. Call, M.S.¹, Leah M. Schumacher, PhD², Evan M. Forman, PhD³, Meghan L. Butryn, PhD³¹Drexel University Center for Weight, Eating, and Lifestyle Science, Philadelphia, PA; ²Weight Control and Diabetes Research Center, The Miriam Hospital/Alpert Medical School of Brown University, Providence, RI; ³Drexel University, Philadelphia, PA

Maintaining a high level of moderate-to-vigorous physical activity (MVPA) after behavioral weight loss (BWL) treatment is key for sustaining weight loss and health benefits. However, prolonged behavior change is challenging and little is known about psychological and behavioral predictors of successful MVPA maintenance. This study examined, among a sub-sample of participants initially successful in adopting the recommended level of MVPA, predictors of MVPA maintenance after BWL treatment. Participants were adults with overweight or obesity who were enrolled in an 18-month BWL treatment in which 250 min/week of MVPA was recommended. Psychological traits (grit, trait self-control) were self-reported at baseline. MVPA was measured via accelerometry and PA-related psychological variables (PA enjoyment, PA acceptance, PA barriers) were self-reported at baseline, during treatment (6, 12, and 18 months), and at follow-up (36 months). PA maintenance at follow-up was coded as a dichotomous variable (>250 min/week of MVPA: Yes/No). Of the 320 participants enrolled in the study, 202 (63%) met MVPA recommendations at >1 time point during treatment (6, 12, or 18 months). At 36 months, 82 (41%) of these participants maintained >250 min/week of unbouted MVPA. Participants who met MVPA recommendations more consistently throughout treatment were more likely to maintain MVPA at 36 months ($p=.003$). Meeting recommendations at 6 and 18 months ($p's<.05$) and engaging in more minutes of MVPA and moderate PA at 12 and 18 months ($p's<.05$) predicted MVPA maintenance at 36 months, controlling for baseline MVPA and accelerometer wear time at each time point. Sedentary behavior, light PA, and vigorous PA during treatment were not associated with likelihood of PA maintenance at follow-up. Baseline psychological variables and change in PA-related psychological variables during treatment were unrelated to MVPA maintenance. Among participants who are successful at adopting a high level of MVPA during treatment, fewer than half maintain the recommended level of MVPA at follow-up, demonstrating the challenge of long-term behavior change. Participants who most consistently engaged in a high level of MVPA during treatment, and did so with the greatest minutes/week, were most likely to maintain MVPA. Future research must think creatively about novel psychological factors and processes that may relate to MVPA maintenance, as the psychological variables examined in this study were not predictive.

IS THE FRAME THE NAME OF THE GAME? THE INFLUENCE OF MESSAGE FRAMING ON FITNESS CLASS ATTENDANCE

Pamela J. Lundeberg, M.S.¹, Dan Graham, PhD²¹Colorado State University, BOULDER, CO; ²Colorado State University, Fort Collins, CO

Background: Despite the inarguable benefits of exercise, less than twenty percent of Americans meet the US Department of Health and Human Service's physical activity (PA) recommendations (CDC, 2017). Many interventions have focused on increasing individual participation in PA, but inspiring participation in group fitness (GF) classes may be more advantageous than promoting individual PA, as GF offers the added benefits of social support and accountability (Estabrooks, 2000). Accordingly, the present study sought to determine the most effective manner to market GF classes by testing the effect of message framing on college students' attendance of a variety of GF classes.

Method: Participants read descriptions of four different fitness classes and selected one of those classes to attend. Each description presented class information with a different type of frame – health-related gain, health-related loss, appearance-related gain, and appearance-related loss – allowing us to compare the within-participant influence of these frames.

Results: Contrary to previous work (Lundeberg & Graham, under review), in which participants' *intention* to attend classes was not influenced by the type of frame, preliminary analyses indicate that participants in this study – who were required to actually *attend* the class they selected – were equally likely to attend classes whose descriptions were framed in terms of appearance gains, health gains, or health losses and were least likely to attend classes whose descriptions were framed in terms of appearance losses.

Conclusions: In our study, participants appeared to be turned away from attending classes whose descriptions were framed in terms of appearance losses (e.g., “don't let your body get flabby!”). Recreation Centers could consider the manner in which they are marketing classes, as including appearance-related loss framing may discourage participants from attending classes.

POSITIVE AND NEGATIVE SOCIAL CONTROL AND PHYSICAL ACTIVITY IN PATIENT-PARTNER DYADS

Zofia Szczuka, MA¹, Karolina Lobczowska, M.A.¹, Monika Boberska, MA², Ewa Kulis, MA², Anna Banik, PhD¹, MAGDALENA KRUK, MA³, Aleksandra Luszczynska, PhD²

¹SWPS University of Social Sciences and Humanities, Wrocław, Dolnoslaskie, Poland; ²SWPS University of Social Sciences and Humanities, Warsaw, Mazowieckie, Poland; ³SWPS University of Social Sciences and Humanities, WROCLAW, Dolnoslaskie, Poland

Background: Interpersonal processes involving social support as well as social control may affect health behavior. Both social support and social control may foster health behaviors, but they are distinct conceptually (Lewis & Butterfield, 2005) and empirically (Franks et al., 2006; Helgeson et al., 2004). Health-related social control refers to individuals' attempts to influence another person's health behavior. Facets of social control may refer to positive direct persuasion, positive reinforcement and modeling, negative control, or making structural changes in the home environment (cf. Thorpe et al., 2008). This study investigated prospective associations between the four facets of social control and moderate-to-vigorous-physical activity (MVPA) in patient-partner dyads. It was tested if perceived social control would predict MVPA of patients and partners, measured at the follow-up.

Methods: A total of 238 dyads of patients with a chronic illness ($M_{age} = 47.03$; 67.2% women) and their partners ($M_{age} = 45.47$; 65.1% women) provided their data at Time 1 (T1). At Time 2 (T2; the 2-3-month follow-up) 176 patient-partner dyads participated. The path analyses were conducted, controlling for baseline MVPA levels

Findings: Analyses explaining patients' MVPA showed that, patients' perceptions of their partners' social control were unrelated to patients' MVPA at T2. However, partners' perceptions of patients' positive social control-persuasion (T1) predicted patients' MVPA (T2). Analyses explaining partners' MVPA indicated that, partners' perceptions of patients' social control were unrelated to partners' MVPA at T2. However, patients' perceptions of partners' positive social control-persuasion (T1) and negative control (T1) predicted partners' MVPA (T2).

Conclusions: Dyadic effects of social control on MVPA were observed, whereas within-individual effects (e.g., patients' perceptions on patients' MVPA) were not confirmed. The consistent significant effects were observed for patients' and partners' perceptions of positive control exerted by the other person in the dyad.

Keywords: social control; moderate-to-vigorous physical activity; adults; dyads

SYSTEMATIC REVIEW OF BEHAVIOR CHANGE TECHNIQUES AMONG PELVIC FLOOR EXERCISE INTERVENTIONS FOR WOMEN TO ADDRESS INCONTINENCE

Anthony McGaughey, MS, CHES¹, Valerie Senkowski, MS¹, Paul Branscum, PhD, RD¹

¹Miami University, Oxford, OH

Background: Pelvic floor dysfunction (PFD) can lead to numerous health concerns such as urinary incontinence (UI), fecal incontinence, and organ prolapse. Currently, 75% of the older adults living in nursing homes and senior living communities report problems related to PFD. PFD is an indicator of pelvic floor health, and while often characterized as a condition impacting older adults, currently 25% of all women in the US also report problems associated with PFD. To treat PFD pelvic floor muscle exercises (PFME) are typically prescribed, and have been reported as an effective behavioral treatment for UI, however little is known about what intervention strategies contribute to the most effective results.

Purpose: Therefore, the purpose of this study was to determine which behavior change techniques (BCTs) are used in PFME interventions, and which techniques are associated with better prevention or management of UI among women.

Methods: A systematic search of peer-reviewed literature of PFME interventions that target adult women was conducted using seven databases (i.e. Medline). We retrieved 157 unique results after duplicates were removed. In the initial search. After screening for inclusion criteria, nine articles were included in the final review. Michie's Behaviour Change Technique Taxonomy v1 (BCTTv1) was used by two researchers to independently code BCTs for each intervention.

Results: Across the nine articles, 25 unique BCTs were identified, and articles ranged from reporting 3 to 12 BCTs. The most frequently coded BCTs was "Instruction on how to perform the behavior" (n=9 studies), "Credible source" (n=8 studies), and "Demonstration of the behavior" (n=7 studies). Theoretical constructs measured as outcomes across the interventions included Attitudes, Barriers, Intentions, Knowledge, Outcome Expectations, Self-Efficacy, and Skills. Most of the interventions focused heavily on education, but a few used additional strategies such as training (i.e. instruction on how to perform the behavior), enablement (i.e. self-monitoring of behavior), and modeling (i.e. demonstration of behavior).

Conclusions: Researchers should attempt to explicitly link intervention methods to BCTs, and these should align with appropriate intervention functions. BCTs provide a common language for public health researchers and practitioners to design and communicate interventions. Existing interventions using PFME can benefit from including additional supplementary BCTs.

THE ROLE OF MEANING IN LIFE FOR CHRONIC DISEASE MANAGEMENT: EXPLORATORY PATH ANALYSES

Maeve B. O'Donnell, Ph.D.¹, Jessica Morse, MS², Bradley T. Conner, PhD³, Michael Steger, MS; PhD⁴¹Seattle Children's Research Institute, Seattle, WA; ²Colorado State University, Denver, CO; ³Colorado State University, FORT COLLINS, CO; ⁴Colorado State University, Fort Collins, CO

Chronic disease affects 60% of the adult population in the United States and is the leading cause of death and disability (CDC, 2017). Despite the robust evidence suggesting that management of chronic disease can reduce risk of morbidity and mortality (e.g., Bodenheimer et al., 2002), average adherence to long-term therapies is 50% (Burkart & Sabaté, 2003). Considering meaning in life has emerged as a powerful predictor of physical health (Czekierda et al, 2017), the purpose of the current study was to test the effect of meaning in life on chronic disease management.

The sample for the current study consisted of 99 people (Mage = 29.1, SD = 16.5) across four disease groups: Type 1 and Type 2 Diabetes, Migraines, and Asthma. The sample was predominantly female (84.8%), European-American (82.8%), and single (73.7%). Data was collected at initial enrollment (T1) and 3 months later (T2). It was hypothesized that meaning in life (MIL) would positively predict chronic disease management (CDM) through a proactive health orientation, social support, and self-efficacy (SEF). Path analyses were conducted using Mplus 7.4 (Muthén & Muthén, 1998–2012). In the cross-sectional model, MIL predicted CDM via SEF such that T1 MIL positively predicted T1 SEF ($b = .44$, $SE = .09$, $p < .001$), and T1 SEF positively predicted T1 CDM ($b = .63$, $SE = .07$, $p < .001$). Bias-corrected bootstrapped confidence intervals revealed that total and specific indirect effects were statistically significant (Total = .02 [.006, .03]; T1 MIL- >T1 SEF- >T1 CDM = .03 [.02, .04]). A longitudinal model ($n=47$) was then tested to predict T2 CDM from T1 MIL and T1 SEF. T1 MIL positively predicted T1 SEF ($b = .44$, $SE = .09$, $p < .001$), and T1 SEF predicted T2 CDM ($b = .39$, $SE = .18$, $p = .03$). Bias-corrected bootstrapped confidence intervals revealed that total and specific indirect effects were statistically significant (Total = .06 [.02, .10]; T1 MIL- > T1 SEF- >T2 CDM = .03 [.001, .05]).

Results from this study provide evidence that people with a chronic disease who report higher meaning in their lives are more likely to report better engagement in chronic disease management and that this effect is, in part, explained by their confidence in managing their respective disease. Future intervention efforts designed to promulgate meaning in life for patients with chronic disease may support reasons “why” one's health matters and have a role in generating and sustaining motivation for disease management.

VIOLENCE, MENTAL HEALTH, AND SEXUAL & REPRODUCTIVE HEALTH RISK AMONG GENDER DIVERSE YOUTH IN THE UNITED STATES

Megan Sutter, PhD¹¹NYU School of Medicine, New York, NY

Transgender and gender-diverse (TGD) individuals experience sexual and reproductive health (SRH) disparities compared to their cisgender counterparts, including increased risk for sexually transmitted infections, impaired fertility, unintended pregnancy, and certain cancers. Increased SRH risk among TGD populations are in part due to lower rates of contraceptive use and misunderstandings of pregnancy risk while taking gender-affirming hormones. In the general population, a history of victimization is directly associated with an increased number of sexual partners, earlier sexual debut, greater likelihood of unprotected sex, and a history of sexually transmitted infections. SRH risk is also indirectly exacerbated by victimization through increased mental health problems and maladaptive coping strategies like substance abuse and number of sexual partners. The current study examines the role of violence on SRH risk factors among a sample of gender-diverse youth using secondary data from the 2017 CDC District Youth Risk Behavior Surveillance System survey. The sample ($n=12,503$) consisted of cisgender female (51%), male (47%), transgender (2%), primarily Hispanic (44%), Black/African American (20%), and heterosexual (78%) youth in 9–12 grade from the New York metro area, Broward County FL, and San Diego CA. Controlling for grade level, logistic regression analyses found that TGD youth were significantly more likely than cisgender youth to report ever having sex (OR=2.00, 95% CI: 1.25, 3.17). Among sexually-active youth ($n=2,881$), TGD youth were more likely to report sexual debut before age 14 vs. 14+ (OR=.35, 95% CI: .19, .63), alcohol/drug use during their last sexual encounter (OR=2.34, 95% CI: 1.22, 4.46), and more than 1 sexual partners in the last 3 months (OR=2.37, 95% CI: 1.24, 4.53); and less likely to use a condom at their last encounter (OR=.50, 95% CI: .27, .92). A series of path analyses were conducted to assess the association between gender and condom use through victimization (sexual dating violence and being threatened at school), suicidal ideation, alcohol/drug use during sex, and number of recent sex partners. There were significant indirect effects of gender on condom use through violence factors and suicidal ideation, but not alcohol/drug use or number of partners. Gender was also indirectly associated with alcohol/drug use through violence factors and suicidal ideation. In conclusion, TGD youth had increased SRH risk compared to cisgender youth in part due to violence exposure and associated mental health problems. Future research and interventions should focus on violence prevention, positive coping and behavioral skills for TGD youth, and TGD-inclusive policies and sex education. Schools and healthcare providers should be aware of increased risk and be prepared to counsel youth on the link between victimization, mental health, and SRH risk behaviors.

VALIDATION OF THE SEXUAL DISCOUNTING TASK FOR USE IN AN ONLINE SETTING WITH FEMALE ADOLESCENTS

Bethany L. Harris, B.S.¹, Sneha Thamotharan, Ph.D. in Clinical Psychology from Texas A&M University², Sherece Fields, PhD³

¹Texas A&M University, Bryan, TX; ²University of Colorado at Denver and Anschutz Medical Campus, Denver, CO; ³Texas A&M University, College Station, TX

Objective: The Sexual Discounting Task (SDT) was developed to evaluate the effects of delay on decision-making as it relates to sexual risk-taking behaviors. Though previously validated with other populations including adolescents and emerging adults, the current study seeks to examine the predictive validity of the SDT for use with adolescents specifically in an online setting.

