Course 1 8:30 AM-11:00 AM

CROSS-NATIONAL COMPARISONS OF PSYCHOLOGICAL STRESS: USING THE HEALTH AND RETIREMENT STUDY AND 9 SISTER STUDIES TO UNDERSTAND STRESS, HEALTH, AND CULTURE

Alexandra Crosswell, PhD, Kimberly Lockwood, PhD, Drystan Phillips, MA,
Elissa S. Epel, PhD¹

¹University of California, San Francisco, San Francisco, CA

This workshop, hosted by leaders of the NIA-funded Stress Measurement Network and the Gateway to Global Aging Data, will introduce researchers to a newly available resource for studying the relationship between stress, health, aging, and culture. Measures of psychological stress that are included in the Health and Retirement Study and 9 other sister studies, have been harmonized. These sister studies are: English Longitudinal Study of Ageing (ELSA), the Survey of Health, Ageing, and Retirement in Europe (SHARE), the Mexican Health and Aging Study (MHAS), the Costa Rican Longevity and Healthy Aging Study (CRELES), the Korean Longitudinal Study of Aging (KLoSA), the Japanese Study of Aging and Retirement (JSTAR), the Irish Longitudinal Study of Ageing (TILDA), the Chinese Health and Retirement Longitudinal Study (CHARLS), and the Longitudinal Aging Study in India (LASI). This means that self-report questionnaires from all waves of all 10 studies have been combed through carefully to identify every survey items that capture a stress-related construct. These items were categorized in to eight domains of stress: early life stress, stressful life events/ traumatic events, chronic stressors, job stress, discrimination, social strain and unsupportive relationships, loneliness, and neighborhood chaos. Our team is hosting this interactive workshop for trainees and junior investigators interested in taking advantage of this tremendous data resource. The attendees will be introduced to the many stress measures harmonized across the studies and receive in-depth training on how to access and utilize this resource. We will lead participants through an exercise in which they identify a research question, the studies and measures they will use, and the analytic technique they will deploy. We will build in time for small group and individual consulting to help attendees brainstorm and refine their own research questions. These workshops will be hosted by a leader of the Stress Measurement Network in collaboration with a member of the Gateway to Global Aging team.

Course 2 8:30 AM-11:00 AM

AN INTRODUCTION TO ADAPTIVE INTERVENTIONS AND SEQUENTIAL MULTIPLE ASSIGNMENT RANDOMIZED TRIALS (SMART)

Ahnalee Brincks, Ph.D.¹, Shawna N. Smith, PhD²

¹Michigan State University, East Lansing, MI; ²University of Michigan, Ypsilanti, MI

Disease prevention and disease management often require adjustment to intervention or treatment based on individual response or changing needs. Adaptive interventions provide an operationalized framework for decisions about whether, when, how and for whom to alter an intervention or treatment for optimal outcomes. In the first half of this course, we introduce adaptive interventions including key elements of an adaptive intervention, contexts in which adaptive interventions are beneficial, and important considerations in the design of adaptive interventions. The second half of this course is devoted to the sequential multiple assignment randomized trial, or SMART. We will demonstrate how SMARTs inform the development of high-quality adaptive interventions, discuss the research questions related to adaptive interventions that SMARTs can address, and offer considerations for designing and powering SMARTs. We will provide examples of adaptive interventions and SMART experiments throughout the course. Resources for further reading and training will also be provided.

CORRESPONDING AUTHOR: Ahnalee Brincks, Ph.D., Michigan State University, East Lansing, MI; brincksa@msu.edu

Course 3 8:30 AM-11:00 AM

NIH CLINICAL TRIALS SHORT COURSE: ENFORCEMENT, FLEXIBILITIES, AND TOOLS FOR THE SOCIAL-BEHAVIORAL COM- MUNITY

William N. Elwood, Ph.D.¹, Christine M. Hunter, PhD², DAWN A. MORALES, Ph.D.³, Alyssa A. Tonsing-Carter, Ph.D.¹, Rebecca J. Williams, Pharm.D, MPH¹, William T. Riley, Ph.D.⁴

¹National Institutes of Health, BETHESDA, MD; ²Office of Behavioral and Social Sciences Research, National Institutes of Health, Bethesda, MD; ³National Institute of Mental Health, Bethesda, MD; ⁴National Institutes of Health, Bethesda, MD

across the lifecycle of clinical research; including application submission, trial registration, submitting progress reports, and reporting final study outcomes. The NIH broadly defines a clinical trial as a “research study in which one or more human subjects are prospectively assigned to one or more interventions (which may include placebo or other control) to evaluate the effects of those interventions on health-related biomedical or behavioral outcomes.” This short course will provide an overview of the clinical trial policies, discuss how they apply to behavioral and social science research, and describe resources and tools to assist with successful grant application and study conduct. In addition to the overview, the course will go into more detail about study registration and reporting, protocol development, and considerations for basic experimental research with humans (BESH). The session will include tips and resources for how to register and report behavioral trial information in ClinicalTrials.gov. This will include discussion of several new research design examples (e.g. cluster randomized trials, micro-randomized trials, fractional factorial designs and adaptive designs) and educational tools to assist with registration and reporting. The course will provide an overview of the new protocol template and e-tool that were developed to support researchers in writing protocols for clinical trials that measure a social or behavioral outcome or test a behavioral or social science intervention. Panelist will also provide an overview of BESH, which are studies “that prospectively assign human participants to conditions (i.e., experimentally manipulate independent variables) and that assess biomedical or behavioral outcomes in humans for the purpose of understanding the fundamental aspects of phenomena without specific application towards processes or products in mind.” Current reporting and registration flexibilities for BESH will be reviewed. The course will also include time for questions and discussion between attendees and panelists.

Course 4 8:30 AM-11:00 AM

CREATING OPEN AND TRANSPARENT BEHAVIORAL MEDICINE RESEARCH: ESSENTIAL CONCEPTS, SKILLS, AND TOOLS

Ian Sullivan, n/a¹, Laura D. Scherer, PhD², Megan A. McVay, PhD³

¹Center for Open Science, Charlottesville, VA; ²University of Colorado, Aurora, CO; ³University of Florida, Gainesville, FL

Description: Increasingly, behavioral medicine researchers are being asked by journal editors and funders (including National Institute of Health) to demonstrate that their science is transparent and reproducible. This workshop will introduce concepts as well as present concrete steps researchers can take to increase the transparency and reproducibility of their research. Topics include project documentation, pre-Analysis plans, and strategies to plan for and facilitate data sharing. Open source tools that facilitate implementation of transparent practices in a scientific workflow will be presented. The workshop will be hands-on and is aimed at graduate students, postdocs, and faculty across disciplines. No knowledge of programming or other specialized tools is required. Attendees will need to bring their computer.

CORRESPONDING AUTHOR: Megan A. McVay, PhD, University of Florida, Gainesville, FL; megan.mcvay@ufl.edu

Course 5**8:30 AM-11:00 AM****CANCER-RELATED DATA RESOURCES TO FACILITATE YOUR BEHAVIORAL RESEARCH**Richard P. Moser, PhD¹, Susan M. Czajkowski, Ph.D.², Frank M. Perna, Ed.D., Ph.D.³, Michelle A. Mollica, PhD, MPH, RN, OCN⁴¹National Cancer Institute/Behavioral Research Program, Rockville, MD; ²Division of Cancer Control and Population Sciences, National Cancer Institute, NIH, Bethesda, MD; ³National Cancer Institute, ROCKVILLE, MD; ⁴National Cancer Institute, Bethesda, MD

The National Cancer Institute (NCI) and other government agencies have many data sources that can be used by behavioral researchers to answer important questions related to cancer prevention and control. These datasets can be valuable sources of information on the relationships between psychosocial, environmental, health policy and health system-level variables and cancer-related behavioral and health outcomes. The purpose of this course is to familiarize SBM attendees with several key NCI-supported data resources and facilitate their ability to utilize these data sources, alone and in conjunction with other health-related datasets through data linkages.

This course will begin with an overview of the federal government's data ecosystem and then describe in detail several relevant cancer-related data sources. These publicly-available resources contain survey data that assess psychosocial, behavioral and policy-related predictors, moderators/mediators and outcomes. Other existing data sources will be described that can be linked with these survey data to extend the utility of the data and offer opportunities to answer novel cancer-related research questions, including the ability to assess factors at multiple levels of influence (e.g., cells to society). Several applied examples—using data particularly suited for behavioral researchers—will be presented demonstrating how the NCI-supported datasets can be linked to other publicly available data in order to educate attendees on these methods and inspire them to conduct similar projects. These datasets include the Surveillance Epidemiology and End Results (SEER) linked data (SEER-MHOS and SEER-CAHPS), Health Information National Trends Survey (HINTS) and the Classification of Laws Associated with School Students (CLASS). Lastly, NCI program officers will discuss several NIH funding mechanisms that can support these types of linkage studies and will answer attendees' questions during a final discussion period.

CORRESPONDING AUTHOR: Richard P. Moser, PhD, National Cancer Institute/Behavioral Research Program, Rockville, MD; moserr@mail.nih.gov

Course 6**8:30 AM-11:00 AM****COMMUNITY HEALTH PROGRAMS: EVALUATION FRAMEWORK, LESSONS LEARNED, AND APPLIED PRACTICE**Ryan J. Kalpinski, Ph.D.¹, Mario G. Nicolas, Ph.D.², Gerald W. Talcott, Ph.D.³, Andrew Dunkle, Ph.D.⁴¹United States Air Force, JB ANDREWS, MD; ²Chenega Corp. (Contractor for Air Force Medical Operations Agency), San Antonio, TX; ³University of Virginia, SAN ANTONIO, TX; ⁴United States Air Force, San Antonio, TX

Community health programming holds great promise. Critically, too few such programs exist, in addition to which many that do exist fail ultimately to produce the outcomes for which they were designed. How can this be so?

Evident on review of the Department of Defense's and Veterans Administration's portfolio of effort are a broad variety of community health programs that have reached dissemination. Resulting are practical considerations for program development, implementation, and evaluation of direct relevance to behavioral scientists who mean to make a difference at the population level.

The goal of this pre-conference course is to leverage Grembowski's (2016) framework for program evaluation to draw 'lessons learned' from among a series of real-world programs noteworthy both for their successes and for challenges they continue to face in the domains of dissemination and maintenance. Topics of central focus will include: Assessment of the needs and preferences of persons and institutions residing within the community; strategies by which to make an inventory of local resources and strengths; integration of stakeholder perspectives; the design of implementation-support tools; and the development of a coordinated plan for evaluation, iterative refinement, and maintenance. The pre-conference course will conclude with an 'application lab' during which attendees will develop or refine a community health program relevant to the community they serve.

Course 7**11:30 AM-2:00 PM****PRACTICAL STRATEGIES FOR COST-EFFECTIVENESS ANALYSIS IN RANDOMIZED CONTROLLED TRIALS**Jennifer Funderburk, PhD¹, Cerissa L. Blaney, PhD², Jeffrey Hoch, PhD³¹VA Center for Integrated Healthcare, Syracuse, NY; ²Lifespan / Brown University, Barrington, RI; ³University of California at Davis, Sacramento, CA

Increasingly, researchers are being asked to provide information on the value of their behavioral treatments. This goes beyond, "How well does the treatment work?" or even, "How much does it cost?" The core issue is considering the extra gains in light of the extra costs. To address this issue, one must analyze costs and effectiveness simultaneously in a cost-effectiveness analysis. This course introduces Practical Strategies for Cost-Effectiveness Analysis in Randomized Controlled Trials.

A recently completed multi-site RCT on a brief behavioral activation intervention for depression in primary care led by Dr. Funderburk serves as the practical example for the session. Brief "theory bursts" will be followed with group discussions focused on how to apply the ideas recently introduced. Given the level of the course and the focus on RCT data, the main analytic technique will be net benefit regression. Dr. Hoch and colleagues invented net benefit regression and published an award-winning article about it in 2002. By varying the value for willingness to pay, it is possible to study both the extra cost, the extra effectiveness, and the incremental net benefit using net benefit regression.

In addition, Dr. Hoch will review key Graphs from cost-effectiveness analysis, including the cost-effectiveness plane, the cost-effectiveness acceptability curve and the incremental net benefit by willingness to pay curve. Participants will learn how to interpret the information in these Graphs and how to explain them to non-experts.

CORRESPONDING AUTHOR: Jennifer Funderburk, PhD, VA Center for Integrated Healthcare, Syracuse, NY; Jennifer.Funderburk@va.gov

Course 8

11:30 AM-2:00 PM

WRITING WINNING TRAINING GRANTS: DEVELOPMENT, RESPONDING TO CRITIQUES, AND INCORPORATING TECHNOLOGY INTO PROPOSALS

Danielle Arigo, Ph.D. in Clinical Psychology¹, Graham Thomas, Ph.D.², Susan D. Brown, PhD³, Lisa Cadmus-Bertram, Ph.D.⁴, Carly M. Goldstein, PhD⁵, Stephanie Manasse, Ph.D.⁶, Jessica Y. Breland, PhD⁷, Charles R. Jonassaint, PhD, MHS⁸, Stephanie P. Goldstein, PhD⁹, Matthew C. Whited, Ph.D, Licensed Psychologist¹⁰

¹Rowan University, Glassboro, NJ; ²Brown Medical School, Providence, RI; ³Kaiser Permanente Northern California, Oakland, CA; ⁴University of Wisconsin - Madison, Madison, WI; ⁵The Miriam Hospital/Alpert Medical School of Brown University, Providence, RI; ⁶Drexel University, Philadelphia, PA; ⁷VA Palo Alto Health Care System, Menlo Park, CA; ⁸University of Pittsburgh, Pittsburgh, PA; ⁹Alpert Brown Medical School/The Miriam Hospital Weight Control and Diabetes Center, Providence, RI; ¹⁰East Carolina University, Greenville, NC

Predoctoral and early career training grants such as NIH F/K and VA CDA awards can accelerate a behavioral medicine research career. These grants offer both project funds and protected time for trainees and junior faculty to spend on research and career development activities. Successful applications for training grants require unique training plan and project considerations that are not explicitly described in program announcements. The processes of initial application preparation and responding to critiques confer unique pitfalls that can be avoided with effective guidance. In addition, as the use of technology to assess and intervene on health behavior becomes more common, applicants must pay special attention to strategies for integrating technology-related research and training aims in training grant proposals.

The goal of this workshop is to provide advice on preparing strong training grant proposals from experienced and successful SBM members. Speakers include current and former awardees, mid-career investigators who have successfully transitioned to R-level funding, and training grant mentors. Presentations and discussions will focus on the unique aspects of F, K, and CDA applications, with emphasis on 1) considerations for initial proposal preparation, 2) best practices for responding to critiques and incorporating technology into research and training plans, and 3) long-range planning for the transition to independent funding. The session also will feature breakout groups for attendees focused on each type of training grant. Attendees at all stages of the proposal process will have opportunities to ask questions and receive guidance in the development of their individual training and research aims.

Participants will be asked to bring a laptop, smartphone, or tablet device to facilitate engagement in activities.

Course 9

11:30 AM-2:00 PM

A PROJECT MANAGEMENT GUIDE FOR THE PLANNING AND EXECUTION OF BEHAVIORAL RESEARCH TRIALS

Jessica L. Bibeau, MA, PMP¹, Kim Massie, B.S.², Julia Berteletti, MSW³

¹University of Connecticut, Storrs, CT; ²Claremont Graduate University, South Jordan, UT; ³Klein Buendel, Inc., Golden, CO

The goal of this workshop is to provide guidance to investigators or coordinators on how to manage research projects using a formal project management approach. Regarding project management, there are many similarities between research and business industries. In both cases, there are temporary endeavors with sponsors, specified deliverables, subcontracts, a set budget, and timeline. However, the use of formal project management guidelines and training is not common in behavioral research. The Project Management Book of Knowledge (PMBOK) is a widely accepted standard that offers a guide for best practices for managing projects. The PMBOK includes a description of each phase of a project (initiation, planning, execution, monitoring/controlling, and closing) as well as the processes to accomplish each phase successfully. Each process has inputs, tools, and outputs for completing the phase objectives. The guide provides a framework for a smooth flow through each phase, starting from project initiation through closing. It provides tools to reduce the risk of the project creeping outside of the budget or timeline, and ensures that what is completed is accurate and meets quality expectations. Many investigators and coordinators receive training from peers, predecessors, or learn as they go. Lack of formal training creates potential for errors, missed deliverables, and overspent or misspent budgets. Certified project managers aren't usually budgeted in a grant due to funding restrictions and/or limited institutional support. This workshop will specifically focus on the planning and execution stages of the process. Using guidelines from the PMBOK, we will: discuss the importance of scope development and how that will drive the foundation of the project management plan; review how to break down the scope to identify specific project activities and deliverables; assign activities to individuals and develop the project calendar; plan project resources and cost; discuss the importance, strategies, and plans for communication; and provide a strategy for managing the project work. Understanding formal project management strategies will help in the successful planning and execution of research projects. Implementing these strategies in a research environment will help align research to the project management standards. This seminar is geared toward new faculty, managers, coordinators, postdoctoral fellows and graduate students.

Course 10

11:30 AM-2:00 PM

YOU ARE MORE THAN YOUR CRAVINGS!

Maria Karekla, PhD¹, Megan Kelly, Ph.D.²

¹University of Cyprus, Nicosia, Nicosia, Cyprus; ²Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA

The application of Acceptance and Commitment Therapy (ACT) for the treatment of many problems where craving is a core feature is growing (e.g., substance use, tobacco use, overeating, gambling, compulsive sexual behavior). Individuals presenting with such difficulties often have difficulty managing cravings, although this is an inevitable aspect of experiencing substance use and other addictive and compulsive behaviors. Difficulties involving cravings are associated with substantial distress, functional impairment, and low quality of life. This workshop will present the latest developments in ACT for the treatment of difficulties where craving is an important component. The workshop will also present the latest developments in ACT for dealing and overcoming cravings, and examine the efficacy, the mechanisms, and processes of change of ACT for the treatment of craving-related problems. Concepts will be illustrated using live demonstrations, experiential exercises, metaphors, and worksheets. This workshop is designed to teach skills needed to explore ACT as an assessment model and intervention method for

addressing craving. It will be mostly experiential and will balance an understanding of the model with a personal connection with the issues raised in ACT, and with skill development.

IDEAS TO IMPACT: SUCCESSFUL PARTNERSHIPS TO CO-DESIGN AND DISSEMINATE DIGITAL HEALTH INTERVENTIONS AT SCALE

Danielle Ramo, PhD¹, Jana Haritatos, PhD¹, Andrew Baker, N/A², Kate Wolin, ScD³, Robert Morris, PhD⁴, Faye Sahai, MBA, SAPM⁵, Sarah Seegal, n/a⁶, Anne Wu, B.A. Psychology, B.A. Economics⁷

¹Hopelab, San Francisco, CA; ²Grit Digital Health, denver, CO; ³Coeus Health, Chicago, IL; ⁴Airbnb, San Mateo, CA; ⁵Vinaj Ventures- Telosity.io, Redwood City, CA; ⁶Affect Mental Health, San Francisco, CA; ⁷HackMentalHealth, San Francisco, CA

Digital interventions offer the opportunity to distribute health behavior change interventions to young people at scale. However, in practice, many interventions developed in academic settings, even the most rigorously designed and evidence-based, lack a clear pathway toward long-term viability and impact. Do you have a digital intervention (early-stage or studied for many years), and want a chance to workshop it with multidisciplinary experts who have worked to evaluate and disseminate digital interventions to audiences beyond your research participants? Then this preconference workshop is for you.

There have been remarkable advances in the science of behavior change and its application to promoting health and wellbeing, including using technology to deliver interventions. Even so, there is an opportunity to make a stronger impact, particularly with adolescents and young adults (AYA), in whose lives technology is so well-integrated. Imagine a world in which young people could benefit from positive messaging around health behavior as easily as they are exposed to messaging from companies who are trying to sell them products that may be harmful to their health. How can researchers efficiently translate the most promising scientific findings about drivers of youth health and wellbeing into real-world products in a meaningful, ethical, and impactful way?

The goals of this AYA Health Translational Science Pre-Conference are to provide researchers with 1) tools for successful translation to tech at scale; and 2) the opportunity to pitch good ideas to interested potential industry partners and investors. The workshop will include a combination of talks from researchers, industry insiders, product leads, and investors who have successfully evaluated and brought a digital health product to market for the benefit of a large population. It will also include an opportunity for participants to pitch their ideas for science-backed tech products benefiting AYA health in front of a multidisciplinary panel of experts and a cash prize will be awarded for the most promising idea. Finally, attendees will be able to make connections with industry and investor representatives and seed potential future collaborations.

DHC PRESENTS: GETTING OUR STUDENTS INDUSTRY-READY: A DESIGN-ORIENTED WORKSHOP TO ADVANCE TRAINING FOR CAREERS IN INDUSTRY

Cynthia M. Castro Sweet, PhD¹, Eric B. Hekler, PhD², Jennifer C. Taylor, PhD², Melanie Hingle, PhD, MPH, RDN³, David Strong, PhD⁴

¹Omada Health, San Francisco, CA; ²UC San Diego, San Diego, CA; ³University of Arizona, Tucson, AZ; ⁴University of California, San Diego, San Diego, CA

As noted by Dr. Sherry Pagoto in her 2019 SBM presidential keynote, there is both strong interest among SBM students and trainees in positions in industry and, simultaneously, a dearth of experience among faculty and training programs to support or assist students in this career pathway. A 2018-member survey indicated that more than half of SBM members are interested in preparing their students for industry careers; at the same time, faculty expressed the need for guidance in how best to support their students in pursuing careers outside of academia. Current masters and doctoral programs in behavioral medicine and related fields do not include training elements designed to prepare students to graduate “industry-ready.” In addition, the major path from graduate and post-doctoral training to an industry job is via internship programs and professional networking, but at present, few SBM-affiliated training programs have active industry-oriented programs.

The purpose of this design workshop is to bring together industry professionals, faculty and training program directors seeking to incorporate industry preparedness into their curricula, and students and trainees interested in industry positions to work together to devise strategies to prepare behavioral medicine trainees to become industry-ready. The workshop will explore issues of mentorship, course offerings, and internship/externship developments with the goal of providing concrete actionable next steps (e.g., an open educational resource) to enhance the industry preparedness training currently offered by SBM faculty at their home institutions.

Participants will be actively involved in crafting an approach for integrating industry-readiness in University-provided training programs. As such, this workshop is intended for those individuals with an active interest and stake in improving the industry-readiness of SBM trainees and who are committed to helping craft the curricular and experiential requirements necessary to impart “industry readiness”. It is not meant for those who are only causally interested in this topic, who would just like to listen in on the discussion.

INCLUSION AND RETENTION OF OLDER ADULTS IN BEHAVIORAL MEDICINE CLINICAL TRIALS: WHY AND HOW?

Kathi L. Heffner, PhD¹, Neha P. Gothe, MA, PhD², Lisa Onken, Ph.D. Clinical Psychology³, Jonathan W. King, PhD⁴, David X. Marquez, PhD, FGSA, FACSM, FSBM⁵, Katherine Hall, PhD⁶, Robert L. Newton, PhD⁷

¹University of Rochester Medical Center, Rochester, NY; ²University of Illinois at Urbana Champaign, Urbana, IL; ³National Institute on Aging, Bethesda, MD; ⁴National Institute on Aging / NIH, Bethesda, MD; ⁵University of Illinois at Chicago, Chicago, IL; ⁶Durham VA Health Care System, Durham, NC; ⁷Pennington Biomedical Research Center, Baton Rouge, LA

For decades, there has been a disparate underrepresentation of older adults in clinical trials. To address this issue, in 2017, the National Institutes of Health changed policy and guidelines regarding the inclusion of individuals across the lifespan, requiring that individuals of all ages, including older adults, be included in NIH-funded clinical research unless there is sufficient justification for their exclusion. This pre-conference course will help behavioral scientists' efforts to comply with this policy to ensure that findings from behavioral medicine intervention trials are generalizable to the older adult population. The workshop will start with a presentation from program directors from the National Institute on Aging Division of Behavioral and Social Research, who will providing an overview of the NIH policy and guidelines, and how NIH grant applicants can be responsive to the guidelines. Next, principal investigators conducting NIH-funded clinical trials targeting older adults will present their experiences, lessons learned, and strategies for recruiting and retaining older adults in behavioral intervention studies with longitudinal follow-up. Topics will include: unique barriers and challenges to recruiting and retaining older adults in research; how to advertise and effectively reach and engage sub-populations of older adults, including informal caregivers and underrepresented older minorities, to ensure their participation in research; existing tools available to support investigators' efforts to engage older adults in clinical trials. The workshop will end with a Q&A with our panel of presenters engaging in open discussion with attendees to answer questions and share ideas. This course will be of particular interest to early-stage and new investigators embarking upon behavioral medicine intervention trials, as well as seasoned researchers whose scientific areas would benefit from expansion of study recruitment to the older adult population.

ENHANCING INTEGRATED BEHAVIORAL HEALTH PRACTICES: EVALUATION AND MEASUREMENT OF REAL-WORLD IMPLEMENTATION

Jennifer Funderburk, PhD¹, Rodger S. Kessler, PhD², Kari A. Stephens, PhD³, Helene Chokron Garneau, PhD⁴, Cerissa L. Blaney, PhD⁵, Mark McGovern, NA⁶

¹VA Center for Integrated Healthcare, Syracuse, NY; ²Arizona State University, Phoenix, AZ; ³University of Washington, Seattle, WA; ⁴Stanford University, Palo Alto, CA; ⁵Lifespan / Brown University, Barrington, RI; ⁶Stanford University School of Medicine, Palo Alto, CA

Integrated healthcare providers have a unique opportunity to help provide and promote evidence-based care to the field and utilize evaluation and measurement to help with practice transformation. This workshop is intended to help healthcare providers working within integrated primary care clinics better understand the value of evaluation and assessment in real-world clinical practice. Measures that can be used to assess levels of integration, progress, and to tailor implementation strategies being used to install and sustain integrated behavioral health in primary care will be presented, as well as their real-world application at Stanford Health Care Primary Care clinics. We will describe a cross-model integrated behavioral health framework as a concrete target and how different types of measures can be used to support efforts within clinical settings to transform care. Measures can be used that reflect organizational readiness and capacity to change along multiple dimensions and levels of current integration for measuring baseline and progress with change. They draw from cutting edge dissemination and implementation science. Participants will be asked to engage in the material and identify ways they may utilize these measures in their practices and how it would contribute to practice transformation. Presenters will then share emerging hybrid implementation research designs that are suitable for practice focused research.

BETTER, FASTER, STRONGER: APPLYING THE AGILE METHOD IN DIGITAL HEALTH INTERVENTIONS AND PROJECT MANAGEMENT

Lyndsay A. Nelson, PhD¹, William Martinez, MD, MS¹, Will Acuff, MAB², Anthony L. Threatt, Ph.D.³, Lindsay S. Mayberry, MS PhD¹¹Vanderbilt University Medical Center, Nashville, TN; ²N/A, Nashville, TN; ³ProviderTrust, Nashville, TN

The agile method is a specific approach to product and software management for developing products rapidly and iteratively. Principles and tools of the agile method include inputs from end-users, continual reflection and iteration, and frequent structured communication among all team members. Teams are often cross-disciplinary, each member representing an aspect of the product or process. Compared to more traditional, linear approaches to product management, work is delivered more quickly with more appeal to end-users and, ultimately, more value.

In the software and product world there are many examples of how the agile method leads to better products that meet real-world needs quickly. However, to date there are few examples of this approach in research. In this course, we will discuss how to apply the agile method to research involving digital health interventions. In traditional models of scientific research, processes are often slow and outcome evaluation can be hindered by ineffective products or solutions. We will demonstrate the benefits of applying agile methods to research such that teams can learn quickly about the best course of action to maximize the likelihood of a successful project.

Our workshop will introduce participants to the agile method including its principal processes and tools, such as timeboxing, sprints, agile meeting structures, and iterative planning and feedback. We will then discuss how and why to apply an agile methodology to research, with a particular focus on digital health interventions. Specifically, we will discuss how an agile mindset and agile processes can be applied at any phase of the research including agile study designs (e.g., MOST and SMART), usability testing, evaluation, and team management. We will demonstrate these applications using examples from our work in diabetes self-management support interventions. Staying true to an agile approach, workshop presenters will include individuals from various disciplines, including behavioral science, clinical care, technology, and user experience.

All participants will leave with the skills and resources needed to apply the agile method to their own research projects and teams. Valuable hand-out materials outlining the tools and processes as well as additional resources will be disseminated. Our goal is to demonstrate how agile methods can be applied in research so teams can operate more efficiently and users can benefit sooner from interventions that meet their needs and meaningfully impact outcomes.

Course 14

2:15 PM-4:45 PM

USING R TO PROCESS AND ANALYZE ACCELEROMETER DATA

David Aaby, MS¹, Whitney A. Welch, PhD¹¹Northwestern University Feinberg School of Medicine, Chicago, IL

Accelerometers are widely used in both epidemiological and clinical research studies for estimating the duration and volume of physical activity (PA) and sedentary behavior (SB), as well as estimating PA at varying intensities. Both uniaxial and triaxial accelerometers have been used to capture movement, typically measured as counts per minute in 60-second epochs (cpm). Processing accelerometer data can be challenging, due to its size (1440 data points per day per participant) and structure. Converting accelerometer data to meaningful physical activity variables typically requires three steps: (1) identifying the period in which the accelerometer was not worn and determine which days have sufficient wear time; (2) calculating physical activity variables of interest for each day of wear; (3) calculate averages across all valid days, and perhaps separately for weekdays/weekends.

R, and its user-friendly workspace application RStudio (and its toolset), is an open-source language and environment for statistical computing and graphics. This workshop will introduce the power of using R for managing, preparing, analyzing, and visualizing accelerometer data. The workshop is designed for beginner to intermediate R users. The workshop will be accessible to those with little to no prior experience using R and there is no expectation that attendees are currently using R or RStudio to manage/analyze their data. We expect users come prepared to “live code” and follow along with the instructors during in-class activities.

A short introduction to the R language and RStudio environment will be given by instructors. The remainder of the workshop will focus on the *accelerometry* package in R, which contains the necessary functions for processing accelerometer data. Example-driven instruction, using data from the 2003–2006 National Health and Nutrition Examination Survey (NHANES), will assist attendees in becoming familiar with reading in accelerometry data for multiple subjects, graphically summarizing accelerometer data within subjects, and summarizing accelerometer data in terms of PA and SB using the *accelerometry* package. Attendees will also learn how to customize their analysis to meet a variety of research questions and interests. The package is compatible with both uniaxial and triaxial minute-to-minute count data. The package was designed for analyzing Actigraph accelerometer data, but can analyze cpm from other devices as well. Attendees will be provided with a copy of all lecture notes, select computer output, and suggested reading lists for future reference. Attendees should be prepared to bring a laptop with R and RStudio already installed so that they may follow along with the examples throughout the course. Instructions on how to install R and RStudio will be sent out to course registrants prior to the start of the course.

ASSOCIATION OF ARTERIAL FUNCTION WITH CEREBROVASCULAR RESERVE CAPACITY IN RESISTANT HYPERTENSIVES

Patrick J. Smith, PhD, MPH¹, James Blumenthal, PhD¹, Stephanie Mabe, MS¹, Alan Hinderliter, MD², Andrew Sherwood, PhD¹

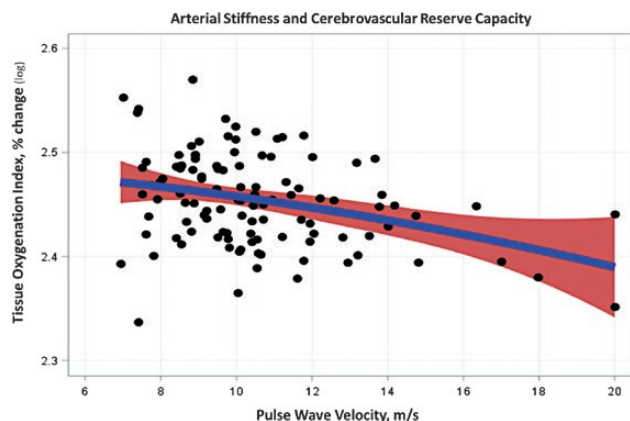

¹Duke University Medical Center, Durham, NC; ²UNC-CH, Chapel Hill, NC

Background: Resistant hypertension (RH) is associated with greater risk of cerebrovascular events and cognitive decline. Cognitive impairments in hypertension are hypothesized to result from subclinical arterial dysfunction, resulting in impaired cerebrovascular reserve. No studies, to our knowledge, have examined this among individuals with RH.

Methods: We examined the associations between task-based assessments of cognitive function and cerebrovascular reserve among adults with RH participating in the TRIUMPH study. Cerebrovascular reserve capacity was indexed by changes in tissue oxygenation index (TOI) levels, assessed using functional near infrared spectroscopy, while participants were performing a complex cognitive assessment of working memory / executive function (mental arithmetic). Arterial function was assessed using pulse wave velocity (PWV) and resting brachial artery blood flow velocity. Regression analyses controlled for age, sex, ethnicity, clinic SBP, resting TOI, BMI, antihypertensive medication burden, and task-based cognitive performance.

Results: Participants included 128 middle-aged and older adults (mean age = 62.7 [SD = 9.1]) with RH (mean SBP = 139 mm Hg [SD = 10]). Participants tended to be obese (mean BMI = 36.0 [SD = 5.8]) and were on an average of 3–4 antihypertensive medications (mean # = 3.7 [SD = 0.7]). Lower PWV ($\beta = -0.22$, $P = .035$) and greater brachial artery flow velocity ($\beta = 0.33$, $P < .001$) were associated with greater changes in TOI during mental arithmetic (Figure 1), suggesting increased reserve capacity.

Conclusions: Healthier arterial function was associated with greater task-based cerebrovascular reserve responses among adults with RH. Results suggest that impaired cerebrovascular reserve may be a mechanism by which impaired arterial function increases the risk of cognitive impairment in RH.

PROCESSES OF HEALTH BEHAVIOR CHANGE AMONG AGING ADULTS WITH SERIOUS MENTAL ILLNESS

Anjana Muralidharan, PhD¹, Amanda Peeples, PhD¹, Alicia Lucksted, PhD¹, Richard W. Goldberg, PhD²

¹Veterans Affairs Capitol Healthcare Network, Baltimore, MD; ²VAMHCS, Baltimore, MD

Purpose: Aging individuals with serious mental illness experience significant medical illness burden and would benefit from proactive medical illness management and sustained health behavior change. In a recent randomized controlled trial, Living Well, a 12-week group intervention that provided didactics and skills training to support medical illness management among adults with serious mental illness, was associated with improvements in illness management behaviors compared to an active control condition. Little is known regarding processes of health behavior change among aging adults with serious mental illness; the present study aimed to examine *how* Living Well led to health behavior changes in a subset of participants.

Methods: Data from qualitative interviews from the randomized controlled trial of Living Well, conducted approximately 3 months after participants completed the intervention, were utilized in the present study. A convenience subset ($n=16$, ages 47–75) of Living Well participants were queried in semi-structured interviews about what they learned in Living Well that they were applying to their daily lives, how Living Well impacted the way they thought about themselves and their health, health changes they made during and subsequent to their participation in the group, and their use of action planning and problem-solving skills taught in the group. All interviews were audio recorded with interviewees' permission and transcribed. Interview transcripts were coded using a general inductive approach, with a combination of a priori and inductive codes. Final coding of each interview was completed independently by two members of the analysis team, in rotating pairs; each pair then met to reconcile coding. All coding was entered into NVivo 11. Three authors engaged in-depth thematic analysis of all coded data relevant to *processes of health behavior change*, with an aim to identifying overarching themes.

Results: Engaging with Living Well increased *salience, self-awareness, agency, and activation* of and for health behaviors, through *information, social learning, skills practice, and non-judgmental accountability*, resulting in *behavior changes* (e.g., improved diet) and *physical and mental health status changes* (e.g., weight loss). Living Well also led to a *shift in outlook* for participants, a holistic and lasting sense of realistic self-agency regarding pursuing health behavior change, solving problems, and persisting in one's efforts despite setbacks.

Conclusions: The present study identified key elements of a psychosocial intervention for aging adults with serious mental illness – personalized didactic information, group-based social learning, opportunity for skills practice with feedback, and a social environment of nonjudgmental accountability – which led to positive attitudinal, behavioral, and health status changes.

BLOOD PRESSURE MNGMT AS A POTENTIAL MECHANISM TO REDUCE RISK OF COGNITIVE DECLINE & DEMENTIA: EDUCATING MDS ON BEHAVIOR CHANGE

Andrea Price, EdM, PMP¹¹American College of Preventive Medicine, Washington, DC

Cognitive impairment, including clinical Alzheimer's-type dementia (CATD), mild cognitive impairment (MCI), or age-related cognitive decline (ARCD), affects a growing number of older adults. Given the impact of cognitive impairment on society and the challenges posed by this epidemic, there is increasing interest in innovations in evidence-informed risk reduction of cognitive impairment.

In 2015, the National Institute on Aging (NIA) asked the National Academies of Sciences, Engineering, and Medicine (NASEM) to participate in a two-part project focused on examining the evidence of interventions for preventing, slowing, or delaying the onset of MCI and CATD, and delaying or slowing ARCD. The resulting 2017 NASEM report, "Preventing Cognitive Decline and Dementia: A Way Forward", indicated that blood pressure management for people with hypertension can prevent, delay, or slow cognitive impairment, including ARCD, MCI, and CATD.

This session highlights the latest scientific findings about the benefits of blood pressure management, as well as other healthy lifestyle behaviors, to cognitive health. Furthermore, the session will highlight CDC's Healthy Brain Road Maps and its public health partnerships to implement associated activities in Indian Country and for the broader population. ACPM will provide information on tools that prepare clinical care teams to recommend behavioral interventions for blood pressure control in middle-aged adults to reduce risk of cognitive impairment in later life.

Professional Practice Gap: Clinical care teams may not be aware of the preventive benefits of controlling blood pressure as prevention for cognitive impairment and may need concrete steps for recommending behavioral health interventions.

BEHIND THE RESPONSES TO FALL PREVENTION: PERCEIVED FALL RISKS, FALL PREVENTION STRATEGIES, AND SELF-IDENTIFY

Hiroko Kiyoshi-Teo, PhD, RN¹, Shigeko (Seiko) Izumi, PhD², Kathlynn Northrup-Snyder, PhD, CNS, MSN, RN³¹Oregon Health and Science University, Portland, OR; ²Oregon Health & Science University, Portland, OR; ³Oregon Health & Sciences University, Ilwaco, WA

Background: Older adults are often reluctant to talk about fall prevention and resist taking an active part in fall prevention strategies.

Objectives: Understand how older adults perceive fall risks and fall prevention, and identify attributes that facilitate or hinder their acceptance and engagement in fall prevention.

Methods: A Motivational Interviewing intervention for fall prevention was conducted as part of a larger clinical trial to facilitate behavior changes related to fall prevention. This presentation reports on qualitative content analysis of fall prevention Motivational Interviews. Thirty Motivational Interviews with inpatients (age ≥ 65; high fall risk [≥ 45 on Morse Fall Scale]) at a VA hospital were audio-recorded and transcribed verbatim. Transcriptions were analyzed using conventional qualitative content analysis methods (Hsieh & Shannon, 2005) by 3 researchers.

Results: While some participants were accepting of their fall risks and engaged in fall prevention activities, others were in denial or resigned from fall prevention. Factors influencing their perception for fall prevention included 1) their perceptions about fall risks, 2) types of fall prevention strategies suggested, and 3) their self-identity. If fall risks were considered temporary or "extrinsic" (e.g., recent surgery), participants were more likely to engage in activities to keep them safe. In contrast, if the fall risk was perceived as intrinsic, permanent, or out of their control (e.g., too sick, have no energy, getting old), participants were likely to deny the risk or resign from engaging in fall prevention. Fall prevention strategies that were visible, require a major adjustment in life, or involved others (e.g., using walker/cane, modification of home, asking other's help) were difficult to adopt than those that require minor modifications. Their perceptions about fall risks and fall prevention strategies were weighted with their self-identity. If the risks or strategies did not agree with their self-identity (e.g., I am not that old), they did not engage or accept the fall prevention strategy.

Conclusion: Participants' perceptions about fall risks, fall prevention strategies, and self-identity influenced their acceptance and engagement with fall prevention. The findings underscore the importance of understanding older adults' perceptions to better facilitate individualized approach to engage patients in fall prevention.

COGNITIVE IMPAIRMENT NO DEMENTIA AND ASSOCIATIONS WITH HEALTH LITERACY, SELF-MANAGEMENT SKILLS AND FUNCTIONAL HEALTH STATUS

Rebecca Lovett, PhD¹, Laura M. Curtis, MS¹, Stephen Persell, MD, MPH¹, James W. Griffith, PhD¹, Derin Cobia, PhD², Alex Federman, MD, MPH³, Michael S. Wolf, PhD, MPH¹

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Brigham Young University, Provo, UT; ³Icahn School of Medicine at Mount Sinai, New York, NY

Background: Cognitive impairment no dementia (CIND) increases as the U.S. ages, and is associated with poor health outcomes. CIND may negatively impact health through the ability to independently self-manage illness, given the cognitive demands associated with many health-related tasks.

Objectives: To determine the prevalence of CIND among a diverse, community-based population, and establish associations between CIND and health literacy, chronic illness self-management and functional health status.

Design: Secondary analysis using baseline data from the prospective ‘LitCog’ cohort study.

Participants/Setting: 865 adults without dementia aged 55–74, from six socioeconomically diverse primary care clinics in Chicago, IL.

Main Measures: CIND was categorized according to severity (None, Mild, Moderate/Severe). Health literacy was measured using the Newest Vital Sign (NVS) and Test of Functional Health Literacy in Adults (TOFHLA). The Comprehensive Health Activities Scale (CHAS) was used to measure self-care performance. Patient-Reported Outcomes Measurement Information System (PROMIS) measures were used to determine physical and mental health status.

Key Results: 36% of the sample exhibited CIND. It was strongly associated with greater likelihood of limited health literacy (NVS: Mild [OR 3.25; 95% CI 1.93, 5.49], Moderate/Severe [OR 6.45; 95% CI 3.16, 13.2]; TOFHLA: Mild [OR 3.46; 95% CI 2.08, 5.75], Moderate/Severe [OR 8.82; 95% CI 4.87, 16.0]; all p 's < 0.001) and poor chronic disease self-management (Mild [B = -11.2; 95% CI -13.5, -8.90], Moderate/Severe [B = -21.0; 95% CI -23.6, -18.4]; both p 's < 0.001). There were no significant associations between CIND and functional health status in adjusted models.

Conclusions: In this cohort of older adults, CIND was prevalent and strongly associated with requisite skills for managing everyday health needs. Greater attention to subtle declines in chronic disease self-care may assist with CIND identification and care management within this population. Conversely, when CIND is observed, clinicians should expect and address difficulties with self-management.

THE BIG REVEAL: FAMILY DISCLOSURE PATTERNS OF BRCA GENETIC TEST RESULTS AMONG YOUNG BLACK WOMEN WITH INVASIVE BREAST CANCER

Claire C. Conley, PhD¹, Dana Ketcher, PhD, MPH, CPH², Maija Reblin, PhD³, Monica Kasting, PhD⁴, Deborah Cragun, PhD⁵, Jongphil Kim, PhD⁶, Kimlin Tam Ashing, PhD⁷, Cheryl L. Knott, PhD⁸, Chanita Hughes-Halbert, PhD⁹, Tuya Pal, MD, FACMG¹⁰, Susan Vadaparampil, PhD³

¹H. Lee Moffitt Cancer Center & Research Institute, Tampa, FL; ²Moffitt Cancer Center, Land O Lakes, FL; ³Moffitt Cancer Center, Tampa, FL; ⁴Purdue University, West Lafayette, IN; ⁵University Of South Florida, Tampa, FL; ⁶Moffitt Cancer Center and Research Institute, Tampa, FL; ⁷City of Hope Medical Center, Duarte, CA; ⁸University of Maryland, College Park, MD; ⁹Medical University of South Carolina, Charleston, SC; ¹⁰Vanderbilt University Medical Center, Nashville, UT

Background: Despite higher incidence and mortality of breast cancer among younger Black women, genetic testing outcomes remain severely understudied among Blacks. Past research on disclosure of genetic testing results to family members has disproportionately focused on White, educated, high socioeconomic status women. This study addresses this gap in knowledge by assessing (1) to whom Black women disclose genetic test results and (2) if patterns of disclosure vary based on test result (e.g., *BRCA1/2* positive, negative, variant of uncertain significance [VUS]).

Methods: Black women (N=149) with invasive breast cancer diagnosed age ≤ 50 years from 2009–2012 received free genetic testing through a prospective, population-based study. At 12-months post-testing, women reported with whom they shared their genetic test results. The exact test by binomial distribution was used to examine whether disclosure to female relatives was significantly greater than disclosure to male relatives, and logistic regression analyses tested for differences in disclosure to any female relative, any male relative, parents, siblings, children, and spouses by genetic test result.

Results: Most (65%) women disclosed their results to at least one family member. Disclosure to female relatives was significantly greater than disclosure to males ($p < 0.001$). Compared to those who tested negative or had a VUS, *BRCA1/2* positive women were significantly less likely to disclose results to their daughters (OR_{*BRCA* positive} = 0.08, 95% CI = 0.01–0.71, $p = 0.024$) and mothers (OR_{*BRCA* positive} = 0.12, 95% CI = 0.02–0.98, $p = 0.048$) by 12 months post-genetic testing. Genetic test result did not predict any other type of disclosure (all p 's > 0.08).

Conclusions: Results suggest that in Black families, one benefit of genetic testing – to inform patients and their family with cancer risk information – is not being realized. To increase breast cancer preventive care among high-risk Black women, the oncology care team should prepare Black *BRCA1/2* positive women to share genetic test results with family members and, in particular, their daughters and mothers.

ASPIRIN USE FOR CANCER PREVENTION: A SYSTEMATIC REVIEW OF PATIENT AND HEALTHCARE PROVIDER ATTITUDES AND BEHAVIOURS

Kelly E. Lloyd, BSc, MA¹, Rachael J. Thorne, BA, MSc, PhD², Louise H. Hall, PhD³, Natalie King, n/a³, Rocío Rodríguez, BA, MA⁴, Samuel Smith, PhD³

¹University of Leeds, LEEDS, England, UK; ²Sheffield Hallam University, Sheffield, England, UK; ³University of Leeds, Leeds, England, UK; ⁴Leeds Institute of Health Sciences, Caerdydd, Wales, UK

Background: The US Preventive Services Taskforce recommend aspirin for colorectal cancer prevention among adults aged 50–69 who have ≥10% cardiovascular disease risk. The UK National Institute of Health and Care Excellence have recommended aspirin for Lynch Syndrome carriers. The implementation of aspirin for cancer prevention depends on informed uptake, high adherence, and understanding barriers to achieving these goals.

Aim: To undertake a systematic review to investigate: 1) uptake and/or adherence to aspirin for cancer prevention, or 2) psychological and/or demographic factors affecting public decisions to use aspirin for cancer prevention, or 3) healthcare provider (HCP) attitudes towards implementing aspirin in clinical care.

Method: A systematic search was undertaken to identify, appraise and synthesise published and grey literature searching the following resources: Medline, Pubmed, EMBASE, CINAHL, Web of Science, Cochrane Library databases, clinical trial registries and ProQuest Dissertations & Theses A&I. Screening and data extraction was completed by one author, with a second duplicating these efforts for 20% of the studies.

Results: 9596 titles/abstracts were screened, resulting in 986 full texts, and 34 included studies. Hand searching identified two additional studies (36 studies total). Three studies reported a high willingness to use aspirin (44%–76%), and three studies reported low uptake (2%–13%). Younger age, higher education, male gender, black ethnicity, having more clinical risk factors, and higher perceived risk were associated with a greater willingness to use aspirin. No studies investigated factors associated with uptake. Adherence estimates varied (30–100%) in 25 studies reporting this outcome, but a large proportion (69%) reported high adherence rates (>80%). No studies investigated factors associated with adherence. Three studies reported moderate support among HCPs for aspirin use in higher risk patients. Support was higher among HCPs who managed more patients with colorectal cancer or Lynch Syndrome, had a genetics specialty, had more experience, or were more aware of aspirin's chemopreventive effects. No qualitative studies were identified for any aim.

Conclusion: Willingness to use aspirin for cancer prevention is high, but uptake is low with some apparent disparities. Adherence is moderate to high among current users. While the role of perceived risk in decision-making was established, there is substantial scope for behavioral medicine research into the psychological factors affecting aspirin uptake and adherence, and the barriers and facilitators to implementing aspirin into clinical care. On behalf of the Aspirin for Cancer Prevention Group (AsCaP)

SELF-MANAGEMENT OF SIDE-EFFECTS AMONG WOMEN WITH BREAST CANCER USING ADJUVANT HORMONAL THERAPY: A SYSTEMATIC REVIEW OF REVIEWS

Louise H. Hall, PhD¹, Natalie King, n/a¹, Christopher D. Graham, PhD DCLinPsychol², Richard D. Neal, FRCGP PhD¹, Galina I. Velikova, BMBS (ie MD), PhD¹, Robbie Foy, PhD¹, Kelly E. Lloyd, BSc, MA³, Jane Clark, DCLinPsych⁴, Samuel Smith, PhD¹

¹University of Leeds, Leeds, England, UK; ²Queen's University Belfast, Belfast, Northern Ireland, UK; ³University of Leeds, LEEDS, England, UK; ⁴Leeds Teaching Hospitals NHS Trust, Leeds, England, UK

Background: Most women with estrogen-receptor positive breast cancer are prescribed adjuvant hormone therapy (HT) medications (e.g. tamoxifen and Aromatase Inhibitors). Medication side-effects are common, can reduce quality of life and compromise medication adherence. Some side-effects can be managed by patients, but an evidence-based overview is required to synthesise the evidence for self-management strategies and to support patient and clinician decision-making.