Methods: A sample of 18-year-old female adolescents ($N = 43$) were recruited to complete the Online SDT (involving choices between immediate unprotected sex and delayed sex with a condom with hypothetical sexual partners). Sexual discounting was assessed using area under the curve (AUC) analyses in that higher sexual discounting values indicate greater willingness to engage in immediate unprotected sex compared to delayed sex with a condom. Additionally, they completed several self-report measures assessing demographic, sexual behavior, and sexual history.

Results: Sexual discounting for partners deemed more desirable was positively correlated with frequency of use of protection during both oral sex ($r = 0.41$, $p < 0.01$) and sexual intercourse ($r = 0.42$, $p < 0.01$). Results were similar for sexual discounting for partners described as having no chance of having a sexually transmitted infection (STI). Sexual discounting for desirable partners was negatively correlated with lifetime oral sexual ($r = -0.32$, $p < 0.05$) and sexual intercourse partners ($r = -0.40$, $p < 0.05$) as well as oral sexual partners within the past 3 months ($r = -0.34$, $p < 0.05$) and sexual intercourse partners within the past 3 months ($r = -0.38$, $p < 0.05$). Sexual discounting for desirable partners was positively correlated with whether they had ever been tested for an STI ($r = 0.38$, $p < 0.05$) as was that for partners described as having no chance of having an STI ($r = 0.40$, $p < 0.01$). Additional analyses are also discussed.

Conclusion: Findings from the current study suggest that the Online SDT is predictive of some adolescent sexual risk-taking behaviors. The Online SDT is shown to be clinically meaningful for female adolescents and is sensitive to factors that influence real-world decisions to use condoms. Future treatment and prevention should consider delay discounting as an important variable affecting sexual risk behavior.

RESULTS FROM A SYSTEMATIC SCOPING REVIEW OF THE LITERATURE ON PARENT-ADOLESCENT SEXUAL HEALTH COMMUNICATION IN THE U.S.

Frances M. Nguyen, MPH¹, Christine M. Markham, PhD¹, Christina J. Sun, PhD, MS², Ross Shegog, PhD³, Lauren B. Frank, PhD⁴, J. Michael Wilkerson, PhD, MPH¹, William E. Lambert, PhD²

¹The University of Texas Health Science Center, Houston, TX; ²Oregon Health & Science University-Portland State University School of Public Health, Portland, OR; ³University of Texas, Houston, TX; ⁴Portland State University, Portland, OR

Background: Effective parent communication about sexual health, including messages, messaging, and delivery, can lead to positive adolescent sexual health outcomes. This study reviewed the academic literature on parent-adolescent sexual health communication and characterized its effectiveness in promoting abstinence, condom use, and sexually transmitted infection (STI)/ HIV testing.

Methods: A systematic scoping review was conducted by searching four electronic databases (Embase, Scopus, Pubmed, Psycinfo) and relevant journals for peer-reviewed articles published January 1, 2000 to February 15, 2018. The search strategy, which included terms for sexual health messaging, adolescents, and communication, resulted in 6,665 articles. Initial abstract and subsequent full article screening were conducted by trained reviewers. Inclusion criteria, determined a priori, included those articles which: 1) were published in English; 2) were conducted in the United States; 3) had a majority of participants aged 13-18; 4) had abstinence, condom use, or STI/ HIV testing as outcomes; and 5) were related to an aspect of sexual health messaging/ communication. Of the total 381 resulting articles included in the final review, the research team reviewed 68 articles specific to parent-adolescent communication.

Results: Articles were grouped into three categories: sexual health topics discussed and their impact on adolescent behavior, characteristics and context of sexual health communication, and parent-based/ focused interventions. The most informative studies used dyadic designs and captured the perspectives of both parent and youth.

Parents were a more valued source of sexual health information for younger adolescents than older ones. Abstinence was a more common topic than condom use and STI/ HIV testing. Effective communication was facilitated by a positive parent-child relationship grounded in trust and openness; embarrassment and lack of knowledge were barriers. Adolescent race, gender, and sexual orientation also shaped parent communication, influencing topics discussed and level of comfort with discussions.

Discussion: While articles on parent-adolescent communication were more numerous than for other messengers, few looked specifically at certain sexual and gender minority and racial/ ethnic groups, such as American Indian/ Alaskan Natives. Further research is needed on how to increase and improve parent-adolescent sexual health communication, especially around condom use and STI/ HIV testing and for certain minority groups.

SYMPTOMS OF SLEEP DISORDERS ARE ASSOCIATED WITH THE MENTAL AND PHYSICAL HEALTH OF COLLEGE STUDENTS

Joanna M. Hobson, B.S.¹, Shannon Gilstrap, B.S.², Burel R. Goodin, PhD³, Stephen J. Thomas, PhD, DBSM¹

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama, Birmingham, Birmingham, AL; ³The University of Alabama at Birmingham (UAB), Department of Psychology, Birmingham, AL

Background: Symptoms of sleep disorders, including insomnia, are associated with mental and physical health outcomes. College students may be at risk for insomnia and/or delayed sleep-wake phase disorder; however, it is unclear exactly how this risk might affect their mental and physical health. Therefore, this study examined the associations between symptoms of sleep disorders and mental and physical health outcomes among college students.

Methods: College students (n=277) were recruited from a Department of Psychology research subject pool to complete the SLEEP-50 questionnaire, which was designed to detect sleep disorders according to DSM-IV criteria. They also completed the Beck Depression Inventory-II (BDI-II), the State Trait Anxiety Inventory (STAI), and the physical health component of the Duke Health Profile. Bivariate correlation analyses were conducted to examine associations among symptoms of sleep disorders and the measures of mental and physical health.

Results: The sample was 66% female, 82% Caucasian, and 64% freshmen with an average age of 18.84. Results revealed that greater symptoms of insomnia symptoms were associated with greater symptoms of depression ($r = .521, p < .001$) and anxiety ($r = .538, p < .001$), as well as worse physical health ($r = -.536, p < .001$). There was also an association between other sleep disorders and health outcomes. More circadian rhythm sleep disorder symptoms were associated with greater symptoms of depression ($r = .291, p < .001$) and anxiety ($r = .241, p < .001$), as well as worse physical health ($r = -.209, p < .001$). More OSA symptoms were associated with greater depressive symptoms ($r = .392, p = .000$) and anxiety ($r = .288, p < .001$) as well as worse physical health ($r = -.282, p < .001$). Symptoms of Narcolepsy were associated with greater depressive symptoms ($r = .286, p < .001$) and anxiety ($r = .240, p < .001$) as well as physical health ($r = -.205, p = .001$). Lastly, symptoms of Restless Leg Syndrome were associated with greater depressive symptoms ($r = .187, p = .002$) and anxiety ($r = .158, p = .008$) as well as physical health ($r = -.246, p < .001$). Discussion/Implications: College students with symptoms of sleep disorders and poor sleep may demonstrate greater depressive/anxiety symptoms and poorer physical health. Student wellness initiatives could potentially benefit student health even more by screening, and providing interventions for, sleep disorders.

THE IMPACT OF A LIFESTYLE INTERVENTION ON SLEEP IN HISPANIC POSTPARTUM WOMEN

Marquis S. Hawkins, PhD¹, Bess H. Marcus, Ph.D.², Penelope S. Pekow, PhD³, Milagros C. Rosal, PhD⁴, Katherine L. Tucker, PhD⁵, Rebecca Spencer, PhD³, Lisa Chasan-Taber, ScD⁶

¹University of Pittsburgh, Pittsburgh, PA; ²Brown University, Sharon, MA; ³University of Massachusetts Amherst, Amherst, MA; ⁴University of Massachusetts Medical School, Worcester, MA; ⁵University of Massachusetts Lowell, Lowell, MA; ⁶University of Massachusetts Amherst, Amherst, MA

Background: Short or disrupted sleep during the postpartum period is associated with adverse maternal outcomes such as obesity, but this has not been well-examined in Hispanic women who experience disproportionately high rates of type 2 diabetes. Studies in general adult populations show that exercise has a beneficial impact on sleep. However, intervention studies among postpartum women are sparse and were primarily conducted in non-Hispanic white populations.

Methods: We, therefore, examined the impact of a culturally modified, individually tailored- lifestyle intervention on sleep quality, duration, and efficiency among participants in Estudio PARTO. Eligible Hispanic women who screened positive for gestational diabetes were randomized to a Lifestyle (n=69) or Health & Wellness control intervention (n=78). The active phase of the intervention began 6 weeks postpartum (baseline) and consisted of face-to-face meetings, mailings, and booster telephone calls targeting exercise and healthy diet. The Pittsburgh Sleep Quality Index (PSQI) was used to measure sleep quality (PSQI global score), duration (hours/night), and efficiency (% of time in bed asleep) at baseline, 6 months, and 1 year postpartum.

Results: At baseline, 54% of participants reported poor sleep quality (PSQI > 5), 46% reported short sleep duration (< 6 hrs/night), and 63% reported low sleep efficiency (< 85%) with no differences between the intervention groups. Mean PSQI score (6.52 ± 3.95), sleep duration (5.95 ± 1.88), and sleep efficiency (75.54 ± 18.81) also did not differ significantly. Overall, there was statistically significant improvement over time in sleep quality (PSQI global score, $-1.30 \pm 4.10, p = 0.003$), sleep duration ($0.61 \pm 2.10, p = 0.003$), and sleep efficiency ($7.68 \pm 21.8, p = 0.0003$) from baseline to 1 year postpartum in both groups. Based on an intention-to-treat analysis using mixed-effects models, we did not observe a statistically significant difference in change in sleep outcomes between the intervention groups.

Conclusion: In this randomized trial among Hispanic women, we found high levels of poor sleep quality, short sleep duration, and low sleep efficiency. However, we were unable to detect a beneficial impact of the lifestyle intervention on postpartum sleep. Subsequent sensitivity analyses will evaluate if findings differ among those compliant with the intervention; among overweight and obese women; and according to self-reported levels of physical activity and diet.

INFLUENCING FACTORS OF SLEEP IN POSTMENOPAUSAL WOMEN WITH AND WITHOUT BREAST CANCER

Inah Kim, PhD¹, Na-Jin Park, PhD²¹Duquesne University, pITTSBURGH, PA; ²University of Pittsburgh, Pittsburgh, PA

Background: Women with breast cancer (BC) is the largest group of cancer survivors in the US. Postmenopausal women with estrogen receptor-positive (ER+) BC are the majority with favorable long-term survival. Sleep problem is common among these aging BC survivors as well as postmenopausal women in the general population, in part, explained by estrogen deficit from menopause. Endocrine therapy with aromatase inhibitors (AI) treats ER+ BC by inhibiting estrogen production up to 98% in postmenopausal women, indicating an additional risk of sleep problem in these women. However, little is known about sleep in BC survivors on AI therapy beyond active chemo- and radiotherapy. Comparison studies, including healthy postmenopausal women, are lacking in the context of menopause experience and reproductive and behavioral factors.

Purpose: To examine the relationships of postmenopausal BC survivorship, menopausal (vasomotor and musculoskeletal) symptoms, reproductive health factors (i.e., pregnancy and hormone replacement therapy [HRT]), and behavior factors (i.e., depression and smoking) with sleep quality in postmenopausal women with and without BC.

Method: This cross-sectional, descriptive study included a total of 102 postmenopausal women (mean age of 60): 64 survivors of early-stage, ER+ BC and 38 cancer-free women. All BC survivors completed the active BC treatment and were on AI therapy at least 2 years or longer (a mean survival of 5.4 years). Data were collected using self-administered questionnaires and medical record reviews. Sleep quality was assessed by the Pittsburgh Sleep Quality Index (PSQI).

Results: The global PSQI scores and individual components (e.g., sleep duration, efficiency etc.) were similar between two groups. About 35% were identified as a poor sleeper (PSQI ≥ 6), but the majority of women also reported shorter sleep duration (mean 5 hours per night) compared to professional recommendations. BC treatment characteristics including AI therapy had no association with PSQI in BC survivors. A series of regression analyses revealed that poorer sleep quality, regardless of BC survivorship, was associated with current smoking, higher depressive symptom, more menopause symptoms, 1st live birth at younger age, and no history of HRT (p values ranged from $< .0001$ to $.046$, adjusted $R^2 = .545$). Depressive symptom and current smoking together explained 44% of variance in sleep quality among postmenopausal women.

Conclusion: Sleep quality was associated with various factors, such as reproductive and behavior factors, in postmenopausal women. Behavior factors, specifically depressive symptom, were the main contributor to poor sleep quality. Assessing depressive symptom and sleep and providing proactive lifestyle change/management strategies needs to be incorporated to the BC survivorship care plan and to the standard primary care plan for postmenopausal women.

INFLUENCE OF A PRENATAL WEIGHT MANAGEMENT INTERVENTION ON SLEEP QUALITY

Abigail M. Pauley, M.S.¹, Krista S. Leonard, MS², Emily E. Hohman, PhD³, Katherine M. McNitt, BS, RD¹, Penghong Guo, Ph.D.⁴, Daniel E. Rivera, PhD⁵, Jennifer S. Savage, PhD⁶, Danielle Symons Downs, PhD⁷¹The Pennsylvania State University, Bellefonte, PA; ²The Pennsylvania State University, State College, PA; ³Pennsylvania State University, University Park, PA; ⁴Arizona State University, Mesa, AZ; ⁵Arizona State University, Tempe, AZ; ⁶Penn State University, University Park, PA; ⁷The Pennsylvania State University, University Park, PA

Prenatal sleep quality may decrease due to increased sleep disturbances. This reduction of sleep quality may result in negative pregnancy outcomes for mother and baby (e.g., excessive gestational weight gain (GWG), and fetal growth restriction). Few, if any, prenatal interventions include sleep hygiene education. The purpose of this exploratory secondary analysis was to examine the effect of an individually-tailored, multicomponent behavioral intervention designed to promote effective GWG regulation on sleep quality.

Methods: Healthy Mom Zone is a randomized control trial comparing an individually-tailored, adaptive intervention to a standard of care control. Pregnant women with overweight/obesity (PW-OW/OB; N=31; 52% obese) were randomized at ~8 weeks gestation. The sleep hygiene component included education on reducing TV time/use of electronics at night, establishing a consistent bedtime, staying hydrated during the day but reducing liquids before bedtime, etc. The Pittsburgh Sleep Quality Index (higher score ≥ 5 indicates poorer sleep quality) was used to assess sleep quality from ~9 -36 weeks gestation. A 2 x 2 factorial design was used to examine main effects and interactions for sleep quality by study group and weight status; significance was set at $p < 0.10$ as appropriate for exploratory analyses. The main effects for study group [INT ($M_{\text{change}} = 1.25$) vs. CON ($M_{\text{change}} = 0.16$)] and weight status group [OW ($M_{\text{change}} = 1.22$) vs. OB ($M_{\text{change}} = 0.19$)] on sleep quality scores were not significant. There was a group X weight status interaction such that PW-OW-CON (n=5; $M_{\text{change}} = 1.60$) had a greater change in sleep quality scores compared to PW-OW-INT (n=6; $M_{\text{change}} = 0.83$; $p = 0.09$). There were no significant changes in sleep quality scores between PW-OB-INT/CON (INT: n=3; $M_{\text{change}} = 1.67$; CON: n=7; $M_{\text{change}} = -1.29$; $p = .29$). PW-OW-INT experienced less of an increase in poor sleep quality scores compared to PW-OW-CON. These exploratory findings suggest that a prenatal weight regulation intervention with a focus on sleep hygiene may have potential for reducing poor sleep quality in PW-OW. However, future research is needed to replicate these findings as well as to better understand why similar effects were not observed in PW-OB in an effort to promote good sleep quality among PW-OW/OB.