Objectives: To a) synthesise existing systematic reviews and guidelines of self-management strategies for side-effects resulting from adjuvant HT, and b) identify effective and safe strategies to recommend to patients.

Method: A search for published systematic reviews and meta-analyses was undertaken in March 2019 in CINAHL, Cochrane, EMBASE, MEDLINE, and Web of Science. The AMSTAR2 checklist was used to assess review quality. Additionally, in July 2019 we searched for grey literature and clinical guidelines on websites of international oncology societies and agencies, and the following databases: CPG Infobase, GIN, NHMRC Australian Clinical Practice Guidelines, NICE Evidence, SIGN, and TRIP. Searches focused on side-effects that two primary care physicians agreed could be safely managed without clinical input (e.g. fatigue, hot flushes). Screening, data extraction, and quality assessment were completed in duplicate.

Results: 472 titles and abstracts of systematic reviews (SRs) were screened, resulting in 62 full texts and 17 included studies. Backwards citation searching identified an additional four SRs (22 in total). Titles of 655 clinical guidelines (CGs) were screened, 60 underwent full text review, and 17 were included. SRs and/or CGs were identified for all symptoms, but overall there was a lack of high quality evidence for effective self-management strategies. SRs focusing on acupuncture for hot flushes (7 SRs) and/or arthralgia (10 SRs) were common, but concluded this strategy had limited efficacy. Physical activity featured in five SRs, and appeared promising for arthralgia management, although definitive trials are needed. The overall quality of SR evidence was compromised by small sample sizes, limited follow-up, and heterogeneity in the strategies tested. Harms were generally well monitored, and were minimal for most strategies. CGs provided further strategies for some side-effects, e.g. paced breathing, wearing layers for hot flushes. While the CGs were not always evidence-based, the advice was generally pragmatic, and no-to-low-risk.

Conclusion: Despite decades of research and a large number of SRs and CGs, effective strategies to support self-management of common side-effects of adjuvant hormonal therapy are lacking. Appropriately designed trials are needed to provide definitive recommendations to women using this therapy, and their clinicians.

ASSOCIATIONS OF OPIOID BELIEFS WITH PAIN SEVERITY/
INTERFERENCE AMONG CANCER PATIENTS PRESCRIBED
LONG-ACTING OPIOIDSChelsea S. Rapoport, BA¹, Emily Wright, BA², Areej El-Jawahri, MD³,
Jennifer S. Temel, MD⁴, Lara Traeger, PhD⁵¹Massachusetts General Hospital / Cancer Outcomes Research Program, Cambridge, MA; ²Harvard T.H. Chan School of Public Health, Boston, MA; ³Massachusetts General Hospital Cancer Center, Boston, MA; ⁴Massachusetts General Hospital, Boston, MA; ⁵Massachusetts General Hospital/Harvard Medical School, Boston, MA**Background:** At least two-thirds of patients with incurable cancer experience moderate to severe cancer pain. Although long-acting opioids are a gold standard treatment for chronic cancer pain, patients commonly report concerns about opioids, such as fears of addiction and other negative effects. This study explored relationships between patient beliefs about opioid medications and patient experiences of pain.**Methods:** We analyzed cross-sectional data from an observational study of Massachusetts General Hospital ambulatory patients with locally advanced or metastatic cancer, who were currently taking a prescribed long-acting opioid for chronic cancer pain (n=131). Participants completed a self-report survey, including measures of patient beliefs about pain medications (9-item Family Pain Questionnaire-Knowledge [FPQ-K]) and pain severity and interference with quality of life in the past 24 hours (items from the Brief Pain Inventory). We conducted a series of multiple linear regression models, adjusting for age, gender, race, and long-acting opioid dose, to evaluate associations of patient beliefs about pain medications with pain severity and interference at p<.05.**Results:** Participants (71% female, 85.5% white, mean [M] age=57.7 [SD=11.9]) were prescribed an oral long-acting opioid medication (75.6%) or a fentanyl patch (24.4%), with morphine equivalent dose M=60.0mg (SD=128.3). 52.3% of participants reported at least moderate pain ($\geq 4/10$) on average in the past 24 hours. In separate multiple regression models, more negative beliefs about pain medications were associated with greater pain severity on average (B=.42[SE=.11], p<.001) and pain interference with daily quality of life (B=.43[SE=.13], p=.001). In follow-up analyses of individual FPQ-K items, beliefs that 1) most patients on pain medicine will become addicted and 2) pain medicine is dangerous and can interfere with breathing were both associated with greater pain severity (addictive: B=.12[SE=.06], p=.04; dangerous: B=.21[SE=.05], p<.001) and greater pain interference (addictive: B=.17[SE=.06], p=.01; dangerous: B=.20[SE=.06], p=.002).**Conclusions:** Most patients reported at least moderate pain on average in the past 24 hours despite being prescribed a long-acting opioid regimen. Patients with more negative beliefs about pain medication risks reported greater pain severity on average and greater pain interference. Results suggest potential barriers to optimal pain control among patients with opioid-related concerns. Longitudinal studies are needed to evaluate whether pain medication beliefs may influence pain over time, via patient pain management behaviors or gaps in patient-clinician communication about residual pain.

THE EFFECTIVENESS OF HOPE- FOSTERING INTERVENTIONS IN
PALLIATIVE CARE: A SYSTEMATIC REVIEW AND META-ANALYSISNatalia Salamanca-Balen, MD¹, Man Chen, n/a², Thomas Merluzzi, Ph.D¹¹University of Notre Dame, Notre Dame, IN; ²Quantitative Methods, Department of Educational Psychology, THE University of Texas at Austin, Austin, TX**Background:** Hope is an important theme in chronic illness and palliative care (PC), and has been positively associated with well-being and quality of life (QOL) in end-of-life (EOL) patients. Also, interventions to increase hope or that measure hope as an outcome have appeared in the PC literature; however, no systematic review has evaluated the effectiveness of those interventions.**Primary Objective:** To describe and assess the effectiveness of interventions for PC patients that measure hope/hopelessness as an outcome.**Search Methods:** Electronic databases were searched up to September 2018, and the references of key primary studies and commonly-cited authors were inspected to find more relevant published papers.**Selection criteria:** Randomized controlled trials (RCTs), multiple-group quasi-experimental studies, and single group pre-post intervention studies with adult PC patients that measured hope/hopelessness as an outcome.**Data collection and analysis:** Two reviewers independently assessed the initial studies (N=2,779) based on title and abstract. Full text review resulted in the inclusion of 30 studies. Disagreements at each stage were resolved by consensus. For quantitative synthesis, we estimated random-effects models combined with robust variance estimation techniques when calculating average standardized mean difference. We conducted mixed-effects meta-regression for variables such as study design, type of therapy-psychotherapy, hope as primary versus secondary outcome, hope as a topic in the interventions, and hope-specific designed intervention.**Results:** Thirty studies (20 RCTs, 4 quasi-experimental, 6 single group pre-post studies) involving a total of 3,227 palliative care patients were included. For the RCTs and quasi-experimental studies, compared with usual/standard care, interventions significantly increased hope levels at a medium effect size (0.575; 95% CI: 0.2, 0.9; = 82%; high heterogeneity); but did not significantly reduce hopelessness (-0.08; 95% CI: -0.19, 0.02; = 0%; low heterogeneity). No significant subgroup differences were found. Results for single-group pre-post studies are forthcoming.**Conclusions:** A variety of interventions (most of them psychotherapies) were effective in increasing hope levels in PC patients. Given their heterogeneity and diversity, further analysis is needed to determine which specific components were effective. The relationship between hope and other important outcomes such as QOL, symptom control, anxiety, depression, and psycho-spiritual well-being, needs to be studied in order to have a fuller understanding of the advantage of increasing hope at the EOL. Further research is also needed to understand the conceptual and empirical relationship between hope and hopelessness given that interventions impacted hope but not hopelessness.

CANCER MANAGEMENT SELF-EFFICACY AND PERCEIVED SOCIAL SUPPORT AMONG YOUNG ADULT SURVIVORS OF CANCER AT A SOCIAL NETWORKING EVENT

Zeba N. Ahmad, Ed.M., M.A.¹, Catherine Benedict, PhD², Jennifer Ford, PhD³¹Hunter College and the Graduate Center, CUNY, New York, NY; ²Stanford University School of Medicine, Palo Alto, CA; ³Hunter College, City University of New York (CUNY), New York, NY

Background: Young adult (YA) cancer survivors are known to face age-specific socio-emotional challenges, but research is needed to tailor supportive interventions. Aims: The study aimed to describe perceived social support and self-efficacy in managing cancer. It was hypothesized that these variables would impact emotional health.

Methods: YAs were surveyed before attending CancerCon, an educational and social networking event for adolescent and YA cancer survivors. Linear regression assessed relationships between perceived social support, self-efficacy in managing the practical and emotional aspects of cancer, and emotional health.

Results: Participants (N=140) averaged 31 years old (SD 6.5) and the majority were female (84%), White (84%), and non-Hispanic (88%). Most (95%) reported having access to necessary healthcare. About half (54%) were single, and a minority of participants were still in active treatment (10%). Moderate symptoms of anxiety (82%) and depression (66.9%) were reported (PHQ4; M=8.4, SD 3.2). Those in active treatment had higher levels of depression ($t(128)=-2.64$, $p=.009$). Higher levels of anxiety were reported by those who were diagnosed with cancer before age 18 ($t(127)=2.39$, $p=.018$), were currently younger than 30 years old ($t(130)=2.1$, $p=.038$), or who were diagnosed with cancer more than once ($t(39)=-2.03$, $p=.049$). More than half reported moderate to high self-efficacy in cancer management. Participants reported perceiving high levels of social support. Better cancer management self-efficacy was significantly correlated with more interpersonal appraisal support ($r=.56$, $n=90$, $p>.01$), more emotional support ($r=.42$, $n=45$, $p>.01$), greater satisfaction with health insurance ($r=.321$, $n=86$, $p>.01$), and fewer symptoms of anxiety and depression ($r=-.62$, $n=93$, $p>.01$). Linear regression, controlling for age, age at diagnosis, number of diagnoses, and treatment status, showed social support and cancer self-efficacy explained 41% of the variance in emotional symptoms ($R^2=.41$, $F(7, 32)=3.13$, $p=.012$). Better cancer management self-efficacy ($\beta=-.61$, $p=.001$) predicted fewer symptoms of anxiety and depression, but perceived availability of emotional support ($\beta=.05$, $p=.74$) and perception of more interpersonal appraisal support ($\beta=.03$, $p>.82$) did not.

Discussion: Interpretation of results is limited by the study's cross-sectional nature. However, relationships between better cancer management self-efficacy and fewer emotional symptoms could guide tailoring of interventions during the survivorship phase. Specifically, intervention research may explore whether cancer management self-efficacy and emotional symptoms predict adherence to the tasks of survivorship, such as medical follow-up, or whether bolstering cancer management self-efficacy among those still in active treatment may predict reduced symptoms of anxiety and depression.

BARRIERS AND FACILITATORS TO CONNECTING CANCER SURVIVORS TO A COMMUNITY-BASED PHYSICAL ACTIVITY PROGRAM: LIVESTRONG AT THE Y

Jamie M. Faro, PhD¹, Melissa A. Clark, PhD², Catherine S. Nagawa, M.S.³, Thomas K. Houston, MD MPH⁴, Stephenie Lemon, PhD⁵, Rajani Shankar Sadasivam, PhD⁶¹University of Massachusetts Medical School, Worcester, MA; ²Brown University School of Public Health, Providence, RI; ³UMASS Medical School, Worcester, MA; ⁴Wake Forest University School of Medicine, Winston-Salem, NC; ⁵UMass Medical school, Worcester, MA; ⁶University of Massachusetts Medical School, Worcester, MA

Background: Physical activity rates in cancer survivors continue to be low despite the known benefits and availability of evidence-based programs. LIVESTRONG at the YMCA is a nationwide community-based physical activity program offered free of cost to cancer patients and survivors. We explored perceptions of LIVESTRONG at the Y program staff and graduates to better understand barriers and facilitators to program referrals and participation.

Methods: Participants were recruited using a snowballing sampling method in collaboration with the YMCA's national office. Program Directors (n=16), Instructors (n=4) and Program graduates (n=8) from 8 US states took part in semi-structured phone interviews. Interviews were digitally recorded, transcribed and evaluated using thematic analysis.

Results: Program Directors reported most participants hear about the program through their cancer care provider or word of mouth. Program Directors and Instructors reported struggling to bring more awareness about the program, make relationships with cancer clinic staff and recruit a greater number and more diverse population of participants. Program Directors stated, "The best way to reach more survivors would be using a referral system directly from providers (preferably electronic)". Programs with high enrollment reported, "We have a positive relationship with oncologists, a referral process in place, and we send providers feedback on patient participation". One program used an electronic referral embedded in an electronic medical record and was not only successful at enrolling a high number of participants but also a diverse population, which other programs reported struggling to do. Program graduates reported hearing about the program from a mix of providers and friends/family. They emphasized the importance of someone in their clinic providing information on physical activity programs because they would be more likely to listen to these trusted sources. They also preferred this information be given both before and after treatment.

Conclusions: Physical activity guidance and referrals for cancer patients/survivors deserves attention. Patients and survivors suggest the need for physical activity education, referrals and follow-up from someone on their healthcare team, while LIVESTRONG at the Y staff report the need for a better referral system to connect participants to the program. Cancer care provider referrals before and after treatment may expedite and increase participation in this community-based program.

DISPOSITIONAL SHAME AND GUILT PREDICT DEPRESSIVE SYMPTOMS AND ANXIETY IN LUNG CANCER PATIENTS: THE MEDIATIONAL ROLE OF STIGMA

Timothy J. Williamson, Ph.D., MPH¹, Jamie Ostroff, PhD¹, Noshin M. Haque, B.S.², Chloe M. Martin, PhD¹, Heidi Hamann, PhD³, Smita Banerjee, n/a¹, Megan Shen, PhD⁴

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²MSKCC, New York, NY; ³University of Arizona, Tucson, AZ; ⁴Weill Cornell Medicine, New York, NY

Background: Lung cancer is a stigmatized disease that often necessitates considerable psychological adjustment. Lung cancer patients evidence higher rates of depression and anxiety, compared to adults with other cancers. It is crucial to understand and promote mental health in this population, particularly because it relates to important clinical outcomes (e.g., disease progression, survival). Most lung cancer patients report experiences of stigma—characterized by feelings of shame and guilt—which are associated with poor mental health outcomes. However, there is a gap in understanding psychosocial contributors to higher lung cancer stigma, which can be used to identify patients early in the care trajectory (e.g., at diagnosis) for psychosocial interventions that aim to reduce stigma and mitigate subsequent psychological maladjustment.

Purpose: This study investigated whether dispositional tendencies to experience shame and guilt (i.e., shame- and guilt-proneness) predicted higher lung cancer stigma and, in turn, higher depressive symptoms and anxiety.

Method: Participants ($N=56$, 57.1% female) were men and women receiving clinical consultations for lung cancer who completed validated questionnaires. Mediation modeling using bootstrapping was conducted to characterize relationships between shame- and guilt-proneness, stigma, depressive symptoms, and anxiety.

Results: Higher guilt-proneness was associated significantly with higher anxiety ($b=0.69$, $SE=0.28$, 95%CI [0.13, 1.26]) and higher shame-proneness was associated significantly with higher depressive symptoms ($b=0.56$, $SE=0.19$, 95%CI [0.18, 0.93]), beyond important sociodemographic, medical, and smoking-related characteristics. Additionally, higher lung cancer stigma significantly mediated the relationship between guilt-proneness and anxiety (indirect effect=0.43, $SE=.20$, 95%CI [0.08, 0.89]). However, stigma did not significantly mediate the relationship between shame-proneness and depressive symptoms.

Conclusions: Shame- and guilt-proneness relate to depressive symptoms and anxiety, respectively. The relationship between guilt-proneness and anxiety is explained, in part, by lung cancer stigma. These findings highlight shame- and guilt-proneness and internalized lung cancer stigma as important psychological processes related to depressive symptoms and anxiety in lung cancer patients. Patients who are high in shame- and guilt-proneness are at risk to experience high levels of stigma and may benefit from proactive supportive care interventions that address stigma and promote health and well-being.

PREVALENCE AND PREDICTORS OF VITALITY/FATIGUE AMONG BREAST, PROSTATE AND COLORECTAL CANCER SURVIVORS IN THE SEER-MHOS DATASET

Jaclyn Leiser, B.A.¹, Morgan Byrne, MPH¹, Sandra A. Mitchell, PhD, CRNP², Elizabeth J. Siembida, PhD, MPH², Erin E. Kent, PhD³, Hannah Arem, PhD⁴

¹The George Washington University, Washington, DC; ²National Cancer Institute, Rockville, MD; ³University of North Carolina at Chapel Hill, Department of Health Policy and Management, CHAPEL HILL, NC; ⁴George Washington University, Washington, DC

Background: The cancer survivor population, currently estimated at 16.9 million, is expected to grow by almost 30% over the next 10 years. Approximately 45% of those undergoing cancer treatment and almost 30% of those post-treatment experience cancer-related fatigue (CRF). CRF is a debilitating condition common among cancer survivors which impairs quality of life. A better understanding of CRF change from pre to post-diagnosis and of the predictors of CRF change are needed to develop strategies to prevent and manage this condition.

Methods: We used the Surveillance, Epidemiology and End Results [SEER] Medicare Health Outcomes Survey [MHOS] linked data to characterize trajectories of fatigue and identify the demographic and clinical predictors of those trajectories in individuals diagnosed with breast, colorectal and prostate cancer. We measured CRF prior to cancer diagnosis (T0) and at two post-diagnosis timepoints [20 months, SD 20 months (T1) and 40 months, SD 32 months (T2)] harmonizing measures from the 4-item Vitality scale of the Short Form questionnaire (SF-36) and a single item from the Veterans Rand-12 questionnaire. Fatigue measures were scored on a t-scale from 0–100, with lower scores indicating worse fatigue. Using a multivariable regression model, we estimated the predictors of four distinct CRF trajectory patterns from pre- to post-cancer diagnosis.

Results: Overall, fatigue t-scores were similar by cancer site at all timepoints (~ 50 at T0, 46 at T1 and 45 at T2). This slight decline indicates worse fatigue over time. Older age, distant stage disease and major depressive disorder (MDD) symptoms were significantly associated with worse fatigue from T0 to T1 [$(\beta_{age}: -0.21, p < 0.0001)$ ($\beta_{distant\ stage}: -4.99, p = 0.001$) ($\beta_{MDD}: -5.31, p < 0.0001$)]. Four groups were identified in the trajectory analysis: Those who started with low levels of fatigue and remained low, those who started with high levels of fatigue and remained high, and two groups that started between the high and low groups but declined over time. The two groups with lowest levels of fatigue at all timepoints tended to have fewer MDD symptoms than the two groups with highest levels of fatigue at all timepoints (71.4% and 91.8% with no risk compared to 39.2% and 44.3%).

Conclusions: Our results suggest that evaluating those with cancer for MDD symptoms prior to treatment and considering their age and stage of disease may help providers better predict CRF trajectories. Targeted interventions to manage CRF may also focus on these risk factors.

PART OF THE PROCESS—THE ROLE OF EMOTIONAL APPROACH COPING IN ADJUSTMENT AMONG YOUNG ADULTS WITH CANCER

Caroline F. Zimmermann, M.S.¹, Katie Darabos, PhD², Megan E. Renna, PhD³, Ashley W. Wang, PhD⁴, Michael A. Hoyt, PhD⁵¹The Graduate Center, City University of New York (CUNY), Astoria, NY;²The Children's Hospital of Philadelphia, Collingswood, NJ; ³The Ohio State University Wexner Medical Center, Columbus, OH; ⁴Soochow University, Taiwan, Taipei City, Taipei, Taiwan (Republic of China); ⁵University of California, Irvine, Irvine, CA

Objective: Cancer, particularly during young adulthood, can evoke difficult and novel emotions. During this time, cancer can interfere with normative development and challenge typical coping responses. Emotion-regulating coping efforts aimed at actively processing and expressing emotions might be particularly beneficial to cancer adjustment and have positive relationships with well-being and perceptions of positive growth. This study examined relationships of emotional approach coping and cancer-related and general indicators of adaptation among young adults with cancer.

Methods: Young adult cancer survivors ($N = 57$; $M_{age} = 34.1$, $SD = 4.9$, range = 24–42) were majority female (94.7%), White (93%), and had a breast cancer diagnosis (71.9%). On average, 2.5 years had passed since diagnosis. Participants completed measures of emotional approach coping (emotional expression, emotional processing), as well as general (depressive symptoms, resilience) and cancer-specific (fear of cancer recurrence, posttraumatic growth) adaptation as part of a larger study on technology-related communication.

Results: Multiple linear regressions revealed that greater use of emotional expression was associated with lower depressive symptoms ($\beta = -0.27$, $p < .05$) and higher posttraumatic growth ($\beta = 0.41$, $p < .01$); while greater use of emotional processing was associated with higher resilience ($\beta = 0.32$, $p < .05$), and higher posttraumatic growth ($\beta = 0.42$, $p < .01$). No additional significant relationships were found.

Conclusions: While both facets of emotional approach had associations with better adaptation, findings highlight differing relationships between emotional expression and emotional processing among young adult cancer survivors. Interventions aimed at increasing emotional expression and processing may prove useful in facilitating positive adjustment and strengthening young adult cancer survivors' ability to cope with the diverse effects of disease and treatment.

DOES THE BROADEN-AND-BUILD THEORY EXPLAIN REDUCTION IN SOCIAL DISRUPTION AFTER A BRIEF RELAXATION PROTOCOL FOR BREAST CANCER?

Hannah M. Fisher, M.S.¹, Chloe Taub, MA², Molly Ream, B.A.², Suzanne C. Lechner, Ph.D.³, David Lee, PhD², Aaron Heller, PhD⁴, Michael H. Antoni, Ph.D.⁴¹Duke University Medical Center, Durham, NC; ²University of Miami, Miami, FL; ³Research Advisor LLC, Parkland, FL; ⁴University of Miami, Coral Gables, FL

Introduction: There is a growing cohort of women surviving early-stage breast cancer (BCa), many of whom struggle with physical, emotional, and social disruption in the months following treatment. Brief cognitive-behavioral (CBT) and relaxation skills training (RT) interventions addressing these concerns are becoming more prevalent. Yet, mechanisms for these protocols are still emerging. Using the Broaden-and-Build Theory of positive emotions as a theoretical model, this study examined whether short-term, CBT- and RT-related increases in positive affect mediate longer-term reductions to social disruption in women undergoing treatment for BCa.

Method: Women ($N=183$) with stage 0-III BCa were enrolled in a randomized-controlled trial comparing 5-week group-based CBT, RT, and health education (HE) interventions. Medical and demographic variables, and scores on the Affect Balance Scale-Positive Affect subscale (PA) and Sickness Impact Scale-Social Interactions subscale (SIPsi) were collected at baseline (T1), 2- (T2), 6- (T3), and 12-month (T4) follow-up. Latent change score and growth models were specified in Mplus to test 6- and 12-month intervention effects on absPOS and SIPsi, respectively; models were then combined into a parallel-process latent growth/latent change model to assess mediation. Covariates were age, stage, and type of adjuvant treatment.

Results: RT demonstrated larger reductions in SIPsi across T1-T4, compared to HE ($B = -.31$, $SE = .11$, 95% CI $[-.44, -.01]$, $p < .05$) and CBT groups ($B = -.33$, $SE = .11$, 95% CI $[-.45, -.02]$, $p < .05$). Residualized latent change in PA from T1 to T3 was significant ($B = .16$, $SE = .05$, 95% CI $[.06, .26]$, $p < .001$) but this was not driven by condition. Indirect paths specified in the parallel-process latent growth/latent change model were not significant. However, the slopes of PA and SIPsi were related ($B = -.65$, $SE = .22$, 95% CI $[-1.00, -.15]$, $p < .05$).

Conclusions: A 5-week RT protocol can produce long-term reductions to SIPsi among women undergoing primary treatment for early-stage BCa. Residualized change in PA did not mediate RT-related effects on SIPsi but the latent slopes of these variables trended together across the breast cancer trajectory. Additional work is needed to elucidate how relaxation strategies motivate women with BCa to resume social activities, and how change in PA might be related to increased social engagement. Such data could refine the development of brief interventions for survivors of BCa.

RANDOMIZED TRIAL OF AN ACCEPTANCE INTERVENTION FOR ANXIOUS CANCER SURVIVORS: PATIENT-REPORTED AND HEALTHCARE USE OUTCOMES

Joanna J. Arch, Ph.D.¹, Jill L. Mitchell, PhD, MSW², Sarah Genung, B.A.³, David Andorsky, MD⁴, Jonathan Bricker, PhD⁵, Charles Judd, Ph.D.³, Annette L. Stanton, Ph.D.⁶

¹University of Colorado Boulder and University of Colorado Cancer Center, Boulder, CO; ²Rocky Mountain Cancer Centers, Boulder, CO; ³University of Colorado Boulder, Boulder, CO; ⁴Rocky Mountain Cancer Center, Boulder, CO; ⁵Fred Hutchinson Cancer Research Center/University of Washington, Seattle, WA; ⁶UCLA, Los Angeles, CA

Background: Elevated anxiety, driven largely by fear of cancer recurrence, represents a common, chronic, and often unaddressed concern among cancer survivors, and predicts both intensive and avoidant use of healthcare. We present findings from a randomized clinical trial evaluating the efficacy of a 7-week acceptance and commitment therapy (ACT) group intervention designed to address the psychosocial needs of anxious cancer survivors.

Methods: Randomized, multi-site clinical trial of the group ACT intervention versus enhanced usual care (EUC) for cancer survivors with moderate to high anxiety symptoms, who were within 2 years of finishing cancer treatment (n=139). The trial was embedded within a large network of community-based oncology private practice clinics and onsite social workers delivered the intervention. Psychosocial outcomes (general anxiety symptoms [primary]; fear of cancer recurrence, cancer-related trauma symptoms, vitality, depression symptoms, sense of life meaning, healthcare utilization [secondary]) were assessed at Pre-, Mid-, Post-intervention, 3- and 6-month follow-up and analyzed using full information maximum likelihood growth modeling. Medical utilization was tracked throughout the study and analyzed using bootstrap regression modeling with bias-corrected estimates.

Results: Condition by time interactions from Pre to 6-month Follow-up showed that ACT led to significantly greater reductions in fear of cancer recurrence and cancer-related trauma symptoms, significantly greater increases in vitality, and marginally greater reductions in general anxiety symptoms, than the EUC control condition. The ACT condition also evidenced significantly fewer missed medical appointments than EUC. Across condition, depression diminished and sense of life meaning increased, with no effects for condition over time. Baseline levels of anxiety symptoms or coping through avoidance moderated general anxiety, vitality, and life meaning outcomes. Specifically, cancer survivors with higher anxiety or avoidance levels benefitted most from ACT relative to EUC. Social workers also showed strong adherence to the intervention.

Discussion: A group ACT intervention led to better fear of recurrence and trauma symptom outcomes for anxious cancer survivors and fewer missed medical appointments than EUC. We discuss the implications of study findings.

Trial pre-registration: Clinicaltrials.gov NCT02550925.

6:15 PM-7:30 PM

ARE ESTIMATES OF ANXIETY DISORDER PREVALENCE IN CANCER POPULATIONS ACCURATE?

Elizabeth Slivjak, BA¹, Joanna J. Arch, Ph.D.²

¹University of Colorado Boulder, Boulder, CO; ²University of Colorado Boulder and University of Colorado Cancer Center, Boulder, CO

Background/Purpose: Elevated anxiety represents one of the most common and enduring symptoms experienced by cancer survivors. Thus, the purpose of this systematic review was to assess the accuracy of estimates of anxiety disorder prevalence among cancer survivors. Reviewing the literature on anxiety and mood disorders among cancer survivors, meta-analyses reported surprisingly low prevalence of anxiety disorders among cancer survivors relative to mood disorders and the general population. We hypothesized that the individual studies comprising these meta-analyses may have failed to assess the full range of anxiety disorders, thereby underestimating the prevalence of anxiety disorders overall.

Methods: We conducted a search in PubMed and Google Scholar for meta-analyses that estimated anxiety disorder prevalence rates among adult cancer survivors. Within eligible meta-analyses (n = 4), we systematically examined the unique individual studies (n = 53) to determine the extent to which they assessed the full range of anxiety disorders among cancer survivors relative to major depressive disorder.

Results: Individual studies in meta-analyses assessing anxiety disorder prevalence among cancer survivors almost universally reported the prevalence of major depressive disorder (96%). However, apart from GAD (assessed in 49% of studies) and panic disorder (assessed in 34% of studies), less than one-third of the studies reported the prevalence of any other anxiety disorder. Social anxiety disorder and specific phobia, the most prevalent anxiety disorders in general populations, received the least attention among cancer populations, reported in only 21% and 8% of studies respectively. Thus, studies that report anxiety disorder prevalence among cancer survivors base estimates on only a few anxiety disorders and omit most others, thereby systematically underestimating the prevalence of anxiety disorders among cancer survivors. This bias was not evident for mood disorders.

Conclusions: Despite reporting the prevalence of 'anxiety disorders' as a category, studies in cancer populations rarely assessed the full range of anxiety disorders. The omitted anxiety disorders show high prevalence in general populations. Thus, the evidence suggests that these studies and the meta-analyses that rely upon them have systematically underestimated the prevalence of anxiety disorders in cancer populations, likely considerably so. We discuss clinical and research implications.

COPING, ILLNESS PERCEPTIONS, AND DEPRESSION IN UVEAL MELANOMA: EXAMINING COMMON SENSE AND COPING RESOURCE MODELS

Megan M. Hoch, BA¹, James J. MacDonald, M.A.¹, Alexandra Jorge-Miller, MA¹, Tara A. McCannel, MD, PhD², Tammy Beran, PhD³, Annette L. Stanton, Ph.D.⁴

¹University of California, Los Angeles, Los Angeles, CA; ²University of California, Los Angeles, Los Angeles, CA, CA; ³Private Practice, Milwaukee, WI; ⁴UCLA, Los Angeles, CA

Background: A rare cancer, uveal melanoma (UM) affects five in one million adults per year. UM patients endorse notable rates of unmet psychological supportive care needs. Research on predictors of mental health outcomes in UM largely has focused on disease-related factors (e.g., metastatic risk), with mostly null results. In this prospective, longitudinal study, we tested the Common Sense (CS; Leventhal, 1980) and Coping Resource Models (CR; Moos, 2003). Accordingly, we hypothesized mediational pathways via illness perceptions and coping strategies on depressive symptoms over one year after UM diagnosis. We also examined interactions between specific illness perceptions and coping processes.

Methods: Participants were patients (N=61) diagnosed with UM at the UCLA Jules Stein Eye Institute who completed baseline assessments at a pre-diagnosis medical visit (T1) and follow-up assessments at one week (T2), three months (T3), and one year after UM diagnosis (T4). Validated measures of depression (CES-D), disease-related coping (COPE), and illness perceptions (BIPQ) were administered. Multiple regression analyses tested associations of coping and illness perceptions with depressive symptoms across time.

Results: Coping through avoidance of the “eye problem” at T1 ($b=11.44, p=.004$) and the UM diagnosis at T2 ($b=8.56, p=.005$) predicted higher depressive symptoms at T4. Perceptions of greater illness chronicity ($b=.80, p=.038$) and lower control over one’s illness ($b=-.84, p=.031$) at T2 also predicted T4 CES-D scores. Mediation analyses testing the application of CR and CS models did not reach statistical significance. Significant avoidance coping x chronicity perception interactions at T1 ($b=1.96, p=.037$) and T2 ($b=2.08, p=.032$) indicated that the positive links of pre- and post-UM diagnosis avoidance coping with T4 depressive symptoms were stronger for patients with perceptions of prolonged (versus limited) illness chronicity (T1 $b=10.79, p=.032$; T2 $b=13.53, p=.001$).

Conclusions: Engagement in avoidance coping, even prior to cancer diagnosis, and perceptions of prolonged illness chronicity at the time of diagnosis are independent and joint predictors of 12-month depressive symptoms in adults with UM. Although the data did not support the CR and CS mediational models, our findings highlight the unique and combined influence of coping and illness perceptions on psychological adjustment to chronic illness, which is consistent with both theoretical frameworks.

PATIENTS’ EXPECTATIONS OF THE BENEFITS OF LARGE-PANEL GENOMIC TUMOR TESTING

Eric Anderson, PhD¹, John DiPalazzo, n/a¹, Paul Han, MD, MPH¹

¹Maine Medical Center, Portland, ME

Background: Large-panel genomic tumor testing (GTT) is a new technology that promises to make cancer treatment more precise, but also has uncertain utility for individual patients. Currently, GTT has been shown to benefit relatively few patients; however, patients may have little understanding and unrealistic expectations of its benefits. The goal of this project is to assess expectations of the benefits of GTT among cancer patients in community oncology practices.

Methods: A survey assessing expectations of the benefits of GTT was administered to cancer patients participating in a statewide study of GTT implementation, prior to receipt of testing. Descriptive and regression analyses were conducted to assess expectations and the factors associated with these expectations.

Results: The study sample (N = 900) consisted of patients with a range of cancer types (most frequent were: 15.6% lung, 10.7% breast, 8.9% brain, 7.8% colon) and cancer stages (4.5% Stage I, 5.6% Stage II, 17.3% Stage III, 66.4% Stage IV). The mean age was 63.6 years (SD = 11), and 426 (58.4%) were female. Generally, patients had high expectations of benefiting from GTT; 80.2% thought GTT was moderately likely to help their doctor choose the best treatment for them, and 62.5% thought GTT was moderately likely to give them greater peace of mind. Greater expectations for GTT ($\beta = .12, p < .002$) were positively associated with age and negatively associated with knowledge of GTT ($\beta = -.16, p < .0001$).

Conclusions: Patients have relatively high expectations of the benefits of GTT, which are associated with age and knowledge of GTT. More research is needed to understand the causes of patient expectations of GTT, and their effects of health behaviors and outcomes.

PREVALENCE OF HEALTH BEHAVIORS AMONG CANCER SURVIVORS IN THE UNITED STATES: HOW FAR HAVE WE COME?

Hannah Arem, PhD¹, Scherezade K. Mama, DrPH², Xuejing Duan, PhD³, Julia H. Rowland, PhD⁴, Keith Bellizzi, PhD, MPH⁵, Diane K. Ehlers, PhD⁶¹George Washington University, Washington, DC; ²The Pennsylvania State University, University Park, PA; ³George Wash University, Washington, DC; ⁴Smith Center for Healing and the Arts, Washington, DC; ⁵University of Connecticut, Storrs, CT; ⁶University of Nebraska Medical Center, Omaha, NE

Background: The number of cancer survivors in the U.S. is expected to reach 21.7 million by 2029, with roughly 67% of survivors living ≥ 5 years post-diagnosis. Survivors are at increased risk for late/ long-term health complications and recurrence; however this risk may be attenuated by a healthy lifestyle. This study updates a 2005 benchmark study in the National Health Interview Survey (NHIS) of prevalence estimates of smoking, physical activity, and alcohol consumption by cancer history. Our goal was to understand current health behaviors by cancer history in a nationally representative sample to inform behavior change priorities for cancer survivors.

Methods: We analyzed data from the NHIS, a cross-sectional household interview survey, combining datasets from 2013–2017. There were 164,692 adults in the combined sample, 12,648 of whom were identified as having a history of cancer. Using weighting to account for survey sampling techniques, we calculated prevalence of smoking, physical activity, and alcohol consumption by cancer history, age, and cancer site.

Results: Overall, a slightly lower percentage of those with a history of cancer reported current smoking (14.1% vs 16.8%) and fewer reported moderate to heavy drinking (18.8 vs 21.9%) than those without a history of cancer. A lower percentage of cancer survivors met physical activity guidelines (14.2 vs 21.1%) than those without a cancer history. However, we found differences in these behaviors by age; individuals aged 18–39 with a cancer history reported a current smoking prevalence 31.3% compared to 16.8% among those without a history of cancer and were less likely to meet physical activity guidelines (22.0% vs 28.6%). Among those age 65+ a slightly greater percentage of cancer survivors reported moderate to heavy drinking (18.0% vs 15.7%). When we analyzed behaviors by cancer site we found that those with a history of respiratory or gynecologic cancers were more likely to smoke than breast, prostate, colorectal or leukemia/lymphoma survivors. Prostate cancers survivors were more likely to be moderate/heavy drinkers than other cancer sites. Respiratory cancer survivors were less likely to meet physical activity guidelines.

Conclusion: Prevalence of poor health behaviors current smoking, physical inactivity, and moderate to heavy drinking were all lower than the previous report 14 years ago. Still, targeted interventions by age and cancer site are needed to improve health behaviors.

HEALTH BEHAVIORS OF CANCER SURVIVORS FROM THE NATIONAL HEALTH INTERVIEW SURVEY (2005–2015)

Patrick Boyd, PhD¹, Mark D. Lowry, PhD², Kasey Morris, PhD³, Kara Hall, PhD⁴, Frank M. Perna, Ed.D., Ph.D.¹¹National Cancer Institute, ROCKVILLE, MD; ²National Cancer Institute, Bethesda, MD; ³Surgo Foundation, Washington, DC; ⁴National Cancer Institute, Rockville, MD

Background: This study examines population-based survey data from the National Health Interview Survey (NHIS) from three time points: 2005, 2010, and 2015. Prior research utilizing the NHIS demonstrates that cancer survivors exhibit similar health behavior profiles to controls for smoking and alcohol consumption, but cancer survivors are more likely to meet physical fitness standards (Bellizzi et al., 2005). The purpose of the current research is to examine additional health behaviors included within the NHIS that inform cancer prevention (e.g., diet and sleep) while also updating previously examined health behaviors.

Method: Data was collected from 92,257 participants whose cancer status was obtained via self-report (e.g., “Have you ever had cancer?”). 8,050 participants reported having had cancer (2,428 in 2005; 2,333 in 2010; 3,289 in 2015). Physical activity, alcohol use, smoking status, diet, and sleep were assessed. Data were weighted and analyzed in SPSS. Demographic and physical function covariates were included in all analyses.

Results: When comparing cancer survivors to those without a history of cancer (2005–2015), survivors were 13% more likely to meet physical activity recommendations ($OR = 1.13$, $CI = 1.03, 1.23$) and 7% more likely to be current drinkers ($OR = 1.07$, $CI = 1.00, 1.14$). Cancer survivors did not differ from those without a history of cancer in their likelihood of being a smoker, meeting dietary guidelines, or getting adequate sleep. Cancer survivors exhibited a significant increase in physical activity from 2005 to 2010 ($p = .013$) but not 2010 to 2015, and a significant decrease in self-reported smoking status from 2010 to 2015 ($p < .001$) but not 2005 to 2010. No significant changes were found for cancer survivors drinking status, diet, or amount of sleep from 2005 to 2010 or 2010 to 2015.

Conclusion: Findings reveal that cancer survivors, compared to controls, are more likely to meet physical activity guidelines, supporting prior research. Cancer survivors are also more likely to report being current drinkers, compared to controls, providing novel evidence that alcohol consumption may need to be examined as a risk factor in this cohort. No differences were found in diet or sleep. Within the cancer survivor cohort physical activity increased and smoking decreased across time. Results from this study update previous health behavior self-report data from the NHIS among cancer survivors and extends it by examining diet and sleep. These results may help inform where interventions might be focused to prevent cancer recurrence among cancer survivors.

ENVIRONMENTAL CORRELATES OF OBJECTIVELY-MEASURED MODERATE TO VIGOROUS PHYSICAL ACTIVITY IN BREAST CANCER SURVIVORS

Marilyn Lu, BA¹, Whitney A. Welch, PhD¹, Emily Diehl, n/a², Kiarri N. Kershaw, PhD¹, Kara L. Gavin, PhD³, Payton E. Solk, BA¹, Jennifer H. La, Bachelor of Science in Health Systems Management¹, Frank Penedo, PhD⁴, Bonnie Spring, PhD⁵, Ronald T. Ackermann, MD MPH⁶, Juned Siddique, DrPH¹, Kerry S. Courneya, PhD⁷, Siobhan M. Phillips, PhD, MPH¹

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Feinberg School of Medicine, Chicago, IL; ³University of Wisconsin, Madison, WI; ⁴Sylvester Comprehensive Cancer Center, Miami, FL; ⁵Northwestern University Feinberg School of Medicine, CHICAGO, IL; ⁶Northwestern Medicine, Chicago, IL; ⁷University of Alberta, Edmonton, AB, Canada

Purpose: Moderate and vigorous physical activity (MVPA) is associated with reduced treatment-related side effects and improved disease outcomes and quality of life among breast cancer survivors (BCS), but most BCS do not meet MVPA recommendations. Environmental factors have been shown to be associated with MVPA in the general population, but few studies have examined these relationships in BCS. This study examined relationships among geographical region, natural environment characteristics, and perceived environmental walkability with MVPA among BCS.

Methods: As part of baseline assessments, insufficiently active BCS [$n=269$; $M_{age}=52.5$ (SD=9.9)], who enrolled in a U.S. nationwide MVPA promotion intervention, wore accelerometers on the hip for 7 consecutive days during all waking hours. Mailing addresses were used to define geographical region and obtain natural environment data (i.e. temperature, precipitation, and day length) from the National Climatic Data Center. BCS completed the Neighborhood Environment Walkability Scale to assess perceived built environment factors (e.g. residential density, land use diversity and access, neighborhood surroundings). Linear regression analyses examined relationships between potential environmental correlates and baseline MVPA minutes/day controlling for relevant covariates, including age, income, education, cancer stage, and treatment with chemotherapy and/or radiation.

Results: BCS averaged 12.5 (SD=11.7) MVPA minutes/day (min/d). BCS living in the West averaged significantly more MVPA than those in the Southwest ($M_{diff}=6.9$ min/d, $p=0.03$). Southwest BCS averaged significantly more MVPA than Midwest BCS ($M_{diff}=7.1$ min/d, $p=0.03$). No other geographical region differences were significant. BCS in locations with no precipitation ($B=3.4$, $p=0.02$) and more hours of daylight/day ($B=3.4$, $p=0.017$) engaged in more MVPA min/d. Greater residential density ($B=0.2$, $p=0.01$), land use access ($B=1.5$, $p=0.04$), and lack of cul-de-sac ($B=1.4$, $p=0.02$) were significantly correlated with higher MVPA min/d.

Conclusions: Findings suggest geographical region, natural environment, and perceived built environment factors may significantly influence objectively measured MVPA among BCS. Future MVPA promotion interventions should consider the best way to address multi-level barriers, including environmental features, to improve intervention efficacy to increase MVPA and, ultimately, improve health outcomes among BCS.

ATTACHMENT, COMMUNICATION, AND PHYSICAL WELL-BEING AMONG COUPLES COPING WITH CANCER

Katherine Ramos, Ph.D.¹, Shelby Langer, PhD², Michael Todd, PhD², Joan M. Romano, Ph.D.³, Neeta Ghosh, MA, MPH⁴, Francis J. Keefe, Ph.D.⁵, Donald H. Baucom, Ph.D.⁶, Karen L. Syrjala, PhD⁴, Laura S. Porter, PhD¹

¹Duke University Medical Center, Durham, NC; ²Arizona State University, Phoenix, AZ; ³University of Washington, Seattle, WA; ⁴Fred Hutchinson Cancer Research Center, Seattle, WA; ⁵Duke University, Durham, NC; ⁶UNC-Chapel Hill, Chapel Hill, NC

A couple's ability to cope with the medical and psychosocial challenges of cancer is often linked to their perceptions of each other's availability and responsiveness. Attachment is an important contributor to couples' communication, which in turn can influence mental and physical well-being. This study examined associations between attachment style and physical well-being, and the mediating role of couple communication.

Participants were 166 dyads enrolled in a larger observational study examining couple communication in cancer. Inclusion criteria for patients were: stage II–IV breast, lung, colon, or rectal cancer; within 2 years of diagnosis of current cancer stage; received or receiving systemic treatment, with a life expectancy of at least 6 months. Patients also needed to be married or in a committed relationship. Recruitment took place at the Duke Cancer Institute and the Seattle Cancer Care Alliance. Couples independently completed self-report measures of adult attachment orientations (e.g., anxious or avoidant), emotional disclosure, holding back from disclosure, and physical well-being. We examined potential indirect associations between a dyad member's scores on dimensions of anxious and avoidant attachment and the partner's physical well-being, as mediated by the dyad member's own communication behavior (holding back or disclosure) using an actor-partner interdependence model (APIM) path analysis for each of the four possible combinations of attachment and communication behavior.

Overall, participants had a mean age of 52.72 years (SD 12.8); 86.6% Caucasian. Patients were 65% female and partners were 63% male. Results indicated that anxious and avoidant attachment were positively associated with holding back and disclosure, which in turn were inversely associated with physical well-being. Moreover, spousal anxious and avoidant attachment were associated with patient reports of lower physical well-being through spouse holding back (IE = -0.45, 95% CI = -0.91 – -0.11; IE = -0.50, 95% CI = -0.94 – -0.18). A similar pattern emerged for spouse anxious attachment and patient physical well-being through spouse disclosure (IE = -0.32, 95% CI = -0.71 – -0.10).

To our knowledge, this study is the first to examine communication as a mechanism underlying the association between attachment and physical well-being, and to examine both patient and partner effects. Attachment appears related to communication quality (e.g., both how communication exchanges are perceived and received among couples). For couples coping with cancer, attachment insecurity may influence communication, which in turn may affect physical health and relationship adjustment. These findings demonstrate a need for development of communication skills-training interventions for couples coping with cancer who may hold back from disclosure in the context of attachment insecurity.

MULTI-THEORY MODEL AND DETERMINANTS OF HPV VACCINATIONS: A CROSS-SECTIONAL STUDY AMONG GHANAIAAN ADOLESCENTS.

Matthew Asare, PhD, MPH, MBA¹, Peter Agyei-Baffour, Ph.D.², Beth A. Lanning, PhD, MCHES¹, Alex B. Owusu, Ph.D.³, Mary E. Commeh, MD⁴, Kathileen Boozer, DNP, APRN, FNP-C⁵, Georges Adunlin, Ph.D.⁶, Lori Spies, Ph.D., RN NP-C⁷, Adofa Koranteng, Ph.D.⁸

¹Baylor University, Waco, TX; ²KNUST, Kumasi, Ashanti, Ghana; ³University, Legon, Greater Accra, Ghana; ⁴Ghana Health Service, Accra, Greater Accra, Ghana; ⁵Baylor University, Waco, TX; ⁶Samford University, Birmingham, AL; ⁷Baylor University, Dalla, TX; ⁸Kwame Nkrumah University of Science and Technology (KNUST), Kumasi, Ashanti, Ghana

Introduction: The human suffering and health economic burden of Human Papillomavirus (HPV) related cancers represents an unmet medical need in Ghana. The HPV related cancers such as cervical, oral, neck, and head cancers are among the leading cause of cancer deaths in Ghana. Prophylactic HPV vaccines such as Cervarix®, Gardasil®, and Gardasil 9® are efficacious in preventing HPV related cancers. However, the HPV vaccination uptake in Ghana is very low. Studies that utilize theoretical frameworks to identify contributory factors to HPV vaccination uptake in Ghana are limited.

Purpose: The purpose of this study was to use Multi-theory model constructs (i.e. participatory dialogue, behavioral confidence, physical environment, practice for change, social environment, and emotional transformation) to predict initiation and completion of HPV vaccination series among Ghanaian adolescents.

Methods: Adolescents (n=285) between the ages of 12 and 17 years old were recruited from four schools in Ghana. They completed a 44-item survey that measured demographic, predictor, and outcome variables. The predictor subscales included perceived belief, participatory dialogue, behavioral confidence, physical environment, practice for change, emotional transformation, and social environment. The outcome variables included the initiation and completion of the HPV vaccination series. We used 3-items for each predictor subscale and 1-item for each outcome subscale, and each item was measured on a 5-point response scale. Using hierarchical linear regression models, we identified predictors of adolescents' likelihood of initiating and completing the HPV vaccination series.

Results: Most participants were female (91.2%), senior high school students (60.0%), and Christians (96.8%). Many of the participants had neither heard about HPV (92.3%) nor HPV vaccinations (95.4%). Significant predictors of adolescents' likelihood of getting the first dose of HPV vaccination were perceived beliefs and change in a physical environment ($p < 0.001$), with each variable accounting for 6.1% and 8.8% of the variance respectively. Significant predictors of adolescents' likelihood of completing HPV vaccination recommended series were perceived beliefs, practice for change, and emotional transformation ($p < 0.001$), with each variable accounting for 7.8%, 8.1% and 1.1% of the variance respectively.