SLEEP EDUCATION TRAINING AMONG PRACTICING CLINICAL PSYCHOLOGISTS ACROSS CANADA AND THE UNITED STATES

Marcella Mazzenga, B.A.¹, Eric S. Zhou, PhD², Monica Gordillo, M.A.³, Kristin Long, PhD⁴¹Boston University, Allston, MA; ²Harvard Medical School, Boston, MA; ³Boston University, Brighton, MA; ⁴Boston University, Boston, MA

Introduction: Approximately 50-70 million Americans have a diagnosable sleep disorder. Psychologists often encounter patients who report sleep disturbance due to a sleep disorder and/or mental health concern, and psychological treatments are efficacious treatments for sleep disturbances alone (e.g., CBT-I) or in combination with medical approaches (e.g., continuous positive air pressure [CPAP] adherence). Despite psychologists' role in diagnosing and treating sleep disorders, previous research suggests minimal sleep training in psychology training programs. Sleep education and perceived efficacy in sleep treatment has not been evaluated among practicing psychologists.

Method: Participants were recruited through state, territorial, and provincial psychological associations' email listservs across Canada and the US. Respondents (N=153) completed an online survey collecting information about: 1) the amount and format of formal sleep education across their training; 2) perceived self-efficacy to evaluate and treat sleep disorders and related problems; 3) interest and preferred format for additional sleep education.

Results: Approximately 97% of respondents reported no clinical sleep training in graduate school, internship, and post-doctoral fellowship. Respondents received an average of 16.16 hours of didactic sleep training across education points. They endorsed feeling somewhat to moderately prepared ($M=2.98$ on a five-point Likert scale) to evaluate a patient presenting with sleep disorder symptoms. Regarding specific sleep disorders, psychologists on average felt most prepared to treat insomnia disorders ($M=2.93$). However, most respondents selected "sleep hygiene instructions" as the first-line treatment, which is inconsistent with recommendations regarding insomnia treatment. Respondents (96.7%) reported wanting additional sleep training. They preferred training via in-person seminar (64.1%), online video (51.6%), video-conference (51.0%), interactive website (41.5%), book (41.2%) or another format (4.6%).

Discussion: Despite receiving minimal sleep training, most psychologists felt moderately prepared to evaluate and treat sleep disorders. However, their treatment recommendations for insomnia were not aligned with recommendations to incorporate behavioral approaches, which raises questions about patient outcomes. This study underscores the critical need for sleep training among psychologists and informs next steps to improve sleep treatment competency.

TESTING SUBSTANCE USE AS A MEDIATOR OF STIGMA-HEALTH LINKAGES IN A SAMPLE OF LESBIAN/GAY INDIVIDUALS.

Kelly Manser, B.A.¹, Steve Du Bois, Ph.D.¹¹Illinois Institute of Technology, Chicago, IL

Compared to heterosexual individuals, lesbian women and gay men experience multi-level health and sociopolitical disparities. According to theories of minority stress and cognitive escape, structural stigma may distally predict health outcomes, and these associations may be mediated by more proximal health behaviors (McKirnan et al., 1996; Meyer, 2003). This study uses 2017 Behavioral Risk Factor Surveillance System data to test a specific example of this mediation model in a large lesbian/gay (LG) sample (total N=3,057). We operationalized structural stigma as the number of LG-protective laws in each of 27 U.S. states (more laws = less structural stigma) using the Movement Advancement Project's (MAP) objective ratings. We predicted these would relate to number of cardiovascular disease (CVD) diagnoses of gay/lesbian individuals in each state. We further predicted that alcohol and tobacco use frequency would each mediate stigma-CVD associations. This model is supported empirically, as evidence suggests LG individuals report relatively high rates of CVD and substance use compared to heterosexual individuals (Conron, Mimiaga, & Landers, 2010; Greenwood & Gruskin, 2007). We examined associations in an aggregated LG sample, and in L and G subsamples, given evidence of differential patterns in health outcomes between L and G individuals (Cochran & Mays, 2017). Mediation models were tested via multinomial logistic regressions, and mediation criteria were based on the work of Baron and Kenny (1986) and Hayes (2009). Spearman correlations and predictor-mediator paths (i.e., a paths) in multinomial logistic regressions revealed that, while structural stigma was associated with smoking in all three subsamples, stigma-alcohol linkages were only significant in females-only and LG-combined samples (versus the males-only sample). However, average binge drinking frequency was higher for males ($p's < .05$). In the LG sample, everyday-smoker status partially mediated the relationship between living in a state with zero or one LG-protective state laws and having multiple CVDs (Sobel's $z = 2.72$ for zero laws, 2.05 for one law; $p < .05$). Key findings are as follows: 1) structural stigma consistently predicts smoking frequency, consistent with prior work (e.g., Hatzenbuehler, Jun, Corliss, & Austin, 2013); 2) smoking frequency may at least somewhat mediate the stigma-CVD relationship; and 3) while binge drinking frequency may be higher on average among gay men, structural stigma may relate to binge drinking more-strongly in lesbian women. Of note, only 27 states collected sexual orientation/gender identity data via the BRFSS in 2017, limiting generalizability. Findings add to literature on stigma and health disparities experienced by LG individuals. Directions for future work include testing sex/gender as a moderator of LG stigma-alcohol linkages and tobacco use as a means of cognitive escape.

THE INTERSECTION OF HIV AND OBESITY: EXAMINING HOW HIV STATUS INFLUENCES WEIGHT STIGMA AMONG ADULTS WITH OBESITY

Emily Panza, Ph.D.¹, Deborah Good, CCRP², Karen Tashima, MD², Bianca Obiakor, n/a³, Rena Wing, Ph.D.¹¹Alpert Medical School of Brown University, Providence, RI; ²The Miriam Hospital, Providence, RI; ³Brown University, Providence, RI

Background: Although the prevalence and negative health effects of HIV stigma have been extensively documented among people living with HIV (PLWH), other sources of stigma in this group are understudied. Obesity affects over 25% of PLWH, and while research in the general population identifies weight stigma as a pervasive and harmful form of bias, little research has examined weight stigma or its effects among PLWH and obesity. This study examined how HIV status influences weight stigma in adults with obesity by comparing the prevalence of weight stigma among PLWH and obesity versus adults with obesity only.

Methods: Weight stigma was assessed in PLWH and obesity ($n = 45$; 60% male; 53% white; mean [M] age = 48 ± 12 ; M body mass index [BMI] = 36 ± 7) versus adults with obesity only ($n = 43$; 47% male; 72% white; M age = 44 ± 12 ; M BMI = 37 ± 7). Participants completed electronic self-report surveys assessing internalized weight bias (Weight Bias Internalization Scale; 1–7 scale) and lifetime experiences of weight stigma (Distressing Interpersonal Interactions Scale [DIIS]; 1–4 scale). Lower scores indicate less stigma. The DIIS was also used to assess lifetime experiences of HIV stigma among PLWH.

Results: Models controlled for the effects of age, BMI, gender, race, and socio-economic status. PLWH and obesity reported significantly fewer lifetime weight stigma experiences ($M = 1.5 \pm 0.6$) relative to adults with obesity only ($M = 1.9 \pm 0.8$; $p < 0.05$, $\eta_p^2 = 0.07$). Lifetime weight stigma was reported by 84% of adults with obesity only compared to 56% of PLWH and obesity. Levels of weight stigma reported by PLWH were similar to levels of HIV stigma endorsed in this group, with 58% of PLWH reporting lifetime HIV stigma ($M = 1.6 \pm 0.8$). Although PLWH reported fewer overt weight stigma events, mean levels of internalized weight bias did not differ between PLWH ($M = 3.9 \pm 1.6$) and adults without HIV ($M = 4.5 \pm 1.5$; $p > 0.05$).

Conclusion: PLWH and obesity report experiencing less frequent weight stigma than adults with obesity only. Given historical associations between HIV and “wasting,” having a heavier body weight may be perceived as a protective factor against HIV progression/disclosure and may reduce perceptions of weight stigma. Alternatively, PLWH internalize similar levels of weight bias despite fewer weight stigma experiences, suggesting that weight stigma events may have more potent negative effects on internalization in PLWH. Future studies with larger sample sizes are needed to clarify how HIV and obesity intersect to influence weight stigma among PLWH and obesity.

THE ROLE OF COUPLE RELATIONSHIPS ON PHYSICAL ACTIVITY CHANGE OVER 12 MONTHS AMONG INDIVIDUALS WITH OSTEO-ARTHRITIS.

Sandra H. Soto, PhD, MPH, BSN¹, Leigh F. Callahan, PhD¹, Christine M. Rini, PhD²¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²Northwestern University Feinberg School of Medicine, Chicago, IL

Purpose: Evidence for effects of couple relationships on physical activity (PA) is mixed, yet theory suggests the importance of relationship quality and dyadic coping in developing healthy behaviors, especially for individuals with chronic illnesses. We examined the role of relationship factors on the trajectory of PA over 12 months among adults with osteoarthritis (OA).

Methods: We collected longitudinal data from 173 insufficiently active (< 120 minutes of moderate-vigorous PA (MVPA) per week) adults with OA of the knee/hip. All attended an educational class 1 week post-baseline to activate couples' efforts to work together to help the person with OA become more active. We used latent growth curve modeling (LGCM) to test the role of relationship satisfaction and dyadic coping (the belief that both partners are responsible for OA management) on the trajectory of objectively-measured daily MVPA minutes over time: baseline, 2 weeks, and 3, 6, and 12 months. The final LGCM included time-invariant covariates (relationship satisfaction and dyadic coping) controlling for participant characteristics (age, education, income, BMI, and OA symptom severity).

Results: Participants were 65 years old ($SD=9$), 65% female, 86% white, and 59% with at least a 4-year college degree. We first tested a linear growth model with the final timepoint freely estimated. The basic model revealed individual variability in the intercept ($s^2=93.97$, $p < 0.001$) and slope ($s^2=0.10$, $p=0.04$). The rate of change in MVPA was negatively related to participants' baseline MVPA ($r=-0.28$, $p=0.05$). In other words, participants with fewer minutes of MVPA at baseline had more rapid increase in MVPA than other participants. In the model adjusting for time-invariant covariates and participant characteristics, relationship satisfaction ($\beta=-0.98$, $p=0.31$) and dyadic coping ($\beta=-2.38$, $p=0.13$) were not associated with MVPA at baseline. However, greater relationship satisfaction was associated with stronger increases in MVPA over time ($\beta=0.13$, $p=0.04$). Teamwork was not associated with the slope of MVPA ($\beta=-0.11$, $p=0.43$). The model explained 21.3% of the variance in the slope.

Discussion: When working with couples to increase PA in adults with OA, it may be important to develop strategies to help couples with lower relationship satisfaction overcome barriers to increasing PA. Contrary to theory, it may not be necessary that couples view the management of OA as the responsibility of the “team” to see changes in PA.

SOCIODEMOGRAPHIC, PSYCHOSOCIAL, AND BEHAVIORAL CORRELATES OF MEDICAL MISTRUST IN LATINO SEXUAL MINORITY MEN

Isaiah J. Jones, n/a¹, Devon Kimball, BA², Aaron J. Blashill, Ph.D.³¹San Diego State University, El Cajon, CA; ²The BISH Lab, San Diego State University Research Foundation, La Mesa, CA; ³San Diego State University, San Diego, CA

Medical mistrust (MM) has been studied in the context of various minority populations, including the Latino community and sexual minority men; however, little research has focused on MM among Latino sexual minority men (LSMM). This study explored the associations of demographic, psychosocial, and behavioral factors with MM among LSMM. 136 LSMM participants, between the ages of 18 to 29, were recruited through Grindr to complete an online survey concerning sexual, psychosocial, and identity topics. Among other measures, participants reported sociodemographic, behavioral, and psychosocial variables. Binary variables were created for sexual orientation (gay vs. bisexual), education (some college vs. below), housing (stable vs. unstable), cigarette use (none vs any) and other substance use (none vs. at least once). A two step hierarchical multiple regression was performed. Sociodemographic variables comprised Step one, including age, ethnicity, citizenship, sexual orientation, education, income, housing stability, and insurance status. Step two included the behavioral and psychosocial variables of machismo and caballerismo traits, depression, alcohol use, cigarette use, and other general substance use. The analyses revealed that in Step one, sexual orientation and unstable housing contributed significantly to the model, $F(8,127) = 4.52, p < .001$, and accounted for 17.3% of the variance in MM when adjusted. Introducing the behavior/psychosocial variables in Step two explained an additional 18.4% of variation in MM ($F(6,121) = 7.01, p < .001$). Within Step two, unstable housing was no longer significant, but sexual orientation did remain significant. The behavior/psychosocial variables of machismo, caballerismo, depression, and substance use significantly contributed to the overall model also, $F(14,121) = 6.36, p < .001$, and explained 35.7% of the variance when adjusted. Among this sample of LSMM, behavioral and psychosocial factors, including machismo and caballerismo, depression, and substance use, were found to account for significantly more variance in MM than commonly used demographic variables. This evidence may further support the notion that cultural factors and personal beliefs play a key role in determining levels of MM, rather than background or demographic characteristics.

TEACHERS' PERSPECTIVES OF HOW ADVERSE CHILDHOOD EXPERIENCES AND TRAUMA-INFORMED STRATEGIES IMPACT STUDENT ENGAGEMENT

Valerie Senkowski, MS¹¹Miami University, Oxford, OH

Background: Exposure to Adverse Childhood Experiences (ACES) impact students' development and ability to engage in classroom activities, but research suggests that trauma-informed strategies can improve outcomes related to health, well-being and school success.

Purpose: The purpose of this theory-based exploratory study was to use the Reasoned Action Approach (RAA) to elicit salient beliefs teachers hold about using strategies to increase engagement among students who have experienced trauma.

Methods: Purposive sampling was used to invite twenty-two in-service teachers with experience working with students who have experienced trauma to participate in our study. Of the twelve respondents, nine participants completed at least half of the questions and were included in the final analysis. The nine participants had high levels of experience (6-25 years), and reported working in public schools in suburban (n=5) and urban (n=4) settings, at the elementary (n=2), middle (n=3) and high School (n=4) levels. Each participant was provided with a definition of ACES, and prompted to provide three strategies to increase engagement of these students for each of the four types: behavioral, cognitive, emotional, and social. Then, each participant completed open-ended RAA-based questions for attitudinal, normative, and control beliefs about using the strategies they described. Responses were thematically coded using content analysis.

Results: This data set includes 101 trauma-informed strategies (behavioral=26, cognitive=27, emotional=25, social=24) organized categorically by type of engagement and frequency of responses. Results suggest that promoting engagement is not a homogenous process, as different strategies come to mind when teachers are prompted to think about promoting either behavioral, emotional, cognitive, and social engagement with students who have experienced trauma. Further, teachers' attitudinal beliefs about the advantages of using those strategies to promote engagement are differentiated by type of engagement.

Conclusions: While there is increasing interest in trauma-informed approaches in health and education as a social determinant of health, literature about teachers' perspectives is rare. Findings from this relatively small sample suggest that further interdisciplinary research is needed to determine how trauma-informed strategies are integrated from theory to practice in professional development, interventions, and policy.

PERCEPTIONS OF INTERDISCIPLINARY TEAMWORK AS A PREDICTOR OF PROVIDER BURNOUT

Stacey Maurer, PhD¹, Taylor B. Crouch, PhD¹, Jeffrey Borckardt, Ph.D.¹¹Medical University of South Carolina, Charleston, SC

Background: Provider burnout among healthcare team members has been associated with decreased patient safety and quality of care. Healthcare is increasingly delivered in interdisciplinary teams, and multiple providers working together may have implications on burnout and team effectiveness. Therefore, identifying factors that protect against burnout is important in delivering high-quality healthcare. The purpose of this study was to examine how perceptions of teamwork among members of healthcare teams may impact provider burnout.

Methods: The study was conducted at a large academic medical center (AMC) via electronic survey and was open to all faculty and staff working as part of a clinical team. Participants (N=109) represented a variety of disciplines and roles. Teamwork perception was measured via the Team STEPPS Teamwork Perceptions Questionnaire (T-TPQ), which includes 5 subscales: team structure, leadership, situation monitoring, mutual support, and communication. Burnout was measured using the burnout subscale of the Maslach Burnout Inventory (MBI). Data was analyzed using multiple linear regression.

Results: Results indicated that teamwork perception overall explained 20.5% of the variance in provider burnout and the regression model was a significant predictor of burnout [$F(5,109) = 5.61, p < .01$]. The only subscale that significantly contributed to the model was situation monitoring ($B = .85, p < .05$).

Conclusions: Among a diverse sample of faculty and staff working on clinical teams at an AMC, perception of teamwork was a significant predictor of provider burnout, highlighting the importance of team-level factors in contributing to burnout. In particular, higher levels of situation monitoring (e.g., scanning for safety problems or problems among other team members) predicted higher levels of burnout. It is notable that the relation between this subscale and burnout was in the positive direction, suggesting that when healthcare providers feel a greater burden to monitor the environment and other staff members' behaviors, they may be at greater risk for burnout. Thus, a top-down approach that focuses on team culture factors and alternative ways to monitor safety, rather than placing this burden on individual providers, may be an important approach to reducing burnout.

STRESSING OVER MASCULINITY: THE EFFECT OF PRECARIOUS MANHOOD ON CARDIOVASCULAR REACTIVITY

Caitlin A. Bronson, MS¹, Richard J. Contrada, PhD¹¹Rutgers, The State University of New Jersey, Piscataway, NJ

Gender often plays a role in appraisal of and physiologically responding to stressors. Among men, increased anxiety-related thoughts typically occur when violating gender norms. These thoughts may arise, because the cultural definition of manhood requires difficult achievements and can be easily lost by violating gender expectations (Vandello, Bosson, Cohen, Burnaford, & Weaver, 2008). How the cardiovascular system responds to gender norm transgressions may inform our understanding of gender disparities in cardiovascular disease. In particular, determining the effects of precarious manhood beliefs (PMB), or the belief that manhood is a status one must earn and continually prove to avoid its loss, on cardiovascular reactivity (CVR) has received little attention. To address whether the culturally shared definition of manhood as precarious influences CVR, men completed a measure of PMB before arriving in lab. In lab, after baseline cardiovascular activity was recorded, men completed a speech task where they either recalled a time they violated gender norms (threat condition) or recalled how they spend a typical day (control condition) while their cardiovascular system was monitored. Men who more strongly endorsed PMB and were in the threat condition, displayed greater cardiac output (CO) reactivity compared to those men in the control condition, $B = .83, SE = .28, p = .02, 95\% CI = [.10, 1.23]$. Further, CO reactivity among men who weakly endorsed PMB was significantly lower compared to those men in the control condition, $B = -.65, SE = .27, p = .02, 95\% CI = [-1.20, -.11]$. Differences in reactivity based on PMB endorsement did not emerge when observing heart rate, blood pressure, total peripheral resistance, pre-ejection period, left ventricular ejection timing, or stroke volume. These results suggest that culture alone does not affect health, rather how much an individual endorses the culture, determines what stressors will impact their cardiovascular system. As patterns of exaggerated or prolonged CVR are linked to worse cardiovascular functioning (Chida & Steptoe, 2010), studying how gender impacts CVR may provide insight on how to improve longevity and wellbeing. Personally endorsing the idea that manhood is precarious may be harmful for cardiovascular health among men insofar as exaggerated CO reactivity is detrimental to cardiovascular functioning.

DETERMINING THE ROLE OF SOCIAL DETERMINANTS OF HEALTH AND HEALTH LITERACY IN ADULTS' MALADAPTIVE EATING BEHAVIORS

Pauline Dimaano, B.S.¹, Patrece Joseph, M.A.², Sasha A. Fleary, PhD³¹Child Health Equity Research Lab in the Eliot-Pearson Department of Child Study and Human Development at Tufts University, Cambridge, MA; ²Child Health Equity Research Lab, Medford, MA; ³Tufts University, Medford, MA

Background: Social determinants of health (SDH), or structural causes and conditions of daily life (e.g., adequate housing and access to food), are related to physical and mental health outcomes. The stress associated with food and housing insecurity may exacerbate poor mental and physical health outcomes via maladaptive coping (e.g., emotional eating). However, health literacy (HL; i.e., the ability to obtain, understand, and utilize health information) skills will dictate how well individuals are able to access and utilize resources to cope with SDH-related stressors. The goal of this study was to examine the relationship between two SDH-related stressors, housing and food insecurity, and poor coping behaviors (i.e., emotional eating) and to determine if these relationships were consistent across individuals with low, medium, and high HL.

Methods: Data (n=590) were collected using Qualtrics Panel and online snowball sampling. Measures included functional HL, mental wellbeing, and poor coping behaviors (i.e., eating when depressed, eating when anxious), and food and housing insecurity. Multiple regressions, controlling for age and gender, were computed to predict the maladaptive eating variables from mental wellbeing, and food and housing insecurity. Regression models were then estimated by HL level.

Results: Food insecurity was positively related to depressed eating in the general sample ($\beta = 0.10$, $p = 0.046$) and in the medium HL ($\beta = 0.15$, $p = 0.036$) sample. Mental wellbeing was inversely related to depressed eating in the general sample ($\beta = -0.22$, $p < 0.001$) and in the low ($\beta = -0.25$, $p = 0.033$), medium ($\beta = -0.22$, $p = 0.001$), and high ($\beta = -0.17$, $p = 0.032$) HL samples. Housing insecurity was positively ($\beta = 0.26$, $p = 0.028$) related to depressed eating in the low HL sample only. Housing insecurity was positively related to anxious eating in the general sample ($\beta = 0.11$, $p = 0.028$) and low HL positively ($\beta = 0.37$, $p = 0.002$) sample. Mental wellbeing was inversely related to anxious eating in the general sample ($\beta = -0.19$, $p < 0.001$) and in the low ($\beta = -0.24$, $p = 0.030$) and medium ($\beta = -0.19$, $p = 0.004$) HL samples. Food insecurity was related to anxious eating in the medium HL sample only ($\beta = 0.17$, $p = 0.017$).

Discussion: The high HL group may have other SDH resources that reduce their risk for food or housing insecurity or high HL may serve as a buffer for poor coping when faced with other SDH stressors. Future studies should utilize a longitudinal design and/or focus on the characteristics within the three HL populations to determine the causal relationship between HL and poor coping. Studies intervening on HL to affect health behavior change should explore the secondary effects of their intervention on coping behaviors.

RACIAL DIFFERENCES IN THEORY-BASED CONSTRUCTS RELATED TO HYPERTENSION MANAGEMENT

Charleen J. Gust, BA¹, Angela Bryan, PhD², Irene V. Blair, PhD¹, Ed Havranek, MD³, John F. Steiner, MD, MPH⁴, Rebecca L. Hanratty, MD⁵, Suma Vupputuri, MD, MPH, FAHA⁶, Julie Maertens, PhD⁷, Stacie Daugherty, MD⁷¹University of Colorado Boulder, Boulder, CO; ²University of Colorado Boulder, BOULDER, CO; ³University of Colorado School of Medicine, Denver, CO; ⁴Kaiser Permanente Institute for Health Research, Aurora, CO; ⁵Denver Health, Denver, CO; ⁶Mid-Atlantic Permanente Research Institute, N/A, DC; ⁷University of Colorado Anschutz Medical Campus, Aurora, CO

Past research has revealed ethnic and racial differences in the prevalence of hypertension, a major risk for heart disease and stroke, among adults living in the United States. For example, data collected in 2010 by the Centers for Disease Control and Prevention (CDC) indicate higher rates of high blood pressure among adult American Indians (34.5%) compared with Whites (25.7%). More recent data from the National Center for Health Statistics (NCHS) further suggest that hypertension is more prevalent among non-Hispanic Black (40.3%) adults than non-Hispanic White (27.8%) adults. Taken together, these statistics demonstrate racial disparities in prevalence of hypertension, with White adults exhibiting lower rates than other racial minority groups. Despite this, few studies have examined differences in hypertension management among racial groups. Drawing from an expanded Theory of Planned Behavior (TPB) including anticipated emotional responses of pride and regret, the current study examines the social psychological processes involved in efforts to reduce or maintain blood pressure, as well as the theory-based constructs that may be instrumental in driving these efforts, in hypertensive patients of three racial groups: Whites (n=415), African Americans (n=395), and American Indians (n=137). As part of a larger intervention study, participants (total N=947) completed a baseline survey assessing attitudes, norms, perceived behavioral control, anticipated emotions, intentions, and past efforts to control blood pressure. Cross group analyses revealed interesting differences in the associations among theoretical constructs between races. For example, the path from past efforts to perceived behavioral control was positive and significant for both Black and Native American participants, but the coefficient was smaller for Black participants ($\beta = .161$, $p < .01$) than Native American participants ($\beta = .368$, $p < .001$). In addition, the path from past efforts to anticipated pride was significant for White participants ($\beta = .331$, $p < .001$) but not for Black participants ($\beta = .062$, ns). Findings such as these have the potential to inform the generalization of theory across racial groups and targeted intervention approaches.

THE LINK BETWEEN ADVERSE CHILDHOOD EXPERIENCES WITH PHYSICAL, BEHAVIORAL, AND MENTAL HEALTH RISKS IN YOUNG ADULTHOOD

Larisa Albers, n/a¹, Timothy J. Grigsby, PhD², Christopher J. Rogers, M.P.H.³, Stephanie M. Benjamin, PhD¹, Marla Eisenberg, ScD⁴, Myriam Forster, BA;MPH;PhD⁵

¹California State University, Northridge, Northridge, CA; ²University of Texas at San Antonio, San Antonio, TX; ³Keck School of Medicine University of Southern California, Castaic, CA; ⁴University of Minnesota, Minneapolis, MN; ⁵California State University, Northridge, Santa Monica, CA

Introduction: Seminal work by Felitti et al. (1998) demonstrated a strong, graded relationship between exposure to childhood abuse and household dysfunction with health status in adulthood. The present study examined these relationships among young adults to better characterize the developmental timing of health problems related to adverse childhood experiences (ACE) exposure.

Methods: A general health questionnaire that included items on ACE was administered to young adults (ages 18-29) at universities in California (n=3,880), Minnesota (n=7,708), and Texas (n=451) from 2017-2018. Seven categories of ACE were included: psychological, physical, or sexual abuse; violence between parents; or living with household members who were substance misusers, mentally ill, or ever imprisoned. Health indicators in young adulthood were regressed on ACE categories of 0 (referent), 1, 2, 3, 4, or more using logistic regression controlling for age, gender, race/ethnicity, and site.

Results: Approximately 51.7% of the sample reported ACE exposure with a significantly higher rate among Texas participants ($p < 0.001$). The seven categories of ACE were strongly interrelated ($p < 0.001$) and tended to cluster with 18-27% of exposed participants reporting two ACE and 39-78% reporting 3 or more ACE. We observed a dose-response relationship between categories of ACE with physical and behavioral health indicators (e.g., obesity, sleep, cigarette use, e-cigarette use, drinking and driving, AORs: 1.38-3.59) along with mental health indicators (e.g., depression diagnosis, suicidal ideation and attempt, non-suicidal self-injury, AORs: 1.29-4.34).

Conclusions: The graded relationship between ACE exposure and health status in young adulthood in the present study reinforces the need to raise awareness about the health consequences of early trauma exposure and provide prevention programs that help young adults cope with stressors that increase risk for premature mortality and morbidity in adulthood. These findings point to the potential benefits of leveraging this critical window of opportunity for intervention. In particular, the role that campus communities could take in developing initiatives that address trauma related health issues.

THE ROLE OF PERCEIVED HETEROSEXISM IN POSTTRAUMATIC STRESS DISORDER SEVERITY AMONG TRAUMA EXPOSED SEXUAL MINORITY INDIVIDUALS

Natalie M. Cereseto, B.A.¹, Madalyn M. Liautaud, B.A.², Corinne E. Zachry, M.A.¹, Madeleine D. Tuten, n/a³, Danielle S. Berke, Ph.D.⁴

¹Hunter College of The City University of New York, Brooklyn, NY; ²CUNY Graduate Center, Brooklyn, NY; ³Hunter College of The City University of New York, New York, NY; ⁴Hunter College of The City University of New York, CUNY Graduate Center, New York, NY

Sexual minority (SM) (i.e., gay, bisexual, lesbian, pansexual, queer) individuals have a significantly greater lifetime risk of developing posttraumatic stress disorder (PTSD) than do heterosexual individuals. Explanatory theories of PTSD provide limited insight into the uneven distribution of PTSD across social groups, nor do they account for contexts in which ongoing exposure to identity-based threats may influence PTSD symptoms. Minority stress theory proposes that SM individuals' disproportionate exposure to stigma-related SM stress contributes to health disparities, including elevated PTSD risk. Yet, important questions remain about the role of SM stress in PTSD etiology and persistence, as well as risk mechanisms accounting for interindividual differences. This ongoing study employs structured PTSD assessments and a micro-longitudinal 30-day daily diary assessment to investigate the unique and interactive effects of traumatic stress and SM stress on PTSD symptoms in a diverse sample of trauma-exposed SM individuals. Specifically, we will test the following hypotheses: 1) Exposure to daily SM stress will be positively associated with greater weekly PTSD symptom severity; and 2) Baseline exposure to sexual identity-based stressful and/or potentially traumatic life events will moderate the relationship between daily SM stress and PTSD symptom severity. Recruitment and data collection is ongoing. Currently, 39 eligible participants (61.5% cisgender female, $M_{age} = 23.4$ [$SD = 10.4$] years, 48.7% White, 41% bisexual) have completed the baseline assessment; 87.2% ($n = 34$) of enrolled participants have completed the daily diary portion of the study (30-day survey completion rate: 77.5%). Among enrolled participants, 33.3% ($n = 13$) met DSM-5 criteria for PTSD, 46.2% ($n = 18$) reported a Criterion A event related to their SM identity, and 84.6% ($n = 33$) reported lifetime exposure to a SM identity-related stressful life event at baseline. Hypotheses will be tested with multilevel models that control for comorbid psychiatric disorders and other baseline characteristics. Full sample descriptives and main analyses will be presented. Final results from the study will have implications for the development of clinical and community-based interventions for trauma-exposed SM individuals.