Conclusion: The findings from our study underscore the lack of awareness of HPV related cancers among adolescents in Ghana. HPV vaccination initiation key predictors included perceived beliefs and a change in the physical environment. Perceived beliefs, practice for change, and emotional transformation were key predictors of HPV series completion. Future HPV vaccination intervention efforts should focus on addressing these modifiable factors to increase HPV vaccination uptake among adolescents in Ghana

THE SOCIAL CONTEXT OF CANCER FOR SEXUAL MINORITY WOMEN: A SYSTEMATIC REVIEW

Tess Thompson, PhD, MPH¹, Katie Heiden-Rootes, PhD², Miriam Joseph, PhD³, Linda A. Gilmore, PhD, RD³, LaShaune P. Johnson, PhD⁴, Emily L. Albright, MD⁵, Maria Brown, PhD, LMSW, MA⁶, Jane A. McElroy, PhD⁵, Christine M. Proulx, PhD⁵

¹Washington University in St. Louis, St. Louis, MO; ²Saint Louis University, St. Louis, MO; ³Pennington Biomedical Research Center, Baton Rouge, LA; ⁴Creighton University, Omaha, NE; ⁵University of Missouri, Columbia, MO; ⁶Syracuse University, Syracuse, NY

Intimate partners and other informal caregivers often provide unpaid tangible, emotional, and decision-making support for cancer patients. Less is known about the social context for sexual minority women (SMW; e.g., lesbian, gay, bisexual, queer, same-gender partnered) with cancer.

This systematic review followed Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines and was designed to examine peer-reviewed, empirical research in English about the cancer experiences of SMW and their partners/informal caregivers. The review centered on 4 questions: 1) What social support do SMW with cancer receive from partners/caregivers? 2) What effect does cancer have on the informal caregiving relationships or intimate partnerships of SMW with cancer? 3) What effects does cancer have on partners/caregivers of SMW with cancer? 4) What interventions exist to support partners/caregivers of SMW or to strengthen the patient-caregiver relationship.

After removing duplicates, 336 abstracts were each screened by teams of 2 coders; 32 full-text articles were assessed for eligibility, and 17 were included in a qualitative synthesis. Most studies were U.S.-based, involved breast cancer, included intimate partners, had primarily white/Caucasian samples, were cross-sectional, and did not ground research questions in theory. Participants reported that partners/caregivers often provide important social support for sexual minority women with cancer, including emotional support, decision-making support, and tangible support (e.g., housework). Effects of cancer on relationships with partners/caregivers were mixed, with some studies finding relationships remained stable and that cancer increased closeness, and others suggesting relationships were often disrupted. Participants reported that partners/caregivers often experience distress and may be affected by factors such as discrimination, discomfort disclosing sexual orientation, and a lack of sexual minority-friendly services. No study involved an intervention aimed at partners/caregivers or the dyadic relationship.

More work is needed to understand SMW with cancers other than breast cancer; samples that are racially, ethnically, or economically diverse; and samples outside the U.S. Longitudinal research will allow examination of the evolution of relationships and patterns of mutual influence over time. These next steps are necessary to develop interventions to support SMW with cancer and the people close to them.

6:15 PM-7:30 PM

FEASIBILITY AND EFFICACY OF AEROBIC & RELAXATION TRAINING FOR IMPROVING FATIGUE IN BREAST CANCER SURVIVORS: A PILOT RCT

Jason D. Cohen, PhD¹, Wendy Rogers, Ph.D.², Steven J. Petruzzello, PhD³, Linda Trinh, PhD⁴, Sean P. Mullen, PhD⁵¹Washington University in St. Louis, St. Louis, MO; ²University of Illinois Urbana-Champaign, Champaign, IL; ³University of Illinois Urbana-Champaign, Urbana, IL; ⁴University of Toronto, Toronto, ON, Canada; ⁵University of Illinois at Urbana-Champaign, Urbana, IL

Chemotherapy has been linked to enduring post-treatment fatigue in breast cancer survivors (BCS). Improvement from separate aerobic exercise training and mindfulness interventions is promising, yet the feasibility and efficacy of a combined approach is unknown. The purpose of this pilot randomized controlled trial (RCT) was to test the feasibility and efficacy of a combined aerobic exercise and technology-based relaxation training compared (AT+RT) to standalone aerobic training (AT) and relaxation training (RT), in an acute paradigm involving pre and post-testing among three training sessions. The AT+RT group was hypothesized to have more favorable outcomes in fatigue and enjoyment relative to the other groups. Participants were screened for cognitive impairment, hearing difficulties, colorblindness, difficulty in exercise, and lack of appropriate cancer treatment. Forty participants ($M_{age} = 57.33 \pm 8.75$, $M_{BMI} = 27.38 \pm 5.27$) completed baseline testing, three 90-minute intervention sessions with three intra-session assessments (pre, mid, and post), and follow-up testing >24 hours between each session. A battery of assessments was repeatedly administered including novel questions about enjoyment, ease of use, & satisfaction, (e.g., "I was satisfied with the effectiveness of my activities for reducing fatigue"), the *Piper Fatigue Scale* (PFS), among other questionnaires, and assessments of cognitive functioning. A one-way ANOVA revealed significant group differences in enjoyment favoring AT+RT ($M = 7.00 \pm 0.00$), relative to AT ($M = 6.31 \pm 1.03$) and RT ($M = 6.79 \pm 0.11$). A repeated-measures ANOVA revealed reductions in fatigue (PFS) to be large in scale ($\eta^2 = 0.17$) and in favor of AT+RT ($M\Delta = -1.55$, AT $M\Delta = -0.61$, RT $M\Delta = -0.60$), although the effects were attenuated after adjusting for covariates (BMI, global score from the *Godin Leisure Time Questionnaire*, treatment composite variable incorporating drug type and time since end of usage, age, and Memory Self-Efficacy). Further, the AT+RT group was the only group to score in the "mild" fatigue level, while the other groups remained "moderate." This study offers preliminary evidence for the feasibility of an acute multi-modal intervention involving aerobic exercise and relaxation training among BCS. Also, preliminary findings suggest the potential for a new method to improve chronic fatigue reduction among BCS, although a larger and longer trial is warranted.

ONLINE COUPLE-BASED MEDITATION INTERVENTION FOR BRAIN TUMOR PATIENTS AND THEIR SPOUSES

Kathrin Milbury, PHD¹, Shiao-Pei Weathers, MD¹, Sania Durrani, MPH¹, Eduardo Bruera, MD¹¹The University of Texas MD Anderson Cancer Center, Houston, TX

Purpose: Although patients with primary and metastatic brain tumors (BT) and their spouses are at risk of experiencing high symptom burden, they are often excluded from psychosocial intervention studies. Thus, we sought to examine the feasibility and preliminary efficacy of a couple-based mediation (CBM) program targeting symptom and wellbeing outcomes.

Methods: Couples completed validated baseline self-report measures and were randomized to the CBM or a usual care control (UC) group. Couples in the CBM groups attended four, weekly (60 min. each) therapist-led sessions that were delivered via FaceTime. The CBM program focused on cultivating mindfulness, compassion, gratitude and purpose and integrated emotional disclosure exercises. Both groups were reassessed 6 and 12 weeks after baseline.

Results: We approached 60 eligible dyads of which 37 (62%) consented and 35 (95%) were randomized and 22 (63%) completed all assessments. Attrition was mainly due to patients' death ($n=8$). Patients (57% male; mean age=57 years) and partners' (59% female; mean age=54 years) in the CBM group attended a mean of 3.33 sessions ($SD=1.09$). All participants in the CBM group reported the intervention as beneficial and useful and would recommend this program to other couples. For patients, significant group differences ($P < .05$) with medium to large effects sizes in favor of the CBM group were found for cognitive ($d=1.05$) and general disease symptoms ($d=.93$), relationship wellbeing ($d=.68$) and compassion ($d=.96$). No significant group differences were revealed for spouses.

Conclusions: It seems to be feasible, acceptable and possibly efficacious to deliver a dyadic intervention via FaceTime to BT couples. Although both patients and spouses in the CBM group rated the intervention as beneficial, significant group differences with medium to large effect sizes were only found for patients. The intervention may have possible benefits for spouses during bereavement.

6:15 PM-7:30 PM

THE EFFECTS OF MENOPAUSAL SYMPTOMS ON PHYSICAL ACTIVITY IN AN EXERCISE INTERVENTION FOR FEMALE CANCER SURVIVORS

Danielle B. Tometich, M.S.¹, M. Tish Knobf, PhD, RN², Sangchoon Jeon, Ph.D.³¹Yale University, New Haven, CT; ²Yale University, Orange, CT; ³Yale University, West Haven, CT

Cancer survivors are at risk for severe symptoms and medical sequelae that may be attenuated by physical activity (PA), yet sedentary lifestyles are common. Self-regulation theories and research suggest that symptoms may be substantial barriers to PA. Symptoms of menopause affecting many female cancer survivors such as hot flashes, fatigue, pain, and cognitive symptoms may also be barriers to PA. Therefore, the aim of this project was to examine the effect of baseline menopausal symptoms on PA over the course of an exercise intervention for peri- and post-menopausal cancer survivors. The current project was a secondary analysis of the Yale Fit study, a 12-month randomized clinical trial of an exercise intervention in comparison to home-based health promotion ($N=154$, mean age=58). Menopausal symptoms were self-reported using the Breast Cancer Prevention Trial Symptom Checklist (BCPT-SCL), a measure of severity of 42 symptoms on a 5-point Likert scale (0=Not at all, 4=Extremely). PA was self-reported using the International Physical Activity Questionnaire (IPAQ), which provides an estimate of PA in Metabolic Equivalent of Task (MET) minutes per week. Latent Class Analysis (LCA) was used to determine subgroups of participants based on their profile of severity for 12 selected symptoms at baseline (hot flashes, headaches, aches/pains, joint pain, swelling in extremities, muscle stiffness, weight gain, poor body image, forgetfulness, tendency to take naps, difficulty concentrating, and easy distraction). Linear mixed effects modeling was then used to examine the effects of symptom subgroup on PA over time, and the interaction between symptom subgroup and intervention group, controlling for age and Aromatase Inhibitor. There were 153 participants with sufficient data for analysis. LCA showed 3 subgroups: class 1 ($n=56$) had moderate+ severity for hot flashes, joint pain, and poor body image; class 2 ($n=24$) had moderate+ severity for hot flashes, aches/pains; joint pain, poor body image, forgetfulness, tendency to take naps, difficulty concentrating, and easy distraction; class 3 ($n=73$) had low severity on all symptoms except hot flashes. Linear mixed-effects modeling showed no main effect of symptom subgroup or interaction effects with time or intervention group on PA ($p > 0.05$). Findings indicated that there were subgroups of women based on their menopausal symptoms at baseline, but these subgroups did not predict their PA over the course of the exercise intervention.

PERCEPTIONS OF TUMOR GENOMIC PROFILING IN AFRICAN AMERICAN CANCER PATIENTS: AN IN-DEPTH QUALITATIVE ANALYSIS

Sarah Bauerle, Bass, Ph.D. and MPH¹, Michael Hall, MD, MS², Yana Chertock, MA², Jesse A. Brajuha, MPH³, Jennie Coleman, MPH³¹Temple University College of Public Health, Philadelphia, PA; ²Fox Chase Cancer Center, Philadelphia, PA; ³Temple University, Philadelphia, PA

Background: Tumor genomic profiling (TGP) is used to examine targetable mutations for personalized oncology, but many patients are unaware it may also detect secondary hereditary cancer risks. African Americans (AA) have an increased cancer risk, lower health literacy and genetic knowledge, and higher medical distrust. Physicians may need to target communicate about TGP with these patients and understand how they perceive of genetic risk, yet little is known about AA's TGP perceptions or their communication needs.

Methods: Five focus groups with AA cancer patients ($n=34$) were conducted at a comprehensive cancer center and the oncology unit of an urban teaching hospital. Groups were audio recorded and transcriptions analyzed. Codes were derived deductively from the moderator's guide and inductively through emergence until thematic saturation.

Results: Participants were 76% female, age range of 27–76, and about 60% had \leq high school diploma. Over 70% had never heard of TGP. All groups discussed stigma of cancer and lack of communication within the family as significant issues when it came to treatment decisions and genetic testing. Key differences in medical trust were observed with those in the urban hospital expressing more mistrust of medical information; participants from both sites were skeptical of having genetic information as part of their medical record. Feelings were mixed related to receipt of secondary genetic information, but most agreed that they would rather doctors talked to them about these results than a genetic counselor. Many were concerned about having to share genetic information with family, or what it might mean for their own health, indicating that specialized cancer communication may need to occur with AA patients.

Conclusion: While TGP is a key advance in cancer care, understanding the unique information needs of AA patients is critical to developing meaningful interventions to assist with informed decision making. Physicians need to think about how to incorporate targeted messaging about TGP that incorporates these beliefs in AA patients or risk exacerbating medical mistrust of information.

PHYSICAL ACTIVITY INTERVENTIONS: STATE OF THE SCIENCE FOR COLORECTAL CANCER SURVIVORS

Yves Paul V. Mbous, M. Eng¹¹West Virginia University, Morgantown, WV

Background: With the growing number of colorectal cancer survivors (CRCS), theory-based, high-quality physical activity (PA) interventions are needed to promote quality and quantity of life.

Purpose: This systematic review and meta-analysis synthesized theory-based PA interventions among CRCS.

Methods: Using PubMed, PsycINFO, CINAHL, MEDLINE, SportDiscus, and Cochrane databases, studies including CRCS participants, a PA outcome, a behavioral theory/model or behavior change techniques (BCT), and a randomized research design were identified. Two reviewers coded BCT, intervention reproducibility (Template for Intervention Description and Replication–TIDier), risk of bias, and quality of evidence.

Results: From an initial screen of 1328 articles, 10 RCTs met our inclusion criteria. The Transtheoretical Model ($n=3$), Social Cognitive Theory ($n=3$), and Theory of Planned Behavior ($n=2$) were the most used theories. “Goal setting (behavior)” ($n=10$), “goal setting (outcome)” ($n=10$), “action planning” ($n=9$), and “problem solving” ($n=9$) were the most commonly used BCTs. Interventions modalities were primarily print material based ($n=4$) and telephone counselling ($n=4$). Findings demonstrated that theory-based PA interventions are successful at increasing PA among CRCS as meta-analysis evidenced a small-to-moderate effect size of 0.26. According to the TIDier, Items 3 (information about location of materials used), 9 (modifications during the intervention), and 12 (assessment of intervention adherence or fidelity) hindered intervention replicability. Serious risk of bias resulted from lack of blinding and bias in the measurement of outcomes by assessors.

Conclusions: In-depth theoretical applications are needed for PA interventions that minimize bias and improve outcomes measurement. Intervention adherence and fidelity, as well as theoretical construct measurement pre- and post-intervention, will enhance the behavioral research enterprise.

PATIENT-REPORTED OUTCOMES IN HNC SURVIVORS: EVALUATING THE “RURAL DISADVANTAGE”

Jenna L. Adamowicz, M.A.¹, Alan Christensen, Ph.D.², M. Bryant Howren, Ph.D., MPH³, Aaron T. Seaman, Ph.D.¹, Nicholas D. Kendell, MS⁴, Shylo Wardyn, MS⁵, Nitin A. Pagedar, MD, MPH⁴

¹University of Iowa, Iowa City, IA; ²East Carolina University, Greenville, NC; ³College of Medicine, FSU, Tallahassee, FL; ⁴University of Iowa HC, Iowa City, IA; ⁵Iowa City VA Health Care System, Iowa City, IA

Background: Approximately 4% of all cancers in the US are head and neck cancer (HNC). The sequelae of HNC and its treatment are extremely visible (e.g. facial disfigurement) making HNC one of the most emotionally traumatic cancers to experience. Many HNC patients experience psychological distress and functional impairments that affect their quality of life (QOL) during and after recovery. Further, research now supports a possible “rural disadvantage,” meaning cancer patients who live in rural locations have poorer physical and psychological outcomes than their urban counterparts. Thus, the present study aimed to examine whether 6-month and 1-year HNC patient psychosocial outcomes differ in patients living in rural v. urban locations.

Methods: This study included 498 HNC patients (male = 63%, age = 60+12.16 years). The majority of patients (54%) were diagnosed with advanced stage cancer and the most common cancer site was oral cavity (38%). Forty-two percent of patients lived in a rural location, as measured by RUCA codes from the US Department of Agriculture. Outcomes were collected at the time of diagnosis, and at 6-month and 1-year follow-ups, and included BDI depression symptoms, mental and physical functioning, and cancer-specific QOL domains of speech, eating, aesthetics, and social disruption. Repeated measures ANOVA's were used to examine the association between rurality and psychosocial outcomes over time, controlling for age, sex, cancer site, and stage.

Results: Tests of between-subjects effects on total depression scores did not differ significantly between groups across the three time points, $F(1, 248) = 3.34$, $p = .069$. Given the overlap in somatic symptoms measured by the BDI and those experienced by HNC patients (e.g., fatigue, weight loss, change in appetite), cognitive-items only of the BDI were also examined. Cognitive depression scores differed significantly between groups, $F(1,249) = 5.23$, $p = .023$, with urban patients reporting fewer symptoms at the 6-month follow-up ($\beta = -1.53$, $p = .01$). Regarding HNC-QOL, there was a significant difference in eating scores at 6-months ($F(1,236) = 3.94$, $p = .048$, $\beta = 6.62$, $p = .021$) as well as aesthetics at baseline ($F(1, 241) = 5.00$, $p = .026$, $\beta = 5.67$, $p = .026$). For both domains, urban patients reported better QOL than rural patients.

Conclusions: Results suggest HNC patients living in rural locations experience more cognitive depression symptoms than their urban counterparts 6-months following their cancer diagnosis. Rural patients were also more likely to report poorer QOL in regard to eating at 6-months and aesthetics at the time of diagnosis. These results underscore the need for depression screening, referral, and management in HNC patients living in rural settings.

SUGAR-SWEETENED BEVERAGE CONSUMPTION AND METABOLIC SYNDROME RISK IN MEXICAN-AMERICANS LIVING ON THE TEXAS-MEXICO BORDER

Jisook Ko, PhD, RN¹, Yan Du, PhD, MPH, RN¹, Shenghui Wu, PhD, MPH², Vivian Nguyen, BS³, Jing Wang, PhD, MPH, RN¹¹UT Health Science Center San Antonio, San Antonio, TX; ²UT Health Science Center, Laredo, TX; ³UT Health Science Center / Biotechnology, San Antonio, TX**Background:** Despite growing evidence for negative effects of sugar-sweetened beverages (SSBs) on weight gain and obesity, the relationships between SSBs and metabolic syndrome risk are not entirely explored in Mexican-Americans (MAs).**Objective:** The purpose of this analysis is to assess the level of SSB and metabolic syndrome risk and explore associations between these two in MAs living on the Texas-Mexico border.**Research Design / Methods:** Participants in this cross-sectional study were drawn from the baseline data of the Cameron County Hispanic Cohort (N=4,618) study from 2004 to 2019. Consumption of SSBs was assessed using a validated food frequency questionnaire including non-diet soft drink, flavored juice drinks, sweetened tea, coffee drinks, etc. The metabolic syndrome was defined using the American Heart Association definition, which requires the presence of at least three of the following: elevated waist circumference, ≥ 102 cm for men or ≥ 88 cm for women; elevated triglycerides ≥ 150 mg/dl; reduced high-density lipoprotein (HDL) cholesterol ≤ 40 mg/dl for men or 50 mg/dl for women; elevated blood pressure $\geq 130/85$ mm Hg or use of medication for hypertension; and elevated fasting glucose ≥ 100 mg/dl. Survey-weighted logistic regressions were used to identify the relationships between SSBs consumption and metabolic syndrome risk.**Results:** A total of 1,752 participants of the cohort (37.9%) were found to have metabolic syndrome (mean age 42.9 ± 17.5). Nearly 64% of the sample consumed one or more SSBs per day. In the bivariate analysis, SSBs drinkers were more likely to be older ($t = -10.67, p < .001$), Spanish-speaking ($\chi^2 = 94.36, p < .001$), smoking ($\chi^2 = 118.98, p < .001$), alcohol drinking ($\chi^2 = 51.28, p < .001$), and unmet fruit and vegetable servings ($\chi^2 = 116.95, p < .001$) as compared to non-SSB drinkers. Metabolic syndrome was not associated with SSB consumption; however, we found significantly increased risk for three subcomponents: increased waist circumference (OR = 2.03; 95% CI: 1.62 - 2.54), higher blood pressure (OR = 2.38; 95% CI: 1.89 - 2.98), and impaired fasting glucose (OR = 1.53; 95% CI: 1.33 - 1.75). There was no association between SSBs consumption and obesity (OR = 0.99; 95% CI: 0.98 - 1.01), noting that there was less variance on body mass index across the participants.**Conclusions:** The findings support the hypothesis that higher SSBs consumption increases the risk of metabolic syndrome in MAs. Results suggest that future research is needed to explore underlying pathways of SSB consumption contributing risk of metabolic syndrome beyond weight gain for this target population. In addition to targeting obesity in MAs consuming SSBs, a precise and personalized behavioral nutrition intervention will be warranted to the groups identified to be most affected by a high risk of metabolic syndrome.

SELF-RATED HEALTH STATUS AND MULTIMORBIDITY IN OLDER PATIENTS WITH ATRIAL FIBRILLATION

Hawa O. Abu, MD MPH PhD¹, Jane Saczynski, PhD², Jordy Mehawej, MD¹, Tenes J. Paul, DO³, Hamza Awad, MD, PhD⁴, Mayra Tisminetzky, MD PhD MPH¹, Catarina Kiefe, MD PhD⁵, Robert J. Goldberg, PhD⁶, David D. McManus, MD, ScM¹¹University of Massachusetts Medical School, Worcester, MA; ²North Eastern University, Boston, MA; ³University of Massachusetts Medical School, Watertown, MA; ⁴Mercer University School of Medicine, MACON, GA; ⁵Univ of Massachusetts Medical School, Sterling, MA; ⁶University of Massachusetts Medical School, Westborough, MA**Background:** In patients with atrial fibrillation (AF) there has been little focus on the perception of their illness experience, especially among older patients diagnosed with one or more chronic medical conditions (multi-morbidity). Self-rated health (SRH) integrates aspects of biological, physical, social, and mental functioning, and has been linked with morbidity and mortality in varying patient populations.**Objectives:** To assess SRH status in older men and women with AF and examine the association between multi-morbidity and SRH.**Methods:** Cross-sectional analysis of baseline data obtained from a prospective cohort study: Systematic Assessment of Geriatric Elements in Atrial Fibrillation (SAGE-AF). Study participants aged ≥ 65 years were recruited from five medical centers in Massachusetts and Georgia between 2015 and 2018. SRH status was assessed with a validated item that asked: "In general, would you say your health is excellent, very good, good, fair, or poor?". Participants were categorized as either having "excellent/good" or "fair/poor" SRH. The presence of 10 previously diagnosed cardiometabolic and 8 non-cardiometabolic comorbid conditions were assessed from electronic medical records. Multivariable logistic regression models were used to examine the association between SRH status and number of all comorbid conditions, cardiometabolic, and non-cardiometabolic conditions respectively.**Results:** Study participants (n=1,235) were, on average 76 years old, 49% were women, and 86% were White. Overall, 17% rated their health as fair/poor. The median number of total, cardiometabolic, and non-cardiometabolic comorbidities were 6, 3, and 3 respectively. The most prevalent cardiometabolic comorbid conditions were hypertension (90%), dyslipidemia (80%), and congestive heart failure (37%). Arthritis (51%), Anemia (31%), and Cancer (30%) were the most common non-cardiometabolic diseases. Patients who rated their health as fair/poor were more likely to be non-White, have less than high school education, and low social support compared with those who rated their health as excellent/good. A greater proportion of those who reported fair/poor SRH had cognitive, hearing, and visual impairment, and more previously diagnosed comorbidities than patients with reports of excellent/good SRH. After adjusting for several sociodemographic and psychosocial characteristics, patients were more likely to report fair/poor SRH with increasing number of all comorbidities (Adjusted Odds Ratio (aOR): 2.39 [1.41–4.05], ≥ 8 versus 1–4) and cardiometabolic comorbidities (aOR: 2.56 [1.46–4.49], ≥ 5 versus 1–2).**Conclusions:** The present results provide insight on the association between multimorbidity and subjective report of health status among older patients with AF which has implications in delivering evidence-based care aimed at improving patient reported outcomes.

DEPRESSIVE SYMPTOMS FOLLOWING CARDIOTHORACIC SURGERY: ARE THERE DIFFERENCES BY SURGERY TYPE?

Allison J. Carroll, PhD¹, Kathleen Grady, PhD, MS, RN², Gail Osterman, Ph.D.³, Patrick M. McCarthy, MD², Kim Feingold, PhD²¹Feinberg School of Medicine, Chicago, IL; ²Northwestern University, Chicago, IL; ³Northwestern Medicine, Chicago, IL

Background: Up to 40% of patients will develop depression after cardiac surgery, and these post-operative depressive symptoms are associated with poorer cardiac outcomes. No studies have directly compared the prevalence and patterns of depressive symptoms between patients undergoing different cardiothoracic surgical procedures. The purpose of this study was to assess the association between valve surgery, coronary artery bypass graft (CABG) surgery, or their combination with patterns of depressive symptoms during the 12 months following surgery.

Methods: Patients who were undergoing cardiac surgery (valve repair/replacement surgery, coronary artery bypass graft (CABG) surgery, or CABG + valve surgery) in the Bluhm Cardiovascular Institute of Northwestern were enrolled in this study. Depressive symptoms were assessed using the Beck Depression Inventory (BDI-II) at baseline and post-operatively at 3 months, 6 months, and 12 months. Demographics and medical variables were obtained from the electronic health record. We assessed the sample's baseline characteristics by cardiac surgery type and evaluated the trends in depressive symptoms through follow-up by cardiac surgery type using repeated-measures Analysis of Covariance (ANCOVA), adjusted for sociodemographics and medical diagnoses.

Results: Of 264 cardiac surgery patients, 155 (59%) had valve surgery, 47 (18%) had CABG surgery, and 62 (23%) had CABG + valve surgery. The sample was predominantly male (63%), married/partnered (64%), had a college degree (52%), not currently working (64%), made < \$50,000/year (52%), and were 68 years old on average. At baseline, average depressive symptoms did not differ between valve surgery (M=7.8, SD=6.7), CABG surgery (M=9.0, SD=7.9) and CABG + valve surgery (M=9.4, SD=7.9), $p=.327$. In the full sample, depressive symptoms were highly correlated across all measurement times, with Pearson's correlation coefficients from 0.50 to 0.90, all $ps < .001$. In the fully adjusted model, the surgery x time interaction was not significant ($F=0.83$, $p=0.549$), suggesting that the patterns of post-operative depressive symptoms did not differ by cardiac surgery procedure. Likewise, the main effect of surgery type did not reach significance ($F=2.51$, $p=0.087$). However, there was a main effect of time ($F=2.78$, $p=0.042$), indicating that depressive symptoms decreased over time from baseline through 12 months.

Discussion: On average, depressive symptoms improved following cardiac surgery, with no significant difference by cardiothoracic surgical procedure. Future studies evaluating the ways in which cardiac surgeries contribute to depression are warranted to better understand the ways in which psychological comorbidities affect cardiac outcomes.

ASSOCIATIONS BETWEEN RACE, WORKPLACE ORGANIZATIONAL FACTORS AND CARDIOVASCULAR DISEASE RISK FACTOR

Starlynn Gornail, MHS¹, Caryn N. Bell, PhD²¹University of Colorado School of Public Health, Denver, CO; ²University of Maryland, College Park, College Park, MD

Background: As the number of individuals with CVD increases, the financial burden will continue to climb as cardiovascular disease (CVD) will cost Americans 1.1 trillion dollars by 2035.¹ For employers, these financial and personal burdens affect the entire workforce, but CVD and its associated risk factors are disproportionate for many racial groups. Research on racial disparities in CVD risk factors like hypertension or diabetes and socioeconomic status has not fully considered workplace organizational factors such as job demands and its association with health. The objective of this study is to evaluate whether associations between workplace organizational factors with hypertension and diabetes vary by race and income.

Methods: Data from the 2015 National Health Interview Survey included 25,318 African Americans and whites. Workplace organizational factors included survey questions referring to the ability to complete job tasks, support from supervisors, decision-making, job demands interfering with personal/family life, and job insecurity. Logistic regressions including multiplicative interaction terms were used to determine whether race and income moderated the associations of occupational factors with diabetes and hypertension.

Results: African Americans had higher odds of diabetes (OR=1.41, 95% CI=1.05–1.90) and hypertension (OR=1.85, 95% CI=1.57–2.18). The associations of workplace organizational factors with hypertension and diabetes differed by race, particularly among those with incomes >\$75,000. For whites, the odds of diabetes were higher among those with poor work-life balance (OR=1.42, 95% CI=1.02–1.97). However, among African Americans, poor work-life balance was associated with lower odds of diabetes (OR=0.39, 95% CI=0.18–0.83). Poor work-life balance was associated with lower odds of hypertension among African Americans (OR=0.47, 95% CI=0.25–0.87), but higher odds among whites (OR=1.35, 95% CI=1.08–1.70) among those with incomes >\$75,000.

Conclusion: This study demonstrates race differences in the associations of workplace organizational factors with hypertension and diabetes, and that higher income also moderated these associations. The presentation will explore recommendations for future studies and innovative digital resources such as CDC Workplace Health Resource Center for workforces to address the disparity.

FITNESS IS ASSOCIATED WITH COGNITIVE FUNCTION IN SYSTOLIC HEART FAILURE

Brooke Fusco, M.A.¹, Mary Dolansky, PhD, RN², Richard Josephson, MD², Joel W. Hughes, PhD, FAACVPR¹¹Kent State University, Kent, OH; ²Case Western Reserve University, Cleveland, OH

Introduction: Almost 6 million Americans have heart failure (HF) and the prevalence is expected to rise in the next decade.¹ HF is associated with significant economic and personal burdens, such as high healthcare costs, high rates of readmission, reduced quality of life (QOL), and high risk of poor health, disability, and mortality.²⁻⁵ Cognitive impairment is highly prevalent in HF patients and is associated with poorer outcomes, such as poor self-management behaviors and greater risk of rehospitalization, compared to HF patients without cognitive impairment.⁶⁻¹¹ Previously, we found that fitness, assessed using the 2-minute step test (2MST),¹² was associated with global cognitive function and the domains of executive function, language, and attention (a trend at $p = .09$), but not memory.⁶ The aim of the current study was to replicate and extend these findings in an independent sample.

Methods: Participants were 120 patients with HF (60.8% male, 84.2% Caucasian). Average age was 68.17 years ($SD=9.91$). Functional fitness was measured using the 2MST.¹² Mean number of steps on the 2MST was 65.60 ($SD=26.35$). Cognitive function was assessed using the Modified Mini-Mental Status Examination (3MS)¹³ and a battery of neuropsychological tests. Composite scores were created for the domains of attention, executive function, and memory by calculating the average T-scores within each domain. Multiple linear hierarchical regression analyses were performed, controlling for important demographic and clinical variables.

Results: The 2MST was associated with global cognitive function ($F [5, 114] = 4.50$ [$p < .01$], $R^2 = .17$, $B = .08$ [$SE B = .02$], $p < .01$) and executive function ($F [5, 114] = 3.94$ [$p < .01$], $R^2 = .15$, $B = .08$ [$SE B = .03$], $p < .05$). The 2MST was also predictive of attention ($F [5, 114] = 5.59$ [$p < .001$], $R^2 = .20$, $B = .09$ [$SE B = 0.03$], $p < .01$) and memory ($F [5, 114] = 6.53$ [$p < .001$], $R^2 = .22$, $B = .06$ [$SE B = .03$], $p < .05$).

Discussion: Fitness was associated with global cognitive functioning, as well as the domains of executive function, attention, and memory. The lack of association between fitness and memory in our previous study⁶ may be explained by differences in sample characteristics. The 2MST is a practical alternative to the 6-minute walk test and may be clinically useful for identifying patients who would benefit from interventions to improve fitness toward the end of preserving cognition. For example, exercise-based cardiac rehabilitation has been shown to prevent cognitive decline and reduce risk of rehospitalization and mortality.¹⁵⁻¹⁷

BEHAVIORAL AND STRESS CARDIAC ATTRIBUTIONS ARE RELATED TO IMPORTANCE OF CARDIAC REHABILITATION AND HEALTH SELF-DETERMINISM

Elizabeth J. Wilson, M.A.¹, Kymberley K. Bennett, PhD¹, Andrew J. Smith, Pharm.D.², Kalon R. Eways, M.A.¹, Kadie M. Harry, PhD³, Jillian Clark, PhD⁴, Marcia Waters, RN⁵, Anahi R. Ramirez, B.A.¹¹University of Missouri-Kansas City, Kansas City, MO; ²UMKC School of Pharmacy, Kansas City, MO; ³Saint Luke's Health System Cancer Institute & Koontz Center for Advanced Breast Cancer, Kansas City, MO; ⁴VA San Diego Healthcare System, San Diego, CA; ⁵Truman Medical Center, Kansas City, MO

Prior research suggests that behavioral attributions for illness/chronic disease are positively associated with health behaviors, outcomes, and health-related attitudes and cognitions. This project tested whether there is an association between the type of attribution made by patients with cardiovascular disease (CVD), including behavioral ones, and attitudes toward cardiac rehabilitation (CR)—a secondary prevention program for patients with CVD. Participants were recruited from a safety-net hospital, resulting in a diverse sample of patients ($n = 167$) with CVD (mean age = 55.3 years; 66% male; 46% ethnic minority; 46% uninsured). Cardiac attribution was assessed with an open-ended item: “If you had to pick one major cause for your cardiac event, in your own words, what would that cause be?” Participants provided a total of 202 distinct attributions—134 produced one attribution, 34 produced two attributions, and two produced three attributions. Attributions were coded into three causal themes: biological ($n = 30$), behavioral ($n = 119$), and stress ($n = 24$). CR importance was assessed with a single item, “How important do you believe cardiac rehabilitation is to you?” which was scored from 1 (*Not at all important*) to 5 (*Very important*). Health related attitudes included health self-determinism and cardiac self-efficacy, which were measured by the Health Self-Determinism Index (HSDI) and Cardiac Self-efficacy Scale (CSE), respectively. CR attendance and the number of sessions completed were collected from participants' medical charts.

Results indicated that those who made behavioral attributions rated CR as more important [$t(164) = -2.833$, $p = .005$], but had lower HSDI scores [$t(158) = 2.275$, $p = .024$], than those who did not make a behavioral attribution. Findings for those who made stress attributions reflected the inverse pattern—they rated CR as less important [$t(164) = 2.12$, $p = .028$], but had higher HSDI scores [$t(164) = -2.052$, $p = .042$], than those who did not make stress attributions. Comparisons between attribution types were not significant regarding CSE, CR enrollment or attendance, and no significant associations were found for biological attributions.

These results suggest that health providers should be aware that the kinds of attributions patients make may relate to the importance they place on CR. Providers should incorporate conversations around patient produced attributions and explore related motivations to engage in suggested treatments.

DOSE-RESPONSE EFFECTS OF AN ONLINE AND IN-PERSON FAMILY INTERVENTION ON PHYSICAL ACTIVITY IN CHILDREN WHO ARE OVERWEIGHT

Brenda Adams, M.Ed., B.Sc.¹¹University of Victoria, Ladysmith, BC, Canada

Background: Family-focused weight management interventions are the principal approach to manage childhood obesity. A blended Internet and in-person intervention can maximize the flexibility of delivering these interventions. However, there is a lack of studies examining the dose-response relationship between blended program engagement and improvements in physical activity (PA) behaviours among children.

Objectives: 1) Examine the engagement patterns of a blended 10-week family-based intervention; 2) explore the dose-response relationship between engagement and physical activity outcomes at 10-week follow-up.

Methods: This is a secondary data analysis from a randomized waitlist-controlled study examining the efficacy of a family-based early intervention program (EIP) for children with BMI \geq 85th percentile for age and sex. EIP was a 10-week blended intervention designed using the Multiple Process Action Control Framework. EIP consisted of 10 weekly in-person sessions and 10 online lessons. We analyzed the engagement pattern of participants in the EIP ($n=48$). In-person usage was defined as the number of classes attended. Online usage was defined as the percentage of content accessed and number of logins. Children's moderate-vigorous physical activity (MVPA) levels, screen time, and parent's support for the child to engage in PA were assessed using validated questionnaires. Descriptive analyses were used to analyze usage patterns and ANCOVA were used to evaluate the dose-response relationship.

Results: The mean (SD) in-person engagement was 6.36 (3.06) sessions, online usage was 21.65 \pm 22.71% of the content accessed and 2.86 \pm 3.26 times of logins over the 10 week period. Usage analysis revealed three distinct groups: i) high engagement (high online and in-person usage: \geq 60% of content; \geq 4 logins; \geq 70% of classes; $n=14$), ii) moderate engagement (high in-person but low online-engagement: attended \geq 70% of classes; $<$ 60% of content; $<$ 4 logins; $n=13$), and iii) low engagement (low online and in-person usage: $<$ 60% of content; $<$ 4 logins; attended $<$ 70% of classes; $n=22$) group. Relative to the low-engagement group, high engagement group showed significantly higher weekly MVPA (mean(SD): -1.4(0.48), $p=.007$) and lower screen-time (-1.2(0.38), $p=.004$) among children, and higher levels of parental PA support (0.5(0.26), $p=.047$) at 10-weeks. High engagement group also showed lower screen-time (-1.2(0.38), $p=.01$) among children and higher levels of parental PA support (0.66(0.28), $p=.02$) than the moderate engagement group at 10-weeks.

Conclusion: Our findings suggest a dose-response relationship between intervention engagement and improvements in PA outcomes at follow-up. Additional online portal engagement may further enhance the effectiveness of in-person interventions. Future research needs to examine optimal ways to combine online and in-person interventions.

THE DYNAMICS OF ADOLESCENTS' PUBERTAL DEVELOPMENT, DEPRESSION AND FRIENDSHIP NETWORKS: STOCHASTIC ACTOR-ORIENTED MODEL

Yifang Yu, n/a¹, Te-Tien Ting, Ph.D.², Meng-Che Tsai, M.D., MSc³, Chung-Ying Lin, PhD, MSc⁴, Carol Strong, PhD, MPH¹¹National Cheng Kung University, Tainan City, Tainan, Taiwan (Republic of China); ²Soochow University, Taipei City, Taipei, Taiwan (Republic of China);³National Cheng Kung University Hospital, Tainan City, Tainan, Taiwan (Republic of China); ⁴The Hong Kong Polytechnic University, Hong Kong, N/A, Hong Kong

Background: How friendship maintains and evolves significantly affects development and health outcomes for adolescents. Adolescents may select friends with a similar level of depression and dissolve friendship when their depression level becomes dissimilar. Pubertal development is also related to adolescent depression and social network, but the interaction between depression and pubertal development was rarely examined in the research of adolescent friendship network. In this study, we examined the changes of network structure over time in relation to depressive symptoms and pubertal development in adolescence.

Method: Data in this study are from the Taiwan Youth Project, a longitudinal study that started in 2000 and surveyed 2,844 students in the 7th grade from 40 junior high schools (Wave 1, age 13). Students were followed annually. Data from the first three waves were used. At waves 1–3, participants were asked to fill out a survey that included a social network assessment. Each student was asked to name three of their best friends in school. The analysis was conducted using stochastic actor-oriented models with the Simulation Investigation for Empirical Network Analysis program in R. We examined two sets of actor covariates: depression and pubertal development. The depressive symptom was measured through a short version of Symptom Checklist-90-Revised administered in each wave. Pubertal maturation was defined by using the Pubertal Development Scale.

Result: A total sample of 2,566 adolescents was used for this study (51.5% male). The Jaccard index among three waves were 0.27 and 0.32, indicating a relatively stable network structure. Adolescents with a higher level of depressive symptoms or early maturation named fewer friends, but not necessarily have less chance to be nominated as a friend. Adolescents with the same gender, or similar depressive level or pubertal development were more likely to be friends. The level of depression tends to be similar after two people become friends. Adolescents who received more nominations or nominated fewer friends over time have increased the level of depression.

Discussion: We observed homophily in the level of depression and pubertal development. It is important to not only target depressed individuals when developing interventions for depression but also to identify their close friends who are also depressed. Our study also highlighted the importance to intervene in possible mechanisms that worsen the depression level of this group.

RECIPROCAL RELATIONSHIPS BETWEEN SELF-EFFICACY AND SOCIAL SUPPORT EXPLAIN PHYSICAL ACTIVITY IN ADULTS - A LONGITUDINAL STUDY

Anna Banik, PhD¹, Monika Boberska, MA², MAGDALENA KRUK, MA³, Ewa Kulis, MA², Zofia Szczuka, MA¹, Aleksandra Luszczynska, PhD²

¹SWPS University of Social Sciences and Humanities, Wrocław, Dolnoslaskie, Poland; ²SWPS University of Social Sciences and Humanities, Warsaw, Mazowieckie, Poland; ³SWPS University of Social Sciences and Humanities, WROCLAW, Dolnoslaskie, Poland

Background: According to social cognitive theory self-efficacy beliefs and social support are the key determinants of health behavior change. They may operate twofold when explaining health outcomes with either self-efficacy acting as the establisher of the support (cultivation hypothesis) or social support enabling the formation of self-efficacy beliefs (enabling hypothesis). However, most of the studies testing the effect of self-efficacy and social support receipt on physical activity (PA) does not explain what comes first. Taking into account that much of the world is getting less active it is crucial to establish how these two factors operate when explaining physical activity (PA). Therefore, the two effects (cultivation and enabling hypotheses) were investigated in terms of PA among adults.

Methods: This study had a longitudinal design. Data were collected at three time-points: at baseline (T1), after 2 months (T2), and 6 months (T3) among adults from general population ($N = 299$ at T1; mean age = 44.43, $SD = 16.72$, 65% of women). Measures of self-efficacy beliefs towards PA, social support for PA, and moderate-to-vigorous physical activity (MVPA) were used. Mediation analyses with two sequential mediators were conducted.

Results: The enabling hypothesis was confirmed: participants who reported higher levels of social support for PA at T1 self-reported higher self-efficacy for PA at T2, and higher levels of MVPA at T2 and T3. The cultivation hypothesis was not supported.

Discussion: Among adults received support for PA may enable the formation of self-efficacy beliefs about one's competence to be physically active rather than self-efficacy beliefs cultivate the social support receipt. This study provides an insight into the order in which modifiable psycho-social variables operate when predicting MVPA among adults.

IMPACT OF HURRICANE EVACUATION EXPERIENCES ON MOTHERS' HEALTH BEHAVIORS: MEDIATION BY POST-TRAUMATIC STRESS SYMPTOMS

Kaitlyn E. Brodar, M.S., MPH¹, Annette M. La Greca, PhD¹, Naomi Tarlow, M.S.¹, Niaayah-Symone Hayes, n/a¹, Jonathan Comer, PhD²

¹University of Miami, Coral Gables, FL; ²Florida International University, Miami, FL

Introduction and Purpose: Families with children are vulnerable during and after hurricanes, but less is known about the impact of the pre-storm evacuation process. Mothers report significant stress during evacuations, particularly in making family decisions. However, research has not assessed the impact of evacuation stressors on maternal health. This study's primary objective was to understand the relationship between stressful evacuation experiences and mothers' health risk behaviors. Also, because posttraumatic stress symptoms (PTSS) have been implicated in the trauma-health association, we examined whether PTSS mediated these relationships.

Methods: After Hurricane Irma, South Florida mothers of children under 18 years ($N=520$) completed an online survey that evaluated stressful hurricane-related experiences before (i.e., evacuation-related), during, and after the storm. They also completed measures of PTSS and health risk behaviors, including substance use, sleep problems, and sedentary behavior. Structural equation modeling assessed direct relationships between evacuation stressors and loss/disruption after the storm and health risk behaviors as well as indirect relationships between all hurricane-related experiences (before, during, and after the storm) and health risk behaviors with PTSS as a mediator.

Results: Structural equation modeling results demonstrated good model fit ($\chi^2(3)=3.42$, $p=.33$; RMSEA=.02, 90% CI [.00-.08]; CFI=1.0; SRMR=.02). PTSS and loss/disruption after the hurricane were each directly associated with health risk behaviors. Further, greater evacuation stress was significantly associated with health risk behaviors through the mediating path of PTSS, even when controlling for stressful experiences during and after the storm. Evacuation stress was not directly associated with health risk behaviors.

Conclusions: Hurricanes are stressful for mothers caring for children. Stressful experiences that occur even before a hurricane may have a lasting impact on mothers' health behaviors via associations with PTSS. Findings underscore the need for better hurricane preparation efforts and for health behavior interventions post-hurricanes. Communities might prioritize efforts that reduce evacuation stress and support healthy behaviors after the storm (e.g., cleaning up parks to encourage physical activity). Mothers who experienced a recent hurricane or hurricane evacuation should be evaluated for health risk behaviors and stress reactions.

EXECUTIVE FUNCTIONING OF SCHOOL-AGE CHILDREN WITH ASTHMA

Jennifer Sonney, PhD, APRN¹¹University of Washington, Seattle, WA

Background: Asthma is one of the most common chronic conditions of childhood, affecting nearly 10% of US children. The school-age years (7–11 years) are a critical time with respect to asthma management, as this is the age when children begin to assume asthma management responsibility alongside their parents. Unfortunately, more than half of school-age children with asthma are uncontrolled, resulting in increased asthma exacerbations, hospitalizations and missed school days. A critical gap is our understanding of a child's capacity to self-manage their asthma. To address this gap, the purpose of this study was to describe the executive functions that contribute to self-management capacity of school-age children with asthma.

Methods: Children ages 6 to 11 years enrolled in this cross-sectional study. Children used an iPad to complete the Childhood Asthma Control Test to assess asthma control and the NIH Cognitive Toolbox executive function battery that assessed learned knowledge (vocabulary, reading) and fluid abilities (attention, inhibition, working memory, cognitive flexibility and processing speed). Descriptive statistics were used to describe the sample demographics and asthma control. One-sample t-tests were used to compare study sample means for executive function subtests with the normed reference values. One-way ANOVAs were used to test group differences (age, gender) in cognitive subtest scores.

Results: Thirty-three children ($M = 8.3$ years + 1.5) enrolled in this pilot study. Fifty-three percent of the participants were male, and the majority were White (70%) and Non-Hispanic (74%). Fifty-three percent of the sample had uncontrolled asthma. Compared to the normative reference sample, children in this study had significantly lower scores in inhibition, $t(32) = -4.18$, $p < .001$, cognitive flexibility $t(32) = -3.35$, $p < .002$, and processing speed, $t(29) = -3.87$, $p < .001$. Interestingly, study participants had higher scores in vocabulary ($t(29) = 4.34$, $p < .001$) and reading ($t(32) = 3.77$, $p < .001$). There were no significant group differences in cognitive subtest scores when comparing by child age, gender, or asthma control.

DISCUSSION: Compared to a normative sample, children in this study demonstrated lower performance on several executive function fluid ability subtests (inhibition, cognitive flexibility, processing speed), all of which support a child's ability to self-manage. Impairments in executive functions that support self-management may represent an innovative area of inquiry to better understand a child's capacity for self-management. Furthermore, if these findings are longitudinally replicated, future interventions may be targeted toward building executive function skills as a novel strategy to increase the self-management capacity and overall health of children with asthma.

DESIGN AND REFINEMENT OF A MHEALTH PARENT TRAINING SYSTEM TO ADDRESS BEHAVIORAL HEALTH CHALLENGING IN YOUNG CHILDREN

Lucy McGoron, Ph.D.¹, Sharmi Purkayestha, B.A.¹, Florentine Friedrich, B.A.¹, Steven J. Ondersma, Ph.D.¹, Elizabeth Towner, PhD²¹Merrill Palmer Skillman Institute, Wayne State University, Detroit, MI; ²Wayne State University, Detroit, MI

This investigation describes the initial creation and refinement of the **Parenting Young Children Check-up (PYCC)**, a technology-based system for detecting and responding to disruptive behavior problems (DBPs) in young children. The program includes 4 parts. **First**, parents complete a screener for DBPs while at a pediatric primary care visit. **Second**, if the screener is positive, parents go through a brief intervention (BI) on a tablet. The BI provides parents with feedback on their child's behavior and promotes learning behavioral parenting skills. **Third**, parents receive tailored text messages based on their goals. **Fourth**, text messages contain links to video-based content on the PYCC website.

Development and evaluation of the PYCC is following the ORBIT model (Czajkowski et al., 2015); a NIH-recommended intervention development framework. Here we present the second step, **Define and Refine**, in which initial intervention materials are created and refined based on mixed methods feedback from key stakeholders. Beta versions of the BI and text messages were created through the Computerized Intervention Authoring System (CIAS). Next, we created parent training videos for the PYCC website.