U.S. PHYSICIANS' INTRINSIC ASPIRATIONS, PSYCHOLOGICAL NEED SATISFACTION, AND OCCUPATIONAL HEALTH

Arlen C. Moller, PhD¹

¹Illinois Institute of Technology, Chicago, IL

Numerous studies have documented deteriorating occupational health among practicing physicians. This trend poses a serious risk not only for physicians but also for the many patients under their care. One protective factor seems to involve the quality of physicians' motivation. When physicians are more autonomously motivated, they tend to experience better occupational health. However, few studies have identified antecedent factors that support physicians' autonomous motivation. To identify and model potential antecedents of physicians' autonomous motivation and occupational health, the current study assessed intrinsic aspirations, need satisfaction at work, and individual characteristics. The hypotheses were tested in a sample of 3,589 U.S. practicing physicians. Structural equation modeling was used to model paths linking physicians' intrinsic aspirations to occupational health, as mediated by need satisfaction and motivation at work. The results showed that physicians who endorsed intrinsic aspirations more strongly also reported better occupational health. This association was mediated by physicians' psychological need satisfaction and autonomous motivation. Selecting training candidates who endorse and otherwise evidence intrinsic aspirations, and fostering these aspirations within and outside of work, may protect physicians' occupational health. Further, system-level interventions that support intrinsic aspirations, need satisfaction, and autonomous motivation may also benefit the well-being of physicians and their patients.

ASSESSING THE NEED FOR AND ATTITUDES TOWARD AN MHEALTH STRESS REDUCTION PROGRAM FOR CAREGIVERS OF KIDNEY TRANSPLANT RECIPIENTS*

Jessica Chandler, PhD¹, Lauren I. Feder, B.S.¹, Alison Neely, HS¹, Samantha Pairet, B.S.¹, Luke Sox, B.S.¹, Frank Treiber, PhD¹, John McGillicuddy, M.D.¹

¹Medical University of South Carolina, Charleston, SC

Background: Caregivers play a crucial role in kidney transplant recipients' (KTR) long-term graft survival, providing physical and emotional support long after initial surgery recovery. Research involving caregivers of chronically ill and other types of solid organ transplant patients indicates a common pattern of caregiving strain characterized by increased general stress, fatigue, and sleep disturbance. Research is scarce regarding the physical and psychological health of caregivers of KTRs (KTR-C). The purpose of this study was to determine levels of stress, sleep quality, caregiver strain, and caregiver demographics of KTR-Cs. We also conducted an exploratory analysis to determine how perceived stress and strain relate to other physical and mental health markers of KTR-Cs.

Methods: A survey was adapted from previously validated questionnaires and administered to KTR-Cs at MUSC's kidney transplant clinic from May–August 2019. Demographics and caregiver information (hours/week, total months since transplant, etc.) were assessed alongside the Perceived Stress Scale, Caregiver Strain Index, and the Pittsburgh Sleep Quality Index. Lastly, we assessed the KTR-Cs' general interest, perceived need, and desire to participate in a previously validated smartphone stress reduction app (Tension Tamer: TT).

Results: Of 97 KTR-Cs approached, 94.8% agreed to participate. Mean age was 52.4 yrs with 72.6% female and 56.6% African American (43.4% white). Respondents averaged 19.4 ± 11.7 hours of caregiving/week, with 60% working full or part time jobs. Using established cut-offs, 87.7% self-reported high perceived stress, 64.5% indicated poor sleep, and 32.3% had high degree of caregiver strain. The top two physical health issues indicated were hypertension (37.6%) and diabetes (32.3%). Of those with elevated stress and poor sleep, 60% indicated need for and interest in the TT stress reduction program if offered for free. Further, 51% and 65.6% of diabetics and hypertensives, respectively, indicated enthusiasm for participation in the Tamer program. Of the subset who viewed a TT video demo, 100% believe TT would reduce their perceived stress and well-being.

Conclusion: KTR-Cs report similar levels of caregiver strain, high stress, sleep disturbance and physical health management issues as other caregivers. With over half indicating interest in receiving assistance related to stress management, implemented a stress management program tailored to KTR-Cs may be warranted.

MINORITY STRESS AND SOCIAL SUPPORT AMONG SEXUAL MINORITY WOMEN: ASSOCIATIONS WITH PSYCHOLOGICAL DISTRESS

Laura D'Adamo, B.A.¹, Emily Panza, Ph.D.², Edward Selby, Ph.D.³

¹Drexel University Center for Weight, Eating, and Lifestyle Science, Philadelphia, PA; ²Alpert Medical School of Brown University, Providence, RI; ³Rutgers, The State University of New Jersey, Piscataway, NJ

Sexual minority women are at heightened risk for psychological distress and poor health outcomes. Experiencing social stigma based on sexuality, or minority stress, may lead to elevated distress and contribute to these outcomes, necessitating research on protective factors for sexual minority women. Social support promotes well-being in this population, but little research has examined it as a buffer against minority stress in daily life. This secondary analysis of an Ecological Momentary Assessment (EMA) study examined 1) whether sexual minority stressors predicted greater distress in daily life, 2) whether social support predicted less distress in daily life, and 3) whether social support buffered the impact of experiencing heterosexist stigma on distress. Participants were sexual minority women with overweight or obese BMIs (n=55; 55% Caucasian; 62% bisexual; mean age = 25 ± 9). Lifetime experiences of heterosexist stigma (e.g., discrimination), internalized stigma (i.e., internalized homophobia, sexuality concealment), perceived stress, depression symptoms, general social support, and sexuality-specific social support were self-reported at baseline. Current levels of stress and negative emotion were then self-reported via a smartphone application five times daily over a five-day monitoring period. Lifetime experiences of heterosexist stigma predicted greater mean stress ($p < .05$) and negative emotion ($p < .05$) over the course of the EMA period. Internalized stigma was unrelated to distress outcomes. High levels of general social support predicted lower levels of daily stress ($p < .05$) and negative emotion ($p < .05$) during the EMA period, but sexuality-specific social support did not. Social support did not interact with experiencing heterosexist stigma to predict distress levels in daily life. Models controlled for demographics, baseline stress and depression, and EMA completion rate. Exposure to sexual minority stress over time may be related to heightened psychological distress in daily life among sexual minority women. In line with prior research, general social support strongly predicted lower distress. Future studies should examine additional factors and processes that may buffer the negative psychological effects of stigma in sexual minority women, as social support did not interact with stigma to predict distress outcomes.

RISK FACTORS ASSOCIATED WITH ENGAGEMENT IN PASSIVE SENSING AND EMA AMONG RURAL ADOLESCENT CANNABIS USERS

Kylie Hill, n/a¹, Tori Humiston, M.S.¹, Maria Drakulich, B.S.¹, Catherine Stanger, Ph.D.², Alan Budney, Ph.D.³, Andrew T. Campbell, n/a⁴, Weichen Wang, n/a⁵, Amy Hughes Lansing, Ph.D.¹

¹University of Nevada, Reno, Reno, NV; ²Dartmouth College, Lebanon, NH; ³Dartmouth College Geisel School of Medicine, Hanover, NH; ⁴Dartmouth College, Norwich, VT; ⁵Dartmouth College, Hanover, NH

Introduction: Mobile health applications that use passive sensing have been elevated to the forefront of research efforts for adolescents experiencing various health concerns. However, the acceptability of using apps to collect data in cannabis using teens has been largely unstudied. In this pilot study, ecological momentary assessment (EMA) and passive sensing data via a mobile health app and wristband were collected. Then risk factors that were associated with acceptability, feasibility, and adherence for collecting data through passive sensing and EMA were explored.

Methods: Adolescents (n=13, 46% female, aged 15-18) who endorsed regular cannabis use in the past 30 days participated in a study where they were asked to wear sensor wristbands (heart rate, accelerometer, electrodermal activity), install a data collection mobile health app on their personal phone (ambient sound/light, phone use, GPS, accelerometer), and complete five EMA entries per day. Participants reported on daily affect, daily craving, and daily substance use via EMA. Physiological data were collected through wristbands and contextual data through smartphones.

Results: Correlations indicate that teens with more severe cannabis cravings were more likely to adhere to the passive sensing app ($r=.65$) compared to the wristband and EMA ($.22 < r < .29$). Past cannabis use disorder (CUD) was also associated with better app adherence and EMA ($.60 < r < .62$) but was not associated with wristband adherence ($r=.32$). Teens who endorsed a higher level of parental monitoring were less likely to adhere to the passive sensing app, EMA, and wristband ($-.03 < r < .29$). Additionally, teens who reported greater emotion dysregulation were more likely to adhere to the app ($r=.49$) but were less likely to complete EMA prompts and wear the wristband ($-.18 < r < .37$).

Conclusion: Participants with greater cannabis use cravings, past CUD, and greater emotion dysregulation were more likely to adhere to the passive sensing app on their personal phone compared to wearing the wristband and completing EMA prompts. Additionally, participants who endorsed higher level of parental monitoring were less likely to use any of the data collection methods compared to those who endorsed lower levels of parental monitoring. Future research should further examine integrating passive sensing on personal phones for mHealth intervention for adolescent cannabis use and examine how to boost adherence where wristband sensors or EMA might be required.

SELF-REPORTED USE OF ALCOHOL AND NICOTINE AMONG WOMEN BEFORE AND DURING PREGNANCY, 2009-2017

Varada Sarovar, n/a¹, Lue-Yen Tucker, n/a¹, Amy Conway, n/a², Stacey Alexeeff, n/a¹, Nancy Goler, n/a³, Deborah Ansley, n/a², Mary Anne Armstrong, n/a¹, Constance M. Weisner, n/a¹, Kelly Young-Wolff, PhD, MPH⁴

¹Kaiser Permanente Northern California, Oakland, CA; ²Early Start Program, Kaiser Permanente Northern California, Oakland, CA; ³Regional Offices, Kaiser Permanente Northern California, Oakland, CA; ⁴Kaiser Permanente Northern California, Oakland, CA

Objective: To examine trends in the frequency of self-reported alcohol and nicotine use among pregnant women in the year before and during pregnancy.

Methods: Cross-sectional study of 361,093 pregnancies from 2009-2017 among women who completed a self-administered questionnaire on frequency of substance use in the year before and during pregnancy at their first prenatal visit (at ~8 weeks gestation) in Kaiser Permanente Northern California. The annual prevalence of self-reported daily, weekly, and monthly alcohol and nicotine use was estimated using Poisson regression with a log link function, adjusting for socio-demographics.

Results: The sample was 64% non-White with a mean age of 30.1 (SD=5.6). Overall, 43.9% of women reported \leq monthly, 20.0% weekly, and 1.6% daily alcohol use in the year before pregnancy; while 3.4% reported \leq monthly, 1.5% weekly, and 5.3% daily nicotine use in the year before pregnancy. From 2009-2017, there was a significant increase in the adjusted prevalence of any alcohol use in the year before pregnancy (63% to 66%), with significant increases in weekly use and significant decreases in \leq monthly use. The adjusted prevalence of any nicotine use in the year before pregnancy decreased significantly (12.6% to 7.7%), with significant decreases in annual rates of \leq monthly, weekly and daily nicotine use. Overall, 7.6% of women reported \leq monthly, 1.6% weekly, and 0.2% daily alcohol use during pregnancy, and 0.9% of women reported \leq monthly, 0.6% weekly, and 1.4% daily nicotine use during pregnancy. From 2009-2017 there were significant decreases in the adjusted prevalence of any prenatal alcohol (11.5% to 8.8%) and prenatal nicotine use (4.3% to 2.0%) (P s < .0001), with significant decreases in annual rates of change in \leq monthly, weekly, and daily use of both substances.

Limitations: Prenatal substance use was based on self-reported use at the initial prenatal visit (at ~8 weeks gestation) and does not reflect continued use during pregnancy. Further, we were unable to differentiate whether substance use during pregnancy occurred before or after women realized they were pregnant.

Conclusions: Despite increases in the prevalence of self-reported alcohol use in the year prior to pregnancy, use of nicotine decreased significantly in the year prior to pregnancy. The frequency of self-reported alcohol and nicotine use during pregnancy have decreased over time among pregnant women in Northern California.

PREDICTORS OF BINGE DRINKING AND MENTAL HEALTH IN GREEK LIFE: A STUDY ON A COLLEGE POPULATION

Sheila Pakdaman, MS¹, Danielle R. Madden, PhD¹, Eric Pedersen, PhD², Jordan Davis, PhD¹, John R. Clapp, PhD¹¹University of Southern California, Los Angeles, CA; ²RAND, Los Angeles, CA

Introduction: High stress can lead to binge drinking as a coping mechanism while in college. Binge drinking is commonplace on college campuses, with 34.8% engaging in binge drinking at least once, a higher rate when compared to non-college attending peers. Members of the Greek community binge at higher rates than non-Greek affiliated students. It is hypothesized that binge drinking for Greek members is associated with environmental settings, peer consumption, mental health and mediated by coping mechanisms due to life stressors.

Methods: A random sample of N=549 was taken at an ethnically diverse private southern California university. Primary predictive measures were demographics, drinking behaviors (e.g. “Did you drink with a friend?” or “Did you drink at a Greek party?”) and the last drinking event was measured with participation in Greek life. Secondary predictors included mental health outcomes such as depression, anxiety, and social interaction anxiety. Descriptive frequencies, crosstabulations, and multiple logistic regression were used for analysis.

Results: Results indicated that N=396 (73%) of students did have a binge-drinking episode in the past 30-days, with an average of 3.5 days total. Demographics included N=330 (60.1%) females and N=194 (35.3%) males, N=76 (14.42%) participated in Greek life, with N=286 (52.1%) having a GPA of 3.6 or higher. Drinking with friends had the highest incidence of binge drinking N=355 (67.36%). Logistic regression models assessed the association between Greek life, mental health and binge drinking (RR= 10.70 95% CI= 5.20, 22.00) were significantly associated. Ordinal logistical models assessed potential effect modification by Greek life and mental health. Depression (OR= 1.29, 95% CI= 1.22, 1.35), anxiety (OR=1.52 95% CI= 1.4, 1.64) and social interaction anxiety (OR=1.01 95% CI= 1.00, 1.02) were significantly associated.

Discussion: College campuses would benefit from creating more regulations in Greek life and facilitating healthy habits as coping mechanisms from college stressors. Prevention programming can be considered in relation to mental health.

IMPAIRED CONTROL IN BINGE DRINKING USING SMARTPHONE ECOLOGICAL MOMENTARY ASSESSMENT

Joanna R. Sells, PhD¹, Matthew E. Sloan, MD², Courtney L. Vaughan, BS, BA³, Bethany L. Stangl, PhD², Andrew J. Waters, PhD³, Vijay A. Ramchandani, PhD²¹San Francisco VA Health Care System, San Francisco, CA; ²NIAAA, Bethesda, MD; ³Uniformed Services University, Bethesda, MD

As of 2010, excess alcohol consumption cost the US approximately \$249 billion (\$2.05 per drink) including lost productivity, healthcare, and criminal justice costs. Binge drinking accounts for 77% of these costs. In order to understand alcohol use disorders and develop treatment, insights into psychological processes underlying drinking are needed. Attempts to limit number of drinks or stop drinking altogether in a drinking episode are not well understood. We examined impaired control and drinking using smartphone EMA captured in the field.

Heavy drinking males and females (21+ and 15+ drinks/week respectively, N=16) who were undergoing a lab-based study of impaired control over drinking completed 2-6 weeks of EMA across 4 daily random assessments. Participants completed 954 assessments (77.64% of the expected number) and the mean number of assessments was 60.56 (30.16). Drinking goal, craving, consumption quantity, motivation to stop drinking, and impaired control measures were collected.

Participants reported being motivated to cut down or avoid drinking on 38.58% of assessments. There was no evidence for moderation of an association by motivation to cut back/avoid drinking for the next 24 hours. As alcohol craving increased, drinking before the next assessment increased ($p = .007$). As motivation to stop drinking increased, drinking before the next assessment decreased ($p = .026$). Finally, when participants indicated they had a goal of reducing/stopping drinking in the next 24 hours, drinking before the next assessment decreased ($p = .022$). This is the first study to report a within-subject association between motivation and subsequent drinking during EMA.

This study suggests that EMA can be effectively administered in the field in binge drinkers undergoing lab-based studies of impaired control over drinking. We found that motivation and goals of reducing/stopping drinking are associated with subsequent reduced drinking, while craving for alcohol is associated with increased subsequent drinking. EMA assessed in the field can provide information on recent impaired control episodes and could be used to evaluate if impaired control is an effective target for drinking interventions.

RACIAL/ETHNIC AND GENDER DIFFERENCES IN NONMEDICAL STEROIDS USE IN ADOLESCENTS: A NATIONALLY REPRESENTATIVE TREND ANALYSIS

Chengbo Zeng, MPH¹, Yunyu Xiao, MPhil²¹University of South Carolina, Columbia, SC; ²New York University, JERSEY CITY, NJ

Backgrounds: Nonmedical use of steroids (NMUS) could result in addiction and severe side effects including reproductive health problems, heart diseases, and liver or kidney failure. Previous studies have shown that adolescents reported high rates of lifetime NMUS than adults (1.3% vs. 0.5%). Additionally, there are racial/ethnic and gender differences in the rate of lifetime NMUS. However, limited research investigated the trend of NMUS among adolescents. Little is known about the plausible racial/ethnic and gender differences in this trend. The current study aims to investigate the racial/ethnic and gender differences in the trend of NMUS among adolescent. Such information can shed light on the importance of exploring determinants of NMUS and inform health professionals designing tailored interventions to reduce NMUS among adolescents.

Methods: Data were derived from the 1999-2017 National Youth Risk Behavior Survey, which involves school-based surveys that generated a nationally-representative sample of 9th-12th grade students in the United States. Students self-reported lifetime NMUS. Logistic regression analyses used to explore the trend of NMUS by racial/ethnic and gender groups after adjusting for grade levels. Linear and quadratic changes were examined.

Results: The prevalence of lifetime NMUS has increased from 1999 to 2003 (from 2.58% to 5.12%), but decreased since 2003 (from 5.12% to 2.98%). White females (OR=0.97, $p < 0.001$), White males (OR=0.98, $p < 0.01$), and Hispanic males (OR=0.99, $p < 0.01$) had decreased trends of NMUS. Both Black females (OR=1.08, $p < 0.01$) and males (OR=1.03, $p=0.04$) had increased trends of lifetime NMUS. No significant trends were found in other racial/ethnic groups.

Conclusion: Racial/ethnic and gender disparities were found in the trend of nonmedical steroids use among adolescents. More attention should be paid to Black males and females. Further studies focusing on investigating the determinants of NMUS are needed. Tailored interventions for specific racial/ethnic and gender subgroups may be more effective in reducing the nonmedical steroids use.

DAILY PREDICTORS OF MEANINGFULNESS AMONG OPIOID PATIENTS: ASSOCIATIONS WITH AFFECT, SOCIAL INTERACTIONS, AND 12-STEP SUPPORT

Kyler S. Knapp, BA¹, H.H. Cleveland, PhD², Timothy R. Brick, PhD², Scott C. Bunce, PhD, MA³¹Pennsylvania State University, State College, PA; ²Pennsylvania State University, University Park, PA; ³Pennsylvania State University, Hershey, PA

Recovery from drug addiction goes beyond achieving and sustaining abstinence to include improved meaningfulness and quality of life. However, research on factors related to the development of a sense of meaningfulness during recovery from opioid use disorder are lacking. We present a study using Ecological Momentary Assessment (EMA) to examine the relationship of positive and negative affect, positive and negative social interactions, and 12-step meeting support with self-reported meaningfulness.

Participants ($n = 73$, 77% Male) were patients at a residential drug and alcohol treatment facility. They were invited to complete smartphone-based surveys four times per day for up to 12 consecutive days. Positive and negative affect were assessed with eight items each, and items of the same valence were averaged to create daily positive and negative affect scores for each individual. Positive and negative social interactions were measured with five binary items each that assessed whether negative (e.g., had a disagreement) and positive (e.g., received a compliment) interactions occurred, and summed to indicate the total number of positive and negative interactions per day for each individual. Twelve-step support was measured with three items (e.g., "How supportive did you find the meeting?"), which were averaged to indicate daily levels of 12-step support for each individual. Meaning was measured with four items (e.g., "Overall, how meaningful was your day?"), which were averaged to indicate daily levels of meaning for each individual.

We used multilevel modeling to assess whether each daily predictor was associated with meaningfulness after controlling for prior day meaningfulness, age, and gender. The final model revealed an interaction between daily positive affect and negative social interactions. Positive affect protected against the effects of negative social interactions, such that meaningfulness was lower on days with more negative social experiences only if positive affect was also low. Further, daily 12-step support moderated the associations between both positive social interactions and positive affect variability with meaningfulness. Experiencing higher-than-usual 12-step meeting supportiveness reduced within-day linkages between having fewer positive social interactions and higher-than-usual positive affect variability and individuals' sense of meaningfulness that day.

DRINKING IDENTITY ENDORSEMENT AND THOUGHT FREQUENCY, AND LONGITUDINAL ASSOCIATIONS WITH PROBLEMATIC ALCOHOL CONSUMPTION

Andrew Hertel, PhD¹, Scott Baldwin, PhD², Kirsten P. Peterson, BA³, Kristen Lindgren, PhD³¹Knox College, Galesburg, IL; ²Brigham Young University, Provo, UT; ³University of Washington, Center for the Study of Health and Risk Behaviors, Seattle, WA

Research suggests that drinking identity endorsement (associating oneself with alcohol, drinking alcohol, or drinkers) and drinking identity thought frequency (frequency of thinking about one's drinking identity, a dimension of drinking identity investment; investment represents disproportionate allocation of cognitive and behavioral resources to maintain one's drinking identity) are social cognitions that can help explain problematic alcohol consumption. We extended this research in two ways. First, we evaluated whether endorsement and thought frequency comprised a latent drinking identity factor. Second, we tested whether there is a reciprocal, positive relationship between drinking identity and problematic alcohol consumption over time. Data were collected from college graduates who began the study in their senior year of college and, at that time, exhibited hazardous drinking (scores ≥ 8 on the Alcohol Use Disorder Identification Test [AUDIT]) (N=422; age M=21.5, 59% female, 61% White). Participants completed self-report measures of drinking frequency (# drinks/week), hazardous drinking (AUDIT), drinking identity endorsement, and absolute and relative drinking identity thought frequency at graduation and again 9 months later. Confirmatory factor analysis indicated that endorsement and thought frequency comprised a latent drinking identity factor at both time points (T1 CFI=0.996, TLI=0.991, RMSEA=0.039, 95% CI [0.000, 0.068]) (T2 CFI=0.988, TLI=0.968, RMSEA=0.080, 95% CI [0.000, 0.150]). Controlling for gender, structural equation modeling indicated that drinking identity was concurrently associated with drinking frequency (T1 $b=0.35$, $p<.001$; T2 $b=0.42$, $p<.001$) and hazardous drinking (T1 $b=0.23$, $p<.001$; T2 $b=0.29$, $p<.001$). Finally, across the 9 months, cross-lagged structural equation modeling indicated that drinking identity predicted increases in drinking frequency ($b=0.10$, $p=.025$) and hazardous drinking ($b=0.10$, $p<.001$) whereas change in drinking identity was predicted by neither drinking frequency ($b=0.00$, $p=.347$) nor hazardous drinking ($b=0.02$, $p=.089$). It is important to assess both endorsement and thought frequency when examining the relationship between drinking identity and problematic alcohol consumption. Moreover, both endorsement and thought frequency are potential targets for curbing problematic alcohol consumption. Further investigation is needed to identify sources of drinking identity.

LONGITUDINAL COURSE OF SUBSTANCE USE DISORDER DIAGNOSES STRADDLING A NEW DIABETES DIAGNOSIS

Eric Schmidt, PhD¹, Cheng Chen, MS², Jodie Trafton, PhD³, Susan Frayne, MD, MPH⁴, Alex Sox-Harris, PhD, MS⁴¹Office of Mental Health and Suicide Prevention, Veterans Affairs, Menlo Park, CA; ²Veterans Affairs, Menlo Park, CA; ³PERC, Veterans Affairs, Menlo Park, CA; ⁴Ci2i, Veterans Affairs, Menlo Park, CA

Background: In the context of diabetes, a co-occurring substance use disorder (SUD) can disrupt behavioral and medical aspects of self-care and disease management. SUDs increase risk for morbidity and mortality in the context of diabetes, making it critical to diagnose and treat co-occurring SUD in a timely manner.

Purpose: This study analyzed patient factors associated with SUD diagnoses before and after new-onset diabetes, data which could inform care management for diabetes but has sparsely been reported.

Methods: We analyzed medical record data to identify a nationwide cohort of Veterans Health Administration (VA) patients with new-onset diabetes in 2008 (N = 155,145) and a SUD diagnosis during 2006–2010 (N = 18,227). SUD diagnoses were made by clinicians during health care provided in VA's integrated medical and behavioral health care system. Patients were categorized into 3 groups: "SUD-resolved" if a clinician made a SUD diagnosis before but not after diabetes onset; "SUD-new" if a clinician made a SUD diagnosis after but not before diabetes onset; and "SUD-ongoing" if a clinician made a SUD diagnosis both before and after diabetes onset. Multinomial regression tested associations between age, sex, or race/ethnicity and group membership using SUD-ongoing as the reference group.

Results: Alcohol (5.3%), cocaine (1.4%), and opiate use disorders (0.6%) were diagnosed most often in the 2 years before new-onset diabetes. Rates of all SUDs increased in the 2 years after new-onset diabetes. In multinomial regression, men were less likely to be in the SUD-resolved group (Odds Ratio [OR] = 0.73, $p<.05$), compared to women. Compared to white patients, black patients were less likely to be in the SUD-resolved (OR = 0.83, $p<.05$) or SUD-new groups (OR = 0.70, $p<.05$) relative to being in the SUD-ongoing group.

Conclusions: Substance use disorders are diagnosed at higher rates in the years following new-onset diabetes, compared to the time immediately before diabetes onsets. A patient's new diabetes diagnosis may be a ripe opportunity to engage patients in SUD treatment when clinically indicated to improve their chances for living healthily with diabetes. However, men appear less likely than women, and black patients appear less likely than white patients, to have SUD resolve in the years straddling their new-onset diabetes diagnosis. Additional study is warranted on whether associations are related to patient preferences, disparities, quality of care, or all the above.

THE EFFECT OF MOMENTARY AFFECT ON SUBSTANCE USE AMONG YOUNG ADULTS WHO EXPERIENCE HOMELESSNESS

Danielle R. Madden, PhD¹, Eldin Dzibur, PhD¹, Sara Semborski, LCSW¹, Harmony R. Rhoades, PhD², Benjamin F. Henwood, PhD, MSW¹¹University of Southern California, Los Angeles, CA; ²University of Southern California, SAN DIEGO, CA

Introduction: To date, little is known about the momentary patterns and predictors of substance use among young adults who experience homelessness. In order to enhance understanding of substance use patterns, smartphone-based ecological momentary assessments (EMA), or short mobile surveys, were utilized to examine the real-time association between affect and substance use.

Methods: Two hundred and thirty-four young adults aged 18-27 who were either residing in supportive housing programs ($n=126$) or were homeless ($n=111$) were assessed for 7 days and completed a baseline survey as well as up to 8 EMA surveys per day. During each EMA survey, which is administered once every two hours, participants reported use of substances as well as current affect. Substance use is defined as any use of alcohol or cannabis. Affective states were separated into positive (i.e., happy, calm, excited) and negative scales (i.e., stressed, irritated, sad) based on exploratory factor analysis. Separate mixed-effects logistic regressions were completed to evaluate whether positive or negative affect predicted lead, current and lagged substance use. Covariates included study day (1-7), age, and housing status.

Results: Participants were on average 22 years old. Approximately 48% of participants reported consuming alcohol and 58% reported using cannabis during the 30 days prior to baseline. Alcohol or cannabis was endorsed on 17% of the 6,600 completed EMAs. Based on results, there were no lead effect for either positive or negative affect on substance use. A significant lagged effect of negative affect on subsequent substance use was found as well as a significant current effect of positive affect on substance use. Within individuals, lower negative affect than one's average was associated with greater odds of substance use on the next EMA survey ($OR = 0.880, p < 0.05$). In addition, greater positive affect than one's typical was associated with substance use on the current EMA ($OR = 1.407, p < 0.05$).

Conclusions: Results highlight the importance of momentary affect as a predictor of substance use among young adults who experience homelessness. These findings suggest that alcohol and cannabis may be used to enhance mood or experiences rather than as a coping mechanism. Nonetheless, more research is needed to determine other predictors of momentary substance use including presence of risky peers or proximity to outlets that sell substances.

PERCEIVED RISK PREDICTS OPIOID MISUSE INTENTIONS AMONG HIGH SENSATION SEEKING YOUTH AND YOUTH WHO HAVE MISUSED

Alexa R. Romberg, PhD¹, Shreya Tulsiani, MPH¹, Michael Liu, MS¹, Elizabeth C. Hair, PhD¹, Donna Vallone, PhD, MPH¹¹Truth Initiative, Washington, DC

Understanding how perceived risk of harm is related to opioid misuse is important for appropriately targeting both individual and population level interventions. While substance use during adolescence and young adulthood is generally more prevalent among youth who perceive lower risk from substance use, prior research has found that for high sensation seeking college students, perceived risk was unrelated to prescription opioid misuse. The objective of the present study was to test whether sensation seeking personality and/or prior opioid misuse moderate the association between perceived risk of harm and intentions to misuse prescription opioids in a nationally representative sample of youth.

Data were collected in spring 2018 as part of the Truth Longitudinal Cohort, a nationally representative sample of youth ages 15-24 ($N=12,374$). Participants self-reported demographic and sensation seeking characteristics, lifetime prescription opioid misuse, perceived risk of harm of misusing prescription opioids once or twice, and intentions to misuse prescription opioids. Logistic regression models with intentions to misuse as the outcome tested the effect of sensation seeking, prior misuse, perceived risk of harm and the interaction of perceived risk with the other predictors.

As expected, higher odds of intention to misuse were associated with higher sensation seeking scores ($OR=1.48, CI=1.40-1.56$), but there was no evidence for an interaction between sensation seeking and perceived risk ($OR=1.00$). Overall, lower perceived risk and prior misuse were each associated with higher odds of intention to misuse and there was a significant interaction between these measures ($OR=1.44, CI=1.51-1.80$). The effect of perceived risk was stronger among those who had misused in the past ($OR=3.53, CI=2.90-4.30$) than among those who had not misused ($OR=2.45, CI=2.21-2.72$).

Findings do not support smaller effects of perceived risk of harm among high sensation seeking youth on intentions to misuse opioids. In fact, the effect of perceived risk on intentions to misuse was stronger among those who had misused in the past than those who had not misused. Perceived risk of harm among those with experience with misuse may reflect positive or negative misuse experiences, which may have shaped their future intentions to misuse. Longitudinal research is needed to better understand the relationship between risk perceptions and prescription opioid misuse.