Through an iterative process, we collected data from 17 physicians and 17 parents across 3 iterations. Participating parents were mothers of children ages 2–5 that reported DBP; mothers were predominately African American (94%). All participants viewed PYCC beta materials, completed a qualitative interview about the PYCC, and completed a feedback survey. Creation of the feedback survey was influenced by the Technology Acceptance Model (Davis, 1989) and included 17-items rated on a 5-point Likert scale (0 = strong disagree; 4 = strongly agree). There were 4–5 items to tap into participants' perceptions of each of the 4 parts of the PYCC. The goal was to achieve ratings ≥ 3 (i.e., "agreeing" that they have a positive perception of each part of the program). We computed a total score, which was the mean of all feedback survey ratings, to reflect ratings of the PYCC at each iteration. Finally, we coded qualitative interviews for positive comments, negative/critical comments, and suggestions for improvements.

At each iteration, positive comments were greater than negative/critical comments and suggestions for improvements. We made changes to the PYCC following each iteration; many of these changes were to the BI. At each of the 3 iterations, parents average ratings of the PYCC exceeded 3 (i.e., $M[SD] = 3.19[.22]$, $3.56[.41]$, and $3.28[.44]$, respectively). For physicians, overall ratings of the intervention increased across the 3 iterations (i.e., $M[SD] = 2.94[.16]$, $3.19[.33]$, and $3.60[.29]$, respectively). We will present examples of program content at each iteration, feedback survey results, and extracted quotes from interviews. Overall, we will present how mixed methods data guided intervention development.

CLINICIAN AWARENESS OF PARENTING CONCERNS IN PATIENTS WITH CANCER

Pamela Williams, MSc¹, Devon A. Artusio, MS, CCLS², Lauren S. Haruno, M.A.³, Catherine Benedict, PhD⁴, Richard Shaw, MD⁵, EMILY L. ACH, PhD⁶, Paula K. Rauch, MD⁷, Lidia Schapira, MD⁸

¹Stanford University, Palo Alto, CA; ²Lucile Packard Children's Hospital at Stanford, San Francisco, CA; ³PGSP-Stanford Consortium, Redwood City, CA; ⁴Stanford University School of Medicine, Palo Alto, CA; ⁵Lucile Packard Children's Hospital, Palo Alto, CA; ⁶Stanford University/Lucile Packard Children's Hospital, Stanford, CA; ⁷Marjorie E. Korff Parenting At a Challenging Time Program, Boston, MA; ⁸Stanford University, Stanford, CA

Background: Oncology patients with dependent children endure the additional stress of communicating with and supporting their children through the cancer journey. Despite the well-recognized need to provide patient-centered comprehensive care, patients' concerns about parenting during treatment often go unaddressed.

Objective: Survey oncology clinicians about practices for addressing the parenting concerns of patients and awareness of locally available patient resources for parenting with cancer.

Methods: Stanford oncology clinicians were invited to complete a survey in Fall 2019. The survey assessed: 1) frequency clinicians discuss parenting concerns, 2) beliefs about the importance and confidence in addressing the topic of parenting with cancer, and 3) barriers. Bivariate analyses evaluated differences by clinician role and disease group specialty.

Results: Respondents (N=54) were mostly physicians (n=35; 65%) or Advance Practice Providers (APPs) (n=11; 20%) from a range of disease group specialties. Almost all clinicians (98%) believed patient-centered oncology care should address family issues/concerns and 80% reported asking patients whether they have children. Fewer (50%) regularly asked patients if they discussed their diagnosis with their children and only 16% regularly gave advice on how to have such discussions. About half (52%) felt comfortable discussing parenting concerns with patients, yet only 17% were confident their patients' parenting concerns were addressed. Common barriers to addressing parenting concerns included: time (41%), resources (35%), and expertise (35%). Twenty-nine clinicians (54%) were aware of a parent guidance program at Stanford and 50 (93%) stated they would (or already) refer patients for a parenting consultation. APPs were more likely than physicians to ask patients if they have concerns about the children's reaction to a parental cancer ($p < 0.01$) and if they have discussed the diagnosis and treatment with their children ($p = 0.05$). Physicians were more likely than APPs to give patients advice on how to discuss diagnosis with children ($p = 0.04$).

Conclusion: This survey showed that cancer clinicians endorse the importance of addressing patients' parenting concerns during cancer treatment but felt unprepared to handle such issues. A supportive care program dedicated to providing counseling services to patients with dependent children may fill a critical gap in care and better support patients in managing parenting concerns.

"I JUST HOLD HER UNTIL MY ARM GETS NUMB": CAREGIVER BEHAVIORS ASSOCIATED WITH INFANT SLEEP SAFETY

Panne Burke, MS¹

¹Fors Marsh Group, Arlington, VA

While caregivers often know of safety guidelines, they tend to be resistant to following recommendations for safe sleep. Many infants sleep in products and environments that are not appropriate and potentially deadly if misused, making it critical to take steps to improve caregivers' application of safety messaging and infant sleep practices. The current study sought to understand: What behaviors do caregivers engage in while putting an infant to sleep? What factors do caregivers consider while making purchase and use decisions for sleep products? What is caregivers' awareness of hazards and adherence to sleep safety messages and warning labels?

We conducted six, 90-minute focus groups with caregivers of children ages 2–11 months old. The discussion progressed in specificity: It began with questions that assessed general behaviors associated with infant sleeping, advanced into sleep messaging reactions, and concluded with questions about knowledge, attitudes, and awareness of infant sleep safety.

Participants often mentioned adding items to their infant's sleep environment to increase comfort, even though doing so goes against current safety messaging. Several competing factors—such as convenience, affordability, sleep product life cycles, advice from others, and product marketing—impact their purchasing decisions, their product use, and their safety message adherence. Participants emphasized that safety messaging tends to change from generation to generation so they do not know the most accurate message to follow. Participants also generally perceived warning labels as redundant, lengthy, and intended to protect the manufacturers from liability, which often leads them ignore labels altogether.

When caregivers disregard the hazards and risks associated with sleep products, they increase the risks of an infant-sleep related death. The purpose of the safety warnings is not clear to the target audience and the warnings are not being implemented effectively. If caregivers are not willing to read the warning labels on products, it is likely that they will miss critical safety information, particularly since they are often considering competing priorities when buying sleep products.

This research presents initial findings that can be further translated into actionable recommendations for safety messaging. It will be pertinent to investigate the most resonant messaging strategies, label revisions, and communication channels with audiences of interest to ensure that safety messaging is effectively reaching those who would benefit from it most. By reducing saturation of sleep safety messaging and taking a more targeted, nuanced approach, there is potential to reduce sleep-product related deaths in the future.

SETTING MEANINGFUL GOALS IN REHABILITATION: A PRACTICAL TOOL

Joost Dekker, PhD¹¹Amsterdam University Medical Centers, Amsterdam, Noord-Holland, Netherlands

Background: Goal setting is a key characteristic of modern rehabilitation. However, goals need to be meaningful and of importance to the client. We have developed a practical tool that facilitates the setting of meaningful rehabilitation goals.

Purpose: To describe a practical tool that facilitates the setting of meaningful rehabilitation goals.

Method: We reviewed literature supporting the importance of a hierarchy of goals: one or more overall goals which clients find personally meaningful; and specific goals that are related to the overall goals. We also reviewed literature suggesting that the client's global meaning (i.e., fundamental beliefs, goals and attitudes) need to be explored before setting any rehabilitation goal. These fundamental beliefs, goals and attitudes can serve as the point of departure for setting rehabilitation goals.

Results: We set out a three stage process to set goals: (i) exploring the client's global meaning (i.e., fundamental beliefs, goals and attitudes), (ii) deriving a meaningful overall rehabilitation goal from the client's global meaning, and (iii) setting specific rehabilitation goals that serve to achieve the meaningful overall rehabilitation goal.

Conclusion: This is an extension of current practice in many rehabilitation teams which may help counter the drive towards exclusively functional goals based around independence.

AN EXERCISE IN DIVERSITY: THE TRANSTHEORETICAL MODEL APPLIED ACROSS CULTURES, POPULATIONS, AND NATIONS

Julian M. Saad, M.Ed.¹, James Prochaska, Ph.D.²¹University of Rhode Island, Newport, RI; ²University of Rhode Island, Kingston, RI

A major area of disagreement in sociopolitical debates is that over healthcare. US political parties differ greatly over which form of healthcare is best for the *population health*. While Republicans and Democrats propose (very different) plans that promote access to *healthcare* in the general population, neither party systematically maps out how they will promote access to *health* in the general population.

Recent reports indicate that one of the greatest predictors of health outcomes in the general population is health behavior (Mokdad, 2018; Li et al. 2018). With the majority of the US adult population having 2+ health risk behaviors (Berrigan et al, 2003); and the underserved populations suffering greater health consequences due to health risk behaviors (Berger, Lund, and Brawley 2007; Perez-Stable et al. 1998; USDHHS, 1996, 2000; CDC, 2009); one could posit that healthcare programs need models of health behavior change that can be applied across the general population.

The present paper will present and integrate empirical, cross-cultural findings on the Transtheoretical Model (TTM) from the last three decades to distill common principles of change that exist across diverse populations. Interventions that have been disseminated across countries, across and within different populations, and in different languages will be reviewed. Cross cultural principles of change will be distilled from important findings in experimental (e.g. Velicer, Redding, Sun, & Prochaska, 2007) and metanalytic (e.g. Hall & Rossi, 2004) research. The present paper will operationalize these underlying *principles of change* to propose that, *what unites human beings* (across cultures and across sociopolitical viewpoints) *is their ability to change*.

An "Exercise in Diversity" is one that creates an inclusive (population health) program that can meet the needs of, and simultaneously increase the strengths of, the general population. Through healthy behavior and (multiple) health behavior change, this can be done in population health. Through decades of research on the TTM, cross-cultural principles of change can and will be proposed.

A MIXED METHODS FORMATIVE ANALYSIS OF ACCEPTABILITY AND BARRIERS TO MINDFULNESS IN AN UNDERSERVED MINDFULNESS NAÏVE POPULATION

Samantha Davis, MPH¹, Collins N. Bradley, PhD²¹Temple University, Philadelphia, PA; ²Temple University, Philadelphia, PA

Background: Low-income smokers have elevated tobacco-related disease risk exacerbating health disparities. Further, low-income female smokers express elevated stress and negative affect, known barriers to smoking behavior change. Mindfulness practice shows potential to influence smoking behavior change either directly, or through its mitigating effects on stress, negative affect and urge reactivity. However, vulnerable groups are less likely to uptake or practice mindfulness activities. Formative research is needed to understand and address this disparity by systematically assessing mindfulness acceptability. Mindfulness interventions for underserved populations can then be adapted, with tailored elements to address elevated barriers to health behavior change.

Methods: Female smokers were recruited from Women, Infant and Children clinics to participate in one-hour phone interviews. Data collection methods enabled assessment of overall mindfulness knowledge, attitudes and subjective norms around content, language used, and pros/cons to different practices. Interviews were transcribed and NVivo software was used to code and explore themes.

Results: The sample ($N = 12$) all self-reported being mindfulness naïve, had less than a college degree, were mostly (75%) African American, with an average age of 31 years old, and on average smoked 7 cigarettes/day. Regarding acceptability, the participants expressed interest in mindfulness and its potential utility in their lives and for managing stress. On a 1–10 Likert Scale (unlikely/not useful to very likely/useful) participants rated using mindfulness daily $M = 8.77$, $SD = 1.47$; mindfulness for managing stress $M = 8.36$, $SD = 2.11$; and mindfulness for managing smoking urges $M = 5.59$, $SD = 2.87$. Interviews generated themes related to meditation uptake and practice, such as barriers (e.g., time, abstract terminology). Participants also expressed preference for more concrete descriptive language in meditation instructions, shorter duration of sessions, prompts for informal practices, examples or analogies and more encouragement around behavior change and adherence. These themes will be presented in greater detail.

Conclusion: This study provides a formative analysis of mindfulness acceptability and barriers in a high-risk underrepresented group of female smokers. The findings show a favorable attitude towards mindfulness, with specific preferences that could guide tailoring of content and delivery to boost uptake and practice.

AWARENESS OF AND PREFERENCES FOR HEALTHCARE CHAPLAINCY SERVICES AMONG U.S. ADULTS

Geila Rajaei, MPH, MPA, MDiv, BCC¹, Minal R. Patel, PhD, MPH²¹University of Michigan, Canton, MI; ²University of Michigan, Ann Arbor, MI

Background: Inadequate support of religious/spiritual (R/S) needs in health care settings is associated with poor quality of life, higher rates of depressive symptoms, and higher costs at end-of-life. Little is known about the awareness of and preferences of U.S. adults for chaplaincy services to address their R/S needs in health care settings.

Methods: Data were collected from a nationally representative sample of U.S. adults through the Ipsos Government & Academic Omnibus survey panel ($n=1,020$). Participants were asked to respond to questions related to preferences for chaplain services that could be provided in inpatient and outpatient settings, their previous experience and awareness of chaplains, and the level of importance that respondents place on having their religious, spiritual, and/or sources of meaning addressed.

Results: Mean age of the sample was 47.6. The majority of the sample were aware of chaplains (85%) but only 15% indicated that they had previous experience with a chaplain. Compared to the population that are aware of what chaplain is, adults who were unaware of chaplains were younger (38 versus 49 years, $p < 0.0001$), and a greater proportion female ($p=0.005$), racial/ethnic minorities ($p < 0.0001$), and lower educational attainment ($p=0.004$). Seventy percent indicated interest in having religious, spiritual, or existential needs met in the context of healthcare. The least desired services in both the inpatient and outpatient setting related directly to religious and/or spiritual needs or resources, whereas more participants indicated desire to receiving support to explore what is most important in the event of a life threatening illness or injury and values related to treatment decisions.

Conclusion: The majority of the U.S. population say they are aware chaplains, and desire the services they offer, yet few report previous experience with them in health care settings. More behavioral interventions are needed to better connect patients to chaplains.

COGNITIVE FUSION AND FATIGUE IN COLLEGE STUDENTS

Jamie Bodenlos, Ph.D.¹, Kate Peglow, BS in Psychology (student)², Rachael Piercey, BS in Biology and Psychology (student)²

¹Hobart and William Smith Colleges, Baldwinsville, NY; ²Hobart and William Smith Colleges, Geneva, NY

College students report high levels of fatigue and decreased energy. Fatigue in college students is associated with poor academic performance and reduced well-being. While sleep deprivation is often thought to be the culprit, research has suggested that even after controlling for sleep, there are still high rates of fatigue in this group. Understanding the factors that contribute to energy levels and fatigue among college students can help prevent burn-out, exhaustion and enhance well-being in this population. High stress, low levels of social support and poor sleep have often been associated with negative emotional states in college students. More recent work has pointed to the role that trait mindfulness may play in health and well-being. A factor that has received less attention is cognitive fusion, or how entangled one is with their thoughts. The purpose of this study was to explore how factors associated with emotional health in college students would predict fatigue and energy levels in this group. Participants (N=353) were students enrolled in introductory psychology courses at a small private college in the Northeast. The participants ranged in age from 17–22 years (M=18.82, SD=0.89). The majority of the sample was female (72%). After informed consent was obtained, participants completed the following questionnaires: The Cognitive Fusion Scale (CFQ), the SF-36 (energy levels component), Perceived Stress Scale (PSS-14), Luben Social Network Scale-Revised (LSNS), Five Facet Mindfulness Questionnaire (FFMQ), and a demographic questionnaire which included an assessment of sleep. Hierarchical multiple regression analyses controlling for stress, social support, mindfulness, sleep and sex, demonstrated a significant effect of cognitive fusion on fatigue/energy ($R^2=.39$, $F(1, 353) = 22.96$, $p < 0.01$). Cognitive fusion emerged as the only predictor of energy/fatigue. Higher levels of cognitive fusion was associated with lower levels of energy ($B = -.16$, $p < 0.05$). The findings suggest that the how fused someone is with their thoughts may play a role in levels of fatigue. Cognitive defusion techniques may be beneficial to use in colleges to help students enhance energy and well-being.

IMPROVING CANCER PATIENTS' INSURANCE CHOICES (I CAN PIC): A RANDOMIZED TRIAL OF A PERSONALIZED HEALTH INSURANCE DECISION AID

Mary C. Politi, PhD¹, Rachel Grant, MSW¹, Nerissa George, MPH², Abigail Barker, PhD³, Aimee S. James, PhD¹, Lindsay Kuroki, MD¹, Timothy D. McBride, PhD⁴, Jingxia Liu, PhD¹, Courtney M. Goodwin, MPH¹

¹Washington University in St Louis, School of Medicine, St Louis, MO;

²University of Albany School of Public Health, Albany, NY; ³Brown School of Social Work, St Louis, MO; ⁴Washington University, Saint Louis, MO

Purpose: Many cancer survivors struggle to choose a health insurance plan that meets their needs due to high costs, limited health insurance literacy, and lack of decision support. We developed a web-based health insurance decision aid, Improving Cancer Patients' Insurance Choices (I Can PIC) to provide plain language education, personalized cost estimates of annual healthcare expenses, and a resource list.

Methods: We used a mixed-methods approach to develop I Can PIC. I Can PIC's personalized cost calculator was based on data from the Medical Expenditure Panel Survey and regional averages of insurance costs by plan type. Eligible individuals (18–64 years old, diagnosed with cancer ≤ 5 years, English-speaking, resident of one of two states where we could provide cost estimates, not eligible for Medicaid or Medicare) were randomized to I Can PIC or an attention control group (American Cancer Society health insurance worksheet). Primary outcomes included health insurance knowledge, decisional conflict, and decision self-efficacy after completing I Can PIC or the control. Secondary outcomes included knowledge, decisional conflict, decision self-efficacy, financial toxicity, and delay of healthcare due to cost at a 3–6 month follow-up.

Results: 284/335 eligible participants (79%) consented and were randomized; 206 (73%) completed the initial survey (106 in I Can PIC; 100 in the control); 180 (87%) completed a 3–6 month follow-up. Most were Non-Hispanic White (80.1%); about half had a college degree (54.9%). Their mean age was 53. At the first time point, health insurance knowledge (mean=89.3% vs. 74.4%; $p < 0.0001$) and confidence understanding health insurance (53.8% vs. 32.3% very confident, $p < 0.008$) were higher in the I Can PIC vs. control group. At the 3–6 month follow-up, the I Can PIC group retained higher health insurance knowledge (mean=82.1% v. 74.9%; $p < 0.002$); confidence was not re-assessed. There were no significant differences between the I Can PIC and control group in decisional conflict, decision self-efficacy, financial toxicity or delay of care due to costs. Both groups reported having limited health insurance options from which to choose. Results did not change when controlling for health literacy and employment.

Conclusions: I Can PIC increased cancer patients' and survivors' health insurance knowledge and confidence using health insurance. System-level interventions may be needed to lower financial toxicity and help patients manage care costs.

NEGATIVE AFFECT TO BREAST CANCER AND CHOICES OF CONTRALATERAL PROPHYLACTIC MASTECTOMY

Michael Silverstein, N/A¹, Clara Lee, MD, MPP², Laura Scherer, PhD³, Crystal Phommasathit, n/a⁴, Andrea L. Merrill, MD⁵, Ellen Peters, Ph.D.¹¹University of Oregon, Eugene, OR; ²The Ohio State University, Columbus, OH; ³University of Colorado, Aurora, CO; ⁴The Ohio State University Wexner Medical Center, Columbus, OH; ⁵OSU, Columbus, OH

Objective: Contralateral Prophylactic Mastectomy (CPM) is an operation to remove the non-affected breast in patients with breast cancer or ductal carcinoma in situ. CPM rates have increased considerably, particularly in patients for whom CPM confers no survival benefit. Negative affect to cancer is thought to contribute.

We explored affect's multiple influences on CPM perceptions and behaviors. In particular, affect can inform risk perceptions (Loewenstein et al., 2001; Slovic et al., 2004) and directly motivate behaviors (Peters, Lipkus, & Diefenbach, 2006). As a direct motivator, affect also may produce motivated reasoning (i.e., people are driven to perceive the world in ways consistent with their goals; Kunda, 1990). Specifically, we expected women with more negative affect to breast cancer to be motivated to feel more positively about treatments they perceived (incorrectly) to reduce cancer risk and to choose those treatments.

We hypothesized that an intervention that increased negative affect to breast cancer would increase positive affect toward and choices of CPM.

Methods: In a hypothetical study conducted over the Internet, healthy women (N=1,030) aged 30–59 years with no prior history of or genetic predisposition to breast cancer were asked to imagine they were diagnosed with early-stage breast cancer. They read one of three randomly selected survivor narratives designed to alter affect to breast cancer (very negative, negative, less negative). Afterward, participants provided their emotional responses to breast cancer and treatment choices (CPM, lumpectomy, or single mastectomy) and their affect to CPM and perceived future breast cancer risk.

Results: As hypothesized, we found that the negative (v. less negative) narrative caused participants to have more negative affect to breast cancer ($b=0.18$, $SE=0.06$, $p < .01$), less negative affect to CPM ($b=-0.18$, $SE=0.07$, $p=.01$), and to choose CPM more, $X^2=7.23$, $p=.03$. Women who felt more negative affect to breast cancer believed CPM had more benefits; this effect was mediated by affect to CPM, $b=-0.06$, $CI=[-0.12, -0.01]$. The very negative condition did not differ substantially from the negative condition.

Conclusions: Perceived affect and motivated reasoning appear to influence patients' decisions to undergo CPM to treat early-stage breast cancer among women for whom CPM provides no survival benefit. Important implications exist for how surgeons communicate with patients including empathic communication.

DEBUNKING MISCONCEPTIONS ACROSS HEALTH DOMAINS: AN EXPERIMENTAL EVALUATION OF CORRECTIVE INFORMATION

Erika Damsgard, n/a¹, Rick A. LaCaille, PhD¹, Lara J. LaCaille, PhD¹¹University of Minnesota Duluth, Duluth, MN

Introduction: The endorsement of misconceptions, unlike ignorance, may be deep-rooted and can be challenging to correct. These erroneous beliefs are prevalent in a variety of areas, including several health domains (e.g., vaccinations, complementary and alternative medicine, diet and exercise, and mental health). Not surprisingly, such misconceptions may lead to harmful consequences, such as increased spread of preventable illnesses or emergency room visits due to supplement misuse. Public health campaign-style posters actively refuting myths have been used in an attempt to not only reduce endorsement of such misconceptions but also influence behavioral intentions. Unfortunately, efforts to reduce misconceptions may, in some circumstances, result in backfire effects, whereby incorrect information is misremembered as fact.

Methods: The current study's aim was to examine the effects of myth debunking posters formatted based upon an actual Centers for Disease Control and Prevention flu vaccination campaign applied to multiple health-related domains. Using a factorial design, participants ($n = 208$, undergraduate psychology students) were randomly assigned to one of six myth debunking conditions: 2 (immediate vs. 30 minute delayed response to facts/myths) \times 3 (facts-only vs. myths-and-facts vs. control). That is, participants were exposed to posters that included either both myths and facts within each of the mentioned health domains ($n = 67$), only facts ($n = 74$), or control posters that included misconceptions about the university's majors and advising ($n = 67$). Participants were then given a test of the health domain myths presented on the posters and were asked about intentions related to each domain.

Results: No significant (all $ps > .05$) main effects for time (immediate vs. delayed) or interactions (condition \times time) across the four content areas were detected. Those in the myths-and-facts as well as the facts-only condition, overall, identified more correct information than the control condition within the domains of vaccinations ($p < .001$, $d = 0.99$ and 1.28 respectively), mental health ($p < .001$, $d = 1.06$ and 0.93 respectively), complementary and alternative medicine ($p < .001$, $d = 0.89$ and 1.01 respectively), and diet and exercise ($p < .001$, $d = 1.36$ and 1.01 respectively). However, intentions within these domains did not differ significantly. Furthermore, performance on the myth test and intentions did not differ between the facts-only and myths-and-facts conditions.

Discussion: The results suggest that refutational style posters, both in a myths-and-facts and a facts-only format, are effective at correcting misconceptions across a variety of health domains with a low risk of backfire effects. Further efforts are needed to demonstrate an impact on intentions and behaviors of targeted consumers of this style of messaging.

AFFECT REGULATION AND HEALTH BEHAVIOR CHANGE: THE CALIBRATE AND QUALIFY MODEL

Paschal Sheeran, MA, PhD¹, Mark Conner, PhD²¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²University of Leeds, Leeds, England, UK

Studies to predict and understand health behaviors and work on emotion regulation appear to occupy different research silos with little in the way of crosstalk. Here, we introduce the Calibrate and Qualify Model to begin to integrate research on affect regulation and regulation of health behaviors. The model proposes that affect regulation capabilities and strategies (ARCS) could influence health behaviors in two ways. First, ARCS could influence the favorability of health-related attitudes, norms, and self-efficacy and thereby promote intentions and behavior (the Calibrate route). Second, ARCS could influence the strength of association between, e.g., affective attitudes and intention or between intentions and health behaviors, and thereby promote behavior change (the Qualify route). We undertook two observational studies of multiple health behaviors to test these predictions. Study 1 ($N = 318$) tested the model in relation to 12 health-related behavioral intentions. Study 2 ($N = 1,294$) was a longitudinal study of 6 health behaviors. Affect regulation capability was operationalized by the Difficulties in Emotion Regulation Scale (Gratz & Roemer, 2004) in Study 1 and by the Emotion Control Scale (Niven et al., 2013) in Study 2. Affect regulation strategies were indexed by the Emotion Regulation Questionnaire (Gross & John, 2003) in both studies. Multi-level modelling of Study 1 data offered evidence to support the Calibrate route: ARCS predicted health-related intentions and this relationship was mediated by behavior-specific cognitions. There was modest evidence that ARCS influenced the strength of relations between cognitions and intentions. Study 2 corroborated these findings for the prediction of intentions and obtained evidence that the ARCS-health behavior relation was mediated by cognitions. ARCS also qualified the consistency between intentions and health behaviors. Greater affect regulation capability and greater use of cognitive appraisal both were associated with improved translation of intentions into health behaviors. The present findings offer new evidence that research on affect regulation can enhance the prediction and understanding of health behaviors. Although experimental tests are needed to corroborate these observational findings, the Calibrate and Qualify Model may offer a useful starting point for future research concerned with integrating the self-regulation of affect and health behaviors.

SELF-EFFICACY AND PHYSICAL ACTIVITY IN THE I-D-HEALTH STUDY: A RANDOMIZED CONTROLLED TRIAL

Claire B. Walker, MS¹, Andrew J. Cooper, MS MPH², Ronald T. Ackermann, MD MPH³¹Feinberg School of Medicine, Hinsdale, IL; ²Northwestern University, Chicago, IL; ³Northwestern Medicine, Chicago, IL

Introduction: The I-D-HEALTH Study was a randomized encouragement trial evaluating the effectiveness of offering primary care patients with type 2 diabetes access to a community adaptation of the Look AHEAD lifestyle intervention, which was designed to support healthy eating, physical activity, and modest weight loss. Though the intervention resulted in modest weight loss, the behavioral mechanisms underlying this effect have not been studied.

Hypotheses: Based on past research linking self-efficacy with physical activity behavior, we hypothesized that higher levels of participation in the I-D-HEALTH intervention would result in increased exercise self-efficacy, which in turn would be associated with higher physical activity.

Methods: I-D-HEALTH randomized individual study participants to receive brief advice for modest weight loss or encouragement to attend a group lifestyle intervention program offered at a nearby community location. At 0, 6, 12, and 24 months, study participants attended study visits where they were weighed and completed questionnaires, which included the PACE self-efficacy scale and the Paffenbarger self-report physical activity instrument, which estimates mean kilocalories per week of energy expenditure. We studied associations between levels of intervention attendance and self-efficacy, as well as whether increases in self-efficacy were predictive of increased energy expenditure.

Results: Our analysis found a dose-response relationship in which each additional lifestyle intervention session attended was associated with a mean increase in energy expenditure of 29.2 kilocalories per week at 12 months ($p = 0.016$) and 13.6 kilocalories per week at 24 months ($p = 0.046$), from a baseline median of 496 kilocalories per week. Self-efficacy did not change as a result of the study, but at 12 months it was associated with an increased expenditure of 256 kilocalories per week ($p = 0.0090$) and at 24 months it was associated with an increased expenditure of 451 kilocalories per week ($p < 0.0001$), after controlling for baseline physical activity and the number of intervention sessions attended at those timepoints.

Conclusions: Intervention attendance was associated with modest increases in self-reported physical activity, but not exercise self-efficacy. Exercise self-efficacy was an important predictor of how much participants would increase their physical activity. Given that this “pragmatic,” community-based lifestyle intervention achieved relatively lower levels of physical activity and weight loss than has been observed in prior efficacy studies, further research should explore if it is possible to enhance its effectiveness using additional strategies designed to increase exercise self-efficacy.

6:15 PM-7:30 PM

A MIXED METHODS INVESTIGATION OF THE BARRIERS AND FACILITATORS TO MEDICATION ADHERENCE IN PATIENTS WITH TYPE 2 DIABETES

Yen-Ming Huang, PhD¹, Olayinka O. Shiyabola, PhD BPharm², Kristen E. Pecanac, PhD, RN³¹South Dakota State University, Brookings, SD; ²University Of Wisconsin-Madison, Madison, WI; ³University of Wisconsin-Madison, Madison, WI

Background: Type 2 diabetes (T2D) incurs tremendous health cost associated with various complications due to poor diabetes control. Medication adherence, which is correlated with patients' health literacy, should be consistently practiced to achieve optimal diabetes control. A deeper understanding of the specific communication and psychosocial factors related to medication-taking behaviors across different levels of health literacy among people with T2D will guide the development of effective interventions and strategies to enhance medication adherence.

Objectives: (1) To examine whether the barriers and facilitators associated with medication adherence differ among people with T2D across different levels of health literacy. (2) To explore patients' perceptions of the barriers and facilitators of medication adherence across different levels of health literacy. (3) To understand how the qualitative interview data complement the quantitative survey results about the barriers and facilitators of medication adherence.

Methods: This mixed-methods study used an explanatory sequential design, including a quantitative study with a survey questionnaire followed by a qualitative study with semi-structured interviews. The Health Literacy Pathway Model was used to identify the psychosocial and communication factors that may influence medication adherence. Participants enrolled were at least 20 years old, diagnosed with T2D, understood English, and prescribed at least one oral diabetes medicine daily. Analysis of covariance and direct content analysis were used respectively in quantitative and qualitative analysis. A joint display was used to present the integrated findings from quantitative and qualitative data.

Results: In the quantitative phase, 205 participants provided complete information in the survey questionnaire. In the qualitative phase, 23 participants completed semi-structured interviews. Confirmed by quantitative and qualitative data, holding stronger self-efficacy, having fewer concern beliefs about medication, and possessing fewer perceived barriers to medication-taking are necessary for better medication adherence. Linking medication-taking to daily routine and focusing on the internal locus of control is an imperative approach to foster self-efficacy of medication use. Addressing patients' life experience and clarifying medication misinformation may help participants cope with their concerns with medications. Solving the high cost of medications and therapy-related problems could lessen participants' perception of barriers to medication-taking.

Conclusion: To optimally support patients' diabetes care, practitioners should address concern beliefs among non-adherent patients with low health literacy, as well as emphasize self-efficacy and perceived barriers to medication adherence among all non-adherent patients with T2D.

THE BENEFITS OF DAILY EXERCISE ON BLOOD GLUCOSE LEVELS AND EMOTIONAL WELLBEING AMONG ADULTS WITH TYPE 1 DIABETES

Eunjin L. Tracy, Ph.D.¹, Cynthia Berg, Ph.D.², Robert G. Kent de Grey, Ph.D.², Nancy Allen, PhD³, Michelle L. Litchman, PhD, FNP-BC², Vicki S. Helgeson, Ph.D.⁴¹University of Utah, SALT LAKE CITY, UT; ²University of Utah, Salt Lake City, UT; ³University of Utah College of Nursing, Salt Lake City, UT; ⁴Carnegie Mellon University, Export, PA

Daily exercise is an important self-care behavior among persons with type 1 diabetes (T1D). Exercise is also related to immediate and long-term effects on emotional wellbeing, but is complicated by hypoglycemia. Previous studies of exercise in the context of T1D were mostly experimental or intervention designs and focused less on effects of naturally occurring episodes of daily exercise on diabetes outcomes and emotional wellbeing. The current study examined concurrent (same day-association) and lagged (following-day associations while controlling for previous day's dependent variable) effects of daily exercise on daily BG levels and emotional wellbeing (affect).

199 adults with T1D ($M_{age} = 46.82$) completed a 14-day diary in which they reported their engagement in moderate to vigorous exercise for 30 minutes and positive and negative affect. Daily blood glucose (BG) values were gathered through study-provided glucometers. We used BG mean, risk for high BG, and risk for low BG to measure BG levels. The present study utilized multilevel models and controlled for other self-care behaviors, comorbidity, gender, BMI, insulin status, CGM, age, gender, and length of diagnosis.

On average, participants exercised moderately to vigorously for 30 minutes on 5.84 of the 14 diary days (i.e., 2.92 days a week).

Concurrent analyses showed that on days when persons with T1D reported they exercised moderately to vigorously for 30 minutes they had lower mean BG levels, lower risk for high BG, lower negative affect, and higher positive affect on the same day. Lagged analyses showed that when persons with T1D reported they exercised moderately to vigorously for 30 minutes, they had lower mean BG levels, lower risk for high BG, and higher positive affect on the following day.

The results indicate that engaging in daily moderate to vigorous exercise for 30 minutes a day is important in maintaining daily blood glucose values and emotional wellbeing. Engaging in daily moderate to vigorous exercise for 30 minutes was not associated with a risk of low BG, which counters fears about hypoglycemia in persons with T1D. When giving recommendations for exercise, clinicians may want to assess persons with T1D for fears related to hypoglycemia, glycemic levels, and exercise management knowledge and provide education accordingly (e.g., insulin dose adjustments, hypoglycemia treatment).

A strength of this study is the conservative estimate of effects of daily exercise by controlling for other self-care behaviors and demographic and illness characteristics in a large sample. Furthermore, the effects of daily exercise persisted into the next day. A limitation is that this study relied solely on a single-item self-report measure of exercise. Future research should use more detailed assessments of frequency, intensity, and type of daily exercise and would benefit from objective measures of exercise such as actigraphy.

ACCEPTABILITY OF SHARING BEHAVIORAL RISK AND GLUCOSE DATA BETWEEN PATIENTS AND CLINICIANS: A PILOT STUDY

Amy G. Huebschmann, MD, MS, FACP¹, Anowara Begum, MPH², Ilona Dewald, MPH³, Bethany M. Kwan, PhD, MSPH⁴, Jodi S. Holtrop, PhD, MCHES⁴, Andrea Dunn, PhD⁵, Russell E. Glasgow, PhD⁶, Alex H. Krist, MD, MPH⁷

¹University of Colorado (CU) School of Medicine, Department of General Medicine, Aurora, CO; ²University of Colorado (CU) School of Medicine, Department of Family Medicine and General Internal Medicine, Aurora, CO; ³Colorado School of Public Health, Aurora, CO; ⁴University of Colorado (CU) School of Medicine, Department of Family Medicine, Aurora, CO; ⁵Klein Buendel, Inc., Lakewood, CO; ⁶University of Colorado (CU) School of Medicine, Department of Family Medicine, Aurora, CO; ⁷Virginia Commonwealth University School of Medicine, Department of Family Medicine, Richmond, VA

Background: Medically complex patients with uncontrolled type 2 diabetes face diabetes self-management challenges, including managing blood glucose levels and lifestyle behaviors. Technology packages have improved clinical outcomes by allowing patients to share data with clinic teams on home glucose (Glooko®) and behavioral health risk data (My Own Health Report, MOHR). However, adoption remains low in primary care. In a pilot study to inform implementation efforts, we evaluated the acceptability of Glooko/MOHR among key stakeholders: patients and clinicians.

Methods: We recruited eligible patients with uncontrolled type 2 diabetes mellitus (Hemoglobin A1c >8%) and their treating clinicians from two academic primary care clinics. Participants provided acceptability ratings after a demonstration of the process of sharing Glooko/MOHR data between patients and clinics. We considered ratings of ≥70% in each of the 7 Technology Acceptance Model (TAM) domains as acceptable. All quantitative data are reported as mean ± SD.

Results: Patients enrolled (n=6) were adults (age = 61.8 ± 13.3 years), 50% non-white, and 83% female. Clinicians (n=10) had 12.6 ± 9.9 years of practice experience.

Patient acceptability: The highest rated TAM domains for Glooko were Intention to use (92 ± 12) and Openness to Change (85 ± 21); for MOHR, the highest rated were Intention to use (83 ± 0) and Perceived usefulness (79 ± 8). Unacceptably rated TAM domains were Perceived ease of use (67 ± 0) and self-efficacy (58 ± 12) for Glooko, and Perceived ease of use (67 ± 0) for MOHR.

Clinician acceptability of sharing Glooko and MOHR data: Highest ratings were for Perceived usefulness (89.9 ± 0.4%) and Intention to use (83.3 ± 11.5%). Only Subjective Norms/Others' support was unacceptably rated (53.0 ± 14.3%); this related to low perceived support among patients (30%), colleagues (60%), and health managers (60%).

Discussion: Medically complex patients with diabetes and their clinicians generally found it useful to share glucose and behavioral risk data with each other. However, many patients anticipated it would be challenging to upload these data. Clinicians thought there would be limited support for this practice from patients, colleagues, and managers. To reach the promise of using remote technology and patient-reported data to address health challenges, clinics will need to address areas of high demand to patients/clinic leaders and provide sufficient technical assistance to patients.

PREDICTOR OF SUBJECTIVE COGNITIVE DECLINE AMONG PEOPLE WITH DIABETES: SECONDARY ANALYSIS OF BRFSS DATA

Ya-Ching Huang, PhD¹, Julie Zuniga, PhD², Alexandra A. Garcia, PhD²

¹Texas State University, Round Rock, TX; ²The University of Texas at Austin, Austin, TX

Purpose: People with diabetes are at nearly double the risk of developing cognitive impairment or dementia that will worsen patients' ability for self-management. Subjective cognitive decline (SCD), the self-reported experience of worsening or more frequent confusion or memory loss within the previous 12 months, is one of the earliest symptoms of dementia. The aim of the study was to explore factors that predict SCD in patients with diabetes.

Methods: This study is a secondary analysis of data obtained from the 2017 Behavioral Risk Factor Surveillance System (BRFSS), a random and cross-sectional survey of adults from 10 states. In addition to descriptive and Chi-square analyses, logistic regression was conducted for SCD with the following sets of predictors: 1) background (race, gender, education, and age), 2) health-related factors (self-rated health, BMI, and comorbidities), and 3) health behavior (smoking, exercise, drinking) were entered simultaneously.

Result: The sample is composed of 5263 participants with diabetes who had completed the 2017 BRFSS. More than one-third were aged 65 to 74 years, about 45% were male, and 53.4% were non-Hispanic Whites; 15% of participants reported having SCD. Increased odds of reporting SCD were observed among individuals who were Hispanic (OR = 2.21, $p < 0.001$), male (OR = 1.47, $p < 0.01$), had depression (OR = 3.84, $p < 0.001$), and arthritis (OR = 1.43, $p < 0.03$). Participants who perceived their overall health was good were less likely to have SCD (OR = 0.51, $p < 0.001$).

Conclusions: Hispanic adults, males, depression, and arthritis were more likely to report SCD. Healthcare providers should target patients with these characteristics for further evaluation of cognitive dysfunction or early intervention.

STRATEGIES TO INCREASE HEALTH SYSTEM REFERRALS TO CHRONIC DISEASE PREVENTION AND MANAGEMENT PROGRAMS: A SYSTEMATIC REVIEW

Krista Proia, MPH¹, Renee Skeete, PhD², LaShonda Hulbert, MPH¹, Stephanie Rutledge, PhD, MA¹¹Centers for Disease Control and Prevention, Atlanta, GA; ²Cyberdata, Inc, Atlanta, GA

Evidence-based prevention and management programs such as the National Diabetes Prevention Program lifestyle change program or Diabetes Self-Management Education and Support are effective in preventing or managing chronic diseases. Referrals from a health care provider offer an opportunity to increase participation in these programs, as patients are more likely to act on their advice. The goal of this systematic review was to examine the effectiveness of strategies to increase referrals to various chronic disease prevention and management programs.

We conducted a systematic search (database inception - May 2019) to identify qualifying studies. We included studies that evaluated any strategy designed to increase health care provider referrals to evidence-based chronic disease prevention and management programs, and reported any measure of referral rates. We excluded studies that assessed referrals to specialist or diagnostic care and non-comparative study designs. Using methods developed by The Community Guide, two reviewers independently abstracted relevant information and assessed study quality. Because of the heterogeneity of the various referral strategies, we summarized results narratively.

We identified 55 studies that met our inclusion criteria. Physicians were the most common referring providers (31 studies; 56.4%) and most referrals were made in a primary care setting (40 studies; 72.7%). The majority of studies reported a statistically significant improvement in referrals (34 studies, 61.8%). The following individual strategies were effective in increasing referrals: providing formal training or professional development to referring providers; providing educational materials; delivering feedback on referral rates; and using a team-based care approach. Additionally, providing formal training in combination with clinical decision support was also effective in increasing referrals.

These findings demonstrate that health care provider referral rates to chronic disease prevention and management programs can be increased through many strategies. These findings also suggest that multiple strategies used in combination may be even more successful. Finding the right balance of strategies so as not to overwhelm referring health care providers should be considered.

DIABETES-RELATED QUALITY OF LIFE: LEARNING FROM PATIENTS MAKING LIFESTYLE CHANGES TO IMPROVE TYPE 2 DIABETES SELF-MANAGEMENT

Sarah R. Fishman, BA¹, Maria Fernandez, BA², Pia Iribarren, MPH², Jill Linnell, MPH³, Victoria Jonas, BA⁴, Jennifer M. Gittleman, BA¹, Molly L. Tanenbaum, PhD⁵, Maya Scherer, MPH⁶, Linda Weiss, PhD⁶, Elizabeth A. Walker, PhD, RN, CDE⁷, Hang Pham-Singer, Pharm. D.⁸, Winfred Wu, MD, MPH⁸, Jeffrey S. Gonzalez, Ph.D.⁹

¹Ferkauf Graduate School of Psychology, Yeshiva University, Albert Einstein College of Medicine, New York, NY; ²Bureau of Equitable Health Systems, NYC Department of Health and Mental Hygiene, Queens, NY; ³Bureau of Equitable Health Systems, NYC Department of Health and Mental Hygiene, Queens, NY; ⁴Ferkauf Graduate School of Psychology, Yeshiva University, Albert Einstein College of Medicine, New York, NY; ⁵Stanford University School of Medicine, Palo Alto, CA; ⁶New York Academy of Medicine, New York, NY; ⁷New York Regional Center for Diabetes Translation Research, Albert Einstein College of Medicine, Bronx, NY; ⁸Primary Care Information Project, NYC Department of Health and Mental Hygiene, Queens, NY; ⁹Ferkauf Graduate School of Psychology, Bronx, NY

Background: Type 2 Diabetes (T2D) has a significant impact on quality of life (QoL). Patients and healthcare providers agree that QoL is an important patient-reported outcome that should inform diabetes care. However, there is substantial disagreement on how best to define and measure QoL in diabetes. Making lifestyle changes associated with T2D self management may enhance or detract from QoL. The aim of this study was to use qualitative methods to explore factors which influence QoL among predominantly low-income Latino and Black adults with T2D and elevated A1Cs after participation in a diabetes self-management intervention.

Methods: Adults treated for T2D in New York City primary care practices were recruited based on having an HbA1c $\geq 7.5\%$. Trial participants (N=812) were randomly assigned to a control condition with mailed print materials for diabetes education or to a telephonic intervention including 6–12 phone calls over 1 year from a diabetes health educator using an intervention manual and participant workbook. Sub-study participants (N=50; 72% Hispanic, 20% Non-Hispanic Black, 4% Non-Hispanic White; 62% Spanish speaking) from both conditions were interviewed by phone after study completion, asked to define QoL in their own words, and to share ways that T2D, treatment, management, and study participation impacted QoL. Interviews were audio-recorded, translated, transcribed and analyzed using thematic analysis by a coding team.

Results: Participants reported factors related to T2D that can impact QoL negatively and positively. Themes were consistent in both control and intervention groups. Participants cited the following negative factors: financial strain; symptom progression and burden; difficulty modifying cultural and lifestyle habits. Positive factors included: social support from family, friends and health-care providers; diabetes education; positive health behavior change.

Conclusion: Results indicate that adults aiming to improve T2D self-management have a multifaceted definition of QoL that includes physical health, independence, social support and engaging in cultural and lifestyle routines. These findings revealed aspects of QoL not currently reflected in available T2D-related QoL measures: socio-cultural impact and social support for diabetes self-care. Results will inform the development of a patient-centered measure of T2D-related QoL.

CASE STUDY: USING EDUCATION TO ADDRESS PATIENT CONCERNS REGARDING WEIGHT PLATEAUS AT A VIRTUAL DIABETES CLINIC

Rebecca N. Adams, PhD¹, Brittanie M. Volk, PhD¹, Amy L. McKenzie, PhD¹, Hyesoo Youn, PhD¹¹Virta Health, San Francisco, CA

Background: Virta Health provides a virtual medical intervention including nutritional ketosis to improve glycemic outcomes among people with type 2 diabetes and prediabetes. Most patients are overweight and experience significant weight loss, and while weight is not a primary intervention target, it is important to patients. When weight loss slows or stops, many patients become concerned and frustrated. Additionally, their confidence in their ability to adequately follow the intervention declines. To promote confidence, as a quality improvement initiative, we developed and assessed an educational module to: (1) help patients better understand weight loss and fluctuations, (2) set realistic expectations, and (3) provide practical tips to identify why their weight has stabilized and if appropriate, what they can do to overcome it.

Methods: Health coaches assigned the educational module to some of their patients. Patients assigned the module were in treatment at least 90 days (M=237 days) and wanted to lose weight. They completed the module at their own pace (M=5 days). At the time of this analysis, 37 patients completed the module at least 1 month prior and 22 completed it at least 2 months prior. We explored changes in their weight over time using paired t-tests. Specifically, we compared patients' average weight over 1 month prior to beginning the module with their average weight over 1 and 2 months post-module. After completing the module, we also asked patients to rate their confidence in their ability to work through "weight plateaus" in the future on a scale from 1 to 5.

Results: Patients' average weight decreased from 1 month pre- to 1 month post-module (-3.2lbs from 226lbs, $p < 0.0001$) and 1 month pre- to 2 months post-module (-3.7lbs from 227lbs, $p < 0.01$). The 78% of participants who completed the post-survey reported high confidence (M=4.2) in their ability to work through future weight plateaus.

Conclusions: After completing a new educational module, patients lost weight and reported high confidence for handling future weight plateaus. Ongoing evaluations will assess the module's impact on a larger sample of patients and over a longer period of time. Future efforts will also focus on identifying the optimal time to introduce this educational content to individual patients (e.g., before vs. after weight loss slows) to prevent frustration and maintain confidence in their ability to follow the intervention.

CLIENT PREFERENCES AND DIABETES MANAGEMENT GUIDELINES INFORM THE DESIGN AND ELEMENTS OF A THERAPEUTIC FOOD BOX INTERVENTION

Eliza Short, RD¹, Jayati Sharma, n/a¹, Debbie Thompson, PhD², Rhonda Gonzalez, MSPH³, Jessi Sheava, BS³, Douglas Taren, PhD¹, Melanie Hingle, PhD, MPH, RDN¹¹University of Arizona, Tucson, AZ; ²USDA/ARS; Baylor College of Medicine, Houston, TX; ³Community Food Bank of Southern Arizona, Tucson, AZ

Background: Type 2 diabetes (T2D) affects >30 million U.S. adults and disproportionately burdens food insecure households. Associations between food insecurity, poor diet quality, and T2D are well established and have prompted medical nutrition therapy (MNT) recommendations designed to prevent complications. Limited food access and low diet quality in food insecure households make these goals difficult to achieve. Food bank assistance often lacks cultural responsiveness and alignment with MNT goals. Incorporating MNT recommendations and food bank client preferences with food assistance efforts will help improve diet quality and mitigate T2D burden among food insecure households.

Purpose: To assess food bank clients' preferences related to a typical food assistance box and determine if alternative foods or resources would help clients with T2D improve diet quality and disease management.

Methods: Twenty participants self-reporting T2D or T2D in their household were recruited from the Community Food Bank of Southern Arizona in June/July 2019. Participants completed a demographic questionnaire and semi-structured interview. Participants viewed a food assistance package of 7 items (e.g., canned/dried legumes, vegetables, grains). Participants described food use and foods they would replace/add from 6 T2D-suitable items. Interviews, conducted in English (n=10) and Spanish (n=10), were digitally recorded, transcribed, and independently verified by two researchers. A script-based codebook was developed and confirmed by a third, senior researcher. All coding was conducted in NVIVO 12 using thematic analysis.

Results: Participants were 45 to 83 years, majority female (n=15, 75%), Hispanic (n=16, 80%), and food insecure (n=18, 90%). Participants used all foods received from the food bank or redistributed undesired items to friends and family members. Emerging themes from ongoing analysis center around existing food use and desired replacement foods. Food assistance use was driven by cultural relevance, household food preferences, and ability to pair foods with other household foods. Desired foods included fresh fruits and vegetables, meat, oats, oil, and herbs; desired resources included recipes, cooking demonstrations, and online support groups.