USE OF CIGARETTES AND E-CIGARETTES FOR WEIGHT CONTROL AMONG YOUNG ADULTS WITH OVERWEIGHT OR OBESITY

Ashley H. Tjaden, MPH¹, Carla J. Berg, PhD, MBA², Meghan Mavredes, MPH³, Melissa A. Napolitano, PhD³¹The George Washington University, Rockville, MD; ²Milken Institute School of Public Health, George Washington University, Washington, DC; ³The George Washington University, Washington, DC

Introduction: The uptake of e-cigarettes and resulting health-related concerns are a public health priority. Data suggest that cigarettes may be used to control weight and dietary intake but less is known about perceptions related to e-cigarettes. The current analysis sought to examine these perceptions and behaviors among a subset of young adults with overweight and obesity in a weight loss trial.

Methods: Young adults with overweight/obesity (n=459; 78.6% female, mean \pm SD: age 23.3 ± 4.4 years, weight: 86.6 ± 15.6 kg, body mass index [BMI] 31.2 ± 4.4 kg/m²) were recruited from two sites and randomly assigned to receive one of three digitally delivered weight management interventions. At baseline, participants completed questions related to their cigarette and e-cigarette use, weight-related behaviors (i.e., diet and moderate-to-vigorous physical activity [MVPA]), and perceptions about e-cigarette use for weight control.

Results: Among the randomized participants, 39% reported having ever smoked traditional cigarettes, 17.8% of participants reported having ever used e-cigarettes, and 14.4% had ever tried both cigarettes and e-cigarettes. Neither cigarette nor e-cigarette use differed by baseline BMI (overweight/obese); however, participants with obesity (BMI ≥ 30) were more likely to report e-cigarettes having tasty flavors than participants with overweight. Among ever e-cigarette users (n=81), 76.5% reported a perception of e-cigarettes coming in tasty flavors compared to 55% of the never users. The diet quality of the participants who had ever used e-cigarettes was lower than the diet quality of the never users but total caloric intake was not different and there were no differences in the perception of e-cigarettes for weight control or physical activity. Among dual users of e-cigarettes and cigarettes (n=66), very few reported using traditional cigarettes for weight control but about half reported using e-cigarettes for weight control. Among the 35 users who reported using e-cigarettes for weight control, weight-related behaviors differed (i.e., on average approximately 12 minutes of MVPA per day less, and 400 fewer calories [p 's $< .05$]) compared with participants who did not report using them for weight control.

Conclusion: Our results suggest that there are differences in the perceptions of how traditional cigarettes and e-cigarettes affect weight. Further research is needed to understand the impact of the perception of e-cigarettes for weight control among young adults.

THE RELATIONSHIP BETWEEN DISPLACEMENT IMPOSITION AND READINESS TO QUIT SMOKING BY CIGARETTE AND E-CIG USE STATUS

Delaney Dunn, B.A.¹, Thad Leffingwell, Ph.D.¹, Emily Birkel, B.A.¹, Ashley B. Cole, PhD¹, Susanna Lopez, M.S.¹¹Oklahoma State University, Stillwater, OK

Background: While public smoking bans are becoming more common, the impact of these policies on cigarette and electronic cigarette (e-cig) users is not fully understood. Smoking bans have demonstrated a reduction in smoking rates in some areas; however, overall *displacement imposition*, a measure of users' cognitive and affective reactions to being displaced to smoke, and whether this burden may differentially impact cigarette users vs. e-cig users' readiness to quit smoking, have not yet been studied (Lechner et al., 2012). The aim of this study was to better understand the relationship between displacement imposition and readiness to quit smoking, and how this relationship may differ between cigarette and e-cig users.

Method: Participants (N=297; 121 cigarette users, 176 e-cig users) were recruited from a large, Southern Plains university. The sample was female (51.6%), Caucasian (71.2%), and undergraduate students (86.7%) between the ages of 18-25 (81.1%). Participants completed online questionnaires that assessed demographics, cigarette and e-cig use frequency, and readiness to quit smoking.

Results: Moderation analyses using bootstrapping (PROCESS; Hayes, 2013) indicated significant main effects for both cigarette vs. e-cig use ($b = 1.07$, $t = 1.99$, $p = .0473$, 95% CI [.01, 2.13] and displacement imposition ($b = .02$, $t = 3.81$, $p = .0002$, 95% CI [.01, .03] in predicting readiness to quit smoking after controlling for length of time smoked (in years). These effects were qualified by a significant interaction between displacement imposition and cigarette vs. e-cig use status, $F(4, 244) = 13.60$, $R^2 = 18.23\%$, $p < .0001$, 95% CI [-.014, -.002]. The interaction was significant when displacement imposition was 1SD below the mean and at the mean but not at lower levels of displacement.

Conclusions: At high levels of displacement imposition, both cigarette and e-cig users exhibited less readiness to quit smoking, an effect that was stronger among cigarette users than e-cig users. Findings may support that greater restrictions imposed on cigarette and e-cig users indicate more reactance and less readiness to quit smoking. The stronger effect found among cigarette (vs. e-cig) users may reflect greater stigma associated with smoking cigarettes compared to e-cigs (McKegany et al., 2018). Future work should assess the effects of smokers' displacement imposition longitudinally to examine whether the present study's findings translate to actual attempts to quit smoking.

TOBACCO AND MARIJUANA USE AND THEIR ASSOCIATION WITH SERUM PROSTATE-SPECIFIC ANTIGEN AMONG AFRICAN AMERICAN MEN IN CHICAGO

David Press, PhD, MPhil¹¹Northwestern University, Chicago, IL

Background: African American (AA) men experience more than twice the prostate cancer mortality as White men yet are under-represented in academic research involving prostate-specific antigen (PSA), a biomarker of lethal prostate cancer.

Methods: We examined the impact of self-reported tobacco (cigarette pack-years and current tobacco use including e-cigarettes) and current regular marijuana use on serum PSA level based on clinical laboratory testing among 928 AA men. We defined outcome of elevated PSA ≥ 4.0 ng/mL for multivariable logistic regression models and continuous PSA increases for general linear models. All models were adjusted for age, sociodemographic characteristics, healthcare utilization, body mass index, and self-reported health.

Results: Among 430 AA men age ≥ 55 years, we observed ~5 times the odds of elevated PSA among those with >1 pack-years of cigarette smoking vs. never-smokers (odds ratio (OR) = 5.03; 95% confidence interval (CI) = 1.56-16.2) and a quarter the odds of elevated PSA among current marijuana users vs. non-users (OR = 0.28; 95% CI = 0.08-0.99). PSA increased on average 1.25 ng/mL among other current tobacco users vs. non-users.

Conclusions: Cigarette smoking history and current tobacco use may increase PSA levels among older AA men. Current marijuana use may impact PSA levels in a counterintuitive direction. Future work with studies of diverse patient populations with cancer outcomes are needed to assess whether these behavioral characteristics contribute to racial/ethnic disparities in prostate cancer outcomes.

Impact: Our study provides novel evidence regarding potential differences in PSA levels among older AA men according to behavioral characteristics.

“I DID MY PART WHILE I WAS PREGNANT AND NOW, I DESERVE A CIGARETTE”! SMOKING CESSATION AMONG LOW-INCOME PREGNANT WOMEN IN THE US

Nikhil A. Ahuja, MDS¹, Satish K. Kedia, PhD¹, April Carswell, PhD², Kenneth D. Ward, PhD¹, Mark W. Vander Weg, PhD³, Isabel C. Scarinci, PhD, MPH⁴

¹The University of Memphis, School of Public Health, Memphis, TN; ²ICF, Atlanta, GA; ³University of Iowa, Iowa, IA; ⁴University of Alabama at Birmingham, Birmingham, AL

Pregnancy creates a unique window of opportunity for smoking cessation. However, pregnant women from disadvantaged groups face personal, social, and environmental challenges that may impede their abilities to quit smoking. This study draws upon the socio-ecological framework (SEF) to explore perspectives on smoking cessation among low-income pregnant or postpartum women in the Mid-south of the United States. Semi-structured interviews were conducted with 60 low-income pregnant or postpartum women. Data were analyzed in Dedoose qualitative software using the grounded theory approach. Findings reveal that at the individual level, the fact of being pregnant, risks associated with baby's health, and desire to breastfeed motivated women to cease smoking during pregnancy. However, some pregnant women perceived that slowing down on smoking during pregnancy was adequate to prevent harm to their fetuses. Other individual level factors that made quitting difficult included nicotine addiction, smoking as a habit, boredom, stressful life circumstances, fear of weight gain, and lack of willpower. At the interpersonal level, living in a smoke-free environment, emotional and practical support from social network members including, partners and family members were thought to facilitate quitting. At the organizational level, access to nicotine replacement therapies and counselling also contributed to their ability to quit smoking. At the policy level, pregnant women viewed increase in cigarette prices, warning labels on the cigarette pack, and ban on cigarette sale as having some effect in helping them to quit smoking. This study offers additional theoretical insights into smoking cessation among low income pregnant and postpartum women in the United States. Designing multilevel smoking cessation interventions while considering the interplay of individual, interpersonal, and environmental factors may lead to better outcomes.

LAPSE TO RELAPSE: HOMELESS YOUTH RETURN TO SMOKING WHEN SUPPORTIVE STRUCTURES AND SELF-REGULATION ARE WEAKENED

Joseph Macisco, MPH¹, Joanne G. Patterson, PhD, MPH, MSW², Julianna M. Nemeth, PhD³¹Ohio State University, Lewis Center, OH; ²Ohio State University Comprehensive Cancer Center, Canal Winchester, OH; ³The Ohio State University, Columbus, OH

Background: Approximately 70% of homeless youth smoke cigarettes; of these, many smoke daily and exhibit strong nicotine dependence. Yet, evidence indicates that homeless youth are motivated to quit smoking and make multiple quit attempts annually. However, there exists little account of smoking relapse patterns in this population. Understanding the factors that contribute to smoking relapse is essential for developing effective smoking cessation interventions for homeless youth. The purpose of this study was (1) to describe the factors associated with smoking relapse in homeless youth and (2) identify critical timepoints during which to intervene and reduce risk of smoking relapse.

Methods: Thirty-two homeless youth current smokers aged 14-24 years were recruited from a drop-in center in a Midwestern city. In-person semi-structured interviews about patterns and determinants of smoking behaviors were conducted with each youth. Study personnel coded interviews inductively for a variety of smoking-related behaviors. Themes were generated from these codes. This analysis focused on emerging patterns involving smoking relapse.

Results: Homeless youth overwhelmingly reported stress as a reason for smoking relapse. However, they also described specific precipitating events that decreased social supports and increased stress, leading to relapse. These events included loss of a loved one, verbal or physical conflict with peers, and intimate partner violence. Experiencing depression, anger, or conflicting emotions in response to precipitating events were commonly reported prior to relapse. Smoking was described in terms of stress management (i.e. to cope with disruptive emotions) and harm reduction strategy (e.g. “stepping out” for a smoke to diffuse conflict). Some youth described a high level of nicotine dependence. Very few reported returning to tobacco products because they wanted to.

Conclusion: Homeless youth are at high risk for smoking relapse after experiencing traumatic events. Specifically, homeless youth engaged in cigarette smoking to self-regulate disruptive emotions precipitated by trauma. Current smoking cessation interventions for homeless youth may undervalue the role of emotional self-regulation in sustaining quit behaviors. An opportunity exists for researchers to study multi-level smoking cessation interventions that expand homeless youths’ social and support systems while building individual-level emotional self-regulation skills.

LATINX SMOKER’S PERSPECTIVES ON AN ACCEPTANCE AND COMMITMENT THERAPY-BASED SMOKING CESSATION PROGRAM: INITIAL FINDINGS

Virmarie Correa-Fernandez, Ph.D.¹, Domenica Cartagenova, B.S.¹, Niloofar Tavakoli, M.Ed.¹, Amanda Broyles, M.Ed.¹, Roseann John, B.S.¹, Susan Day, Ph.D.¹¹University of Houston, Houston, TX

Background: Acceptance and Commitment Therapy (ACT) has demonstrated promise as an efficacious treatment for smoking cessation, depression, and anxiety separately, but more research is needed to declare ACT as an evidence-based intervention for the co-occurrence of cigarette smoking with depression or anxiety, including among Latinx groups. The extent to which this intervention should be culturally tailored to the Latinx population and how to incorporate cultural considerations in treatment remains to be determined. This study aims to examine the perspectives of Latinx smokers with depression or anxiety symptoms on 1) the perceived utility of ACT-based components for smoking cessation and psychological distress, and 2) cultural factors that may enhance the intervention.

Method: Participants complete a brief questionnaire about demographics, tobacco use, depression, anxiety and psychological traits relevant to ACT. Focus groups (FG; 2 women and 2 men) and individual in-depth interviews are being conducted (expected N = 48). A pilot run-through of the protocol demonstrated the acceptability of the interview guide and the feasibility of conducting the study. Three in-depth interviews have been conducted. Study is ongoing.

Results: Three major themes have emerged so far: emotion regulation, social support, and applicability of ACT-designed metaphors. Emotion regulation was consistently linked to smoking and difficulty quitting; plus, it seemed to influence the understanding of ACT metaphors. Social support was identified as beneficial in their quitting efforts. Some adjustments to the presentation and content of the ACT-metaphors were suggested.

Conclusion: The content of an ACT-based smoking cessation wellness program targeting Latinx smokers seems to be acceptable; however, additional adjustments may tailor the intervention to be more culturally relevant. Findings after study completion will contribute to the adaptation of the treatment protocol to be culturally relevant for Latinx smokers with depression and/or anxiety.

10:30 AM-11:30 AM

OVERLAPPING RISK OF USE OF TOBACCO, VAPE, AND PRESCRIPTION OPIOIDS AMONG YOUTH AND YOUNG ADULTS

Alexis A. Barton, PhD, MS¹, Jessica M. Rath, PhD, MPH, CHES¹, Elizabeth C. Hair, PhD¹, Siobhan N. Perks, MPH¹, Donna Vallone, PhD, MPH¹¹Truth Initiative, Washington, DC

Current e-cigarette use increased from 2% in 2011 to 21% in 2018 among US high school students, and recent research has been devoted to understanding this epidemic and the risk factors for use. This study examines the degree to which young people at risk for vaping are also at risk for other substance use behaviors like smoking or prescription opioid misuse.

Data were collected from a national continuous tracking survey of 15-24-year-olds, with daily surveys conducted among approximately 260 participants per week. A 12-week period ending in May 2019 was analyzed for this study (n=3,183). Survey items measured participants' ever and current (past 30-day) smoking, vaping, and ever prescription opioid misuse. Additional items measured intentions for smoking (e.g. "If one of your best friends offered you a cigarette (even 1 or 2 puffs) in the coming year, would you smoke it?"), vaping, and prescription opioid misuse either recreationally or medically. Never smokers answering, "definitely not" to all smoking intention questions were coded as "closed to smoking," whereas never smokers reporting any next-year smoking intentions were coded as "at risk for smoking." Vaping and prescription opioid misuse risks were similarly coded. Sensation seeking was measured using an 8-item scale (e.g. "I prefer friends who are exciting and unpredictable"). Participants scoring 4+ on this scale were coded as "high sensation seekers."

Among ever vapers, 51% had previously smoked a cigarette, and 38% were at risk for smoking. Among never vapers, 36% were at risk for both smoking and vaping. Similarly, 43% of ever vapers had previously misused prescription opioids, and 24% were at risk for prescription opioid misuse. Altogether, 11% of the sample reported ever smoking, vaping, and prescription opioid misuse. Risk for use was significantly associated with high sensation seeking. Compared to low sensation seekers, 37% of high sensation seekers were at risk for smoking (vs. 18%), 49% for vaping (vs. 28%), and 65% for prescription opioid misuse (vs. 36%) (all p's < 0.0001).