Conclusion: Participants desired culturally relevant, cost-effective, and healthy foods and recipes in accordance with MNT guidelines. This feedback can inform tailored food assistance supporting diabetes management in food bank clients.

A SPANISH-LANGUAGE VERSION OF THE TYPE 2 DIABETES STIGMA ASSESSMENT SCALE: PSYCHOMETRIC PROPERTIES IN U.S. LATINOS WITH T2D

Kevin Joiner, PhD, RN, ANP-BC¹, Jane Speight, PhD², Gretchen Piatt, PhD¹¹University of Michigan, Ann Arbor, MI; ²The Australian Centre for Behavioural Research in Diabetes, Diabetes Victoria, Melbourne, Victoria, Australia

Background: There is increasing awareness of social stigma surrounding type 2 diabetes (T2D), with many people feeling blamed and judged by others for ‘bringing it on themselves’ or for food choices, and being treated differently by others (potentially leading to rejection, discrimination, exclusion). Such stigma can also be internalized (self-stigma). There is emerging evidence that diabetes-related stigma is associated with worse physical and emotional health outcomes. The Type 2 Diabetes Stigma Assessment Scale (DSAS-2) was developed and validated in Australia to enable research to determine the extent and impact of diabetes-related stigma. The purpose of this study was to assess the psychometric properties of a newly developed linguistically and culturally adapted Spanish-language U.S. version (DSAS-2 Spa-US) in U.S. Latino adults with T2D.

Methods: Data were collected via an online survey from 520 Spanish-speaking Latino adults with T2D living in the U.S. (mean age 54±10 years, 72% women, 53% with Mexican heritage). Exploratory factor analysis was used to determine the structure of the 19-item DSAS-2 Spa-US using STATA 15. Internal consistency reliability was assessed with Cronbach’s alpha. Concurrent validity was assessed (expected correlation $r > 0.4$) against a measure of perceived stigma across chronic conditions (SSCI-8). Convergent validity was assessed (expected $r > 0.4$) against measures of depressive symptoms (PHQ-8), anxiety symptoms (GAD-7), diabetes-related distress (DDS), loneliness (3-Item Loneliness scale), and general self-esteem (RSE). Discriminant validity was assessed (expected $r < 0.3$) against diabetes duration.

Results: Exploratory factor analysis supported a single scale (eigenvalue=8.20), accounting for 82% of the variance for the 19 items of the DSAS-2 Spa-US, which all loaded > 0.5 on this factor. The internal reliability was high (Cronbach’s $\alpha = 0.93$). DSAS-2 Spa-US had significant (all $p < 0.001$), at least moderate ($r > 0.4$), correlations as expected with the: SSCI-8 ($rs = 0.65$), PHQ-8 ($rs = 0.45$), GAD-7 ($rs = 0.43$), DDS ($rs = 0.56$), 3-Item Loneliness scale ($rs = 0.41$) and RSE ($rs = -0.49$). As expected, DSAS-2 Spa-US was weakly associated with diabetes duration ($rs = 0.07$, NS).

Conclusions: This study contributes evidence that the DSAS-2 Spa-US is a valid and reliable measure of diabetes-related stigma. This will facilitate future research about the extent and impact of diabetes stigma in U.S. Latino adults with T2D.

CHRONIC DISEASE PREVENTION AMONG YOUNG ADULT LATINAS: BUILDING A DIGITAL HEALTH INTERVENTION

Kelly L’Engle, PhD, MPH¹, Evelin R. Trejo, MPH, MSBH²¹University of San Francisco, San Francisco, CA; ²Zuckerberg San Francisco General Hospital, San Francisco, CA

Background: Latinos are the largest racial/ethnic minority in the U.S., and by 2060 more than half of Californians will be of Latino descent. Rates of obesity, smoking, cardiovascular disease, and some cancers are higher among Latinos than other groups. Latinos are at high risk for developing diabetes yet have some of the lowest rates of diabetes awareness and control. Poor health outcomes from chronic disease typically are not felt until later in life, but younger Latinos need targeted interventions to reduce morbidity and mortality from diabetes and other health challenges. Mobile phone use is high in this population and provides an important platform and opportunity for reaching young Latinas with health information and support.

Methods: We conducted four focus groups with 18-29-year-old Latina women recruited from community locations in Northern California. Perceptions of health and chronic disease, mental and physical health concerns for participants and families, and ideas about health promotion approaches and digital health messaging were discussed. Data was analyzed using NVivo.

Results: Diabetes was reported in almost every participant’s family, along with concerns about overweight, nutrition, cancer, and stress. Participants reported wanting more information about “nutrition and healthy eating because if we learn how to eat right I feel like I can prevent myself from getting all this stuff,” and stating that “diabetes runs in my family and if I was more informed I could make better day-to-day decisions.” Mental health and well-being also were common concerns, stating that “stress is a big topic that needs to be talked about,” and that depression is common in their families but “it’s very taboo where there is no talking about it or you just leave it behind closed doors.” Culturally tailored chronic disease resources were seen as limited: “There aren’t a lot of resources for Latinos like for someone who speaks Spanish” and “When Latinos are diagnosed with diabetes the recommendations are not culturally appropriate and they provide recommendations that are not workable for [Latinos].” Health communications that “feel like a friend is talking to me, and [show] culturally relevant foods and dancing,” include Spanish and “Spanglish” phrases that “remind you of home,” and that are “Latina-based” were appealing. A mobile phone intervention was viewed as an optimal way to reach young Latina women.

Conclusions. Young adult Latinas are worried about chronic disease prevention and management for themselves and their families. A digital health program designed for Latina women that provides text messages, short videos, self-assessments, and recipes and tips promoting physical and mental health is a promising intervention approach.

A MULTI-METHOD APPROACH FOR IDENTIFYING HIGH-RISK PATIENTS WITH UNMET BEHAVIORAL HEALTH NEEDS IN A SAFETY-NET HOSPITAL SETTING

Haley M. Sandoval, BA¹, Julia I. Bravin, MS², Kimberly Luu, B.S.³, Johanna Euyoque, MA¹, Linda C. Gallo, PhD⁴, Taylor L. Clark, BA⁵, Kim L. Savin, BA², Daniela G. Vital, B.S.⁶, Jessica L. Preciado, B.A.⁷, Athena Philis-Tsimikas, MD¹, Addie L. Fortmann, PhD⁸

Hispanics experience higher rates of chronic cardiometabolic diseases and unmet behavioral health needs than non-Hispanic whites. In turn, these comorbidities place this population at high risk for hospital readmissions. A randomized controlled trial is underway to evaluate the effectiveness of *Mi Puente* ("My Bridge"), a Behavioral Health Nurse + Community Mentor team intervention in reducing readmissions among 560 patients with multiple chronic cardiometabolic conditions (e.g., obesity, diabetes, cardiovascular disease) and behavioral health concern(s) (e.g., anxiety or depression symptoms, chronic stress, health-related distress) who are hospitalized at a safety-net hospital located near the US/Mexico border in San Diego, CA. Here we present important "lessons learned" from our 2-step, multi-method [i.e., electronic medical record (EMR) + paper screener] approach for systematically identifying these high-risk patients in the hospital for intervention.

From June 2016 and July 2019, N=5,273 Hispanic adult admissions with ≥2 chronic cardiometabolic conditions were identified via an automated EMR report (Step 1). However, the majority (n=4,515, 86%) did not complete a behavioral health screening (Step 2) for the following reasons: 42% were unavailable (e.g., discharged; undergoing procedure or sleeping) or refused (e.g., felt unwell); 38% were not approached due to poor current health status, as indicated by nurse/physician report or intensive care unit placement; 6% started but did not complete screening. Of the 758 (14% of those eligible after Step 1) who were successfully screened, 624 (82%) endorsed ≥ 1 unmet behavioral health need(s); significant anxiety (38%) or depressive symptoms (44%), chronic stress (50%), health-related distress (39%), and lack of routine medical care (61%) were most commonly endorsed.

A bedside, paper-based screener identified high rates of unmet behavioral needs that elevate readmission risk, which are often not systematically or comprehensively documented in the EMR. However, only 14% of at-risk patients with multiple chronic conditions were successfully evaluated. Once admitted to the floor, poor and rapidly fluctuating health status, combined with barriers inherent to the acute, inpatient care environment pose challenges to behavioral health screening. In order to effectively intervene and reduce readmissions in high-risk patients, behavioral health screening should be conducted as part of the admission process.

THE INFLUENCE OF IMPULSIVITY AND PARENTAL CONTROL ON DIET AND WEIGHT IN EMERGING ADULTS

Christiana M. Field, B.A.¹, Emily P. Wyckoff, M.S.², Tricia M. Leahey, Ph.D.², Amy A. Gorin, Ph.D.²

¹University of Connecticut, Hartford, CT; ²University of Connecticut, Storrs, CT

College marks a critical developmental phase, where emerging adults transition from a period of parental control to increased autonomy in a food-rich environment. As such, college is a high-risk time for weight gain, particularly for students with higher impulsivity- a known risk factor for weight gain and overeating throughout life. In childhood, the degree to which parents control their child's diet (Parental Regulation of Eating) predicts eating behavior. Research suggests an interacting effect of impulsivity and parental regulation on eating behavior in children, however, little is known about the effects of parental regulation of eating in emerging adults.

This study examined the association between impulsivity, parental regulation on eating in emerging adults, eating in the absence of hunger (EAH), and weight change during the first semester of college. It was hypothesized that: (1) greater impulsivity and parental regulation of eating would be associated with EAH and weight change; (2) parental regulation of eating would moderate the effect of impulsivity on EAH and weight change, such that for those with high parental regulation of eating, there would be a greater detrimental effect of high impulsivity on EAH and weight change, than in those with low parental regulation of eating.

This study used self-reported data from second semester college students. Participants (N=785; Age=18.33 +/-0.98; BMI=23.32 +/-4.95) completed measures of impulsivity, parental regulation of eating, EAH, and weight change. Controlling for BMI and gender, higher impulsivity was associated with weight gain (p=.044), with parental regulation of eating's association with weight change approaching significance (p=.059). Parental regulation of eating was not associated with EAH (p=.229), however, there was a trend level interaction between impulsivity and parental regulation of eating (p=.053). At high impulsivity, EAH was similar, regardless of the level of parental regulation of eating. At low impulsivity, high parental regulation of eating was associated with more EAH, compared to those with lower parental regulation of eating.

Findings indicate that impulsivity is associated weight gain in college and that strict parental regulation of eating during adolescence could indeed be detrimental to emerging adults with better self-control, whereas its effects may be overshadowed among adolescents with low self-control.

AFRICAN AMERICAN FATHERS' PERCEIVED ROLE FOR THE DIETARY BEHAVIORS OF THEIR CHILDREN: A QUALITATIVE STUDY

Ledric Sherman, Ph.D., M.A.¹, Matthew Smith, PhD, MPH, CHES²¹Texas A&M University, College Station, TX; ²Texas A&M University School of Public Health, College Station, TX

Introduction: Mothers have chiefly been the center of research on child-feeding practices with maternal effects being exclusively assessed or used as a proxy for both parents. However, research has rarely focused on fathers or their ability to impact the health behaviors of their children. The purpose of this study is to investigate African American fathers' involvement in promoting healthful decisions and influencing dietary patterns among their children and within their households.

Methods: This exploratory study gathered data via semi structured focus groups (n = 3), which were thematically analyzed utilizing a grounded theory approach. Participants included AA fathers (n = 20) with a mean age of 37 years (± 11.79), all of which had one or more children between the ages of 6 and 18 years.

Results: Three significant subthemes emerged from the focus group sessions, which included fathers' perspectives about: (a) teaching by example; (b) eating healthy is expensive; and (c) cooking and eating at home.

Discussion & Conclusion: Understanding AA fathers' perceived and desired role in their children's health edification can inform initiatives that actively engage these men, and nurture their level of involvement, to promote positive health behaviors among their children. Such efforts are necessary for AA fathers to realize their potential to effectively serve as change agents and actively improve the health of their children, families, and communities.

COLLEGE STUDENT DIETARY RECALLS AND THE THEORY OF PLANNED BEHAVIOR

Megan Douglas, Ph.D.¹, Heidemarie Blumenthal, PhD², Charles A. Guarnaccia, Ph.D.³¹Baylor Scott & White Institute for Rehabilitation, Dallas, TX; ²University of North Texas, Denton, TX; ³University of North Texas, Denton, TX

Evidence consistently demonstrates that a healthy diet can both directly and indirectly reduce risk for cardiovascular disease, type 2 diabetes, certain types of cancer, hypertension, and dyslipidemia throughout all stages of the lifespan (Dietary Guidelines Advisory Committee, 2010; NCHS, 2015; Via, 2012; World Health Organization, 2003). However, modifying eating behaviors in emerging adulthood may serve as the most effective approach for primary prevention of chronic disease risk later in life (Liu et al., 2012). Unfortunately, the transition to college is marked by poorer eating behaviors (Anding, Suminski, & Boss, 2001; Deforche et al., 2015; Nelson et al., 2008). The Theory of Planned Behavior (TPB) represents a promising tool for developing targeted behavioral interventions through the examination of attitudes (ATT), subjective norms (SN), perceived behavioral control (PBC), and intention (INT) for healthy eating behaviors. However, there exist several key methodological issues in the literature. The present study utilized an enhanced dietary assessment methodology, the ASA24 dietary recall, and a short-term prospective study design to examine the relative contributions of these psychosocial factors to intent and actual dietary intake using the TPB. Dietary recalls of 68 participants (average age = 20.76 years; 70.6% female; 70.6% non-Hispanic, 48.5% White, 22.10% Black/African American, 13.20% Asian) were analyzed using the Healthy Eating Index (HEI)-2010 scoring system. None of the sample met all of the recommended dietary guidelines and very few (e.g. 0% to 4.4%) met any recommendations, with the exception of protein intake (20.6%). Linear regression indicated that the indirect TPB variables (ATT, SN, and PBC) were related to INT ($F[3,64] = 19.67, p < .001$), although SN did not account for unique variance. Further, the direct TPB variables (INT and PBC) were related to HEI-2010 scores ($F[2,65] = 4.00, p = .023$); however, only PBC accounted for significant variance. Overall, findings suggest that more favorable attitudes relate to intention, but only perceived behavioral control consistently relates to actual healthy eating behavior. Implications of these results suggest that interventions should focus on enhancing the perceived behavioral control of healthy eating behaviors.

PREVENTION OF EATING DISORDERS USING CHATBOT CONVERSATION

Naira W. Topooco, n/a¹, Ellen E. Fitzsimmons-Craft, PhD², William Chan, MS³, Marie-Laure Firebaugh, LMSW⁴, Arielle C. Smith, N/A⁵, Burkhardt Funk, n/a⁶, Nicholas C Jacobson, PhD⁷, Shiri Sadeh-Sharvit, PhD⁸, Denise E. Wilfley, PhD⁹, Craig B. Taylor, MD¹⁰

¹Center for m2Health, Palo Alto, CA; ²Washington University School of Medicine, St. Louis, MO; ³PGSP-Stanford PsyD Consortium, Sunnyvale, CA; ⁴Washington University School of Medicine, St Louis, MO; ⁵Washington University in St. Louis, Sunnyvale, CA; ⁶Institute of Information Systems, Lueneburg, Niedersachsen, Germany; ⁷Dartmouth College, Lebanon, NH; ⁸Palo Alto University, Towson, MD; ⁹Washington University in St Louis, St Louis, MO; ¹⁰Stanford/Palo Alto University, Stanford, CA

Introduction: Eating disorders (EDs) – including anorexia nervosa, bulimia nervosa, and binge eating disorder – are some of the most common and disabling mental health disorders. Once developed, they can be difficult to treat and chronic, highlighting the great need for accessible prevention programs. Online guided self-help prevention programs for EDs, such as StudentBodies[®], have demonstrated efficacy (ES > 0.40) when delivered with coach support. However, human coaching limits the program's scalability (e.g., due to cost, training). What is needed is a fully automated prevention program for EDs that retains some of the benefits of what human coaching provides (e.g., follow-up, personalized guidance, support).

Intervention: The StudentBodies[®] program was reworked to be delivered in the form of 8 brief interactive psychoeducational and skill training conversations with an automated chatbot, delivered via text messaging or Facebook messenger. Conversations entail the key tenets of the original program, with participants prompted to complete 2 conversations per week, although access to the chatbot intervention is provided for 3 months. The chatbot is hosted by X2AI, a mental health chatbot company.

Methods: A two-arm randomized controlled trial is currently underway at the national level in the U.S., enrolling 700 women aged 18–30 at risk for an ED, but without a current clinical presentation. Participants are being recruited from 1) online ED screening from the National Eating Disorders Association, or 2) Facebook, and eligible participants are randomized to either the program or a waitlist. Participants are assessed at baseline, 3 months, and 6 months. Primary outcomes include key ED risk factors such as weight/shape concerns and thin-ideal internalization, measured by the Weight Concerns Scale and the Internalization Thin/Low Body Fat subscale of the Sociocultural Attitudes Toward Appearance Questionnaire-4R, respectively.

Results: Preliminary outcomes at post-treatment will be presented.

Conclusion: This study investigates whether a chatbot can be used to deliver and provide support for a preventive ED intervention. If effective, this chatbot-based program could provide a cost-effective, first-line prevention program anywhere, anytime, to females at high risk for the onset of an ED.

TEN YEAR RESULTS FOR A WORKSITE WEIGHT MANAGEMENT CAMPAIGN: UPMC MYHEALTH WEIGHT RACE

Amanda Gabarda, EdD, MPH, NBC-HWC¹, Valerie Silfee, PhD¹, Lydia Hartzell, n/a¹, Sarah Bowen-Salio, MPH², Michelle Casavale, MS, RDN, LDN³, Frank Seguiti, n/a³

¹UPMC Health Plan, Pittsburgh, PA; ²WorkPartners/ UPMC Health Plan, Pittsburgh, PA; ³WorkPartners/ UPMC Health Plan, Pittsburgh, PA

Background: The number of individuals who are overweight or obese in the U.S. has continued to rise over the past few decades. As a result, employers struggle with the costs associated with increased absenteeism and presenteeism for employees who have health problems associated with obesity. In recent decades, employers have implemented various worksite wellness campaigns to improve health and productivity. Overall, the evidence indicates that worksite weight management programs can positively influence health outcomes and reduce employer costs over time. The UPMC MyHealth Weight Race is a 12-week worksite weight management campaign which features weekly emails and online resources within the framework of a workplace competition to reach weight goals. Employees participate to lose or maintain weight.

Methods: Historic campaign data was queried using Microsoft SQL Server Management Studio 2012 for the years 2008 to 2017. Weight loss was calculated by determining the average and percent weight loss among all participants.

Results: The number of participants ranged from 4,044 in 2008 to 10,054 in 2017. Among participants who lost weight, average weight loss ranged from 6.0 pounds in 2017 to 7.0 pounds in 2008. The average percentage of weight loss ranged from 3.1% in 2017 to 3.6% in 2008. Across all participants in the campaign, the average weight loss ranged from 3.14 pounds in 2016 to 4.30 pounds in 2010. The average percent weight loss for all participants ranged from 1.6% in 2016 to 2.2% in 2008. The number of participants who lost weight ranged from 2,702 in 2008 to 6,367 in 2017; the number of maintainers (those who did not gain or lose any weight) ranged between 883 in 2008 to 1,886 in 2017; the number of weight gainers ranged from 459 in 2008 to 1,801 in 2017. Overall, most participants joined the program in teams as opposed to individuals across all ten years, and most participants completed the program.

Conclusions: As overweight and obesity continue to rise, creative approaches to weight management are necessary across a variety of settings. Worksite wellness campaigns are an important tool to improve reach and address overweight and obesity among large numbers of individuals. The UPMC MyHealth Weight Race findings suggest that an internet-based weight management campaign is a scalable and effective way to engage thousands of employees in weight management education and behavior change. The ten years of results presented are remarkably consistent benchmarks for advancing future campaign development and weight management technology research.

REPEATED CONSUMPTION OF A FOOD IS NECESSARY FOR HABIT FORMATION, BUT UNDERMINES ENJOYMENT: AN EXPERIMENTAL TEST OF A SOLUTION

Richie Lenne, PhD¹, Traci Mann, PhD², Rachel J. Burns, PhD³, Zata Vickers, Ph.D.⁴, Joseph Redden, P.H. D.²¹University of Minnesota, Kensington, CA; ²University of Minnesota, Minneapolis, MN; ³Carleton University, Ottawa, ON, Canada; ⁴University of Minnesota, St. Paul, MN

Objective: The formation of healthy eating habits is supported by repeatedly eating specific foods, but repetition can also reduce enjoyment of those foods. There is burgeoning evidence that *salience* of dietary variety (in addition to *actual* variety) increases enjoyment of repetitiously consumed foods, but it is unclear whether variety salience can affect consumption outside of a laboratory setting. In a longitudinal field experiment we tested a brief intervention to remind participants of the variety in their diet. We hypothesized that increasing salience of dietary variety would prevent declines in enjoyment of the food and would increase the likelihood that participants would be willing to eat the food again, after the study ended.

Design: Participants (n = 139) ate a granola bar at the same time each day for two weeks, as they went about their daily life activities. On alternate days, before eating the bar, participants randomly assigned to the treatment condition recalled other recently consumed foods (to increase salience of dietary variety). Control subjects recalled variety in an unrelated domain (music). Participants reported their enjoyment of the granola bar after they ate it each day. At the end of the study, participants returned to collect their compensation, and were free to help themselves to snacks, including granola bars.

Results: Self-reported feelings of enjoyment persistently declined with each additional day of consumption, and contrary to our first hypothesis, increasing salience of dietary variety did not reduce this decline. In support of our second hypothesis, however, increasing salience of dietary variety increased the likelihood that participants would choose to consume the same kind of granola bar again two weeks later.

Conclusion: Brief exercises that make variety in one's diet more salient may not prevent reductions in enjoyment of a repetitiously consumed food, but may still support continued consumption of the food.

A DEFAULT OPTION FOR HEALTH: IMPROVING NUTRITION WITHIN THE CONSTRAINTS OF FOOD INSECURITY USING ON-LINE GROCERY SHOPPING

Jaime A. Coffino, MA, MPH¹, Gloria Han, MA², E. Whitney Evans, PhD, RD³, Rachel Luba, MA⁴, Julia M. Holmes, Ph.D.⁵¹University at Albany, SUNY, Providence, RI; ²Vanderbilt University, Providence, RI; ³The Miriam Hospital / Brown University Medical School, Providence, RI; ⁴Stony Brook University, Brooklyn, NY; ⁵University at Albany, SUNY, Albany, NY

Food insecurity, the limited availability of nutritionally adequate food, is associated with an increased risk for obesity and associated health problems. There is a need for sustainable interventions that improve diet-related health in individuals with food insecurity. In behavioral economics, the default option is the option a consumer selects if they do not make an active choice. The current study tests if the use of a prefilled online grocery cart (i.e., a default option) improves the nutritional quality of groceries purchased online by food pantry users with food insecurity. Thirty-eight adults enrolled and were given \$48.50 to purchase groceries weekly using an online grocery website for five weeks. At baseline, participants were instructed to purchase groceries keeping in mind nutrition, cost, and taste. For the subsequent four weeks (T1-T4), participants were randomized to receive 1) nutrition education or 2) a prefilled online grocery shopping cart that met their nutritional needs based on age and sex (Default). From baseline to T1, participants in the Default condition, had an immediate and significant increase in Healthy Eating Index (HEI) scores (i.e., a measure of diet quality ranging from 0–100; Cohen's $d = 1.13$) and a significant decrease in total calories (kcal; $d = 1.39$) and energy density (kcal/grams; $d = 1.32$) relative to those in the Nutrition Education condition. The initial improvement in diet quality was maintained throughout the treatment period for those in the Default condition (HEI Score $M(SD) = 64(17.38)$, 95% CI for the slope from T1-T4=[-4.10, 0.24]). While calories and energy density gradually increased in the Default condition from T1 to T4, these values were always lower (i.e., consistent with less energy dense grocery purchases) compared with the Nutrition Education condition ($[M_{diff}]$ calories T1: 6,285 kcal, T2: 4,477 kcal, T3: 2,448 kcal, T4: 418 kcal; $[M_{diff}]$ energy density T1: .48, T2: .40, T3: .23, T4: .06). Furthermore, diet quality, calories, and energy density did not significantly increase or decrease during the active treatment period in the Nutrition Education condition (HEI Score $M(SD) = 55(15.12)$, 95% CI for the slope from T1-T4=[-3.35, 0.93]; Calories $M(SD) = 16,140(8,662.20)$, 95% CI=[-1410, 263]; Energy density $M(SD) = 1.57(.60)$, 95% CI=[-0.14, 0.07]). The use of a default option while online grocery shopping may improve food purchasing behavior in individuals with food insecurity. In light of current work by the USDA to test the use of online grocery platforms by SNAP beneficiaries, implementation of this intervention may specifically benefit those living in food deserts with limited access to healthy options.

AVAILABILITY OF FOOD LABEL INFORMATION IN ONLINE GROCERY STORES

Jennifer Falbe, ScD, MPH¹, Laurel Denyer, BS Candidate², Abraham Karimi, BS Candidate², Lisa S. Miller, PhD¹¹University of California, Davis, Davis, CA; ²UC Davis, Davis, CA

Background: The popularity of online grocery shopping has surged in recent years with 20% of Americans now shopping online for groceries. However, unlike in brick-and-mortar locations where consumers can view ingredient lists and Nutrition Facts labels (NFLs) on food packages, as mandated by the Nutrition Labeling and Education Act (NLEA), in online retailers, consumers depend on the retailer to post this information. Moreover, the FDA regulates the content of nutrition and health claims on food packages, but there is no oversight of claims made for these same foods when sold through retailer websites. Thus, we sought to examine the extent to which ingredient lists, NFLs, and nutrition or health claims (here, referred to as marketing statements) are present, and easily accessible, at the point of online sale for leading online grocery retailers.

Methods: We coded websites of 15 of the leading online grocery retailers representing traditional, mass merchandise, health, or discount supermarkets. The product types (e.g., soda, pizza) examined were among the leading contributors to calories, food groups, added sugar, saturated fat, and sodium in the U.S. diet. We selected 31 top selling brands (covered by the NLEA), within each product type. Foods were coded for the presence and accessibility (number of arrow downs) of legible ingredient lists and NFLs as well as the presence of marketing statements, and stores were coded for the theme of their homepage. Chi-square tests were used to examine associations among these variables.

Results: Seventy-five percent of products had ingredient lists and NFLs, while 28% of products had marketing statements. Only 2 retailers had ingredients and NFLs for all products; 10 retailers had this information for 68–97% of products; and 3 retailers had this information for < 50% of products. Notably, the largest online retailer of groceries provided ingredient lists and NFLs for only 46% of products examined. Products without marketing statements had more accessible ingredient lists and NFLs ($P < 0.01$). Retailers with a health-oriented theme were more likely to provide both ingredient lists and NFLs (89% vs. 72%; $P < 0.01$), less likely to include marketing statements (10% vs. 32%, $P < 0.001$), and more likely to have easily accessible information (ingredient lists and NFLs) ($P < 0.001$).

Conclusion: Across all stores, ingredient lists and NFLs were available for the majority of foods we examined. However, the frequencies were markedly lower for some retailers and when marketing statements were present. Given past work suggesting that online grocery shopping may discourage the use of nutrition information, it is important to push for legislation to mandate full disclosure of nutrition, calorie, and ingredient information that is easily accessible and to limit nutrition and health statements to only those that are FDA-approved.

Introduction: The need for effective eating disorder (ED) treatment surpasses available face-to-face resources. Digital guided self-help (GSH) that includes on-line coaching is effective for EDs; however, the perceptions of program participants and their communications with their coaches should be further detailed to better define the needs of the service users.

Methods: Participants in this study were 383 college students (mean age = 22.5, $SD = 5.7$) from 16 U.S. colleges and universities who screened positive for a sub-clinical/clinical ED and received a digital GSH program based on cognitive behavioral therapy for treating their ED. Participants were each assigned a coach who helped them better utilize the intervention through text correspondence. A thematic and affective analysis of texts between users and coaches was conducted by doctoral-level researchers with expertise in mental health and qualitative analysis. Each message was assigned one or more themes, as appropriate.

Results: Participants sent a total of 4,646 text messages to their coaches (range of messages: 0–115, mean = 15.85 messages, $SD = 20.8$). In the initial assessment, 989 messages (21.3%) were coded as detailing technical requests and were excluded from further analyses (Krippendorff's $\alpha = .77$), leaving 3,657 messages of which 732 (20%) were randomly sampled and coded. In the preliminary analysis, 96 codes emerged, which were collapsed into 6 primary themes (Krippendorff's $\alpha = .81$ for overall thematic message coding and .78 for messages' affective tone). The messages mostly focused on (a) their efforts to utilize intervention tools to change their ED-related cognitions, behaviors, and relationships (59.6% of messages), (b) describing symptoms without expressing an active endeavor to change (39.3% of messages), and (c) participants' relationship with their coach (30.3% of messages). Most texts also conveyed either positive (23.1%), negative (32.4%), or mixed affective content (29.8%), demonstrating emotional engagement with the intervention.

Conclusion: Findings suggest that GSH for EDs produces participant involvement, and that participants discuss themes that can inform program development. This study also provides further support for the use of GSH as an effective resource for individuals with EDs, thereby increasing scalability and accessibility of evidence-based ED interventions.

DELAY DISCOUNTING AND DIET QUALITY

Rachel N. Foster, BA¹, Lauren T. Ptomey, PhD, RD², Laura E. Martin, Ph.D.³, Derek Reed, Ph.D., BCBA-D, LBA-KS⁴, Joseph Donnelly, EdD², Cary R. Savage, Ph.D.⁵

¹University of Kansas Medical Center, Lawrence, KS; ²University of Kansas Medical Center, Kansas City, KS; ³University of Kansas Medical Center - Hoglund Brain Imaging Center, Kansas City, KS; ⁴University of Kansas - Applied Behavioral Economics Laboratory, Lawrence, KS; ⁵University of Nebraska - Lincoln, Lincoln, NE

Background: Research indicates that individuals with a higher BMI are more likely to choose immediate food and monetary rewards, suggesting a relationship between a high energy dense diet and food impulsive choices. Choice-making behavior measured by delay discounting has been associated with higher energy intake in obese individuals. However, the extent to which impulsive behaviors specifically impact nutrient intake is unknown. The purpose of this analysis was to examine relations between delay discounting and diet quality in individuals with obesity.

Methods: This study represents baseline data from participants with obesity enrolled in a nine-month weight loss intervention. Participants completed a 3-day food record (2 weekdays/1 weekend day) and diet intake was analyzed using NDSR. Diet quality was calculated using the Healthy Eating Index-2015 (HEI-2015). Higher HEI-2015 scores are associated with better diet quality. The total maximum score is 100. Impulsivity was measured using a delay discounting task for money (*lnk*). Higher *lnk* is associated with greater impulsivity. All relations between *lnk* and HEI-2015 components were analyzed using IBM SPSS Statistics 25.

Results: Data was collected from 93 participants (~38 years of age, 71% female). The mean HEI-2015 total score was 49.5 ± 7.54 . *lnk* was not associated with HEI-2015 total score ($R^2 = .207$, $\beta = -.026$, $p = 0.78$). However, higher *lnk* scores predicted lower added sugar scores ($R^2 = .067$, $\beta = -.347$, $p = 0.14$), and higher sodium scores ($R^2 = .067$, $\beta = .296$, $p = 0.14$). There were no associations between *lnk* and the other HEI-2015 components.

Discussion: Our results indicate impulsive behaviors do not impact total HEI-2015 scores, but may have an impact on added sugar and sodium intake. Those who had greater *lnk* values tended to consume more added sugar but interestingly consumed less sodium. While additional research is still needed to better explore the relationship between impulsivity and diet quality, our results suggest interventions targeted at decision-making (i.e. self-regulation in the presence of food) may have a positive impact on added sugar intake.

PATTERNS OF E-HEALTH BEHAVIORS: A LATENT CLASS ANALYSIS

Lillian Madrigal, MPH¹, Cam Escoffery, PhD, MPH, CHES², Regine Haardörfer, PhD³

¹Emory University Rollins School of Public Health, Chamblee, GA; ²Rollins School of Public Health, Atlanta, GA; ³Emory University Rollins School of Public Health, Atlanta, GA

Background: To maximize the potential of e-health for health promotion and management it is important to explore and understand how people are engaging in e-health behaviors and if there are any populations that are differently engaged in particular e-health behaviors over others. This will allow for more effective targeted recruitment for health interventions, programs that engage individuals with their preferred e-health channel, and/or identification of populations with barriers to e-health use.

This study explored patterns of informational and participatory e-health behaviors within a population of U.S. adults and categorized users into distinct groups based on their e-health behavior patterns and individual characteristics (e.g. demographics).

Methods: Latent Class Analysis (LCA) was used to identify classes of e-health usage patterns of 401 adults surveyed in 2017. The survey contained a total of 109 items with the goal to descriptively understand how individuals were using the Internet for health and engaging in e-health behaviors. The LCA included 14 manifest variables assessing specific informational and participatory e-health behavior engagement. To estimate associations between derived latent classes and participant characteristics, multivariable multinomial logistic regression was conducted using “low e-health users” as the reference group.

Results: The LCA revealed five classes with distinct e-health behavior patterns: “only online searchers” (29.7%), “health trackers” (14.0%), “all-around high e-health users” (7.8%), “shared health experience seekers” (21.2%), and “low e-health users” (27.3%). Compared to the reference group of low e-health users, members of all other classes had high rates of online information seeking. The regression analysis compared the “low e-health users,” to the other classes and found differences in age, sex, health literacy levels, and technology ownership. The “low e-health users” had significantly lower e-health literacy scores compared to the other classes. Higher, more participatory, and more diverse patterns of e-health use were more likely to include adult females.

Discussion: The findings from this study indicate that participants are selective about their e-health use and these patterns are associated with certain demographics, e-health literacy levels, and access to technology. Healthcare providers and practitioners should seek to understand patterns of e-health engagement in their populations of focus to develop interventions and devise strategies appropriate for individuals based on their patterns of e-health access and behaviors.

MONITORING AND BLUNTING COPING STYLE EFFECTS ON COLLEGE STUDENT PROCESSING OF HEALTH INFORMATION VIA SOCIAL MEDIA

Katherine M. Aguirre, PhD, MA¹, Lawrence D. Cohn, PhD²¹Texas Tech University Health Sciences Center El Paso, El Paso, TX; ²University of Texas at El Paso, El Paso, TX

The dissemination of public health messages via social media is a growing phenomenon that is changing the health communication landscape (Chou, Hunt, Beckjord, Mojer, & Hesse, 2009). Few studies have investigated how individuals process health-threatening information. This study addressed this gap in knowledge. Specifically, the current study investigated the impact of coping style on an individual's attention to health-threatening and health-promoting words on an attention task. The current study also investigated the impact of coping style on the recall of health-threatening, health-promoting, and neutral words contained in a diabetes health message. In addition, the current study investigated if coping style influences the way individuals frame a message when "sharing" information with other social media users after reading a diabetes health message.

This study addressed those aims using two experimental tasks. The first task was a dot probe task to detect any difference in attention to health-threatening and health-promoting words. The second task asked participants to read a diabetes health message and Tweet about what they read. This novel approach was used to measure memory recall, Tweet valence, and the number of health-threatening and health-promoting words or phrases used to construct Tweets. Data analyses included a three-step hierarchical regression model. Step 1 included health anxiety and perceived risk for developing diabetes scores. Step 2 included state anxiety and trait anxiety scores. Finally, Step 3 included monitoring and blunting coping scores.

The final models for all dependent variables were not statistically significant. However, several bivariate correlations were found. Namely, the higher the health anxiety score, the fewer health-promoting keywords recalled ($\beta = -0.19$, $p = 0.01$). Exploratory analyses revealed a primacy effect. Specifically, when health-promoting information was presented first, participant Tweets contained more health-promoting keywords, demonstrated a higher health-promoting valence, and used more health-promoting words and phrases. The results from this study will inform future health communication research on dissemination via social media. This study's innovative approach of investigating reaction times and responses to a health message to create a fuller picture of information processing will add to the health communication literature on how to better assess attention to, and use of, health information.

WEARABLE ACTIVITY MONITORS EFFECT ON AUTONOMOUS MOTIVATION: RESULTS FROM A PILOT COMPARATIVE EFFECTIVENESS INTERVENTION

Zakkoyya H. Lewis, PhD¹, Maria C. Swartz, PhD, MPH, RD, LD², Elizabeth J. Lyons, PhD, MPH³¹California State Polytechnic University, Pomona, CA; ²UT MD Anderson Cancer Center, Houston, TX; ³The University of Texas Medical Branch, Galveston, TX

Self-Determination Theory (SDT) outlines several different forms of motivation that fulfill our basic needs of autonomy, competence, and relatedness. The motivational continuum ranges from fully extrinsic to more autonomous forms including identification, integration, and intrinsic motivation. This pilot randomized controlled trial compared the effects of a basic pedometer to a wearable electronic activity monitor (henceforth referred to as "wearable") on SDT constructs. Because wearables provide a number of behavior change techniques not available via pedometer, we hypothesized that autonomous forms of motivation would be higher at the end of the intervention in participants that used the wearable.

Methods: Participants ($n=40$) 55–74 years of age took part in a 12-week physical activity intervention; which included one brief counseling session, followed by 12 weeks of self-monitoring. Participants were randomized to receive a pedometer (Digi-Walker CW-700/701, YAMAX, San Antonio, TX) or a wearable (UP24, Jawbone, San Francisco, CA) and the partnering UP application. The pedometer provided feedback and self-control. In addition, the wearable provided goal setting, information on consequences, barrier identification, action planning, instruction, prompts and cues, social comparison and social support. SDT constructs were evaluated using the Behavioral Regulation in Exercise Questionnaire—2 and the Psychological Need Satisfaction in Exercise Scale. Analysis of covariance was completed using the intent-to-treat principle. Participants with missing outcome data ($n=8$) had a significantly higher baseline identified score than those that completed the intervention ($p=0.02$).

Results: The wearable group produced significantly large effect sizes for amotivation ($d=-0.42$), identified regulation ($d=0.70$), intrinsic regulation ($d=0.85$), competence ($d=1.01$), autonomy ($d=1.13$), and relatedness ($d=0.59$) (all $p < 0.05$).

Conclusions: Motivation for physical activity may be influenced by the type of activity monitor used, absent of continual support from counseling. Future research is needed to determine the most impactful monitor features on motivation and their long-term effects.

DIGITAL MENTAL HEALTH INTERVENTION FOR MOOD MANAGEMENT IN INCARCERATED INDIVIDUALS

Jennifer Duffecy, Ph.D.¹¹University of Illinois-Chicago, Chicago, IL

Introduction: In the United States, over 2.2 million people are incarcerated. Within any given year, approximately 73% of females and 55% of males in jail will experience a mental health problem. This results in the criminal justice system serving as a de facto mental health treatment facility for hundreds of thousands of individuals. More than one in five jails have no access to mental health services.

There is strong evidence that digital mental health interventions for the treatment of mood disorders are efficacious and cost effective. Digital mental health care has many strengths, including the ability to deliver treatment reliably, increase privacy for those seeking services, and to provide scalable evidence-based care. The aim of this project was to develop and pilot a CBT based intervention for mood management to be delivered via tablet to incarcerated individuals.

Methods: Individuals incarcerated in the Middlesex County, MA and Woodford County, IL jails enrolled to receive 4 weeks of a CBT mood intervention delivered via tablet. The intervention consisted of eight lessons related to CBT concepts released twice per week and three tools to practice the CBT concepts. Participants completed assessments at baseline, week 2 and week 4.

Results: 52 participants enrolled in the intervention. Depression and anxiety scores decreased over time, falling from the moderate range (BDI = 18.8; GAD = 11.5) to the mild range (BDI = 11.4; GAD = 7.1). Lessons completed decreased over time, with 41 participants completing the first lesson and only 11 participants completing the eighth lesson. However, if participants completed a didactic lesson, they were likely to complete the associated tool. Satisfaction ratings were high (5.8 out of 7). Drop out was high, with only 10 participants completing the week 4 assessments.

Conclusions: Approximately 80% of participants who completed the intervention showed improvement or remained stable in mood symptoms. Those who completed lessons also completed the interactive tools and rated them highly for satisfaction and ease of use. Although the drop out rate was high, the pilot jails were short-term facilities and we were unable to track release dates, thus it is unknown how many individuals discontinued use due to release/transfer. This pilot suggests it there is interest and potential benefit in digital mood interventions for incarcerated individuals but that modifications are needed to improve adherence.

FEASIBILITY AND ACCEPTABILITY OF WEB-BASED BEHAVIORAL INTERVENTION IN MEN WITH PROSTATE CANCER (PCA): A RANDOMIZED PILOT TRIAL

Erin Van Blarigan, ScD¹, Stacey Kenfield, ScD¹, Justin Ramsdill, MS², Kimi Daniel, MS³, Greta Macaire, MA, RD, CSO¹, Elizabeth R. Kessler, MD⁴, Tomasz M. Beer, MD⁵, Karen S. Lyons, PhD⁶, Jeanette M. Broering, PhD, MPH, RN⁷, Peter Carroll, MD⁸, Kerri M. Winters-Stone, PhD⁹, June Chan, ScD¹

¹UCSF, San Francisco, CA; ²OHSU, Portland, OR; ³Oregon Health and Science University, Lake Oswego, OR; ⁴University of Colorado School of Medicine, Aurora, CO; ⁵OHSU Knight Cancer Institute, Portland, OR; ⁶Boston College, Chestnut Hill, MA; ⁷University of California San Francisco, San Francisco, CA; ⁸University of California, San Francisco, San Francisco, CA; ⁹Oregon Health & Science University, Portland, OR

Background: Diet and exercise may be associated with quality of life and survival in men with prostate cancer. Yet, few men follow national nutrition and physical activity guidelines for cancer survivors. A web-based program could be a scalable approach to disseminate information and provide support for behavior change. We aimed to determine the feasibility and acceptability of a remotely delivered web-based behavioral intervention among men with prostate cancer.

Methods: We conducted a 4-arm pilot trial of a 12-week intervention among men with prostate cancer (clinicaltrials.gov Identifier: NCT03406013). The study was conducted at Oregon Health and Sciences University (OHSU), University of California San Francisco (UCSF), and University of Colorado Denver. Men were recruited through cancer registry databases, CaPSURE (a nationwide prostate cancer registry study), and in clinic. To be eligible, men had to self-report a prostate cancer diagnosis, have a personal device that connected to the Internet, be 18 years or older, able to read English, and able to receive text messages and email. Men currently receiving chemotherapy or radiation, or who reported potential contraindications to exercise, could participate with physician clearance. Each site recruited patients; OHSU performed study-related tasks; UCSF performed data analysis. Participants were randomized (1:1:1:1) to additive intervention levels: (1) static website; (2) website plus personalized diet and exercise prescription; (3) website, personalized prescription, plus Fitbit and text messages; and (4) website, personalized prescription, Fitbit, text messages and a 30-min call with an exercise trainer and a 30-min call with a registered dietician. Participants completed surveys at enrollment, 12-weeks, and 24-weeks. Our primary outcomes were feasibility (accrual, attrition, website use) and acceptability (survey data).

Results: Between August 2017 and September 2018, we screened 259 men for eligibility. Of these, 217 were eligible and 202 were randomized (Level 1: 49, Level 2: 51, Level 3: 50, Level 4: 52); 198 men received their assigned interventions (47, 49, 50, 52 in Levels 1–4, respectively). Follow-up was 85% at 12 weeks and 79% at 24 weeks. Preliminary analyses indicate that the average age was 69 years, average body mass index was 27.3 kg/m², 93% were non-Hispanic white, and 93% had 2-year college or more education. Website visit frequency varied by level (median: 3, 10, 11, 6 visits for Levels 1–4, respectively) and the majority of men were satisfied or very satisfied with the intervention (53%, 68%, 58%, 67% for Levels 1–4, respectively).

Conclusions: A remote behavior intervention is feasible and acceptable among men with prostate cancer.

FACTORS PREDICTING CLINICAL DECISION SUPPORT USE BY EMERGENCY DEPARTMENT PROVIDERS

Safiya Richardson, MD, MPH¹, Stuart Cohen, MD¹, Sundas Khan, MD¹, Meng Zhang, PhD¹, Guang Qiu, MD, PhD¹, Michael Oppenheim, MD¹, Thomas McGinn, MD, MPH¹

¹Hofstra Northwell School of Medicine, Manhasset, NY

Background: Computed tomography pulmonary angiography (CTPA) use for the evaluation of pulmonary embolism (PE) has quadrupled over the past decade since the landmark PIOPE II trial established it as both highly sensitive and specific for the diagnosis of PE. Increased utilization however, has been associated with decreasing diagnostic yields (*fewer positive studies*) and rising concerns about the harms of unnecessary testing. The object of this study was to determine if clinical decision support (CDS) use would be associated with increased imaging diagnostic yields, determine if this association would remain after controlling for patient and provider factors and characterize CDS use.

Methods: We performed a retrospective cohort study in the Emergency Departments (ED) of two tertiary care hospitals of all CTPAs performed between August 2015 and September 2018. Providers ordering a CTPA are routed to an optional CDS tool which allows the providers to use a well validated clinical prediction rule for estimating pre-test probability for PE. Based on calculated pre-test probability there is a recommendation for either a blood test or CTPA. Logistic regression compared CDS users and non-users. CTPA diagnostic yield was calculated for users and non-users for all performed studies and stratified by provider type. Propensity score matching based on patient age, gender, race, number of comorbidities and ED crowdedness, time and month of visit and provider type was used to address selection bias among the user and non-user groups.

Results: A total of 7,367 CTPAs were ordered to evaluate for PE during the study period, excluding those with a previous abnormal d-dimer. Of those, providers used the CDS tool in 2,568 (35%) cases and did not use the tool in 4,799 (65%) of cases. In cases of tool use patients had more comorbidities, the ED was less likely to be crowded and use was more likely to occur during the Spring and Winter seasons and during daytime hours. Resident providers were more likely to use tool compared to Attendings and Physician Assistants. After propensity score matching CTPA yield was 11.99% in the tool user group and 8.70% in the tool non-user group ($p < 0.001$). Attending, Resident and Physician Assistant CDS users demonstrated a 56.5% ($p = 0.006$), 38.7% ($p = 0.01$) and 16.7% ($p = 0.03$) increased yield compared to non-users of same provider type respectively.

Conclusion: We found CDS tool use differed based on several factors including provider type, ED crowdedness and test time of day. The percent of CTPA studies positive for PE was 38% higher in tool users vs. non-users when controlling for selection bias in tool use with propensity score matching. Further research should focus on targeting factors associated with low CDS use.

THE RELATIONSHIP BETWEEN MOBILE APP ENGAGEMENT AND MEDICATION ADHERENCE IN ASTHMA AND COPD

Leanne Kaye, PhD, MPH, RD¹, Rahul Gondalia, PhD, MPH¹, Esther Rummelink, PhD neuroscience¹, Kelly Henderson, MPH¹, Shivani Parikh, n/a², Alesha Thompson, MPH³, Meredith Barrett, PhD¹

¹Propeller Health, San Francisco, CA; ²Propeller Health, Palo Alto, CA; ³Council of State and Territorial Epidemiologists (CSTE), Atlanta, GA

Introduction: Respiratory illnesses like asthma and chronic obstructive pulmonary disease (COPD) often place a burden on patients, and adherence to daily medication regimens can be challenging, resulting in suboptimal treatment. Digital health solutions like smartphone applications (apps) may help ease this burden and promote adherence through tailored reminders and education. However, little is known about patient behavior within a self-management app and how this affects medication adherence.

Methods: We examined up to 19 months of data from adults (18+) with self-reported asthma or COPD. Patients downloaded a smartphone application on their phone (Propeller Health, WI) and attached a small electronic sensor to their rescue and controller inhaler medications. Patients received daily audio and visual reminders to take their controller medication. Medication usage was monitored passively and data was provided back to the patient through the app in real time. All patients agreed to Propeller's Terms of Use. We examined the frequency of app engagement (defined as app opens per day) as well as time spent in the app (duration in seconds). We classified patient days as low or high engagement, where high engagement was defined as any app open and with an average app session duration > 90th percentile. We ran linear mixed-effects longitudinal models to estimate the relationship between engagement and adherence in asthma and COPD.

Results: 4,670 patients were included in the analysis: 75% ($n=3,511$) with asthma (mean [SD] age: 38.2 [12.4], 80% female) and 25% ($n=1,159$) with COPD (mean [SD] age: 59.7 [9.4], 68% female). Overall, unadjusted mean adherence was higher among patients with COPD (50%) than with patients with asthma (36%). Among patients with asthma, at least one app open and high session duration were associated with 8.6% (95% CI: 8.3%, 8.9%) and 8.5% (8.2%, 8.8%) higher absolute adherence ($p < 0.001$), respectively. Among patients with COPD, at least one app open and high session duration were associated with 6.6% (6.2%, 7.0%) and 5.1% (4.7%, 5.6%) increase in higher absolute adherence ($p < 0.001$), respectively. Finally, for every one app open there was a 3.6% increase in adherence in asthma and 1.7% in COPD (both $p < 0.001$).

Conclusion: Patient engagement with mobile applications is associated with improved medication adherence in asthma and COPD. Further, patients with COPD, while older, had greater app engagement and better adherence to inhaler medications. Findings should be explored further in a more robust trial design, with attention given to both passive and active behaviors within a mobile app.

Endocrinology, obesity and preventive medicine, Oslo, Vestfold, Norway; ¹⁰Department of Psychiatry & Psychology / Obesity, Bariatric Surgery & Eating Disord. Program, Mayo Clinic, Rochester, MN; ¹¹University of Twente, Center for eHealth and Wellbeing Research, Enschede, Overijssel, Netherlands

Background: Maintaining weight after weight loss is a significant challenge, as only 1 in 4 maintain such weight loss long-term. New and innovative approaches are called for, and eHealth technologies might be one solution to meet user needs and support people with obesity to maintain weight loss long-term.

Aim: To identify; a) unmet needs of people with obesity aiming to maintain weight loss, as well as solicit input from other related stakeholders, b) persuasive system design features and behavior change techniques matching user needs, and c) design requirements for an eHealth solution in support of long-term weight maintenance.

Method: First, a scoping literature review was performed to identify persuasive and behavior change techniques stimulating motivation and adherence for long-term weight loss maintenance. Second, participants (N=38) have contributed in individual interviews and workshops, performed to identify user needs and preferences. Users were defined as a) people with obesity experiencing weight maintenance challenges (n=20; i.e., adults ≥18 years, BMI ≥30 kg/m²), and b) healthcare providers (n=16; i.e., medical specialists, health psychologists, nurses, nutritionists, general practitioner). Additional stakeholders (n=2) interviewed were policy makers (i.e., from the Norwegian Directorate of eHealth) and a user organization representative (i.e., the Norwegian association for people with obesity).

Results: The scoping review identified the most common behavior change techniques (e.g., goal setting, monitoring, planning, shaping knowledge) and persuasive design features (e.g., personalization, praise, real-time feedback, rewards) used to stimulate motivation and adherence in weight maintenance interventions for patients with obesity. Interviews and workshops revealed that personalization, planning and monitoring, goal setting, insights into own behavior, habit and decision support, motivation to keep focus, positive feedback, social support and rewards are some essential user needs to establish and maintain healthy behaviors over time.

Conclusion: Digital developments carry the opportunity to develop smart, value-driven and personalized solutions that can motivate and aid sustainable health behaviors in support of long-term weight loss maintenance. The presented results provide input for further technology development and multicenter testing of an eHealth intervention in support of long-term weight maintenance.

TESTING PROTOTYPES OF THE “HEALTHY JUNTOS” DIGITAL OBESITY PREVENTION INTERVENTION FOR HISPANIC ADOLESCENTS AND THEIR PARENTS

Rafael Leite, BA¹, Dario Vanegas, BS², Blanca Noriega Esquivel, MD, MSPH³, Yaray Agosto, MPH², Marissa Kobayashi, MHS⁴, Rana Saber, MS MSL⁵, Carolina Velasquez, M.S.², Sara M. St. George, PhD⁶

¹University of Miami, Boca Raton, FL; ²University of Miami, Miami, FL; ³University of Miami - Miller School of Medicine, Doral, FL; ⁴University of Miami, Coral Gables, FL; ⁵Valorous Health Innovation, Chicago, IL; ⁶University of Miami Miller School of Medicine, Miami, FL

The aim of the study was to conduct formative research of a family-based eHealth obesity prevention intervention for Hispanic parents and adolescents. As part of our user-centered design approach, we developed visual mock-ups to gather user feedback and assess product usability. Grounded in behavior change and family systems theories, the 8-week intervention consists of educational tools (didactic health videos, games, recipes, workouts), behavior skills training (step count, monitoring diet/physical activity), and parenting and family motivational tools (podcast, comparing goals, family activities). Hispanic parents (N=15, 92% female; 45.7±4.8 years; BMI=30.3±4.0) and adolescents (N=15, 54% female; 14.3±1.2 years; 46% normal weight, 54% overweight) participated separately in a semi-structured interview. We showed them paper and minimally-functioning prototypes and asked them to “think aloud” while interacting with the mock-ups to understand their navigation of the intervention, identify potential problems, and assess their interpretation of the prototype’s design elements. Afterwards, participants rated prototype usability through the Computer System Usability Questionnaire (CSUQ). Transcripts were analyzed by three researchers independently using a rapid assessment approach to identify key themes. Participants provided suggestions for improving aesthetics (icon design, image quality), comprehension (simple directions, better feature descriptions), and content (removal of certain features). Participants reported mostly positive feedback on prototypes, including ease of use, functionality/organization, ability to compare parent and adolescent progress, as well as enthusiasm for recipes and exercise components. Based on participants’ feedback, significant changes were made to the intervention prototypes, including aesthetics (icons, logo), comprehension (clearly labeled icons, development of instructional welcome video), and content (focus on proper form in workout videos, healthy alternatives to typical Latin foods). Results from the CSUQ showed high scores for adolescents and their parents (range 1–7) in the subscales of usefulness (5.9 vs. 6.3), ease of use (6.0 vs. 6.5), ease of learning (6.5 vs. 6.8), and satisfaction (5.9 vs. 6.2) with non-statistical significant difference. Study findings were used to inform the development of a fully functional prototype of the intervention for use in an upcoming pilot randomized controlled trial.

AN EXPLORATION OF RACIAL DIFFERENCES IN A PILOT RANDOMIZED CONTROLLED TRIAL OF THE PTSD COACH APP AFTER CRASH-RELATED INJURY

Maria Pacella-LaBarbara, PhD¹, Brian Suffoletto, MD, MS¹, Eric Kuhn, PhD², Anne Germain, PhD¹, Stephany Jaramillo, MD¹, Melissa Repine, M.S.¹, Clifton Callaway, MD, PhD¹

¹University of Pittsburgh, Pittsburgh, PA; ²Stanford University School of Medicine, Stanford, CA

Objective: Compared to other races, Black/African Americans (herein referred to as Black) have the highest lifetime prevalence and risk of developing posttraumatic stress disorder (PTSD) after trauma; yet, they are also less likely to seek out and complete treatment for PTSD. Traditional psychosocial interventions are costly and resource intensive, thus limiting implementation. Mobile health (mHealth) strategies present a unique opportunity to engage minorities in need of mental health care. The “PTSD Coach” smartphone app is an evidence-based biopsychosocial tool for PTSD symptom (PTSS) monitoring and management. We explored whether PTSD Coach serves to prevent or reduce posttraumatic sequelae among a subgroup of acutely injured Black patients involved in a motor vehicle crash (MVC); we also explored racial differences in post-injury sequelae.

Method: Within 24 hours post-MVC, we recruited 64 injured adults (56% non-White) from two emergency departments (EDs) into a pilot randomized controlled trial (RCT) testing the feasibility and efficacy of PTSD Coach. Subjects were randomized to either PTSD Coach ($n = 33$) or treatment as usual (TAU; $n = 31$). A subgroup of 27 patients self-identified as Black (63% Female; M age = 36), with 14 (52%) assigned to PTSD Coach and 13 to TAU (48%). PTSD Coach subjects were instructed to use the app as desired for 1-month. Follow-up assessments occurred at 1-month and 3-months post-enrollment.

Results: Retention rates throughout 3-months post-injury were high among Black (78%) and White (73%) patients. Black (vs. White) patients reported higher levels of pre-injury ($M = 12.04$ vs. 6.61; $p = 0.02$) and 3-month PTSS ($M = 24.71$ vs. 13.39; $p = 0.08$), and lower PTSS coping self-efficacy at baseline ($M = 64.83$ vs. 74.27; $p = 0.059$) and 3-months post-injury ($M = 61.43$ vs. 81.42; $p = 0.03$). Whereas no group differences emerged for the full sample, subgroup analyses indicated significant improvements in outcomes for minorities: Specifically, Black subjects in the app group (compared to those in TAU) reported significantly fewer PTSS ($M = 14.90$; $SD = 10.45$ vs. 33.64; $SD = 27.13$; $F = 4.12$; $p = 0.05$) and higher PTSS coping self-efficacy ($M = 77.62$; $SD = 22.25$ vs. 46.72; $SD = 35.32$; $F = 5.62$; $p = 0.03$) at 3-months; effect sizes were large (Cohen's $d = 0.91 - 1.05$).

Conclusions: This sample reflects a typically underserved population who is particularly vulnerable to adverse post-injury sequelae but may have limited resources and contact with the healthcare system post-ED discharge. These preliminary findings suggest that Black patients benefited from PTSD Coach after injury; larger scale future research is needed to determine if and how these effects are related to ethnic disparities. Despite the small sample size, PTSD Coach may serve as an appropriate and scalable candidate for further investigation among groups who may not have access to other treatment modalities.

A 12 MONTH INHALER SENSOR-BASED, MHEALTH INTERVENTION IMPROVES PEDIATRIC ASTHMA CONTROL AND CAREGIVER QUALITY OF LIFE--AN RCT

Christopher Warren, PhD¹, Jamie Feirstein, PhD², Kathy Boon, MPH², Madeleine Kanaley, BA², Kristin Kan, MD MPH³, Alexandria Bozen, BS², Ruchi Gupta, MD MPH⁴

¹Stanford University School of Medicine Sean Parker Center for Asthma and Allergy Research / Northwestern University Center for Food Allergy and Asthma Research, Stanford, CA; ²Northwestern University, Chicago, IL; ³Lurie Children's Hospital of Chicago, Chicago, IL; ⁴Northwestern University School of Medicine, Lurie Children's Hospital of Chicago, Chicago, IL

Background: Asthma imposes substantial burdens upon society affecting nearly 10% of school-aged children in the US and costing approximately \$82 billion annually. Research suggests that approximately 1 in 4 asthma exacerbations and over half of asthma-related hospitalizations are attributable to ICS non-adherence. While sensor-based electronic monitoring of daily inhaled corticosteroids (ICS) may improve asthma-related outcomes via improved ICS adherence, the effectiveness of sensor/app-based, clinically-integrated mobile technology interventions, particularly among Black and Hispanic pediatric asthma patients is largely unknown.

Methods: In the iTRACC randomized-controlled trial, 252 racially/socioeconomically diverse caregiver-child dyads were randomly assigned to receive Propeller Health's app-based inhaler sensors that allowed for caregiver and clinician electronic monitoring of ICS/short-acting beta antagonist medication. The primary endpoint was asthma symptom control as assessed by the asthma control test. Secondary end points included pediatric asthma caregiver quality of life (QoL), ICS adherence, emergency department (ED) visits, hospitalizations, and oral corticosteroid prescriptions. Questionnaires were administered at baseline, 3, 6, 9 and 12 month follow-up. Multilevel general linear models estimated changes in adjusted mean values from baseline.

Results: In total, 252 caregiver/child dyads were randomized to the routine-care control ($n=127$) or intervention ($n=125$) groups. At 12 months, the adjusted mean ACT score increased from 19.1 (SE=0.3) to 21.8 (SE=0.4) among the intervention and from 19.4 (SE=0.3) to 19.9 (SE=0.4) among the control (Δ Intervention-Control=2.2; SE=0.6; $p < 0.01$). Relative to the control, caregiver asthma QoL was greater at 12 months (Δ Intervention-Control=.26; SE=.15; $p=.09$). Adjusted 12-month rates of ED visits and hospitalizations among intervention participants were also greater (IRRED=2.2; 95% CI: 1.4 - 3.6; IRRHospital=3.4; 95% CI: 1.5 - 7.8) relative to controls. While observed intervention effects on asthma control were invariant across insurance status (public vs private) some evidence of effect modification was present by race, with non-Hispanic Black children observing the greatest, most sustained improvements in asthma control across the study period. No effect modification by sociodemographic factors was observed for any of the other assessed outcomes.

Conclusions: Intention to treat analyses from this RCT shows that a sensor/app-based MTI can improve asthma control and quality of life over a 12 month period among a diverse sample of children with moderate/severe persistent asthma. Follow-up per-protocol analyses will seek to identify subpopulations who may be particularly likely to benefit from similar mobile technology-based interventions in the future.

A DARK SIDE TO MOBILE HEALTH? WORRY AND NOCEBO EFFECTS ABOUT NEW TECHNOLOGY

Frank T. Materia, M.S., M.H.S.¹, Kate Faasse, Ph.D.², Joshua M. Smyth, PhD¹¹Pennsylvania State University, University Park, PA; ²The University of New South Wales Sydney, Sydney, New South Wales, Australia

New technologies and innovations have often bettered population well-being and societal function; yet, these are also often initially accompanied by worry and fear. In some cases, such worries can impede, or even prevent entirely, the adoption of the technology. Mobile health (mHealth), a discipline broadly focused on employing ambulatory technologies to improve the affordability, reach, and effectiveness of health promotion and clinical intervention approaches, offers new innovations and opportunities. Despite emerging evidence supporting mHealth efficacy (e.g., for improving health outcomes), some individuals have concerns about mHealth technology that may impede scalability, efficacy, and, ultimately, the public health benefits of mHealth. We present a review and conceptual framework to examine these issues, focusing on three overarching themes: biophysiological, psychological, and societal concerns. There are features of mHealth that produce worry about the potential negative effects on individual health (e.g., due to exposure to electromagnetic or radio waves), despite evidence supporting the safety of these technologies. When present, such beliefs can lead to worry that gives rise to the experience of unpleasant and concerning physical symptoms (i.e., the nocebo effect). This may represent an important implementational barrier due to apprehension towards beneficial mHealth products (or features thereof, such as wireless charging, wearable or implantable sensors, etc.) and may also have broader ramifications (e.g., leading to economic, governmental and legislative actions). In addition to reviewing evidence on these points, we provide a broad three-step model of implementation research in mHealth focused on understanding and preventing health concerns to facilitate the safe and effective scalability of mHealth (and that may be generalizable and applied to similar technologies): first, evaluating and better discerning public (mis)perceptions (and how these may differ between populations); second, developing theory-based public health communication strategies regarding the safety of mHealth; and third, disseminating this messaging using evidence-based

Methods: Collectively, these steps converge on reviewing evidence regarding the potential role of worry and nocebo in mHealth and providing a model for understanding and changing attitudes and preventing unfounded negative perceptions related to mHealth technology.

BASELINE PREDICTORS OF ENGAGEMENT IN A DIGITAL WEIGHT MANAGEMENT INTERVENTION FOR YOUNG ADULTS

Ashley H. Tjaden, MPH¹, Laura L. Hayman, PhD, MSN, FAAN, FAHA, FPCNA², Samuel J. Simmens, Ph.D.³, Jessica A. Whiteley, PhD⁴, Melissa A. Napolitano, PhD⁵¹The George Washington University, Rockville, MD; ²UMass Boston, 100 Morrissey Blvd. Boston, MA 02125-3393, Boston, MA; ³George Washington University, Washington, DC; ⁴UMass Boston, Boston, MA; ⁵The George Washington University, Washington, DC

Introduction: Digital interventions for the delivery of weight loss treatments for young adults with overweight and obesity offer an opportunity to deliver lifestyle interventions at a low cost and with wider reach. It is important for researchers and health care providers to identify the participants most likely to engage in such programming.

Methods: Young adults with overweight/obesity (n=459; 78.6% female, mean \pm SD: age 23.3 ± 4.4 years, weight: 86.6 ± 15.6 kg, body mass index [BMI] 31.2 ± 4.4 kg/m²) were recruited from two sites and randomly assigned to receive one of three digitally delivered weight management interventions. We calculated an engagement score as percent of highest possible engagement (0–100%) using three weekly components cumulatively summed over 6 months (N=78 possible points): responding to text messages, “seeing” or “liking” intervention content on Facebook, or viewing summative/personalized reports. We also constructed a binary indicator of engagement (< 66% vs. $\geq 66\%$) to compare the engaged to the unengaged. We assessed 15 baseline candidate predictors including demographics (age, sex, race/ethnicity, and site), physical characteristics (BMI, waist circumference, weight, fasting glucose, and HbA1c), and behavioral characteristics (total caloric intake, diet quality, physical activity, self-efficacy, perceived stress, and self-report of social media engagement).

Results: Six-month percent engagement among all participants was 54.5 ± 21.5 . Age, race/ethnicity, and school were significantly different between those engaged and those unengaged in treatment. In univariate analyses, the engaged participants were more likely to be older (p=0.039), non-Hispanic white (p=.015) and have higher fasting glucose (p=0.029) but lower HbA1c (p=0.025). Engagement was positively associated with both social engagement (p=0.007) and total caloric intake (p=0.007). Several predictors of engagement as a continuous measure met the criterion of being statistically significant (p< .05) in the univariable analyses and selected by the Lasso regression. The predictors (ordered from highest to lowest squared semipartial correlation coefficient) race/ethnicity, age, social media engagement, school site, HbA1c, total caloric intake, and fasting glucose accounted for 13% of the variation in engagement.

Conclusions: Uptake of digital interventions for weight loss among young adults may be most likely for individuals with certain characteristics. Our results suggest that the older non-Hispanic white graduate students already engaged in social media appear to be the most likely to engage with the intervention. Uptake of digital interventions for weight loss among young adults may be most likely for individuals with certain characteristics, continuing to identify and understand those characteristics may lead to deeper engagement with digital interventions.

DEVELOPING AN AUTOMATED VIRTUAL WALKING COACH FOR UNDERSERVED, SEDENTARY PATIENTS IN PRIMARY CARE: ANALYSIS OF PILOT DATA

Nadia A. Nabulsi, MPH¹, Mary H. Smart, PharmD, MS², Tiffany Kuo, BS¹, Itika Gupta, BTech², Brian Ziebart, PhD², Barbara Di Eugenio, PhD², Ben Gerber, MD, MPH³, Lisa K. Sharp, PhD²

¹University of Illinois at Chicago College of Pharmacy, Chicago, IL; ²University of Illinois at Chicago, Chicago, IL; ³University of Illinois at Chicago - Department of Medicine, Chicago, IL

Introduction: Low-burden, scalable interventions to increase daily steps in underserved patients are needed. Artificial intelligence can automate health coach-patient dialogue to increase accessibility to health coaching. We pilot-tested an mHealth intervention within a busy clinic to help ethnic-minority, sedentary patients set weekly walking goals. The long-term goal is to develop an automated virtual walking coach.

Methods: Sedentary adults ages 21–65 with body mass index (BMI) >25kg/m² and a smartphone were recruited from a primary care clinic in a minority-serving academic health center. Patients received a Fitbit and two-way text-based coaching for 8 weeks. Using texts, patients set weekly specific, measurable, attainable, relevant, timely (SMART) step goals with reminders and encouragement from a coach. Daily steps were tracked through MyTapp, a research texting platform. In addition to descriptive statistics, a linear mixed-effects model assessed overall trends in steps and simple linear regression assessed trends within patients. Bivariate linear mixed-effects models examined associations between patient characteristics and daily steps.

Results: The analytic sample consisted of 1,323 days with step data from 28 patients with multiple comorbidities, of whom 21 (75.0%) were female, 23 (82.1%) were African American, 4 (14.3%) were Hispanic, and 1 (3.6%) was White. Average baseline age was 47.3 years (SD=9.9). Average baseline weight in pounds and BMI were 237.3 (SD=58.6) and 39.3 (SD=9.3), respectively. The daily average number of steps was significantly higher in Week 8 than in Week 1 (8,336 [SD=3,913] vs. 7,018 [SD=3,704]; p=0.04). Each day in the intervention was associated with a non-significant average increase of 9 steps (p=0.17). Linear regression revealed that 7 (25.0%) patients had a significant increase in daily steps during the intervention, while 2 (7.1%) had a significant decrease, and 19 (67.9%) had no significant change. In bivariate analyses, variables significantly associated with increased steps were younger age, lower BMI, Hispanic and White vs. African American ethnicity, higher self-reported health, and employment vs. unemployment.

Conclusion: The results from this pilot of weekly facilitated text-based goal setting showed early promise towards increasing steps in vulnerable patients. Future work will use imitation learning, sentiment analysis, dialogue modeling, and behavior change theory to continue building an automated virtual coach.

DEVELOPMENT OF A BILINGUAL FACEBOOK MESSENGER CHAT TO PROMOTE SMOKING CESSATION AMONG YOUNG ADULTS

Patricia Chalela, DrPH, MPH¹, Alfred L. McAlister, PhD², Edgar Muñoz, MS¹, Cliff Despres, BJ¹, Pramod Sukumaran, PhD, MPH³, Sahak Kaghyan, PhD⁴, David Akopian, PhD⁴, Amelie G. Ramirez, DrPH, MPH⁵

¹UT Health San Antonio - Institute for Health Promotion Research, s, TX; ²UT Health, San Antonio, TX; ³UT Health San Antonio - Institute for Health Promotion Research, San Antonio, TX; ⁴University of Texas at San Antonio, San Antonio, TX; ⁵UT Health San Antonio, San Antonio, TX

Background: Despite major advances in tobacco control and treatment, tobacco use remains the single largest preventable cause of morbidity and mortality in the US. Smoking rates vary by age group, with young adults 18–29 experiencing the highest smoking rates in South Texas (24%). Research shows that support delivered through mobile phone text messaging doubles rates of biochemically validated smoking cessation rates. Quitxt is a mobile phone texting system for smoking cessation promoted in South Texas via social media advertising. A group analysis of 798 Quitxt participants with a mean age of 29.3 found that 21% of the enrollees reported abstinence at 7 months. This confirmed that a text and mobile media service specifically designed for young adults provides a feasible, potentially cost-effective approach to promoting cessation. Quitxt is now being tailored to not only reach Latinos but also non-Latino white and African American young smokers. In addition to the original texting platform, we developed a protocol to deliver Quitxt via Facebook Messenger Chat.

Objective: We present the design and development process of a theory-based, bilingual, interactive Facebook Chat to promote smoking cessation among young adults.

Methods: We conducted focus groups (3) and an online survey (200 young adult smokers) to assess images, video testimonials, and messages for social media and updated webpages linked to in Quitxt text messages. Results informed the development of the Facebook Messenger Chat prototype. After pre-testing, the final chat version is now active for recruitment.

Results: Survey respondents and focus group participants positively reviewed the images, messages, and videos, within the Quitxt mobile program, with the suggested addition of more information on negative consequences of smoking. Suggestions to improve the linked-to web content included adding more color and logos for credibility. Facebook was the most popular social media platform for participants, making the Messenger Chat a viable, appropriate way to offer the program. This platform also enabled additional graphic content (gifs and memes) to make the messages more appealing to young adults.

Conclusions: We followed an iterative design process to develop a bilingual, culturally tailored and interactive Facebook Messenger Chat prototype to deliver our Quitxt smoking cessation program. The anticipated outcome is a scalable, evidence-based, easily disseminated smoking cessation intervention.

BARRIERS AND FACILITATORS TO IMPLEMENTING A DIGITAL TOOL TO SUPPORT SHARED DECISION MAKING IN CHRONIC HEALTH CARE

Berit Seljelid, RN, MSc¹, Cecilie Varsi, PhD¹, Lise Solberg Nes, Prof. LP PhD¹, Elin Børøsund, PhD²¹Center for Shared Decision Making and Collaborative Care Research, Oslo University Hospital, Oslo, Oslo, Norway; ²Center for Shared Decision Making and Collaborative Care Research, Oslo University Hospital, OSLO, Oslo, Norway

Background: Digital health and shared decision making (SDM) interventions have shown to positively impact chronic disease management by improving access to care, patient-provider communication, clinical outcomes and health related quality of life (HRQoL). Despite these benefits, successful implementation of such interventions into regular clinical practice is challenging. This underlines the need to understand why and how different factors can affect the translation of research findings into clinical practice.

Objective: To identify; a) potential barriers and facilitators for the use of a digital SDM tool to improve patient-provider communication regarding symptom management for patients with chronic disease at two outpatient clinics, b) key aspects for an implementation plan.

Method: The Consolidated Framework for Implementation Research (CFIR) was used to guide the data collection and analysis from focus group discussions and workshop with health care providers (n=14) from two outpatient clinics at a university hospital. Transcripts were analyzed using thematic analysis.

Results: Data were coded into the five CFIR domains; 1) **Intervention characteristics:** a digital tool was perceived to potentially improve patient-provider communication compared to current practice with no system for symptom assessment or no opportunity for digital communication. Lack of integration with existing digital systems was perceived as a barrier. 2) **Outer setting:** patients experience symptoms that impact HRQoL, which are not always known to providers in current practice. A digital symptom assessment, could improve patient-provider communication and symptom management. 3) **Inner setting:** Current practice was hectic, including many phone calls from patients. Engagement from leaders and dedicated personnel, which wanted to improve patient-provider communication, could support the implementation. 4) **Characteristics of individuals:** Some participants were concerned about increased workload, others were skilled and motivated. 5) **Process:** Suggestions for the implementation plan; involving key stakeholders in development of content and software design, external facilitation, information, training, coaching, and a pilot test.

Conclusion: The CFIR framework was useful for identifying pre-implementation barriers and facilitators. Addressing stakeholder-identified barriers and facilitators, before implementing a digital SDM tool in chronic health care settings, may support successful implementation and sustained use. This study highlights directions for future research related to implementation of digital health technology into clinical practice.

TRANSLATING AN EFFICACIOUS ILLNESS MANAGEMENT INTERVENTION FOR YOUTH WITH POORLY CONTROLLED ASTHMA TO REAL WORLD SETTINGS

Meghna Shukla, MSN, RN, CPNP-AC¹, Michael Mooney, MSN, RN, CPNP-AC², Deborah Ellis, Ph.D.³, April Idalski Carcone, Ph.D., MSW⁴, Nirupama Kannikeswaran, MBBS⁵¹Wayne State University, Troy, MI; ²Wayne State University, harper woods, MI; ³Wayne State University, Detroit, MI; ⁴Wayne State University School of Medicine, Detroit, MI; ⁵Children's Hospital of Michigan, Northville, MI

Urban low-income adolescents with asthma are at risk for frequent emergency department (ED) visits. They are also at risk for poor asthma management, a potentially modifiable factor in reducing disparities. EDs present an opportunity for referrals for behavioral health services to improve asthma management. Electronic referral portals have been shown to improve both quality of care and patient outcomes. However, use of these portals by healthcare providers is variable. The purpose of the study was to explore barriers and facilitators to the use of an ED-based electronic referral portal for urban adolescents with asthma and multiple ED visits to a community-based agency providing home-based asthma education services. Six urban pediatric ED healthcare providers (i.e., physicians and nurse practitioners) participated in semi-structured individual interviews. Interview development and subsequent coding was based on the Theoretical Domain Framework (TDF), an implementation framework consisting of 14 domains of behavioral determinants including cognitive, affective, social and environmental influences. Two ED providers conducted interviews and coded the transcribed interview data using directed content analysis. Transcripts were independently coded to consensus with Nvivo v12, with acceptable inter-rater reliability (weighted kappa=0.75, 97% agreement). Four TDF domains were relevant for understanding portal use: Environmental context/resources, Social influences, Reinforcement, Memory attention and decision processes. Environmental context/resources emerged as a barrier to portal use when it was explained that time constraints secondary to heavy workload and high volumes lead to forgetting to make referrals. Reinforcement was frequently identified as a facilitator as participants reported the need for reminders to help remember to use the portal, such as EMR-generated prompts, signage in the ED, and physician champions. Optimism about the usefulness of the portal to connect eligible families with care also emerged as a potential facilitator to its use. In sum, TDF helped elucidate several important barriers and facilitators to ED providers' use of a referral portal for behavioral care for high-risk asthmatic youth. Additional studies are needed to develop effective strategies to increase usage of such ED referrals which can lead to better health outcomes for high-risk urban youth with asthma.

IMPLEMENTATION OF SCHOOL-BASED DENTAL SEALANT PROGRAMS: IMPLEMENTATION CHALLENGES & ADAPTATIONS.

Eiman E. AlEissa, MPH, RDH¹, Joseph Catania, Ph.D.¹¹Oregon State University, Corvallis, OR

In Behavioral Medicine and Public Health, very little research has involved the dissemination and implementation of dental health programs. Emphasis has been mainly on efficacy trials. There is an ample body of evidence supporting the effectiveness of School-Based Dental Sealant Programs (SBDSPs) with regards to increasing access to dental health care, reinforcing oral health behaviors, and direct application of preventative treatments that reduce dental caries for school-aged children (most commonly 6–13 years old). However, it is unclear if the implementation of these programs can be accomplished more efficiently. The purpose of this study was to assess the implementation processes and adaptations associated with the delivery of SBDSPs. We conducted a multiphase study to characterize the implementation processes employed by SBDSPs in Oregon which involved 1) a semi-structured focus group interview with SBDSP state representatives; 2) participant observation of statewide SBDSPs certification training; and 3) semi-structured interviews with locally managed SBDSPs (the focus of this study). The Semi-structured phone interviews in phase III were guided by the Implementation Stages Framework and were conducted with a purposive sample of SBDSPs agencies ($n=5$ agencies; 18 personnel including program directors, supervisors, & dental providers) implementing SBDSPs in elementary and middle schools in the State of Oregon. Through qualitative analysis, we identified multiple challenges associated with school, and parent/guardian engagement, staff training and scheduling, school preparedness, and compliance, intra-agency and inter-agency communication, workforce turnover, program reach, and program service delivery and client flow. We also identified program adaptations employed by the agencies to address these challenges. For instance, agencies used the Oregon Health Authority SBDSPs annual certification training as an informal ad hoc networking opportunity to share adaptations specific to other implementation challenges (e.g., client recruitment). Our findings contribute to dissemination and implementation research knowledge on programs intended to improve oral health and oral health behavior. We have identified essential communication strategies, adaptations to improve reach, and potential solutions to facilitate efficient service delivery and client flow.

6:15 PM-7:30 PM

IMPROVING KNOWLEDGE OF EMERGING THERAPEUTICS FOR HIV PATIENTS THROUGH A SOCIAL-CONSTRUCTIVIST CONTINUING EDUCATION ACTIVITY

James D. Morgante, PhD¹, Angie Ladas, n/a¹, Adelfo San Valentin, n/a¹, Krista Sierra, n/a¹¹Haymarket Medical Education, Paramus, NJ

Antiretroviral therapy (ART) regimens are associated with fewer toxicities and better efficacy, yet, clinical challenges persist. Patients with HIV/AIDS may be on decades-long ART treatment regimens, so maximizing the safety and tolerability of therapy, while preventing the development of resistance, remains precariously imperative.

Current guidelines recommend ART regimens incorporating two nucleoside reverse transcriptase inhibitors (NRTIs) plus a third drug from either the boosted protease inhibitors, integrase strand transfer inhibitor, or the non-NRTI classes. While effective, NRTIs have been associated with long-term adverse effects. ART regimens using only two drugs may potentially limit drug exposure and reduce risks for adverse events, drug interactions, and long-term toxicities, while fostering adherence. Because these regimens may challenge current standards of care, clinicians must be aware of emerging clinical trial data and ready to incorporate them into practice. Clinicians must also be prepared to meet the clinical needs of patients classified heavily treatment-experienced (HTE), whom are often resistant to multiple classes of ART drugs, leaving few viable treatment options.

To address these clinical gaps, we developed, implemented, and evaluated the effectiveness of a live instructional webcast. It aimed to provide clinicians with in-depth perspectives on recent advances in HIV treatment and, specifically, therapeutic paradigms for both treatment-naïve and HTE patients that utilize two active drugs. Using a social-constructivist approach, the instructional design was an interactive, case-based program featuring real-world cases, discussed by national and international HIV thought leaders. Clinicians considered options for individualized treatment and chemoprophylaxis across patient types; in parallel, thought leaders provided evidence-based clinical trial results.

Participating clinicians mostly identify as pharmacists or physicians with infectious diseases or primary care specializations. Within-session learning was assessed for those who provided complete activity evaluations ($n = 24$). Learning scores were calculated by: (1) totaling correct responses across five pre- and post-test questions, (2) dividing by the total number of questions in each condition, and (3) multiplying each resulting value to derive a total pre- and post-test score percentage (i.e., measure of clinician knowledge prior to and after the education). A paired-samples t-test was used to compare pre- and post-test scores, which revealed a significant increase in knowledge for assessed advances in HIV treatment (pre-test: $M = 45.000$, $SD = 25.876$; post-test: $M = 80.830$, $SD = 17.173$; $t(23) = -6.659$, $p < .001$). Results suggest that our webcast had an effect on knowledge of therapeutic paradigms for both treatment-naïve and HTE patients that utilize two active drugs.

EFFICACY AND ACCEPTABILITY OF AN INTERDISCIPLINARY CULINARY MEDICINE WORKSHOP FOR FAMILY AND INTERNAL MEDICINE RESIDENTS

Alyssa M. Vela, PhD¹¹McLaren Flint, Fenton, MI

Introduction: Students at U.S. medical schools receive fewer than 20 hours of nutrition education, on average (Adams et al., 2010), which is of particular importance for primary care providers who manage conditions impacted by lifestyle. The purpose of culinary medicine is to incorporate nutrition and cooking into medicine to treat and prevent disease (LaPuma, 2016). While many medical schools, and some residency programs, have developed a full curriculum for trainees that is not feasible for all.

Method: The current project aimed to assess the efficacy and acceptability of a one-time interdisciplinary, culinary medicine workshop for 25 family and internal medicine residents in a low SES urban community. Residents engaged in a half-day workshop that included: introduction to culinary and lifestyle medicine, nutrition, hands-on preparation, communal meal and discussion of barriers, benefits, and behavioral strategies for healthy lifestyles.

Results: At baseline, participants reported moderate knowledge of nutrition ($M=5.72$, $SD=1.82$; 1=not at all and 10=completely), comfort providing general nutrition information to patients ($M=5.44$, $SD=1.68$) and to patients with specific health conditions (e.g., diabetes; $M=6.12$, $SD=1.52$). They also expressed little likelihood of providing a recipe to patients ($M=3.8$, $SD=1.52$) and little familiarity with community resources to address these needs ($M=3.96$, $SD=1.68$). Following the completion of the workshop, participants reported increased knowledge of nutrition, and increased likelihood of discussing home cooking, recipes, and community resources with patients. While these results are promising, paired-samples *t*-tests indicated no statistically significant changes in these measures, though this may be partially explained by small sample size. Participants provided anonymous open-ended feedback (analyzed using constant comparative analysis), which indicated the workshop was useful, relevant, and highly acceptable. Specific themes derived from this analysis will be discussed.

Conclusions: The current study demonstrated the acceptability of a one-time introductory culinary medicine workshop to primary-care based medical residents. While results indicated a one-time workshop was not sufficient to demonstrate statistically significant changes in clinical practice, these results are potentially meaningful clinically and educationally and indicate a need for further research.

GENETIC AND ENVIRONMENTAL INFLUENCES ON POST-TRAUMATIC STRESS DISORDER SYMPTOMS AND DISINHIBITED EATING SYMPTOMS

Cara Dochat, M.S.¹, Jennalee S. Wooldridge, PhD², Marianna Gasperi, PhD³, Matthew Herbert, PhD⁴, Ellen Schur, MD,MS⁵, Dedra Buchwald, MD⁶, Niloofar Afari, PhD⁷

¹San Diego State University/University of California San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; ²University of California San Diego/VA San Diego, San Diego, CA; ³UC San Diego, La Jolla, CA; ⁴VA San Diego Healthcare System, San Diego, CA; ⁵University of Washington, Seattle, WA; ⁶washington state university, Seattle, WA; ⁷VA Center of Excellence for Stress and Mental Health and Department of Psychiatry UC San Diego, San Diego, CA

Post-traumatic stress disorder (PTSD) and eating disorders (ED) are often comorbid, yet mechanisms underlying this comorbidity are not well understood. Disinhibited eating behaviors and cognitive dietary restraint are key components of ED symptomatology and important to assess in relation to PTSD symptoms. Previous research has evaluated the heritability of PTSD symptoms, disinhibited eating, and cognitive dietary restraint individually, but no studies have evaluated the contribution of genetic influences to their covariance. Understanding genetic and environmental overlap may elucidate underlying biological mechanisms and potential treatment targets for those with comorbid PTSD and ED. We examined these relationships in a community sample of 400 twins (102 monozygotic pairs and 98 dizygotic pairs; $M_{age} = 29 \pm 12$ years; 63% female) from the Washington State Twin Registry who completed the PTSD Check List – Civilian Version (PCL-C) for PTSD symptoms and the Three-Factor Eating Questionnaire Revised 18-item version (TFEQ) for disinhibited eating and dietary restraint. We used biometric modeling to assess genetic and environmental contribution to the association between PTSD symptoms, disinhibited eating symptoms (uncontrolled eating, emotional eating), and dietary restraint. We estimated heritability for each of the domains as well as the degree of genetic overlap between PTSD symptoms and disinhibited eating domains. There were significant phenotypic correlations between PCL-C total score and TFEQ total score ($r=.32$), uncontrolled eating ($r=.31$), and emotional eating ($r=.29$) subscales, but not with the cognitive restraint subscale ($r=.08$). Heritability was estimated at 48% for PCL-C total score and 45% for TFEQ total score. TFEQ subscale heritabilities were estimated at 48% for dietary restraint, and 34% for both uncontrolled eating and emotional eating. There were significant genetic correlations between PCL-C total score and TFEQ total score ($r=.34$), and TFEQ uncontrolled eating ($r=.53$), but not with other TFEQ subscales. In the phenotypic correlation between PCL-C total score and uncontrolled eating, 69% was due to genetic effects. Together, findings reveal genetic overlap between PTSD symptoms and ED symptoms, especially uncontrolled eating. Shared genetic influences contribute to the phenotypic relationship between PTSD symptoms and disinhibited eating, but there is little relationship between PTSD symptoms and cognitive dietary restraint. A genetic link between PTSD and disinhibited eating highlights the need for additional research to examine the shared risk factors and biological mechanisms responsible for the co-occurrence of PTSD and ED symptoms and to further elucidate any relationship between PTSD and cognitive restraint. Future research and clinical efforts might focus on evaluating the utility of trauma-informed eating disorder treatments.

US ONCOLOGISTS' REASONS FOR NOT USING NEXT GENERATION SEQUENCING

Lisa Spees, PhD¹, Andrew N. Freedman, PhD², William Klein, PhD³, Irene Prabhu Das, PhD⁴, Ebonee Butler, PhD MPH⁵, Janet S. de Moor, PhD, MPH⁶, Megan C. Roberts, PhD⁷

¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²NCI, Rockville, MD; ³National Cancer Institute, NIH, Bethesda, MD; ⁴National Institutes of Health, Rockville, MD; ⁵National Cancer Institute, Bethesda, MD; ⁶National Cancer Institute, Rockville, MD; ⁷UNC Eshelman School of Pharmacy, Chapel Hill, NC

Purpose: Next generation sequencing (NGS) may aid in treatment management based on molecular tumor characteristics. The objectives of this project was to evaluate organizational-, provider-, and patient/family- level factors associated with NGS use to guide patient care.

Methods: Using data from the National Cancer Institute's *National Survey of Precision Medicine in Cancer Treatment* (n=1,281), we evaluated the association between organizational-, provider-, and patient/family- level and NGS use. Modified Poisson regressions were used to estimate prevalence ratios and determine if multilevel factors were associated with NGS use to guide patient care in the past 12 months.

Results: "Testing not being relevant" was most frequently reported as "sometimes" or "often" a reason for not ordering multi-marker tumor panels (57%), followed by not enough evidence of the tests' utility (41%). More than half of oncologists cited difficulty obtaining sufficient tissue for testing (57%) and using tests for individual genes (72%) as "sometimes" or "often" a reason for not using multi-marker testing. On the patient/family level, 59% of oncologists reported at least one barrier to involving patients/families in decision-making about multi-marker tumor panel testing. While patient/family barriers were not significantly associated with NGS use, the unavailability of multi-marker panels in an oncologist's practice (adjusted prevalence ratio (aPR): 0.70, 95%CI: 0.61–0.81), lack of personnel resources to interpret results (aPR: 0.87, 95%CI: 0.76–0.99), and insufficient time to order tests or review results (aPR: 1.10, 95%CI: 1.02–1.18) were associated with lower NGS use. Those reporting these barriers tended to have fewer genomic resources in their practice, to be in rural or suburban areas, and to have a higher proportion of Medicaid patients.

Conclusion: Modifiable, organizational factors were associated with low NGS use. Receipt of genomics training as well as organizational policies related to the use of genomics were associated with lower reporting of barriers to NGS use, pointing to potential targets for future studies aimed at increasing NGS testing for cancer treatment.

PROMOTING COMMUNITY SUICIDE PREVENTION INTERVENTION THROUGH AN ONLINE BYSTANDER INTERVENTION MODEL-INFORMED TOOL: AN RCT

Karien Hill, n/a¹, Shawn Somerset, PhD², Ralf Schwarzer, PhD³, Carina Chan, PhD⁴

¹La Trobe University, Rochedale South, Queensland, Australia; ²University of Canberra, Bruce, Australian Capital Territory, Australia; ³Freie Universität Berlin, Berlin, Berlin, Germany; ⁴La Trobe University, Bendigo, Victoria, Australia

Background: The World Health Organisation has declared suicide a global epidemic and public health priority. Previous research advocates for more innovative technology-based suicide prevention campaigns (e.g., online training modules) that target the community as opposed to professionals only. Emerging evidence suggests addressing the Bystander Effect through the Bystander Intervention Model (BIM) in education material may have potential for suicide prevention. The current study is the first known investigation of this model in the field of suicide prevention.

Method/Design: A sample of 281 adults recruited from the general community participated in a randomised controlled trial comprising a standard factsheet about suicide and mental health (control), and a factsheet designed according to the BIM (experimental group). Their self-reported suicide risk detection and response readiness, confidence and intent when presented with a suicidal peer was tested just prior to and post-intervention and compared across time and between groups.

Results: Results showed the intervention group had significantly higher ($p < 0.01$) levels of suicide risk detection and response readiness, confidence and intent than the control group post-intervention.

Conclusion: This study indicated that BIM-informed suicide risk training material may have potential to improve readiness, confidence and intent, and therefore enhance suicide prevention. Further testing in this area is recommended as, while results were statistically significant with moderate-to-large effect sizes, clinical significance requires further exploration. Larger and more diverse contexts will determine the extent of this finding.

PREVENTING PROVIDER MISINFORMATION AND IMPROVING OVERSIGHT OF ABUSE-DETERRENT OPIOID FORMULATIONS: A POLICY ANALYSIS

Elizabeth T. Adams, MA¹¹UNC-Chapel Hill and RTI International, Chapel Hill, NC

America's opioid epidemic resulted from a confluence of events, including the Food and Drug Administration's (FDA) mislabeling of Oxycodone® as a "less addictive opioid" in 1995 and the American Pain Association's declaration that physicians should address pain as the "fifth vital sign" (deShazo, Johnson, Eriator, & Rodenmeyer, 2018). Pharmaceutical developers have pledged to increase the safety and transparency of opioid products by investing in the development of abuse-deterrent opioid formulations (ADFs). The Food and Drug Administration (FDA) has rewarded such efforts by expediting the review and process for drugmakers seeking the ADF label.

The FDA hails ADFs as "a step toward products that may help reduce abuse"; yet, the agency concedes that these drugs are not "abuse- or addiction-proof" (FDA, 2019). The FDA's guidelines for ADF evaluation and labeling acknowledge that the science of abuse deterrence is nascent, and clinical, analytical, and statistical methods for testing ADF products are rapidly evolving. Recent data suggests the introduction of ADFs to the medical market has shifted drug use trends in a deadly direction (Cicero, Ellis, & Surratt, 2012).

Furthermore, few health care providers are receiving accurate information regarding the inherent risks and limitations of ADFs. Nearly half of all prescribing physicians erroneously believe the ADF label signifies enhanced drug safety (Hwang, Turner, Kruszewski, Kolodny, and Alexander, 2016). The FDA's privileging of ADF therapies also undermines a holistic, multimodal approach to combating the opioid crisis.

This analysis seeks to address the problematic nature of expediting the approval of understudied ADFs by identifying structural solutions and protective measures that will prevent provider misinformation and opioid overreliance. The analysis isolates two structural inadequacies as root causes of provider overconfidence in and misinformation about ADFs, including the expedient nature of the FDA review process and the elective, often neglected, nature of provider education for new-to-market ADFs.

Proposed structural solutions include 1) formal research to understand how providers become misinformed or overly confident in the abuse-deterrent capacities implied by the ADF label and terminologies 2) incentivizing opioid prescription education for early-adopter providers who commonly prescribe opioid analgesics, and 3) mandate that pharmaceutical companies receiving the expedited ADF label for a product conduct more rigorous evaluation of the Risk Education Mitigation Strategies (REMS) program.

NEWS COVERAGE VERSUS SPONSORED ONLINE PROMOTION AS PROMPT FOR PATIENT CONSIDERATION OF ASPIRIN, HEART HEALTH, AND STROKE

Brian Southwell, PhD¹, Milton Eder, PhD², John R. Finnegan, MA, PhD², Russell Luepker, MD, MS², Sue Duval, PhD², Carol Russell, M.S.³, Robert N. Graves, n/a⁴

¹RTI International, Research Triangle Park, NC; ²University of Minnesota, Minneapolis, MN; ³Russell Herder, Minneapolis, MN; ⁴Russell Herder, Inc., Minneapolis, MN

Most patients in the United States live amidst a bounty of health information that includes an array of posts, stories, and advertisements from many different sources. In the case of patient consideration of using aspirin to lower risk of heart attack and stroke, previous research suggests one type of information – targeted online promotion such as purchased advertisements on search platforms – clearly can attract attention to and engagement with decision tools to encourage patient-physician discussion. Online advertising campaigns, however, also operate in an information environment that includes forces such as news coverage that might encourage patients to search for and find other information not directly crafted by campaign staff. Using time series analysis of weekly data from September 2014 through December 2018, we investigated the predictive ability of weekly newswire coverage about aspirin and heart health, e.g., Associated Press stories, to explain two distinct outcomes: number of patient engagements with an online tool and the relative search volume for "aspirin" and "heart" in Minnesota. We analyzed newswire mentions as a predictor over and above the predictive ability of sponsored online promotion (i.e., campaign advertising expenditures with Google, Yahoo, Facebook, and Twitter) for the two main outcomes (tool engagement and search). We coded major newswire stories mentioning "aspirin" and heart (achieving Krippendorff's alpha of .80 or higher for all coded variables) and queried Google Trends for searches from Minnesota on "aspirin" and "heart." As expected, weekly patient engagement with the campaign online tool was a function of online campaign promotion expenditure, $p < .01$, as well as the newswire appearance of a story on aspirin and heart with a Minnesota byline in a given week, $p = .04$, but tool engagement was not a function of weekly newswire story count for references to research on aspirin and heart health generally, ARIMA (1, 0, 0), $R^2 = .76$. Minnesota-based searches for aspirin and heart as key words (via Google), in contrast, were not a function of online campaign promotion but were a function of weekly newswire story count for references to aspirin and heart health research, $p = .03$, ARIMA (0, 0, 0), $R^2 = .03$. The separate spheres of influence for aspirin-related news stories and online campaign promotion is noteworthy, in part because such news stories have not universally championed aspirin use: although 64% of stories mentioning aspirin and heart refer to empirical research, 21% of those stories mention research finding no effect of aspirin on heart health or a negative effect and 32% of those stories mention aspirin side effects. Health news matters as a rival force in encouraging patient searches. Although online promotion can attract patients to targeted information, practitioners should monitor news stories for sources of influence on patient information seeking.

BARRIERS TO ACCESSING ONLINE MEDICAL RECORDS IN THE U.S.: RESULTS FROM HINTS 2017–2018

Neha Trivedi, PhD, MPH¹, Wen-ying Sylvia Chou, PhD, MPH¹¹National Cancer Institute, Bethesda, MD

Patients' access to and use of online medical records (OMRs) can facilitate better management of their healthcare needs; however emerging disparities in OMR access and use persist.

This study aims to: 1) determine the prevalence of and predictors to individuals being offered OMR access; 2) determine the sociodemographic and healthcare predictors of individuals accessing their OMR; and 3) identify common barriers cited for not accessing one's OMR. Multivariable logistic regression models examined predictors of being offered, accessing, and cited barriers to accessing OMRs.

This is a secondary analysis of cross-sectional data from Health Information National Trends Survey 5 (HINTS 5) Cycle 1 (2017) and Cycle 2 (2018) (n=6,670). Multivariable logistic regression analyses were used to determine the association among standard sociodemographic variables (e.g. gender, age, race/ethnicity, etc.) and healthcare-related variables (e.g. health insurance status, frequency of provider visit, etc.) on being offered OMR, accessing OMR, and reasons for not accessing OMR in separate models.

In 2017–2018, 54% of U.S. adults reported have been offered OMRs, and among those offered, 57% reported accessed their records in the last year. Those who were less likely to access their OMRs included individuals with lower education, lower household income, living in rural areas, and non-internet users. The previous characteristics, along with racial/ethnic minorities and the uninsured were also less likely to report being offered OMRs. Among the 43% of U.S. adults who did not access their records, the top reasons for not accessing included: preference to speak to their provider directly, perceived lack of need, concerns about privacy or security, and having no way to access the website. Respondents who were more likely to cite that they preferred to speak to a provider directly as a reason for not accessing OMRs included those who visited a provider in the past year and those with chronic conditions.