Young people at risk for vaping may also be at risk for smoking and prescription opioid misuse. This susceptibility is related to the degree to which they are sensation seekers. Results can inform messages for mass-media health communication campaigns and other behavioral health interventions so that youth and young adults can make informed decisions about their use of these high-risk products.

10:30 AM-11:30 AM

ADDRESSING INTERNAL AND SOCIAL CONTEXT IN THE DEVELOPMENT AND OPTIMIZATION OF SMOKING CESSATION TREATMENT FOR HOMELESS YOUTH

Julianna M. Nemeth, PhD¹¹The Ohio State University, Columbus, OH

Background: 70% of homeless youth smoke combustible tobacco. A majority of those have tried to quit but do so without supported evidence-based cessation treatment. We used the Capability-Opportunity-Motivation framework for contextually focused behavior change (COM-B) to guide theoretical model development in response to the research question: What internal capabilities and social/physical environmental opportunities need to be in place for homeless youth to be motivated to quit smoking and engage supported tobacco cessation treatment?

Methods: Recruited on age (14-17 and 18-24) and motivation to quit in the next 30 days, homeless youth smokers from a drop-in center completed qualitative interviews (n=36). Each interview transcript was coded twice, and themes were inductively identified by subgroup (14-17 year olds, 18-24 year olds motivated to quit, and 18-24 year olds not motivated to quit). For each subgroup, themes were grouped into a theoretical model highlighting key capabilities and opportunities necessary for homeless youth to engage supported cessation and mechanisms of change to target for treatment success (Inter-rater reliability Krippendorff's $\alpha=.791$).

Results: Knowledge of evidence-based cessation methods was the key internal capability identified for homeless youth to engage cessation treatment; whereas, stress reactivity, emotion regulation and executive function are theorized mediators of cessation success for the population. External opportunities include on-site tobacco treatment, immediate support following cessation lapse, structured social activities with non-smoking peers, and drop-in center tobacco free policies. Other capabilities and opportunities by subgroup will be presented.

Conclusions: The internal and environmental context must be considered when designing a smoking cessation intervention for homeless youth given the chaotic circumstance in which they live and are trying to make behavior change. Generated models will serve as the theoretical foundation for the selection of contextually-targeted cessation intervention components for homeless youth to be tested using the *Multiphase Optimization Strategy* (MOST), a novel intervention optimization approach.

CULTURAL AND DEMOGRAPHIC CORRELATES OF DUAL TOBACCO USE IN A SAMPLE OF ALASKA NATIVE SMOKERS WITH HEART DISEASE RISK FACTORS

Anna Epperson, PhD¹, Maria Crouch, MS², Jordan D. Skan, M.S.³, Neal Benowitz, MD⁴, Matthew Schnellbaecher, MD⁵, Judith J. Prochaska, PhD, MPH⁶

¹Stanford School of Medicine, Turlock, CA; ²ANTHC, Wasilla, AK; ³Alaska Native Tribal Health Consortium, Anchorage, AK; ⁴University of California, San Francisco, San Francisco, CA; ⁵Alaska Native Tribal Health Consortium, Anchorage, AK; ⁶Stanford University, Stanford, CA

Background/Objective: Approximately 9 million U.S. adults use two or more tobacco products regularly. In Alaska, where tobacco is not native, 41% Alaska Native people smoke cigarettes, compared to a state smoking prevalence of 19%. Studies suggest that Alaska Native smokers average fewer cigarettes per day when compared to non-Alaska Native smokers, which may be due in part to dual use with other tobacco products. Previous research suggests that dual tobacco product use may be especially high among Alaska Native people when compared to non-Alaska Native people. The current study examined associations among Alaska Native cultural and demographic characteristics with dual tobacco use.

Methods: Alaska Native smokers in the Norton Sound region of Alaska were recruited as part of a treatment trial targeting cardiovascular disease risk behaviors. The sample was 299 Alaska Native smokers (48.5% female) averaging 46.3 years of age (SD=14.0); identifying as 28% Yup'ik, 61% Inupiaq, and 11% other. In addition to demographics, participants reported whether they spoke their tribal language, how much they identified with their tribal heritage, and tobacco-related behaviors. The primary outcome was dual tobacco product use (cigarette smoking plus use of chew/snuff, e-cigarettes, and/or iqmik, an ash from the birch tree fungus mixed with tobacco leaves to be chewed), defined as used every day or some days and within the previous month.

Results: The majority (85%) reported somewhat or strongly identifying with their Alaska Native heritage. The sample averaged 12.4 cigarettes/day (SD=10.0), and past 30-day dual tobacco use (10%) was reported by gender as: chew/snuff (14% males, 3% females), e-cigarettes (1% males, no female use), or iqmik (1% males, 3% females). Regression models indicated that men (OR = 3.18, $p = .014$) and participants identifying as Yup'ik (OR = 2.90; $p = .029$) were more likely to be dual tobacco users. Dual use was less likely among participants who were older (OR = 0.95, $p = .003$) and those who more strongly identified with their Alaska Native heritage (OR = 0.33, $p = .024$).

Conclusions: Dual tobacco use may challenge successful tobacco cessation efforts. E-cigarette use was next to nonexistent. Cultural factors, such as tribal affiliation and identification with Alaska Native heritage, associated with dual tobacco use among Alaska Native people warrant further consideration and attention in tobacco treatments. Commercial dual use, particularly among men and those identifying as Yup'ik, is more common as a dual use pattern in this Northern Alaskan community and should be included as a target in tobacco treatment.

10:30 AM-11:30 AM

PERCEIVED HARM AND VAPING/MARIJUANA DUAL-USE AMONG LATINO AND NON-LATINO HIGH SCHOOL STUDENTS IN COLORADO

Bethany Canales, MPH¹, Patricia A. Valverde, PhD MPH²

¹University of Colorado Denver, Denver, CO; ²Colorado School of Public Health, Aurora, CO

Youth perception of harm of vaping and marijuana products is low. As more young adults begin to vape both tobacco and marijuana, it is important to evaluate risk factors for their use. This study evaluates the association between perceived harm and vaping/marijuana dual-use among Latino and non-Latino high school students in Colorado.

Methods: We analyzed data on 13,546 students aged 12 to 18+ years participating in the 2017 Healthy Colorado Kids Survey. Variables included: grade (9/10/11/12/Ungraded), ethnicity (Latino/non-Latino), race (White/Black/Asian/American Indian or Alaska Native/Native Hawaiian or Pacific Islander/Multiracial), sexual orientation (LGBQ/heterosexual), grades (A's or B's/C's/D's, F's, or Not Sure), perceived harm of vaping and marijuana products (No or Slight Risk/Moderate or Great Risk), and dual-use (No Products Used/At Least One Product Used/Both Products Used) based on whether a student used a vapor and/or marijuana product in the past 30 days. We calculated odds ratios and 95% confidence intervals using 2 multinomial logistic regression models to evaluate the association between perceived harm and dual-use while controlling for other variables.

Results: 19.3% of students identified as Latino and 80.7% as non-Latino. 17.2% of Latinos were dual-users compared to 13.6% of non-Latinos. Among Latino dual-users, 58.7% believed vaping and marijuana products had no/slight risk of harm and 11.2% believed both had moderate/great risk of harm; among non-Latino dual-users, 58.1% and 11.5% believed both had no/slight and moderate/great risk of harm respectively. Latinos had a 3.7 greater odds (CI:2.7-5.1; $p=0.00$) and non-Latinos had a 5.9 greater odds (CI:4.8-7.2; $p=0.00$) of using at least one product if their perception of harm was no/slight for both products compared to non-users who believed both products had moderate/great risk of harm. Also, Latinos had a 5.8 greater odds (CI:3.4-9.8; $p=0.00$) and non-Latinos had a 10.18 greater odds (CI:8.1-12.8; $p=0.00$) of being a dual-user if their perception of harm was no/slight for both products. Race and sexual orientation appeared to have a larger effect on dual-use for Latinos compared to non-Latinos, with Latino Black students having a 3.2 greater odds (CI:1.8-5.7; $p=0.00$) of dual-use compared to Latino White students and LGBQ Latino students having a 2.0 greater odds (CI:1.2-3.6; $p=0.01$) of dual-use compared to heterosexual Latino students.

Conclusion: Latino students were more likely to be dual-users than non-Latino students. Although perceptions of harm did not differ by ethnicity, the effect of believing these products had no/slight risk of harm was much larger for non-Latino students. However, Latino minorities had a greater risk of being dual-users compared to non-Latino minorities. Additional studies are needed to evaluate protective factors among Latino students and other influencers of dual-use.

TRAUMA, COPING, AND GROWTH FOLLOWING COMPLICATED CHILDBIRTH: DIFFERENCES FOR NICU MOTHERS

Meghan Sharp, PhD¹, Julia Dodd, PhD², Christyn Dolbier, Ph.D.³¹Women's Medicine Collaborative, Lifespan, Providence, RI; ²East Tennessee University, Johnson City, TN; ³East Carolina University, Greenville, NC

Introduction: Mothers who experience adverse medical events in childbirth report greater postpartum emotional distress. Mothers of infants hospitalized in the neonatal intensive care unit (NICU) are at even higher risk, as they face unique NICU stressors that complicate postpartum psychological adjustment. Little is known about differences in trauma experiences for NICU mothers following medical adversity in childbirth.

Method: Women who had a difficult/adverse childbirth ($N = 204$) were recruited in the first year postpartum via social media advertisements for an online survey about perinatal experiences. The majority were White (89%), married (76%), and primiparous (60%) with $Mage = 29.46$. 41% ($n = 83$) had a baby admitted to the NICU. Participants completed measures assessing traumatic childbirth, posttraumatic stress disorder (PTSD), postpartum depression, coping strategies, posttraumatic cognitions, and posttraumatic growth.

Results: NICU mothers were more likely to have a traumatic childbirth [86% vs. 64%, $\chi^2(1) = 11.13$, $p = .001$]. There were no differences between NICU and non-NICU mothers on measures of PTSD, posttraumatic cognitions, or depression. Univariate analyses revealed significantly higher emotional disengagement coping, but this difference did not persist in multivariate analyses with relevant demographic and obstetric covariates. Linear regression analyses including relevant covariates indicated that NICU mothers engaged in more maladaptive self-criticism to cope ($B = 2.98$, $t = 2.73$, $p = .008$). NICU mothers also reported significantly more posttraumatic growth pertaining to spiritual change ($B = 1.65$, $t = 2.23$, $p = .029$) and appreciation of life ($B = 2.28$, $t = 2.27$, $p = .026$).

Conclusion: All participants in this sample experienced adverse medical events during childbirth, but only a subset had a baby admitted to the NICU. There was no difference in postpartum emotional distress between NICU and non-NICU mothers; however, NICU mothers were more likely to engage in self-critical maladaptive coping. These results are consistent with the literature citing self-blame as a common problem for NICU parents, particularly mothers. Programs designed to support NICU mothers should include stressor-specific skills aimed at building adaptive coping. Spiritual change and appreciation of life may represent areas of resilience in this population, as NICU mothers reported more personal growth in these areas.

FEASIBILITY OF A HOME-BASED ONLINE YOGA INTERVENTION IN WOMEN WHO HAVE EXPERIENCED STILLBIRTH?

Jennifer Huberty, PhD¹¹ASU, Phoenix, AZ

Introduction: Over 2.6 million babies die each year from stillbirth, (death of a baby 20 wks gestation to birth). Bereaved mothers are at increased risk for symptoms of post-traumatic stress, anxiety, and depression. Yoga has been used in other populations to reduce symptoms of post-traumatic stress and may be feasible following a stillbirth. The purpose of this study was to determine the feasibility of a 12-wk, home-based, online-streamed yoga intervention and a stretch-and-tone control group with varying doses. Data from this study will be combined with other formative data and used to inform a multiphase optimization strategy (MOST) design trial.

Methods: Participants were recruited nationally. Ninety women were randomized into one of three groups (low dose, 60-min per wk; moderate dose, 150-min per wk; and stretch-and-tone control group). All participants completed weekly logs for attendance and minutes of participation in yoga was also tracked online with Wistia software. Satisfaction surveys were completed post-intervention.

Results: Thirteen participants (14%) dropped out (e.g., pregnant, mood related) and 29 (32%) did not complete the intervention, with 48 (53%) completing the study. Benchmarks were met for all groups related to enjoyment, and satisfaction. Benchmarks were met in the low dose and control groups regarding appropriateness of the prescribed dose. In the moderate dose group, 57% thought the prescribed dose was too much. Benchmarks for attendance (i.e., time spent in yoga) were not met in either the low or moderate dose groups, 29% and 8% respectively. Across the intervention, low, moderate, and control groups averaged 21, 85, and 55 min/wk of yoga, respectively. Over 60% of participants reported they would continue practicing online yoga or exercise and recommend the intervention to women who have experienced stillbirth. Almost 70% reported they would have participated more if the study had a social support group and 96% reported social support should be included in future studies.

Discussion: The online yoga intervention (and control group) was feasible. Although participants were satisfied with the intervention, they did not meet expected benchmarks for participation. Sixty min/wk of yoga was reported to be more appropriate than 150 minutes. Future studies should explore the feasibility of online yoga with a social support component as well as determining the resources women need to be successful at participating in online yoga.

Objective 1: Identify the need for mental and physical health interventions for stillbirth mothers.

Objective 2: Identify components of an online yoga intervention that may be necessary to improve compliance to the intervention.

PROVIDER RECOMMENDATIONS AND PATIENTS' DECISIONS TO ENGAGE IN LIFESTYLE BEHAVIORS FOR OSTEOPOROSIS PREVENTION AND MANAGEMENT

Veronica M. Pereira, B.S.¹, Katherine M. McLeod, PhD¹, Shanthi Johnson, PhD, RD²¹Frank H. Netter School of Medicine, Quinnipiac University, Hamden, CT;²University of Alberta, Edmonton, AB, Canada

Introduction: Adequate calcium and vitamin D intake and physical activity are key lifestyle behaviors to prevent and manage osteoporosis, yet remain sub-optimal among older adults. While effective patient-physician communication is integral in clinical practice, little is known of the impact on patients' decisions to engage in lifestyle behavior change for osteoporosis prevention or management. The objective of this study was to 1) determine the prevalence of patient-physician communication on recommendations for lifestyle changes, including calcium and vitamin D intake, and physical activity after DXA screening, and 2) evaluate the impact of patient-physician communication on lifestyle behavior change.

Methods: Patients 50 years and older who had no prior diagnosis of or treatment for osteoporosis, and whom their physician referred for initial DXA screening at a hospital in Saskatchewan, Canada were eligible. Calcium and vitamin D (diet and supplement) and physical activity were assessed at baseline and 6-months after DXA. Patient-physician communication and lifestyle recommendations were assessed 6-months after DXA.

Results: The mean age of participants ($n = 188$) was 60.1 ± 7.3 years and 85% were female. Participants who discussed DXA results with their physician and received recommendations to engage in lifestyle behaviors ($n = 68$) were more likely to start or increase calcium intake ($p < 0.01$) and vitamin D intake ($p = 0.02$) and had a greater mean change in total calcium and vitamin D ($p < 0.01$) compared to patients who discussed results with their physician but received no recommendations ($n = 35$) or had no physician follow-up ($n = 85$). In adjusted models, receiving lifestyle recommendations from a provider and receiving osteoporosis education were independently associated with patients' decisions to engage in lifestyle behaviors to prevent or manage osteoporosis.

Discussion: The present study takes an important step toward understanding the role that patient-physician communication plays in fostering a patient's lifestyle behavior change to prevent and manage osteoporosis.