Disparities in OMR access remain in the US and continue to be a critical challenge. Sociodemographic, internet use, and healthcare factors are associated with variation in being offered access and actual use of OMRs. In addition, the most common reason cited for not accessing one's OMR was the preference to speak to a provider directly. To realize the values of OMR use for patients, it is important to ensure OMR does not replace the importance of interpersonal patient-provider relationship and communication, and to further integrate OMR into clinical care.

INFORMATION PROCESSING OF CANCER MESSAGES ON SOCIAL MEDIA: A MIXED METHODS EYE TRACKING STUDY

Neha Trivedi, PhD, MPH¹, Mark D. Lowry, PhD¹, Wen-ying Sylvia Chou, PhD, MPH¹¹National Cancer Institute, Bethesda, MD

While social media has facilitated the sharing of health information, these platforms have increased the risk for users to be exposed to and affected by health-related misinformation. It is critical to understand factors, such as message features and user characteristics, associated with how people process and evaluate information on social media. Such endeavors can then inform ways to disseminate accurate health messages and mitigate the spread of misinformation.

Using data from an experimental eye-tracking study on simulated cancer Facebook posts, this study examines the association between message source, format, accuracy and users' health literacy on time spent on posts. Participants (n=53) were asked to view simulated Facebook posts about HPV vaccination and sunscreen. Message conditions varied by source (government agency, healthcare organization, or lay individual), format (narrative vs. non-narrative information), and veracity (credible vs. non-credible message). Participants then responded to a survey to assess message believability of posts. Message accuracy was dichotomized into low and high accuracy by message veracity and believability. A Bayesian hierarchical model was conducted to analyze the role of health literacy on accuracy assessment and dwell time across conditions.

Overall, health literacy did not predict accuracy nor dwell time. However, further looking into dwell time by conditions and controlling for pixel size, participant order, and health topic, participants spent 4.43 more seconds viewing narrative posts than non-narrative posts, 95% HDI [1.8, 7.22]. This result was qualified by a 3-way interaction between participant message accuracy, format, and source. Participants whose accuracy assessment was high, spent more time on narrative posts than non-narrative posts, regardless of source. Participants with low accuracy assessment looked at government and individual narratives 7.35 seconds longer than non-narratives, 95% HDI [2.62, 12.4], but spent only 0.03 seconds more on health organizations narratives than non-narrative posts, 95% HDI [-3.39, 3.57].

When designing social media messages for health promotion, message format (e.g. narrative vs. non-narrative) can affect information processing. Our results showed that individuals spend more time on narratives than non-narrative messages. Although individuals' health literacy did not predict dwell time on post, findings suggested participants with low accuracy assessment spent more time scrutinizing narrative posts. Future public health interventions should ensure health promotion messages disseminate accurate and believable information. In an effort to mitigate the effect of misinformation, health literacy interventions can help individuals determine accuracy of information on social media.

SOCIAL AND BEHAVIORAL DRIVERS OF REPORTING DEATHS TO A NATIONAL CALL CENTER IN SIERRA LEONE AFTER THE END OF AN EBOLA OUTBREAK

Maïke Winters, MPH¹, Mohamed F. Jalloh, MPH², Reinhard Kaiser, MD, MPH³, Mariam Diop, MSc⁴, Amara Jambai, MD, MPH⁵, John Redd, MD, MPH³, Evelyn Castle, BA⁴, Sara Hersey, MPH⁶, Rebecca Bunnell, PhD³, Anna Mia Ekström, MD, PhD¹, Helena Nordenstedt, MD, PhD¹

¹Karolinska Institutet, Stockholm, Stockholms Lan, Sweden; ²Karolinska Institutet, Atlanta, GA; ³Centers for Disease Control and Prevention, Atlanta, GA; ⁴eHealth Africa, Freetown, Western Area, Sierra Leone; ⁵Sierra Leone Ministry of Health, Freetown, Western Area, Sierra Leone; ⁶CDC Country Office Sierra Leone, Atlanta, GA

Background: An outbreak of Ebola Virus Disease (Ebola) was detected in Kailahun district in the Eastern region of Sierra Leone in May 2014, while the largest number of confirmed Ebola cases and deaths were recorded in the North and West. The Government of Sierra Leone repurposed a national toll-free line (1-1-7 system) in August 2014, and mandated its use to report all sick persons and deaths. Reporting to the 1-1-7 system continued but sharply declined after the outbreak ended. Reasons for the decline were not understood as well as motivations to continue reporting. Flare-up of new Ebola cases after the end of an outbreak is possible and occurred in Sierra Leone, mainly because of the risk posed by sexual transmission due to viral persistence of the Ebolavirus in the semen of survivors. Reporting and screening of deaths help to detect re-emergence of Ebola. This assessment aimed to examine social and behavioral drivers of reporting deaths in a post-Ebola outbreak setting in order to inform risk communication efforts to improve routine death reporting.

Methods: A telephone survey was conducted with a national random sample of 1291 respondents who reported a death to the 1-1-7 system a year after the last flare-up of Ebola ended in Sierra Leone. Pearson Chi-square test was first used to examine differences in motivations and concerns across geographic regions. Secondly, differences in motivations and concerns were examined by past experience of personally knowing someone who died of Ebola.

Results: Motivations and concerns related to death reporting significantly varied across geographic regions. Wanting to find out the cause of the death was less frequently cited as a motivation among respondents in the West (17%) compared to those in other regions (36%–47%). However, motivation to obtain a burial permit was significantly higher in the West (44%) compared to other regions (20%–29%). Motivation to prevent possible infections was higher in the North (42%) compared to other regions (17%–18%). Expressing a concern about the consequences if the death turned out to be Ebola was higher in the North (39%) compared to other regions (14%–32). Overall, of those who were concerned about the consequences if the death turned out to be Ebola, significantly more of them (59%) knew someone who died of Ebola compared to those that did not (41%). Among those who were motivated to report the death to prevent possible infections, significantly more of them (54%) knew someone who died of Ebola compared to those that did not (46%).

Conclusions: Motivations and concerns associated with death reporting largely varied across geographic regions in Sierra Leone following the end of the Ebola outbreak, and may have been influenced by the past experience of knowing someone who died of Ebola during the outbreak. Risk communication to improve death reporting should be regionally targeted and address the concerns of families and their communities.

KNOWLEDGE AND SUPPORT FOR INDOOR TANNING LAWS AMONG MOTHERS AND TEEN DAUGHTERS IN 34 STATES IN A RANDOMIZED TRIAL

David B. Buller, PhD¹, Sherry Pagoto, PhD², Katie Baker, DrPH, MPH³, Barbara Walkosz, PhD¹, Joel J. Hillhouse, PhD³, Julia Berteletti, MSW¹, Jessica L. Bibeau, MA, PMP², Kimberly Henry, PhD⁴

¹Klein Buendel, Inc., Golden, CO; ²University of Connecticut, Storrs, CT; ³East Tennessee State University, Johnson City, TN; ⁴Colorado State University, Fort Collins, CO

Indoor tanning (IT) is associated with elevated risk for melanoma. Several states restrict IT by age and/or require parental permission for adolescents to use IT facilities. Mothers' knowledge of state laws may reduce their permissiveness for daughters to indoor tan. In a randomized trial testing a social media campaign to prevent IT by adolescent girls, mothers (n=777) were recruited from 34 states that do not ban IT under age 18 (9 have no restrictions; 3 have age restrictions; 9 require parental permission; and 16 have both). Mothers' knowledge of their states' IT laws was collected at baseline. Responses to the 12-month posttest by control group mothers estimated support for IT policies without our IT prevention intervention. Daughters were invited to complete a survey at baseline (n=441), but were not required to do so for mothers to enroll. Between December 1, 2017 and March 31, 2018, 17.8% of mothers (M=1.3 sessions, SD=5.0) and 11.5% of daughters (M=0.7, SD=3.2) reported at least one IT session. A minority of mothers accurately reported whether their state has an age restriction (18.5%) or requires parental permission (19.1%). Of these mothers, few correctly knew the age of restriction (22.9%) or when parental permission was required (31.2%). Most did not know these aspects of state IT laws (68.7% and 70.7%, respectively). Few daughters accurately reported their state restricted IT (14.1%) and at what the age (13.5%). Most daughters were not knowledgeable (11.6% answered incorrectly) or uncertain (74.3% responded "I Don't Know") of the law. Over half of mothers (58.9%) said IT should be banned for children under age 18 and would vote for a candidate who supported a ban (57.3%). Also, several mothers would sign a petition (66.8%) or create/share an online petition for a ban (35.4%); write (34.2%), call (31.3%) or speak with (29.8%) an elected state representative about supporting a ban; or testify to a state legislative committee (20.9%) supporting a ban. Mothers reporting IT were more aware of parental permission requirements (tanned: 49.3%, not tanned: 30.8%, p<0.001) but not age bans (tanned: 40.6%, not tanned: 37.8%, p=0.536), and had less support for a ban under 18 (tanned: 41.6%, not tanned: 65.4%, p<0.001). State policy solutions are a first step. Efforts to inform mothers and daughters may be needed to create a norm against IT, to prevent moms from permitting IT by daughters, and to build support for further restrictions on minors' access.

RESPONSIBILITY FOR HEALTH PROMOTION AND CARE COORDINATION IN URGENT CARE: PATIENT AND PROVIDER PERSPECTIVES

Danielle Blanch-Hartigan, PhD, MPH¹, David M. Murungi, PhD¹, Sandeep R. Purao, PhD¹¹Bentley University, Waltham, MA

As patients increasingly seek care in urgent care (UC) settings, we must consider the role of UC providers in health promotion and communication with primary care physicians (PCPs) and other providers. This study examined the perspectives of UC patients and providers on care coordination and responsibility for health promotion.

We surveyed 69 providers working in a large UC network based in the southern United States (33.3% male, mean age=43.6, SD=9.28, 42% nurse practitioners, 33.3% physicians assistants, 21.7% physicians). An additional online survey of 402 patients who reported visiting UC within the past year (52.7% male, modal age 25–34) assessed if they intended to share the visit to UC with their PCP or other providers, preferences for visiting UC over other providers, and whether they would rather discuss medical issues with UC or other providers.

58% of UC providers agreed that providers working in UC settings should be responsible for communicating or coordinating care with a patient's PCP or other providers. 72% believed that UC providers should be responsible for discussing health promotion and disease prevention with their patients. UC providers who reported greater symptoms of depersonalization and emotional exhaustion and less personal accomplishment on the Maslach Burnout Inventory were significantly less likely to support UC providers taking on these responsibilities.

78% of UC providers perceived that patients share what happens at their urgent care visit with their PCP or other healthcare provider. However, 45% of UC patients said they did not intend to share and 55% said they would visit UC again without first contacting their PCP or another provider. Older patients and those with a usual source of care were significantly more likely to report intending to share their UC visit with their other providers. A sizeable proportion of patients reported they would prefer to visit UC over other providers (33%) and would prefer to discuss their medical concerns with UC providers as compared to other providers (21%).

Burnout may play a role in UC providers' perspectives on health promotion and care coordination. UC providers may be overestimating their patients' intentions to communicate about their UC visit with their PCP or other providers. Best practices for health promotion and care coordination should be established as the UC model of healthcare delivery continues to grow.

HEALTH LITERACY IN MULTI-MORBIDITY – LATENT PROFILE AND NETWORK ANALYSES TO IDENTIFY THE BEST TARGETS FOR INTERVENTIONS

Konstadina Griva, MSc, PhD, FEhps¹¹Lee Kong Chian School of Medicine, Imperial College and Nanyang Technological University Singapore, singapore, N/A, Singapore

Aims: Health literacy (HL) represents extent to which people can access and understand health information and communicate their health needs to service providers. Although health literacy interventions should target particular health literacy strengths and difficulties of local communities, limited research has examined which groups of individuals or which domains of health literacy might be suitable targets for these interventions. To address these questions, the present study examined health literacy profiles and networks of health literacy skills in multi-morbid patients with co-existing diabetes and end-stage renal disease.

Methods: A total of 221 patients completed the Health Literacy Questionnaire (comprising 9 domains to measure district HL skills), the Beck Hopelessness Inventory and Hospital Anxiety and Depression Scale. Treatment adherence was measured with self report and concurrently assessed biochemical markers, i.e., HbA1c, phosphate and potassium levels and inter-dialytic weight gains. R package qgraph were used to identify profiles and networks of HL Skills.

Results: Latent Profile Analysis identified three distinct HL profiles: low (16%), moderate (63%) and high (21%). Low HL was associated with Chinese ethnicity, lower education, hopelessness, anxiety and depression. Adherence markers were not consistently associated with HL profiles - only non adherence to medication was associated with low HL profile. Network Analysis identified "ability to find information" (CS= 1.12; ZCS= 1.14), "ability to engage with providers" (CS= 1.05; ZCS= 0.84) and "health-system navigation" (CS= 1.00; ZCS= 0.61) as the most central domains in HL whose activation is likely to activate other domains/skills.

Conclusions: This is the first study to conduct both LPA and NA on the domains of health literacy in a sample of patients with DM-ESRD. Analyses suggest that parents of Chinese Ancestry and individuals with lower education might benefit from health literacy interventions, and that these interventions should target the ability to find good health information, the ability to actively engage with healthcare providers, navigating the healthcare system and social support for health. Targeting these domains might make interventions more cost-effective.

OPTIMIZING VISUAL DEPICTIONS OF RISK IN THE CONTEXT OF LUNG CANCER SCREENING: A MIXED METHODS APPROACH

Dannielle E. Kelley, PhD, MPH¹, Elizabeth L. Seaman, PhD, MHS², Megan C. Roberts, PhD³, Paul Han, MD, MPH⁴, Hormuzd Katki, PhD⁵, William Klein, PhD⁶

¹National Cancer Institute, Bethesda, MD; ²Behavioral Research Program, National Cancer Institute, Rockville, MD; ³UNC Eshelman School of Pharmacy, Chapel Hill, NC; ⁴Maine Medical Center, Portland, ME; ⁵National Cancer Institute, ROCKVILLE, MD; ⁶National Cancer Institute, NIH, Bethesda, MD

Background: Guidelines call for the use of risk-based algorithms and decision-support to aid shared decision-making about computed tomography (CT) lung screening. Given the complexities of identifying CT lung screening candidates, prior work on visual risk depictions offer little guidance on how to convey risk information to those eligible for screening. The Risk-based NLST Outcomes Tool is an online tool that provides personalized risk estimates of lung cancer death and diagnosis with and without screening, and risk of receiving a false positive with screening. To determine the most effective visual risk depiction format to relay personalized risk information to current and former smokers, we used a mixed methods approach to test four distinct presentations of icon arrays via interview, eye-tracking and survey methodologies.

Method: Current or former smokers (N=12) were randomized to view an icon array depicting the impact of screening on the risks of lung cancer death and diagnosis in 1 of 3 ways: 1) separate square-shaped icons depicting risks with and without screening (n=4), 2) separate person-shaped icons (n=4) depicting risks with and without screening, 3) a single square icon array depicting incremental risk with and without screening (n=4). All participants saw condition 4) visual area-manipulated person icon array depicting incremental risk with and without screening.

Results: Participants were primarily Black (83%), female (67%), current smokers (67%), had an average of 34.9 pack-years ($SD=6.76$), 58 years ($SD=4.96$), completed some college or more (58%) or high school or trade school (42%). Interview and eye-tracking data suggest participants preferred person icons to square icons and separate with and without screening estimates to incremental risk estimates. Although some participants indicated preference for the visual area manipulation area in condition 4, interview and survey data show this condition elicited inaccurate risk perceptions. Overall, participants were surprised by the high false positive rate and expressed interest in more information about the screening process, especially regarding false positives.

Conclusion: Results highlight the importance of design choices on how visual risk estimates are construed and interpreted in the context of lung screening. Meaningful differences across 4 types of icon array visual risk depictions are described in terms of conveying risk, preferences, affective reactions and trustworthiness.

CLASSIFYING AND UNDERSTANDING FLU VACCINE MISINFORMATION ON TWITTER

Jingwen Zhang, Ph.D¹, Qiusi Sun, M.S.¹

¹University of California, Davis, Davis, CA

Social media have enabled and accelerated the creation and spread of misinformation on a global level. Misinformation is defined as false information judged by expert consensus contemporaneous with the time period. Exposure to vaccine misinformation has been linked to the formation of false beliefs and the recent upsurge of disease outbreaks. This study developed an automatic machine learning algorithm to classify vaccine misinformation and analyzed semantic structures of classified tweets.

In this study, we focused on examining messages about flu vaccines posted on Twitter during the peak of 2018 flu season, we collected a sample of 120,379 original tweets (excluding retweets and quotes) from January 1st to February 11th 2018, using keywords specifying “flu” or “influenza” and “shot” or “vaccine,” “vaccination,” “vax,” “immunization,” “immunization,” with Twitter’s Premium API. Then we built a fact-checking classifier to automatically distinguish misinformation from non-misinformation. Lastly, we conducted semantic network analyses to pinpoint the different semantic structures of misinformation tweets and non-misinformation tweets.

To build the machine-learning classifier, we first conducted human annotations on a subset of randomly selected 1,235 tweets. Two pairs of two coders annotated half of the tweets. All pairwise inter-coder reliabilities reached the criterion of Cronbach’s alpha of 0.7. The discrepancies were resolved. Based on coded labels we built a machine-learning model to predict whether a tweet contained misinformation or not. The multi-layer perceptron (MLP) classifier achieved a F1-score of 91.1% on the sample tweets. We then applied the finalized predictor to the rest of the tweets and classified 7,814 misinformation tweets (8.6%) and 82,576 non-misinformation tweets (91.4%).

To understand the differences in semantic structures of the misinformation and non-misinformation tweets, we performed semantic network analyses separately on the misinformation tweets and the non-misinformation tweets with ConText for preprocessing, network construction Gephi for network visualization. Modularity analysis was conducted to determine sub-clusters within the networks. We found in the network of misinformation tweets, the most central words were *flu*, *vaccine*, *not*, *get*, and *death*. Whereas in the accurate tweets, the most central words were *flu*, *vaccine*, *not*, *get*, and *health*. In brief, the misinformation networks centered on conspiracies about government, media scam, and citing Trump.

Developing automatic approaches to identify misinformation will make a significant contribution to improve the social media environment and if employed, may benefit individual decisions. The insights of our study can inform tailored misinformation correction and vaccine promotion strategies on social media to improve vaccine discussions and vaccine coverage.

BODY IMAGE AND DISORDERED EATING DIFFERENCES AMONG RACIAL AND SEXUAL MINORITY WOMEN

Cassidy M. Sandoval, M.A.¹, Lindsay Howard, M.S.², Kristin E. Heron, Ph.D.³¹Virginia Consortium Program in Clinical Psychology, Norfolk, VA; ²Virginia Consortium Program in Clinical Psychology, Newport News, VA; ³Old Dominion University, Norfolk, VA

Research suggests White women have more body image concerns and dissatisfaction than Black women, and there are limited studies examining racial differences in eating pathology with mixed findings. Findings are also equivocal regarding body image concerns and disordered eating behaviors among sexual minority women (SMW), with some studies detecting differences between SMW and heterosexual women and others finding none. However, there is limited research in this area investigating the intersectionality of race and sexual minority status. Thus, the aim of the present study was to explore differences in body image and disordered eating behaviors among Black and White heterosexual, lesbian, and bisexual women. Participants were 990 college women (471 Black, 519 White) identifying as heterosexual ($n=885$), lesbian ($n=53$), or bisexual ($n=52$). Participants completed surveys about body dissatisfaction (Body Shape Questionnaire [BSQ-16]) and body checking (Body Checking Questionnaire-Shortened [BCQ]). Disordered eating thoughts and behaviors were measured using the Eating Disorders Examination-Questionnaire (EDE-Q) and dichotomous (yes/no) items asking about past month overeating and loss of control of eating. Consistent with previous literature, results of a 2 (Race: Black, White) x 3 (Sexual Orientation: Heterosexual, Lesbian, Bisexual) factorial ANOVA indicated a small main effect for race on the BSQ ($p=.034$), suggesting White women reported more body dissatisfaction than Black women. No other main effects or interaction effects were found for the BCQ or EDE-Q. Chi-square analyses were conducted for the dichotomous overeating and loss of control of eating variables. Results indicated a significant effect for loss of control ($p=.019$), and follow-up analyses revealed White bisexual women have higher rates of loss of control of eating than Black bisexual women (42.3% vs. 7.7%). The present study provides initial evidence that differing patterns in body image and disordered eating may exist for those belonging to multiple minority groups. Future research considering intersecting identities for body image and disordered eating behaviors with larger samples and more diverse participants (e.g., Latina women, other sexual identities) is warranted. Such research is critically important because it may inform the need for culturally tailored interventions for eating disorders or related conditions (e.g., obesity) for minority groups.

“TAKE CARE OF THOSE SICK PEOPLE...I’M FINE.”: A QUALITATIVE STUDY OF ATTITUDES TOWARD RESEARCH PARTICIPATION AMONG LATINX ADULTS

Vanessa M. Kauffman, M.A.¹, Jacqueline Chow, n/a², Leslie N. Martinez, n/a³, Cintia Y. Quan Kiu Kuang, n/a⁴, Javier Guerrero, n/a⁵, Celeste M. Villegas, Undergraduate⁶, John M. Robb, n/a⁷, John Billimek, PhD⁸¹University of California, Irvine, San Clemente, CA; ²University of California Irvine, Chino Hills, CA; ³University of California, Irvine, Orange, CA; ⁴University of California Irvine, IRVINE, CA; ⁵UCI HPRI, Fillmore, CA; ⁶University of California, Irvine, Irvine, CA; ⁷University of California, Irvine; the HELIOS Lab, El Dorado Hills, CA; ⁸University of California, Irvine, Irvine, CA

Members of racial and ethnic minority communities are considerably underrepresented in biomedical research. African American and Latinx individuals represent 30% of the U.S. population, but make up only 6% of research participants in clinical and biomedical research. Although many research programs are committed to including communities that historically have been underrepresented it remains unclear whether these efforts will address the root causes of minority underrepresentation. To better understand why Latinx adults may be hesitant or decline to participate in biomedical research and how professionals understand and address this problem, we conducted 25 in-depth interviews with Latinx community members recruited from a safety net clinic in Santa Ana, California and 30 interviews with medical and research professionals involved in health disparities research. Among the community interviews with Latinx adults (18 to 72 years old), 15 of the interviews were conducted in English (9 women, 6 men) and 10 were conducted in Spanish (8 women, 2 men). We asked open-ended questions on perceptions of biomedical research, health care experiences and barriers to receiving care. Our results are drawn from open and focused qualitative coding of the interview transcripts. We found that participants often viewed biomedical research using an illness mindset, reflecting on preexisting or acute health issues and basing participation on whether the study might alleviate these problems. Additionally, when asked directly about participating in research, participants often expressed reluctance and strong feelings of mistrust in medical professionals from prior research or health care experiences. Examining the 30 interviews with professionals (17 women, 13 men) perspectives fell into two camps: Some suggested that minority underrepresentation was a top-down problem that required more institutional pressure and regulations, while others proposed a bottom-up approach arguing that community based participatory research methods inherently address barriers that typically make research within minority communities challenging. Our findings suggest that successful biomedical recruitment within clinic settings may be complicated by the fact that people are often seeking immediate help for an acute illness but are being asked to think more generally about health promotion and participate in research that may have delayed or very diffuse benefits. Structural, cultural, and social barriers to minority participation in biomedical research may be better understood and addressed through community engagement processes focused on preventative health education and engendering trust through open communication and community-researcher collaborations.

STIGMA, GENDER, AND SOCIAL TIES: VIRAL NON-SUPPRESSION AMONG PATIENTS IN HPTN 065 AND INTERVENTION IMPLICATIONS

Allysha Maragh-Bass, PhD, MPH¹, Theresa R. Gamble, PhD¹, Elizabeth Tolley, PhD, MA¹¹FHI 360, Durham, NC

Background: The HIV Care Continuum includes progression from diagnosis to sustained viral suppression, although minority populations experience challenges in navigating this continuum. Barriers have included poor quality of care, particularly among women, African Americans, and men who have sex with men (MSM).

Methods: HPTN 065 evaluated the role of financial incentives in viral suppression among adults enrolled at HIV clinics in NY and DC; baseline data from the Prevention for Positives component were analyzed. The outcome of interest was viral non-suppression (>40 copies/mL). Key variables included medication adherence attitudes, social support and stigma, which were selected based on insights from qualitative analyses with a sub-study of HPTN 065 exit interview participants. Descriptive statistics were calculated. Logistic regression with robust standard errors was implemented and stratified by sex.

Results: Participants (N=745) were predominantly male (68.8%), African American (61.9%), with 64.3% with under \$40,000 annual income. Men were more likely to identify same-sex partners (38.5% vs. 5.4%), and less likely to report yearly income $< \$10,000$ (22.5% vs. 41.3%) than women. In adjusted analyses, MSM had 1.7 times odds of non-suppression as non-MSM (Adjusted Odds Ratio [AOR] = 1.71; 95% Confidence Interval [95% CI] = 1.00, 2.92; $p < .05$; N=535). Men with more positive medication adherence attitudes had 62% lower odds of non-suppression than men with less positive attitudes (AOR=0.37; 95% CI=0.13, 1.00; $p < .05$). Women more open about their HIV status had greater odds of non-suppression than women less open ($p < .08$). Finally, women with multiple barriers to medication adherence had over 3-fold the odds of non-suppression as women who identified no barriers (AOR: 3.31; 95% CI=1.13, 9.73; $p < .05$).

Discussion: Associations between socio-demographics, medication adherence attitudes, and viral load non-suppression differed by sex. Irrespective of sex, presence of social support and less experiences of stigma did not appear protective against non-suppression. More research is needed to better understand and address barriers to achieving and maintaining viral suppression, particularly among MSM and women, who continue experiencing inequities in positive HIV health outcomes.

STRESS AND LEVELS OF DISCLOSURE: DIFFERENTIAL RELATIONSHIPS BY GENDER THROUGH A PERSON-CENTERED LONGITUDINAL PERSPECTIVE

Chengbo Zeng, MPH¹, Xiaoming Li, PhD¹, Shan Qiao, PhD¹, Xueying Yang, PhD¹, Zhiyong Shen, MD, Yuejiao Zhou, MD¹University of South Carolina, Columbia, SC

Background: Previous studies have documented an inconsistent relationship between stress and HIV disclosure among people living with HIV (PLWH), and mostly used a cross-sectional design. Little is known about levels of HIV disclosure and their relationships with stress from longitudinal perspective. Therefore, this study explored different levels of HIV disclosure and examined whether stress could predict disclosure levels among PLWH. This study also investigated the potential gender difference in the relationship between stress and disclosure levels.

Methods: Data were derived from a prospective cohort study conducted from November 2016 to January 2018 in Guangxi, China. Four hundred forty-four PLWH were recruited. Participants were assessed on perceived stress at baseline, sociodemographic characteristics, and their numbers of HIV disclosure targets at baseline, 6-month, and 12-month follow-ups. Person-centered approach (i.e., growth mixture modeling) was used to characterize the levels of disclosure based on numbers of disclosure targets. Multinomial logistic regression was used to predict levels of disclosure with baseline stress after adjusting for covariates. The interaction effect of stress by gender was examined.

Results: Three levels of HIV disclosure were characterized using mean number of disclosure targets at each time point. Level one ("low levels of disclosure") contained 81.2% of the individuals while 6.4% for level two ("increased levels of disclosure") and 12.4% for level three ("high levels of disclosure"). Compared to PLWH in level one, PLWH in level two with higher level of education ($std.\beta=0.34$, $OR=3.39$ [1.27~9.07]) are more likely to increase their levels of HIV disclosure over time. PLWH who were young ($std.\beta=-0.19$, $OR=0.96$ [0.93~1.00]), married/cohabitated ($std.\beta=-0.20$, $OR=0.40$ [0.20~0.79]), and perceived stress ($std.\beta=0.41$, $OR=1.13$ [1.00~1.28]) were inclined to have high levels of disclosure from baseline to follow-ups ("level three"). The interaction of baseline stress by gender was statistically significant in differentiating levels one from three ($std.\beta=-0.17$, $OR=0.84$ [0.73~0.96]) while it was not significant between levels one and two ($std.\beta=-0.02$, $OR=0.99$ [0.85~1.16]). Compared to male counterparts, female PLWH with high levels of baseline stress were more likely to have consistent high levels of HIV disclosure over time.

Conclusions: High levels of education was positively associated with increased levels of disclosure over time, and young, married/cohabited female with high levels of baseline stress have consistent high levels of disclosure over time. To increase disclosure, structural interventions are needed to promote health education of HIV and disclosure at both community and clinical settings, and tailored individual-based interventions are needed to improve disclosure skills and stress management among PLWH.

SEX DIFFERENCES IN THE PSYCHOLOGICAL AND ENVIRONMENTAL CORRELATES OF INJECTION RISK AMONG PEOPLE WHO INJECT DRUGS IN MEXICO

Jennifer P. Jain, MPH, PhD (candidate)¹, Steffanie strathdee, PhD², Brooke West, PhD³, Patricia Gonzalez-Zuniga, MD², Gudelia Rangel, PhD⁴, Eileen Pitpitan, PhD⁵

¹University of California, San Diego, San Diego, CA; ²University of California, San Diego, La Jolla, CA; ³Columbia, School of Social Work, New York, NY; ⁴United States-Mexico Border Health Commission and El Colegio de la Frontera Norte, Tijuana, Baja California, Mexico; ⁵San Diego State University, La Jolla, CA

Background: HIV and HCV transmission among people who inject drugs (PWID) is often fueled by injection risk behaviors (e.g., injection equipment sharing), which are shaped by the dynamic interaction between personal and environmental-level factors.

Purpose: We utilized the social ecological model and studied PWID in Tijuana, Mexico to identify potential sex differences in the psychological and environmental correlates of injection risk, hypothesizing that females would face greater barriers to practicing injection risk reduction compared to males.

Methods: From 2011–2013, 734 PWID (female: 277, male: 457) were enrolled into a prospective cohort study in Tijuana. At baseline, participants completed interviews on injection and sexual risks. Utilizing baseline data, we conducted multiple generalized linear models stratified by sex to identify personal and environmental factors associated with injection risk scores. Injection risk scores ranging from 1–5 were calculated by averaging responses from five likert-scaled injection risk indicators (e.g., syringe sharing), with higher scores representing higher risk.

Results: For both sexes, difficult access to sterile syringes was associated with elevated injection risk scores ($b=1.24$, 95% confidence interval [CI]=1.16–1.33), using syringes from a safe source (e.g., needle exchange program) was associated with lower injection risk scores ($b=0.87$, 95% CI=0.82–0.94), and for every one-unit increase in safe injection self-efficacy we observed a 20% decrease in injection risk scores ($b=0.80$, 95% CI=0.76–0.84). Females had a higher median safe injection self-efficacy score compared to males (median=2.8, Interquartile range [IQR] =2.2–3.0 vs. median=2.8, IQR=2.0–3.0, $p=0.01$). Among females, incarceration ($b=1.22$, 95% CI=1.09–1.36), and police confiscation of syringes in the past six months ($b=1.16$, 95% CI=1.01–1.33), were associated with elevated injection risk scores. Among males, sex work ($b=1.16$, 95% CI=1.04–1.30), and polysubstance use in the past six months ($b=1.22$, 95% CI=1.13–1.31), were associated with elevated injection risk scores.

Conclusions: Interventions to reduce injection risk among PWID in Tijuana should be sex-specific, and address different levels of HIV and HCV risk. Prevention programs for females should address punitive policing practices and the criminalization of drug use. Interventions for males should consider the heterogeneity in drug use behaviors and promote safer sex work environments.

FAMILY PLANNING AND HIV PREVENTION INTERVENTION NEEDS OF SOUTH AFRICAN ADOLESCENT GIRLS: CULTURAL CONSENSUS MODELING APPROACH

Jennifer L. Brown, PhD¹, Lochner Marais, PhD², Jessica Sales, PhD³, Carla Sharp, PhD⁴, Jan S. Cloete, M.Soc.Sc (Sociology)², Molefi Lenka, Researcher², Kholisa Rani, MSoc.Sc², Gause Gause, M.A.⁵, Anthony Hitch, M.A.⁶

¹University of Cincinnati College of Medicine, Cincinnati, OH; ²University of the Free State, Bloemfontein, Free State, South Africa; ³Emory University, Rollins School of Public Health, Atlanta, GA; ⁴University of Houston, Houston, TX; ⁵University of Cincinnati, Cincinnati, OH; ⁶University of Cincinnati, Cincinnati, OH

Purpose: South African adolescent girls experience high rates of unintended pregnancies and STI/HIV. To inform the development of a culturally-tailored dual protection intervention emphasizing the prevention of *both* unintended pregnancies and STI/HIV, cultural consensus modeling (CCM) was employed. CCM is a methodology to determine shared cultural beliefs or norms using a four-phase mixed quantitative and qualitative methodology. The aim of this study was to qualitatively examine South African adolescent girls' pregnancy and HIV prevention intervention needs.

Methods: Participants were Sesotho-speaking South African adolescent girls aged 14 to 17 years ($N=25$; Mean age = 15.8) recruited from the Mangaung Metropolitan Municipality in the Free State Province. Participants were a subset of adolescents who previously participated in a quantitative data collection phase and who were identified as highly consistent with the prevailing cultural consensus model. Interviews focused on participants' perceptions of *other adolescent girls'* pregnancy and HIV prevention needs to elucidate shared cultural beliefs and norms rather than individual beliefs. Interviews were conducted in Sesotho, transcribed verbatim in Sesotho and translated into English. Two independent coders identified key themes in the data using a Grounded Theoretical approach with discrepancies resolved by a third coder.

Results: Results focused on themes related to intervention content and desired implementation setting. Participants identified limited overall exposure to pregnancy prevention information, with existing sexual health education content focused on HIV prevention and condom use. The importance of including content to address the role of peers as a key motivating factor for pregnancy and STI/HIV prevention method selection was emphasized. Participants preferred that sexual health interventions be delivered by trusted community organizations serving adolescents or via school-delivered programs. Participants also reported that there would be adolescent interest in assisting with the development of new sexual health interventions.

Discussion: Results point to the importance of cultural context for tailoring of dual protection intervention content among South African adolescent girls. There were identified gaps in information related to pregnancy prevention. In line with prevalent South African HIV prevention messaging (Abstinence, Be Faithful, and Condom Use: ABC), ABC prevention themes emerged along with an important role of peers. Interventions with a youth-focused format delivered within schools or via trusted community organizations were viewed as most acceptable. Development of culturally-sensitive dual protection intervention approaches incorporating study findings are urgently needed to address reproductive health disparities among South African adolescent girls.

ADOPTION OF PRE-EXPOSURE PROPHYLAXIS: QUALITATIVE ANALYSIS OF THE PERSUASION STAGE OF DIFFUSION FOR AFRICAN AMERICAN YOUNG MSM

Ashley Schuyler, MPH¹, Zainab Alidina, MPH¹, M. Margaret Dolcini, PhD¹, Gary W. Harper, PhD, MPH², J. Dennis Fortenberry, MD, MS³, Ryan R. Singh, MPH¹, Omar B. Jamil, Ph.D.⁴, Lance M. Pollack, PhD⁵, Joseph Catania, Ph.D.¹

¹Oregon State University, Corvallis, OR; ²University of Michigan, School of Public Health, Ann Arbor, MI; ³Indiana University School of Medicine, Indianapolis, IN; ⁴University of Michigan, Chicago, IL; ⁵University of California, San Francisco, San Francisco, CA

Background: African-American MSM represent the population with the greatest risk of HIV infection in the US, yet adoption of pre-exposure prophylaxis (PrEP) among African-American MSM remains low. Applying Diffusion of Innovations (DOI) theory can aid in the identification of antecedents to PrEP adoption, with perceived characteristics of the innovation (i.e., PrEP) playing a key role in the persuasion stage of adoption decision-making. We apply DOI theory to examine qualitative data describing perceptions of PrEP among a sample of high-risk African-American young MSM (AAYMSM).

Methods: Qualitative data were collected from a sample of HIV-negative and HIV-status unknown AAYMSM (N=181; 17–24 yrs.; 67% ≤ high school education) via individual interviews. Open-ended questions asked broadly about participants' experiences with and thoughts about PrEP. Descriptive coding techniques were used to analyze data and identify perceptions of PrEP's key characteristics.

Results: Data revealed AAYMSM to be at three stages of PrEP diffusion: knowledge (PrEP-unaware; 11.6%), persuasion (aware but hadn't adopted; 72.4%), and adoption/discontinuance (current or prior use of PrEP; 16.0%). Men in the persuasion stage discussed characteristics of PrEP they had learned about through vicarious experience via media/social networks. Perceptions of PrEP's efficacy and side effects emerged as the most prominent among men in this stage. Many men in this stage perceived PrEP to be effective and beneficial, while others described uncertainty or negative perceptions of PrEP's efficacy. Perceptions of side effects were more mixed. Collectively, data regarding efficacy and side effects revealed three sub-strata of readiness to adopt PrEP for men in the persuasion stage – highly ready (n=40), moderately ready (n=20), and least ready (n=9). Other less frequently mentioned characteristics of PrEP included those related to its relative advantage (e.g., compared to condoms) and compatibility (e.g., low level of HIV risk).

Conclusions: Applying DOI theory revealed key perceptions of PrEP among men who are aware of the HIV prevention tool, but had not yet adopted it. Future research aimed at developing quantitative measures to examine stages of PrEP diffusion and related factors can help in identifying and mitigating important barriers to PrEP adoption among AAYMSM.

SOMETIMES YOU GOTTA CHOOSE: INDEPTH QUALITATIVE ANALYSIS ON BARRIERS AND FACILITATORS TO PREP USE IN WOMEN WHO INJECT DRUGS

Sarah Bauerle, Bass, Ph.D. and MPH¹, Jesse A. Brajuha, MPH², Patrick J. Kelly, BSPH³, D'Avanzo A. D'Avanzo, MS¹, Jennie Coleman, MPH², Jose A. Benitez, MSW⁴

¹Temple University College of Public Health, Philadelphia, PA; ²Temple University, Philadelphia, PA; ³Temple University, Conshohocken, PA; ⁴Prevention Point Philadelphia, Philadelphia, PA

Background: Women who inject drugs (WWIDs) are at risk for HIV as they may engage in needle sharing and survival sex work. Pre-exposure prophylaxis (PrEP) reduces the risk of HIV acquisition yet little is known about the barriers this population may have to use this prevention medication.

Objective: To understand WWID's conceptualization of barriers and facilitators to PrEP use to inform the development of a targeted PrEP intervention that would be carried out in a syringe exchange program that also offers social services.

Methods: Four focus groups (n= 24) with WWID clients of a large urban syringe exchange were audiorecorded and transcripts were analyzed by content analysis; codes were derived deductively from the moderator's guide and inductively through emergence until thematic saturation and refinement was achieved.

Results: All participants were HIV negative; 58% were white; average age 35.3. Over half had income of \$500 or less in the past month, 62.5% said they were homeless "most of the time". Of the total, 66% had heard of PrEP and 41.6% had tried it. Most participants indicated an interest in PrEP but noted that seeing a doctor was a significant barrier. Other barriers included homelessness and potential theft of medication. Plans to dispense PrEP on site at the syringe exchange was encouraged, as well as providing it on a daily basis and in pill packs because prescription bottles can be sold on the street or to small pharmacies, a disincentive to adhere to PrEP. An intervention embedded in the syringe exchange was noted as an important strategy to decrease medical mistrust.

Conclusions: Barriers to PrEP use are significant in vulnerable WWID populations. Interventions must decrease perceptual, informational, and structural barriers for WWIDs, including how best to integrate services in existing, trusted community locations.

“A TARGET ON OUR BACKS”: EXPERIENCES OF PREP DECISION-MAKING AT AN LGBTQ YOUTH CENTER

Michael Holtzman, MA¹, Samantha L. Klein, B.A.², Sam Marcus, MA²¹The New School for Social Research, Brooklyn, NY; ²The New School for Social Research, New York, NY

The conversation around HIV prevention underwent a dramatic shift following the FDA's 2012 approval of the prescription drug Truvada as a pre-exposure prophylactic (PrEP) for HIV infection. Early trials demonstrated that adherence to a daily dosage of the drug may effectively reduce the risk of HIV-1 infection by more than 90% (CDC, 2014). Despite these findings, the decision to begin a PrEP regimen is a complicated process, involving frank discussions of sexual practices with medical providers, healthcare costs associated with the prescription, a mandated quarterly HIV/STI evaluation, and personal beliefs on medicalization (Biello et al. 2016; Strauss et al., 2016). For young people, this complex decision may be one of their first interactions as legal adults within the healthcare system. Published research on PrEP has focused on factors before and after the decision-making process, including various populations' knowledge about the drug, cultural perspectives and stigmas around PrEP users, issues of adherence, and changes in sexual practices following uptake (Blumenthal et al., 2015; Dolezal et al., 2015; Rucinski et al., 2013; Strauss et al., 2016; Thrun, 2013). Little attention, however, has been paid to the actual experiences of individuals labeled “high-risk” as they make the decision whether or not to begin a PrEP regimen. This qualitative study examined the PrEP decision-making experience of visitors at a Long Island-based non-profit dedicated to serving LGBTQ youth in the New York Metro area. Three semi-structured focus groups were run with a total of 14 participants, the data from which was developed into themes using Braun and Clarke's guide for thematic analysis (Braun and Clarke, 2013). Participants were aged 19–26, and self-identified as African American (n=6), Latinx (n=4), or Caucasian/White (n=4). All participants identified as men who have sex with other men. The following four themes were developed from the research: The Impact of Being Targeted; Feeling Protected; Moving through Ambivalence; Communal Responsibility versus Personal Choices. This research was undertaken with the aim of developing recommendations for advocacy organizations and medical providers on how to best guide young, diverse populations towards healthy and confident medical decision-making, despite a political and sociocultural climate that frequently threatens their personal agency.

“WALKING IN FAITH” - POSITIVE RELIGIOUS COPING ASSOCIATED WITH RESILIENCE FOR BLACK WOMEN LIVING WITH HIV AND HISTORIES OF TRAUMA

Sannisha K. Dale, PhD¹¹University of Miami, Miami, FL

Background: Black women in the U.S. account for over 60% of women living with HIV, a disproportionate burden linked to both structural (e.g. poverty) and psychosocial factors (e.g. stigma, trauma) that place Black women at increased risk. The HIV literature has historically focused on factors that place women with HIV at risk and less on factors that place them “at promise” for good psychological and physical outcomes. Religious coping has been noted as a particularly relevant and culturally congruent coping strategy within the Black community, and is therefore important to understand in relation to resilience factors, especially among Black women living with HIV (BWLWH). In the present study we investigated the cross-sectional associations between positive religious coping and resilience, post-traumatic growth, social support, generalized self-efficacy, and self-esteem among BWLWH and histories of trauma.

Methods: One hundred and nineteen BWLWH were enrolled and completed baseline assessment self-report measures for an intervention development study in the Southeastern U.S. Women completed measures on positive religious coping (Positive Religious Coping Subscale of the of the Brief RCOPE), resilience (i.e. Connor Davidson Resilience Scale), post-traumatic growth (i.e. Post-traumatic Growth Inventory), social support (i.e. Multidimensional Scale of Perceived Social Support), self-efficacy (i.e. Generalized Self-Efficacy Scale), and self-esteem (Rosenberg Self-Esteem Scale).

Results: Multivariate linear regressions controlling for age, education, and income showed that positive religious coping was significantly associated with higher resilience ($\beta=.663$, $p<.001$), post-traumatic growth ($\beta=.62$, $p<.001$), perceived social support overall score ($\beta=.21$, $p<.05$) and all three subscales (someone [$\beta=.34$, $p<.001$], family [$\beta=.65$, $p<.001$], friend [$\beta=.67$, $p<.001$]), generalized self-efficacy ($\beta=.77$, $p<.001$), and self-esteem ($\beta=.77$, $p<.001$).

Conclusion: For Black women living with HIV and histories of trauma it is essential to enhance our understanding of factors that may place this community at “promise” for good outcomes. Our findings highlight that positive religious coping is significantly associated with a wide-range of resilience factors. Therefore both research and interventions aimed at increasing resilience among Black women living with HIV need to consider and integrate positive religious coping.

*Equal contribution

Background: Stigma in healthcare settings is a continuing barrier to HIV prevention and treatment in the United States (US) and is particularly urgent to address in the US South. We aimed to assess HIV-related and intersectional stigma, as well as effects of stigma on health outcomes, at HIV clinics in this priority region.

Methods: We conducted a mixed methods study with a convergent parallel design at seven HIV clinics in rural and urban settings in Alabama and Tennessee during 2018. For qualitative research, we conducted 14 focus groups, including a total of 56 healthcare workers and 44 people living with HIV (PLWH). Quantitative surveys were also completed by 192 healthcare workers and 762 PLWH at these sites. Qualitative data were analyzed using a thematic analysis approach, while quantitative analyses utilized ANOVA and logistic regression methods.

Results: Primary themes emerging from qualitative data around healthcare setting stigma related to understanding and changing stigma, coping with stigma, and intersecting stigmas (e.g., stigma due to sex, gender identity, Southern culture). Clients described experiencing stigma in healthcare settings, particularly negative interactions with healthcare workers. They also discussed anticipated stigma from other community members who may frequent the same healthcare settings, and described how this stigma negatively affected their engagement in HIV care. Quantitative analyses revealed that clinic workers differed significantly on a measure of observations of discrimination in their healthcare setting by occupation, with administrative and support staff reporting significantly higher discrimination than allied health and prevention staff ($F(3, 188)=3.91, p=.01$). Clients reported higher perceptions of discrimination in healthcare settings relative to that reported by healthcare workers, and higher perceptions of discrimination were related to greater likelihood of suboptimal antiretroviral adherence among clients (standardized $b=1.66$, 95% CI: [1.09, 2.54]).

Conclusions: Our qualitative and quantitative findings indicate that stigma in healthcare settings is a continuing problem in HIV clinic settings in the US South, and may contribute to sub-optimal HIV outcomes. Interventions are needed to address stigma, even in HIV clinics where health workers are assumed to be more knowledgeable and empathic, but may not be aware of their stigmatizing attitudes and behaviors related to the various identities of PLWH.

A SYSTEMATIC REVIEW OF INTENSIVE OUTPATIENT CARE PROGRAMS FOR HIGH-NEED, HIGH-COST PATIENTS

Rebecca K. Delaney, PhD¹, Brittany L. Sisco-Taylor, PhD¹, Angela Fagerlin, PhD¹, Peter Weir, MD, MPH¹, Elissa M. Ozanne, PhD¹

¹University of Utah, Salt Lake City, UT

Background: A small proportion (5%) of the patient population account for 50% of U.S. healthcare expenditures. This population of high-risk, high-need patients are medically complex for numerous reasons, often including behavioral health needs. Intensive outpatient care programs (IOCPs) are emerging, innovative clinics which provide patient-centered care leveraging multidisciplinary teams. The overarching goals of IOCPs are to reduce emergency department (ED) visits and hospitalizations (and related costs), improve care continuity, and patient outcomes.

Purpose: The purpose of this review was to examine the effectiveness of IOCPs on multiple outcomes (e.g., costs, healthcare utilization, patient-reported outcomes) to inform clinical care.

Methods: A systematic search of the literature yielded 6 articles that met selection criteria.

Results: Studies varied in rigor of research design, analysis, and measurement of outcomes. Most studies reported evaluations of healthcare utilization ($n=4$) and costs ($n=3$), with fewer reporting results on patient-reported outcomes ($n=2$). Overall, there were decreasing trends in ED visits and hospitalizations. However, results on healthcare utilization varied based on time of follow-up, with shorter follow-up time yielding more significant results. Two of the three studies that evaluated costs, found significant reductions associated with IOCPs and one was identified as cost-neutral. Two studies reported improvements in patient-reported outcomes (e.g., satisfaction, depression, and anxiety).

Conclusion: Few studies evaluated patient characteristics and behaviors (e.g., engagement) which may serve as key mechanisms of program effectiveness. Future research should examine patient characteristics, behaviors, and clinic engagement metrics to inform clinical practice.

ADDRESSING DIABETES IN A SAFETY NET PRIMARY CARE CLINIC: EFFECTIVENESS OF LIFESTYLE REDESIGN OCCUPATIONAL THERAPY

Beth Pyatak, PhD, OTR/L, CDE¹, Jesus Diaz, OTD, OTR/L², Megan Linderman, OTR/L³, Stacey L. Schepens Niemiec, PhD, OTR/L¹, Elissa S. Lee, OTS⁴, Khatira Mehdiyeva, MD, MPH¹, Jeanine Blanchard, PhD, OTR/L¹, Elia Salazar, MPH⁵, Jagruti Shukla, MD, MPH⁶, Josh Banerjee, MD, MPH, MS⁷

¹University of Southern California, Los Angeles, CA; ²USC, Los Angeles, CA; ³University of Southern California, Rancho Santa Margarita, CA; ⁴University of Southern California, Berkeley, CA; ⁵USC Chan Division of Occupational Science and Occupational Therapy, Los Angeles, CA; ⁶LAC+USC Medical Center/LA Department of Health Services, Los Angeles, CA; ⁷LAC+USC Medical Center, Los Angeles, CA

Background: Primary care is an essential component of a well-functioning health care system. With the rise of chronic conditions, the US healthcare system has experienced enhanced demand for primary care services combined with a shortage of primary care professionals, increased burnout rates, and decreased access to health services. To address these issues, restructure of this sector is necessary, with interprofessional team-based care playing a key role in improving access and quality of care. To investigate the impact of integrating occupational therapy (OT) services within an interprofessional primary care team, we completed a hybrid effectiveness-implementation study of Lifestyle Redesign OT (LR-OT) in a safety net primary care clinic, with an initial focus on improving diabetes care.

Methods: Patients with diabetes and HbA1c >9.0% were enrolled using a randomized consent design in which patients were assigned to (a) be referred to LR-OT (n=73), or (b) serve as a no-contact comparison group (n=69). Patients who accepted the LR-OT referral (n=51) completed informed consent, pre-post surveys (SDSCA, SF-20), and up to 8 sessions of LR-OT. All randomized patients (n=142) had HbA1c and systolic and diastolic blood pressure (SBP/DBP) data extracted from the EMR for 6 months prior to, and 6 months following, their study enrollment date. EMR data from all randomized participants were compared on an intention-to-treat basis; pre-post surveys were analyzed among program completers (n=37).

Results: The average change in HbA1c in the 6-month intervention period, compared to the 6 months prior to the intervention, was -1.14 and -0.83 for the LR-OT and control groups respectively (Cohen's d=0.32). Similarly, blood pressure decreased in the LR-OT group and increased in the control group, producing effect sizes of 0.33 (SBP) and 0.35 (DBP). Pre-post data among program completers demonstrated significant positive changes in HbA1c (-0.9% decrease, p=0.003), health behaviors (SDSCA healthy eating +1.1 days/wk, p< 0.0001; blood glucose monitoring +1.3 days/wk, 0.003), and health status (SF-20 physical function +11.9, p=0.0003; mental function +7.3, p=0.02).

Discussion: Overall, findings demonstrate improvements in HbA1c, health behaviors, and overall health status among program completers, and favorable changes in HbA1c and BP in all patients, with a trend towards a more positive rate of change in the LR-OT group as compared to control group. We theorize that the improvements in HbA1c and BP among both treated and untreated patients may be, in part, due to positive changes in practice patterns clinic-wide attributable to the introduction of OT. As the pilot study lacked a comparison clinic with which to compare outcomes, further research is needed to investigate to what extent the improvement in untreated patients reflects such changes in practice patterns relative to other factors.

UNDERSTANDING THE RELATIONSHIP BETWEEN NUTRITION AND ADOLESCENT'S MENTAL HEALTH: FOOD FOR THOUGHT

Kyler Lehrbach, B.A.¹, Anthony Spirito, PhD², Shira Dunsiger, PhD³, Megan Ranney, MD, MPH, FACEP⁴

¹Rhode Island Hospital/Brown University, Providence, RI; ²Brown University, Providence, RI; ³The Miriam Hospital and Brown University, Portsmouth, RI; ⁴Alpert Medical School, Brown University; Rhode Island, Providence, RI

Nutrition impacts adolescent mental health during a crucial time when depressive symptoms often develop. One previous study found connections between teens' depressive symptoms and dietary habits: higher depressive symptoms were associated with higher intake of energy-dense food (e.g. junk food/soda) but were not associated with vegetable consumption. This study concluded that attention to negative emotions might be beneficial and important to preventing and treating obesity, but also begs the question of whether attention to healthy eating may positively affect mood. To further elucidate this relationship, the present study examined the association between depressive symptoms, soft drink consumption, and vegetable consumption among a sample of adolescents (N=1243, 47% female, 29% Hispanic, mean age 14.9 years) presenting to an emergency department for any reason. Self-report data from screening surveys for iDOVE1, a study to prevent depression and peer violence in teens, were analyzed to identify associations between depressive symptoms and nutrition. Past 2-week depressive symptoms were measured by the Patient Health Questionnaire-9; nutrition habits were measured by the Youth Risk Behavior Survey about vegetable consumption and soft drink consumption in the last week. For the purpose of the present analysis, depressive symptoms and vegetable consumption were analyzed as continuous variables, while soft drink consumption was dichotomized (at least 1 soft drink in the last week vs. none due to skewed distribution). A multiple linear regression model was used to test the association between vegetable consumption and soft drink consumption on depressive symptoms, adjusting for age, gender, race, and SES. Results suggest a significant association between at least some soft drink consumption (B=.59 SE=.275 (p< .05)) and depressive symptoms but no significant association between vegetable consumption and depressive symptoms. Specifically, after adjusting for demographic and SES variables, as well as vegetable consumption, those who reported drinking at least one soft drink/week had a .59 unit higher mean depressive symptoms score compared to those who reported no consumption. Forthcoming analyses will explore the potential interaction between the two nutrition variables and their association with depressive symptoms. While the current study did not examine reciprocal effects of depressive symptoms on nutrition habits, the results do suggest a need for understanding the role of nutrition on mental health outcomes. Future research should explore how consistently these associations are found in other populations and focus on implementing programs to educate adolescents on the importance of nutrition and its relationship with mental wellness.

IF YOU BUILD IT, WILL THEY COME? A MIXED METHODS STUDY OF CARE MANAGER PERSPECTIVES ON INTEGRATING MHEALTH INTO CLINICAL WORKFLOWS

Jared Bechtel, BA, BS¹, Amy M. Bauer, MD, MS¹, Erin M. LePoire, MPH¹, Deborah J. Bowen, Professor¹, John Fortney, PhD¹¹University of Washington, Seattle, WA

Background: Despite high interest in mobile platforms to transform care for chronic illnesses, including mental health disorders, there are few reports in the literature documenting implementation at scale in real-world settings.

Purpose: To understand Behavioral Health Professionals' (BHP) perspectives on the adoption and use of an Android-only mobile health platform deployed in the context of a pragmatic trial testing a collaborative care program for patients with PTSD and/or bipolar disorder in rural settings.

Methods: BHPs currently employed at one of 12 rural Federally Qualified Health Centers (FQHCs) in Washington, Arkansas, or Michigan with at least 1 Collaborative Care patient encounter recorded were invited to participate in a 60-minute semi-structured interview. Interviews used the Unified Theory of Adoption and Use of Technology 2 (UTAUT2) as a conceptual model and explored BHPs' experiences using the mobile platform, barriers to integration, and perceptions of its impact on clinical care. Interviews were audio-recorded, transcribed, and coded by 2 independent coders with reasonable agreement. When disagreements arose they met with an arbitrator to achieve consensus.

Results: Of 25 eligible BHPs, we interviewed 15 from 10 FQHCs. All BHPs agreed the platform only being available on Android phones restricted recruitment and integration. BHPs suggested making it available on iPhones and web browsers. BHPs also reported that the limited technology infrastructure in communities served by rural FQHCs was a barrier to adoption. Some patients who were not willing to engage in care via traditional methods would monitor their symptoms asynchronously via the app, but some BHPs expressed concern that use of a mobile app does not constitute active treatment. BHPs generally felt comfortable using mHealth tools, but incomplete adoption by patients and incompatibility with existing workflows interfered with wider use. The UTAUT2 model provided partial understanding of use patterns, but additional factors important to behavioral health use emerged such as crisis management and patient engagement.

Conclusions: To maximize adoption, mobile platforms should be deployed in settings with sufficient technological infrastructure and fully integrated into the clinical workflow. Future analyses will explore additional barriers and facilitators to system adoption using meta-data from the mobile platform, patient data from evaluative surveys, and encounter data from a care management tracking system.

MEASURING RESPONSES TO HEALTH ANXIETY: DEVELOPMENT OF A NEW QUESTIONNAIRE

Salene M. Jones, PhD, MA, LP¹, M. Robyn Andersen, PhD, MPH¹, Paul Litwin, MS¹¹Fred Hutchinson Cancer Research Center, Seattle, WA

Background: Health anxiety includes fear that one has a serious illness that has not been diagnosed. Previous research on health anxiety tends to focus on one coping mechanism, seeking reassurance that one is healthy, while the coping response of avoiding health information has received less attention. This study developed new measures of responses to health anxiety (avoidance, reassurance seeking).

Methods: Participants recruited through Prolific Academic completed an online survey (n=398). Eleven items were generated to measure health anxiety avoidance and reassurance seeking, based on previous literature. A patient advocate reviewed the questions. Psychometric analyses included tests of factor structure, reliability and validity.

Results: Exploratory and confirmatory factor analysis suggested four factors for the responses to health anxiety measure: general avoidance of health reminders; avoidance of medical care; general reassurance seeking; and reassurance seeking through medical care. Scores showed good internal consistency considering the number of items. The four measures of health anxiety response were moderately correlated (0.23–0.51) suggesting each measures a unique construct. All were positively associated with overall health anxiety (b's range 0.11 to 0.37) in multivariate analyses. General avoidance (b=0.06, p=0.02) and avoidance of medical care (b=0.04, p=0.046) were associated with general anxiety while general reassurance seeking (b=0.03, p=0.16) and medical reassurance seeking (b< 0.01, p=0.79) were not significantly associated with general anxiety in multivariate regressions. None of the four factors were associated with global mental health (p's >0.06).

Conclusions: Assessing the response to health anxiety may be crucial for determining impact on patients and planning treatments for health anxiety. The new measure can be used in research and, pending further validation, clinical care. Future research is needed on the impact of responses to health anxiety in populations with chronic illness, such as for fear of recurrence in cancer.

ACCEPTANCE OF ILLNESS AMONG PATIENTS PURSUING TRANSPLANTATION

Lisa R. Miller-Matero, PhD, ABPP¹, Mary Kate Miller, Psy.D.², Leah Hecht, PhD¹, John Son, MPH³, Shu Ling, MA⁴, Farah Elsis, M.S., TLLP⁵, Kelly Bryce, PhD⁶

¹Henry Ford Health System, Detroit, MI; ²Henry Ford Health System, Randolph, MA; ³Wayne State University School of Medicine, Detroit, MI; ⁴Henry Ford Health System, Copley, OH; ⁵Henry Ford Health System, Dearborn Heights, MI; ⁶Henry Ford Health System, Royal Oak, MI

Introduction: Acceptance of illness (i.e., continuing to find value in life despite the illness) has been linked to better mental health outcomes in patients with chronic diseases. This may be especially important among patients being considered for organ transplant, as emotional distress is related to poorer medical outcomes. However, acceptance of illness has not been assessed among patients pursuing transplant. The purpose of this study was to create a measure of illness acceptance and examine this construct's relationships with known risk factors for negative health outcomes following transplant.

Methods: Retrospective chart reviews were conducted for patients who completed a required pre-surgical psychological evaluation for lung or heart transplant, or left ventricular assist device (N= 290). During the evaluation, patients completed measures to assess mental health symptoms (Hospital Anxiety and Depression Scale), cognitive functioning (Montreal Cognitive Assessment), health literacy and numeracy, and catastrophizing. Patients also completed the Illness Acceptance Scale (IAS). To create the IAS, potential items were developed by two psychologists. These were then rated on goodness of fit to the construct from poor to excellent by 7 additional psychologists. Items were retained for the scale if they had an average rating of good to excellent fit.

Results: Patients primarily identified as African American (65.9%) and male (66.2%), with a mean age of 56 years. Patients were being considered for a left ventricular assist device and/or heart transplant (53.1%), lung transplant (46.6%), or both (.3%). Internal consistency for the IAS was excellent (Cronbach's alpha = .92). Acceptance of illness was negatively correlated with depression ($p < .001$), anxiety ($p < .001$), and catastrophizing ($p < .001$). Acceptance of illness was not related to cognitive functioning ($p = .07$), health literacy ($p = .35$) or health numeracy ($p = .29$).

Discussion: The Illness Acceptance Scale is a reliable measure for patients who are pursuing transplant. There was also evidence of convergent and divergent validity. A greater level of illness acceptance was related to fewer depressive and anxiety symptoms as well as lower levels of catastrophizing. This suggests that interventions aimed at increasing acceptance of illness may improve these symptoms among transplant candidates. Future research should evaluate whether increasing illness acceptance leads to better psychological and medical outcomes.

LIFESTYLE MEDICINE FOR MENTAL HEALTH: A META-REVIEW OF THE TOP-TIER EVIDENCE

Joseph Firth, PhD¹

¹University of Manchester, Manchester, England, UK

There is increasingly large global interest in how behaviours typically associated with physical health (such as physical activity, diet, and smoking) may also be instrumental in mental health and psychological well-being. Within this, multiple national health bodies and professional organisations have begun to produce guidelines around the role of health behaviours such as physical activity, diet, sleep and smoking cessation in the promotion of mental health, and prevention of mental disorders. However, the overall evidence for using these lifestyle factors to reduce the risk of mental illness, or to improve recovery in those with mental health conditions, is unclear. Therefore, we performed a meta-review of all of the published 'top-tier evidence' (including meta-analyses of randomized controlled trials and prospective studies, along with Mendelian randomization studies) examining the role of physical activity, sedentary behaviour, sleep quality and duration, various dietary factors and smoking/tobacco consumption in the incidence and prognosis of mental illness. Through systematic aggregation of the findings from these multiple forms of top-tier evidence, we have produced evidence overviews for targeting specific lifestyle factors in the prevention and treatment of various mental disorders, including depression, anxiety, psychotic and bipolar disorders and ADHD. The results of the evidence syntheses, and directions for lifestyle interventions each of these disorders, will be presented in the session.

IS SCROLLING BAD FOR EVERYONE? EXPLORING INDIVIDUAL NETWORKS OF INSTAGRAM USE AND MOOD

Allison D. Altman, M.A.¹, Aaron Fisher, Ph.D.²

¹University of California, Berkeley, Oakland, CA; ²University of California, Berkeley, Berkeley, CA

Instagram has over 1 billion active users per month, and recent research has connected its use with myriad negative outcomes, including depression and lower self-esteem. Other findings, however, have produced equivocal results, indicating that use is not harmful. This present study investigated Instagram use on an idiographic basis to see if the true answer lies within the individual; that use is bad for specific people, but not necessarily for everyone. Using ecological momentary assessment, we examined the relationships amongst Instagram use and mood. We employed contemporaneous analyses to examine how these specific constructs were associated at any given point in time. Subjects ($n=51$) were surveyed on Instagram use and mood for 21 days. Nomothetic and idiographic network models were employed to the data, using strength centrality as a measure to indicate the strength of using Instagram with other nodes in each individual network. Results indicate a significant variability in the relationship between Instagram use and mood amongst the networks. The mean was 0.194, indicating that for the average participant there was not a very strong relationship between the *Used Instagram* node and the other nodes in the networks. The method's potential for analysis of individual symptom patterns is further demonstrated by three exemplar participants, with normalized strength centralities ranging from 0.020–0.502. Our findings highlight individual differences amongst social media use and underscore the importance of investigating the potential detrimental effects of social media use on an individual basis.

TOBACCO CESSATION SERVICES IN LGBT-SERVING MENTAL HEALTH FACILITIES IN THE U.S.

Alexandra Budenz, MA, DrPH¹, Yvonne A. Prutzman, PhD, MPH¹¹National Cancer Institute, Rockville, MD

Background: LGBT populations have higher rates of both tobacco use and mental health conditions than heterosexuals, suggesting a need for integrated mental health and tobacco cessation services specific to these populations. However, the extent to which LGBT-serving mental health treatment facilities offer integrated tobacco cessation resources is unknown. Furthermore, the prevalence of smoke-free policies in these facilities (smoking prohibited on the premises) has yet to be examined.

Methods: We used the 2017 National Mental Health Services Survey of 11,582 mental health treatment facilities in the U.S. to describe the characteristics of LGBT-serving mental health facilities that provide tobacco cessation services. We also assessed the prevalence of smoke-free policies in these facilities.

Results: Approximately 16% of mental health treatment centers provided LGBT-focused services. Of these LGBT-serving facilities, 63% provided any tobacco cessation service. The state with the most LGBT-serving facilities providing cessation services was New York (88% of New York LGBT-serving facilities). The most common cessation services provided across facilities were tobacco screening (87%) and cessation counseling (77%). The least common services were non-nicotine cessation medications (54% did not provide) and nicotine replacement therapy (NRT) (55% did not provide). Only half of LGBT-serving facilities had smoke-free policies.

Conclusions: A large proportion of U.S. LGBT-serving mental health treatment facilities provide tobacco cessation services. However, the provision of these services is not ubiquitous, and not all facilities provide comprehensive services. Specifically, non-nicotine cessation medications and NRT may be provided less frequently, despite demonstrated efficacy. Increased provision of comprehensive tobacco cessation services and implementation of smoke-free policies in all mental health facilities can improve both tobacco cessation and mental health outcomes in LGBT populations.

FAMILY STRAIN PREDICTS SUBSEQUENT DEPRESSIVE SYMPTOMS: HOPE MEDIATES AND SELF-COMPASSION MODERATES THE RELATION

Erin G. Mistretta, M.A.¹, Mary C. Davis, Ph.D.², Ellen M. Yeung, Ph.D.³¹Arizona State University, Mesa, AZ; ²Arizona State University, Tempe, AZ;³George Washington University, Washington, DC

Interpersonal strain is linked with depressive symptoms in middle-aged adults. One possible mechanism accounting for this relation is a reduction in hope, defined as the belief in one's capacity both to reach and to generate a variety of ways to obtain goals. The strength of the strain-depressive symptoms relation is not uniform across individuals, however, pointing to the likelihood that individual differences in the ability to successfully navigate relationship strain play a role in mitigating its negative effects. One potential moderator of the strain – depressive symptoms relation is self-compassion, which encompasses the capacity to respond to one's own negative thoughts and experiences in a kind and nonjudgmental way. Although theory and empirical evidence suggest that self-compassion is protective against the impact of stress on mental health outcomes, little research has investigated how self-compassion operates in the context of relationship strain. In addition, few studies have examined psychological mechanisms by which self-compassion protects against mental health outcomes, depression in particular. Thus, this study examined 1) the extent to which hope mediates the relation between family strain and depressive symptoms, and 2) whether these indirect effects are conditional on self-compassion in a community sample of middle-aged adults.

Self-reported family strain, self-compassion, hope, and depressive symptoms were assessed in a community sample of 762 middle-aged adults aged 40–65. Follow-up measures of depressive symptoms were assessed approximately 20 months later. Results from structural equation models indicated that hope mediated the relation between family strain and depressive symptoms and the indirect effect was conditional on levels of self-compassion. For individuals high versus low in self-compassion, strain-related declines in hope predicted smaller increases in depressive symptoms.

Taken together, the findings suggest that family strain may lead individuals to experience less hope and subsequent increases in depressive symptoms. However, a self-compassionate attitude may serve as a resilience resource, weakening the hope – depressive symptoms relation, a finding that holds promise for future research on the development and refinement of self-compassion interventions.

SOCIAL MEDIA EXPERIENCES AMONG DEPRESSED AND NON-DEPRESSED YOUNG ADULTS

Ariel Shensa, MA¹, Beth L. Hoffman, MPH¹, Cesar G. Escobar-Viera, PhD, MD¹, Eleanna Melcher, BA, BPhil¹, Jaime E. Sidani, PhD, MPH, CHES¹, Sara Myers, MD, MS¹, Brian A. Primack, MD, PhD², Jessica G. Burke, PhD¹

¹University of Pittsburgh, Pittsburgh, PA; ²University of Arkansas, Fayetteville, AR

Introduction: While an increasing amount of social interaction occurs on social media (SM), the impact of SM on mental health among young adults is not fully understood. In this qualitative investigation, we explored the positive and negative aspects of SM experiences in order to provide insight into the range of SM experiences for depressed and non-depressed young adults.

Methods: We conducted a national online survey of U.S. adults ages 18 to 30 in March 2018. Participants were asked about how SM has had 1) positive and 2) negative effect(s) on their lives using two open-ended questions. The 9-item Patient Health Questionnaire (PHQ-9) was used to select a purposeful random sub-sample of 50 participants with severe depressive symptoms and 50 without depressive symptoms. We utilized thematic analysis incorporating elements of content analysis to systematically identify themes in participants' responses which were then compared between depressed and non-depressed cohorts using descriptive statistics.

Results: Sixteen themes emerged regarding the perceived effects of SM: nine positive and seven negative. For both depressed and non-depressed participants, *connection with others* and *exposure to others' negativity* were the most frequently mentioned positive and negative effect of SM, respectively. Whereas positive effects of SM were reported with similar frequency between depressed and non-depressed participants, more variation was observed in reports of negative effects between the two cohorts. SM was noted as a *distraction from real life* more often by non-depressed than depressed participants (n=15 and n=5, respectively). *Fear of being judged* was mentioned solely by depressed participants (n=7).

Conclusion: While SM may be beneficial for both depressed and non-depressed participants insofar as it is perceived as a method of social connection, participants reported negative effects for which tools to filter exposure to negative content may be useful. Depressed participants more frequently reported several negative effects of SM, which may reflect cognitive and emotional sensitivities associated with depression. Future research using more in-depth qualitative probing may further elucidate these findings and inform recommendations for optimal SM use.

A MENTAL HEALTH INFORMED PHYSICAL ACTIVITY INTERVENTION DELIVERED ONLINE FOR FIRST RESPONDERS AND THEIR INFORMAL CARERS

Grace McKeon, n/a¹, Ruth Wells, PhD¹, Zachary Steel, PhD¹, Jill Newby, PhD¹, Simon Rosenbaum, BSc, PhD²

¹University of New South Wales, Sydney, New South Wales, Australia; ²UNSW Sydney, SYDNEY, New South Wales, Australia

Background: First-responders (police, fire and ambulance officers) are at a significantly increased risk of experiencing poor mental health, including depression, anxiety and post-traumatic stress disorder. Physical activity (PA) interventions can improve mental health outcomes in populations experiencing poor mental health. More research is however needed to evaluate accessible, low cost ways of delivering such programs. Social media may be a potential platform for delivering group-based PA interventions. It is well established that informal caregivers including partners, family and friends play an important role in supporting people with mental health problems but often at the expense of their own health. This study therefore aims to determine if an online PA intervention delivered through Facebook is feasible, acceptable and efficacious in improving mental health in first-responders and their informal caregivers. The iterative development of this intervention has occurred through collaboration with advisors with lived experience of working as a firefighter, and of living with mental illness.

Methods: We co-designed a 10-week, PA program delivered via a private Facebook group. The research team delivered education and motivation around different weekly topics (e.g. goal setting and reducing sedentary behaviour) and provided participants with a FitBit. First-responders were asked to nominate an informal caregiver to also participate. We assessed feasibility and also explored the impact on mental health symptoms, sleep quality, quality of life and PA levels. A multiple time series design compared slope of change between baseline and intervention in levels of psychological distress, measured every 2 weeks. A slope was fitted to the repeated scores during the baseline (control) and the intervention.

Results: Twenty-four participants (12 first-responders and their caregivers) were recruited and 88% (n=21) completed post-assessment questionnaires. The program was feasible and well accepted. Exploratory analyses of pre and post outcomes found significant reductions in total depression, anxiety and stress scores (p=0.047), and quality of life (p=0.0005). A significant improvement in self-reported minutes of walking (p=0.037) was found, but not in sedentary time or structured exercise. Changes in perceived social support to exercise (p=0.065) and sleep quality (p=0.2846) were not significant. Levels of psychological distress did not change significantly during the baseline; b = -0.09, p = 0.765, while during the intervention they decreased significantly, b = -1.067, p = 0.003.

Conclusion: The results of our pilot show that using Facebook to deliver a mental health informed PA program is feasible and yields significant improvements in mental health symptoms and quality of life. These promising pilot results have informed a large-scale trial which is currently underway.

ASSOCIATIONS OF MEETING 24-HOUR MOVEMENT GUIDELINES AND MENTAL HEALTH AMONG US CHILDREN AND ADOLESCENTS.

Ciarán P. Friel, EdD¹, Andrea T. Duran, PhD², Jeffrey L. Birk, PhD², Ari Shechter, PhD¹, Keith M. Diaz, PhD¹¹Columbia University Medical Center, New York, NY; ²Columbia University Irving Medical Center, New York, NY

Background: Emerging evidence suggests optimal child health is maintained by concurrently attaining appropriate levels of physical activity (PA), screen time, and sleep (i.e., a “healthy 24 hours”). However, few data exist on the association between meeting guidelines for these movement behaviors and mental health – data vital to inform interventions designed to combat increasing rates of mental health disorders in children. The purpose of this study was to examine the associations of meeting movement guidelines (PA, screen time, and sleep) separately, and in combination, with mental health disorders (depression, anxiety, and attention-deficit/hyperactivity disorder [ADHD]) among US children.

Methods: This analysis used data from the 2016–2017 National Survey of Children’s Health, a nationally representative sample. Children’s PA, screen time, and sleep were assessed by parental report. To assess depression, parents were asked: “Has a doctor or other health care provider EVER told you that (child’s name) has Depression?” Analogous questions were asked for anxiety and ADHD. Logistic regression was used to examine the association of meeting movement guidelines (7 d/wk with >60 min of PA; < 2 h/day of TV viewing and computer use; 9–12 h sleep for ages 6–12; 8–10 h for ages 13–17) with mental health disorders.

Results: Meeting each of the movement guidelines was associated with a lower odds of depression (PA odds ratio [OR]: 0.58; 95% CI: 0.43, 0.78; sleep OR: 0.50; 95% CI: 0.41, 0.62; screen time OR: 0.50; 95% CI: 0.38, 0.65), anxiety (PA OR: 0.59; 95% CI: 0.48, 0.73; sleep OR: 0.57; 95% CI: 0.48, 0.67; screen time OR: 0.74; 95% CI: 0.61, 0.89), and ADHD (PA OR: 0.80; 95% CI: 0.66, 0.97; sleep OR: 0.76; 95% CI: 0.62, 0.92); with the exception of screen time and ADHD (OR: 0.89; 95% CI: 0.74, 1.07). Meeting a greater number of movement guidelines was dose-dependently associated with lower odds of depression, anxiety, and ADHD (Table).

Conclusion: Among US children, meeting one or more movement guidelines is associated with reduced likelihood of having depression, anxiety, and ADHD, with the greatest reduction found when meeting PA, screen time, and sleep guidelines simultaneously. The present findings cannot test causal associations but raise the possibility that initiatives targeting 24-hour movement behaviors may help to combat rising mental health disorder rates in US youth.

Table. Odds Ratio of Depression, Anxiety or ADHD Among Children meeting 0, 1, 2 or 3 Guidelines in the 2016–2017 National Survey of Children’s Health

	Depression	Anxiety	ADHD
Movement Guidelines Met	OR (95% CI)	OR (95% CI)	OR (95% CI)

EXPERIENCES OF LAYERED STIGMA AMONG PATIENTS WITH CO-MORBID DIABETES AND DEPRESSIVE SYMPTOMS IN INDIA

Leslie Johnson, PhD, MPH, MLitt¹, Lydia Chwastiak, MD, MPH², Deepa Rao, PhD², Nikhil Tandon, MBBS, MD, PhD³, Viswanathan Mohan, MD, PhD, DSc⁴, Ranjit Mohan Anjana, MBBS, MD, PhD⁴, Subramani Poongothai, PhD⁴, Mohammed Ali, PhD, MSc, MBA⁵¹Emory University, Stone Mountain, GA; ²University of Washington, Seattle, WA; ³All India Institute of Medical Sciences, New Delhi, Andhra Pradesh, India; ⁴Madras Diabetes Research Foundation, Chennai, Tamil Nadu, India; ⁵Emory University, Atlanta, GA

Persons with comorbid type 2 diabetes mellitus (T2DM) and depression face self-care challenges due to the stigma of mental illness and diabetes. There is evidence that the health effects of stigma are additive when a person is affected by multiple stigmatized conditions, or if he/she also belongs to a socially deviant or marginalized group, yet, research on the phenomenon of stigma layering has almost exclusively been investigated among persons with HIV/AIDS. As the global prevalence of diabetes continues to rise, particularly in low- and middle-income countries, it is critical to assess how chronic-disease self-management and treatment-seeking behaviors change when individuals experience intersecting forms of stigma. We, therefore, explored perceptions of stigma among patients with T2DM and depressive symptoms. Patients participating in an integrated depression and diabetes treatment care model across two urban diabetes clinics in India were recruited to complete semi-structured interviews as a part of a trial process evaluation. Sixty-two individuals participated, twenty-seven from a government clinic in north India and thirty-five from a private clinic in south India. An intersectional analysis was conducted to analyze the qualitative data. The analysis identified 3 salient themes: fear of becoming a burden, controlling the narrative, and shifting concentration to promote health. These themes reflected experiences of stigma in interpersonal relationships. Patients expressed a greater willingness to disclose and seek treatment for secondary diagnoses as a result of what circumstances patients qualified as evoking shame. Additionally, experiences of socioeconomic disadvantage were described as increasing individuals’ vulnerability to mental illness and creating barriers to chronic disease self-care and treatment adherence. Results may inform intervention efforts to minimize patients’ self-stigma in chronic care settings.

FRAMEWORK MATRIX ANALYSIS FOR INTERVENTION DEVELOPMENT, AN EFFICIENT AND EFFECTIVE APPROACH TO QUALITATIVE DATA

Katherine D. Vickery, MD, MSc¹, Sarah Clausen, MA¹, Rochelle K. Rosen, PhD², Andrew M. Busch, PhD³¹Hennepin Healthcare Research Institute, Minneapolis, MN; ²Brown University School of Public Health, Providence, RI; ³Hennepin Healthcare/University of Minnesota, Saint Paul, MN

Introduction: The value of qualitative data in intervention development has long been recognized. It is especially helpful in Phase 1 and 2 trials during the process of intervention development or adaptation. Many health behavior researchers, however, may lack the training and time that traditional thematic analysis approaches (e.g., grounded theory) require. Further, these techniques may not align with goals and timelines of efficient behavioral intervention development. We describe the application of an established, but under-used, qualitative research method, framework matrix analysis (FMA). We present a schema for applying FMA to intervention development using a recently completed project adapting an intervention for depression and multiple health behavior change in cardiac event patients as an example.

Methods: We conducted semi-structured qualitative interviews with 10 depressed cardiac event patients and 8 providers who regularly treat these patients. We applied FMA to verbatim transcripts. This involved a five-step process of: (1) familiarization, (2) identifying a thematic framework, (3) indexing, (4) charting, and (5) mapping and interpretation. All steps in this process involved iterative review of transcripts by two or more trained researchers and structured team meetings to review, compare, and discuss emergent content.

Results: (1) Familiarization with transcripts resulted in parallel thematic frameworks for patients and providers. (2) Themes included *a priori* topics from the semi-structured interview guides (e.g., barriers to behavior change) and emergent themes (e.g., stigma regarding mental health treatment). Our conclusions were informed by our application of codes to transcripts (3, indexing) and abstraction of key content for each theme in each transcript (4, charting) and the formation of a unified document summarizing input from all transcripts for each theme (5, mapping). FMA results informed adaptations in intervention structure (in-person vs. telephone vs. home visits), content (e.g., sequential rather than concurrent behavior change), and language (e.g., de-stigmatizing language regarding mental health). FMA findings also reinforced aspects of the planned manual that did not need adaptation (e.g., choice of interventionist, overarching treatment approach).

Discussion: FMA offers a structured, approachable method for using qualitative data collection to develop behavioral interventions in a timely manner.

DOES RACIAL/ETHNIC CONCORDANCE BETWEEN PARTICIPANTS AND RESEARCHERS PREDICT STUDY ENGAGEMENT? A MULTI-LEVEL ANALYSIS

Irina Mindlis, MPH¹, David Livert, PhD², Alex Federman, MD, MPH³, Juan P. Wisnivesky, n/a³, Tracey A. Revenson, PhD⁴¹The Graduate Center, City University of New York, New York, NY; ²Penn State University, Lehigh Valley, Easton, PA; ³Icahn School of Medicine at Mount Sinai, New York, NY; ⁴Hunter College, City University of New York, New York, NY

Introduction: The differential attrition of racial/ethnic minority participants in clinical research is a major threat to advancing medical and behavioral science. Racial/ethnic concordance between study participants and research staff has not been systematically explored. Our aim was to examine the influence of racial/ethnic concordance between participants and research staff on study attrition.

Methods: Pooled data from participants and clinical research coordinators (CRCs) in six longitudinal studies of adults with asthma or chronic obstructive pulmonary disease. Dyads were concordant if the patient and research coordinator were of the same racial/ethnic group. Attrition was operationalized as lack of participation in the second study interview (Time 2), and one year after enrollment. Multilevel modeling examined the effect of racial/ethnic concordance on attrition at each study time point while accounting for nesting by CRC and controlling for sociodemographic factors previously identified as relevant to attrition.

Results: The sample of 509 adults (71% female) had a mean age of 66 years (SD = 9.7). Participants were diverse in terms of race and ethnicity: 47.7% identified as Latino; 31.6% as Black; and 20.7% as non-Hispanic White. Spanish language, lower education, and greater depressive symptoms predicted greater attrition, but these main effects disappeared in adjusted models. Race/ethnicity, age, gender and health literacy did not predict attrition. Racial/ethnic concordance was significantly associated with attrition at time 2 ($b = 1.59$, $SE = .47$, $p < .001$) and at one year ($b = 1.35$, $SE = .48$, $p = .005$). That is, there was greater attrition among concordant than discordant dyads and this effect was substantial: Participants in concordant dyads had 5 times greater odds of dropping out at Time 2, and 4 times greater odds at one year compared to those in discordant dyads.

Conclusion: Racial/ethnic concordance between participants and research staff was related to greater attrition in a large sample of individuals with respiratory illness. If the individuals who complete longitudinal studies are not representative of those experiencing poorer health outcomes, the validity of the study's conclusions is threatened. Interactions with research staff may be critical to bridging the health disparities gap and should be considered important parts of the study environment.

DEVELOPING AN INSTRUMENT TO EVALUATE THEORY-BASED PSYCHOSOCIAL CONSTRUCTS RELATED TO INCREASED FIBER CONSUMPTION

Paul Branscum, PhD, RD¹¹Miami University, Oxford, OH

Background: Obesity is a major public health concern, with low consumption of fiber-rich foods, such as fruits and vegetables, commonly cited as a causal factor. Public health interventions should have a strong theoretical basis, as theory-based interventions are more effective than those that do not utilize theory. The Reasoned Action Approach (RAA) is a new and emerging theory in social and behavioral science, containing constructs from theories such as the Theory of Planned Behavior, and Health Belief Model. While a promising theory, the RAA has not been extensively used in research and practice. Moreover, valid and reliable surveys have yet to be developed for this model.

Purpose: The purpose of this study was to show the development of an instrument measuring the constructs of the RAA in regards to fiber consumption. Both direct and indirect measures were developed.

Methods: First, all of the constructs of the RAA were constitutively and operationally defined. Next, a qualitative study was done to elicit behavioral beliefs (advantages/disadvantages), injunctive normative beliefs (referents who approve/disapprove), descriptive normative beliefs (referents who are most/least likely), and control beliefs (factors that enable/prevent). Afterwards, a panel of 6 experts established face and content validity of the survey. Finally, data were collected from an adult sample (n=878), and psychometric data revealed indices of construct validity (confirmatory factor analysis) and internal consistency reliability (Cronbach's alpha).

Results: The average age of adults was 51.5 years (± 12.8), and a majority were Caucasian (81%), and women (93%). Results showed the top beliefs as: behavioral beliefs [a] lose weight, b) have more energy; injunctive normative beliefs [a] parents, b) doctor; descriptive normative belief [a] people who are trying to lose weight, b) friends; and control beliefs [a] planning my meals ahead of time (enable), b) having someone else plan my meals (enable), and c) not having enough time (prevent). With regards to construct validity, the model structural had adequate fit [Root Mean Square Error of Approximation=0.063; Tucker Lewis index=0.952; Comparative Fit Index=0.960], and all items significantly loaded on its corresponding scale. For internal consistency reliability, Cronbach's alpha scores were >0.70 , indicating strong reliability for each scale.

Conclusions: Overall this survey appears to be promising for helping researchers and practitioners study the determinants of fiber consumption, and its theoretical antecedents. Understanding the theoretical determinants of fiber consumption will help bridge the gap between theory and practice, and provide health practitioners information to aid in the development of effective public health interventions.

DO RESEARCH PARTICIPANTS DIFFER BY RECRUITMENT SOURCE? OBSERVATIONS FROM A STUDY OF NEWLY-DIAGNOSED BREAST CANCER PATIENTS

Anya Agrawal, B.S.¹, Catherine Benedict, PhD¹, Bitu Nouriani, M.S.¹, Johnna Medina, Ph.D.¹, Allison W. Kurian, M.D., M.Sc.², David Spiegel, M.D.¹¹Stanford University School of Medicine, Palo Alto, CA; ²Stanford University, Stanford, CA

Background: It can be difficult to recruit newly-diagnosed cancer patients for research, as they are often navigating an emotionally fraught period. Social media groups and cancer-specific virtual platforms are increasingly being used to connect patients to researchers and appear promising given their wide reach. However, differences in participant characteristics recruited from these sources are not well understood.

Objective: This study aimed to: (1) compare recruitment strategies (hospital-based, breast cancer-specific networks, social media) in enrollment metrics, and (2) among enrolled participants, evaluate demographic differences based on recruitment approach.

Methods: Data from an NCI-sponsored study of factors influencing the choice of breast conserving surgery vs. bilateral mastectomy for breast cancer were evaluated. The main recruitment sources included (1) hospital-based methods that involved screening electronic medical records to identify eligible patients, (2) nation-wide email "blasts" through a program called Army of Women (AOW) that aims to connect breast cancer studies with interested volunteers, and (3) posts on Facebook breast cancer support groups. Descriptive statistics evaluated demographic characteristics and recruitment metrics. Chi-square and One-Way ANOVA compared demographic characteristics between the recruitment sources.

Results: Participants (N=136) averaged 49 years old (SD=11.1), were primarily White (78%), employed (68%), high-income (61% had a yearly income $> \$100,000$), and educated (44% achieved $>$ bachelor's degree). The majority of screened participants were found via Facebook (40.7%, n=122/300), followed by hospital-based (25.3%, n=76/300) and AOW (15.7%, n=47/300). Hospital-based methods yielded the highest enrollment rate from eligible participants (81.7%, n=49/60), compared to AOW (61.8%, n=21/34) and Facebook (44.2%, n=38/86). No significant differences in age, race, ethnicity, education, income, employment, or cancer stage were identified between the recruitment sources ($p's > .05$).

Discussion: Findings suggest that, while hospital-based recruitment methods may yield higher success at enrolling newly-diagnosed cancer patients, studies with limited resources may use social media to reach a wider audience that is equally as representative. Future research should explore differences in patient reported outcomes based on recruitment source to confirm equivalence among recruitment strategies.

ARE CURRENT ELICITATION TECHNIQUES CONFOUNDED WITH MOTIVATION? HOW NATURAL LANGUAGE MAY HINDER THEORY-GUIDED RESEARCH

Paul Branscum, PhD, RD¹, David M. Williams, Ph.D.², Ryan E. Rhodes, Ph.D.³¹Miami University, Oxford, OH; ²Brown University School of Public Health, PROVIDENCE, RI; ³University of Victoria, Victoria, BC, Canada

Background: In quantitative research the use of natural language has raised concerns in regards to the validity of standard self-efficacy scales. This has yet to be demonstrated in qualitative research. To understand what factors may prevent or promote one's self-efficacy to perform a behavior, Fishbein and Ajzen recommend eliciting 'control beliefs' by asking individuals what 'prevents' and 'enables' them to perform a behavior. Natural language words, such as prevent and enable are often ambiguous, and thus may not give an accurate picture of what impacts one's self-efficacy.

Purpose: Therefore, the purpose of this study was to compare standard elicitation techniques for barriers and enablers for physical activity and sleep behaviors, to an alternative technique in which participants were told to only consider the literal meanings of the words 'prevent' and 'enable' (and not the figurative meaning).

Methods: College students were randomized into two groups. Group 1 (n=177) used the standard elicitation methodology outlined by Fishbein and Ajzen (i.e. what prevents you from doing behavior X; what enables you to do behavior X). Group 2 (n=176) however was given a small vignette before each elicitation, to encourage participants to think of the literal meaning of the words "prevent" (i.e. something that would not make it possible for you to perform behavior X) and "enable" (i.e. something you would need to make it possible for you to perform behavior X). Participants were required to give at least two factors for each type of belief (sleep/physical activity and prevent/enable). Responses were then analyzed by two blinded researchers, and codified. Later, these codes were labeled as 'threat to capability', 'potential threat to capability' and 'priority/not a threat to capability'.

Results: Students in both groups reported significantly different types of control beliefs. Those in the control group reported significantly more overall beliefs for each category ($p < 0.05$, except sleep/enable), suggesting poorer discrimination in interpreting what was meant by "prevent" and "enable". In addition, students in the control group reported significantly more beliefs that were labeled as a 'priority/not a threat to capability' while students in the treatment group reported significantly more beliefs labeled as 'threats' or 'potential threats' to capability.

Conclusions: This study demonstrates when self-efficacy-related control beliefs are elicited, natural language words such as 'prevent' and 'enable' have the potential to confuse people about the intent of the question. These evaluations are meant to help us understand what impacts one's self-efficacy to perform a behavior, but in fact are informing us about what factors also impact their motivation. Alternative elicitation procedures, such as vignettes that clarify terms beforehand, may result in greater fidelity when eliciting beliefs.

"I FEEL COMFORTABLE BECAUSE SHE IS NOT MY FAMILY": YOUNG WOMEN'S EXPERIENCES UNDERGOING PROXY PARENTAL CONSENT IN SOUTH AFRICA

Courtney Peasant Bonner, PhD¹, Celia Fisher, PhD², Tara Carney, PhD³, Jacequeline Ndirangu, MsGH⁴, Felicia Browne, ScD⁵, Brittini Howard, BA⁵, Leslie Turner, BA⁶, Wendee Wechsberg, PhD⁵¹RTI Global Gender Center, New York, NY; ²Fordham University, Bronx, NY; ³South African Medical Research Council, Cape Town, Western Cape, South Africa; ⁴RTI International, Washington, D.C., DC; ⁵RTI International, Research Triangle Park, NC; ⁶Harvard T.H. Chan School of Public Health, Boston, MA

South Africa has one of the highest incidence of HIV among adolescent girls and young women (AGYW) ages 15–24 in the world. Research is needed to reduce HIV risk among AGYW, but laws state that the age of consent for research purposes is 18 years of age. This poses challenges to research and may limit the impact of HIV prevention strategies among AGYW. This study explored the experiences of AGYW who were under 18 years old at the time of consent and who engaged in a parental proxy consent procedure called In Loco Parentis (in place of parent) to enroll in a behavioral HIV prevention trial. Older women identified by the participant or community leaders identified by research staff consented for the AGYW, in place of their parent, to participate in the trial. In Loco Parentis was approved by the U.S. and South African-based IRBs. Participants were Black African (n = 13) and Coloured (n = 18) AGYW who were ages 18 or older at the time of the focus group discussion (FGD), were younger than 18 during enrollment into the trial, and had completed the trial. Following consent, FGDs (2 with Black African and 2 with Coloured AGYW) were conducted. FGDs were audio-recorded, notes taken, and translations done. Transcriptions were coded by two independent coders using open coding

Methods: Results identified four main themes related to the In Loco Parentis consent procedure: (1) comfort and confidentiality related to the In Loco Parentis, (2) clarity and respect related to how the procedure was explained and implemented, (3) maternal figures who served as the In Loco Parentis, and (4) the potential influence of parental consent on participation. The In Loco Parentis consent process was experienced as respectful. Participants were comfortable with community leaders, aunts, or older sisters as parental consent proxies. Many participants reported that if parental consent was required that they would not participate, while others reported that they would still participate in the study. AGYW reported that they were concerned that their parents would try to breach their confidentiality regarding their HIV status, pregnancy, and positive drug test results if parental consent was required. Our findings suggest that the experiences of AGYW who enrolled in this HIV prevention trial using In Loco Parentis consent were positive. In Loco Parentis consent methods may be a viable alternative or supplement to parental consent in HIV-related studies among AGYW.

VETERAN BELIEFS ABOUT THE CAUSES OF GULF WAR ILLNESS AND EXPECTATIONS FOR IMPROVEMENT

Naomi S. Kane, PhD¹, Nicole L. Sullivan, PhD², Fiona S. Graff, PsyD³, David R. Litke, Ph.D.⁴, Karen S. Quigley, Ph.D.⁵, Wilfred Pigeon, PhD⁶, Joseph F. Rath, PhD⁷, Lisa M. McAndrew, PhD⁸

¹VA New Jersey Health Care System, Department of Veteran Affairs, East Orange, NJ; ²Veterans Administration New Jersey Health Care System, East Orange, NJ; ³VA NJ Healthcare System, East Orange, NJ; ⁴VA NJHCS, East Orange, NJ; ⁵Northeastern University, Needham, MA; ⁶Veteran Affairs, Canadaigua, NY; ⁷Rusk Rehabilitation at NYU Langone Health, New York, NY; ⁸War Related Illness and Injury Study Center, Veterans Affairs New Jersey Healthcare System, East Orange, NJ

Approximately one-third of Veterans deployed to the Gulf region during Operations Desert Storm/Desert Shield experience persistent medically unexplained physical, neurocognitive, and affective symptoms collectively referred to as Gulf War Illness (GWI). While the specific etiologies remain unknown, Veterans' causal attributions of these chronic physical symptoms may impact expectations for improvement and influence best clinical practices. Therefore, our goal was to explore the relationship between attributions of GWI and patients' expectations for improvement.

Veterans who met the Kansas definition for GWI participated in an RCT of Problem Solving Therapy. Participants also completed self-report measures assessing causal attributions of GWI symptoms (e.g., military deployment-related exposure, psychological stress, physical, behavior including lifestyle choices such as diet, physical activity) and expectations for improvement over 6-months. Regression examined main effects of Veterans' attributions of GWI symptoms and covariates on expectations for improvement.

Participants ($N=262$) were predominantly middle-aged (mean[SD]=52.9[7.3] years old), male (88%), and White (72%), Black (21%), and had household incomes over \$40,000 (79%). 74.4% strongly agreed that military deployment was a cause while only 22.6% agreed or strongly agreed that behavior was a cause. Black Veterans reported higher expectations for improvement ($M=7.2, SD=4.6$) than non-Black Veterans ($M=4.7, SD=4.2$; $t(260)=-3.90, p<.001$). Endorsing behavior was associated with greater expectations ($\rho=.26, p<.001$), while endorsing military deployment was associated with worse expectations ($\rho=-.14, p<.03$). Neither psychological nor physical causes were related to expectations for improvement ($ps>.05$). When all causes were entered together in a regression model ($R^2=.11, p<.001$), only the individual's own behavior retained its significance ($B=.23, p<.001$).

Those who partially attributed GWI symptoms to their own behavior showed greater expectations for improvement than those who attributed their symptoms to military exposure. Understanding patients' causal attributions of medically unexplained symptoms may be important for health professionals to consider when communicating about symptoms, treatment, and goals. A study limitation is that this was a self-selected sample of Veterans with GWI and thus these results may not generalize to those with other chronic illnesses or non-treatment-seeking samples.

ADDRESSING PSYCHOLOGICAL DISTRESS IN A NATIONAL WEIGHT MANAGEMENT PROGRAM: RESULTS OF AN INTEGRATED PILOT STUDY

Gina Evans-Hudnall, PhD¹, Mary O. Odafe, M.A.², Jennifer O'Neil, PhD³, Lisa H. Trahan, PhD⁴

¹Baylor College of Medicine, Houston, TX; ²University of Houston, Katy, TX; ³Michael E. DeBakey VA Medical Center, Houston, TX; ⁴Trahan Counseling, San Marcos, TX

Obesity is highly comorbid with psychological symptoms in Veterans, particularly posttraumatic stress disorder (PTSD), depression, and anxiety. Obese veterans with comorbid psychological symptoms often display suboptimal weight loss and poor physical functioning when participating in weight management programs. The MOVE! program aims to increase healthy eating and physical activity to promote weight loss in obese Veterans. Addressing psychological barriers is necessary to maximize outcomes in MOVE! for Veterans with PTSD, depression, and anxiety. We examined the preliminary outcomes of administering the Healthy Emotions and Improving Health Behavior Outcomes (HERO) intervention. HERO is an adjunctive CBT to MOVE! that addresses PTSD, depression, and anxiety symptom barriers to engagement in physical activity.

Methods: Thirty-four obese Veterans with a diagnosis of PTSD, depression, and/or anxiety, who were attending MOVE! were assigned to the 8-session HERO group or the usual care (UC) group. Veterans completed assessments of PTSD, depression, and anxiety symptoms, physical activity, physical functioning, and weight at baseline, 8- and 16-weeks post-treatment. Changes from baseline to 8- and 16-week follow-up were assessed using independent samples t-tests and analyses of covariance.

Results: At 8 weeks post-treatment, participants in the HERO group had significantly higher step counts per day in comparison to the UC group (5,699 steps vs. 3063; $p<.01$). Similarly, at 16 weeks post-treatment, the participants in the HERO group continued to experience a significant increase in daily steps taken per day (5,485 steps vs 3084; $p<.01$) as well as statistically and clinically significantly lower scores on the depression symptom (6.3 + 7.1; $p=0.02$) and PTSD symptom (32.1 + 20.8; $p=0.05$) severity. Participants in the HERO group also demonstrated significantly higher scores on the physical functioning inventory in comparison to the participants in the UC group (44.1 + 12.1 vs. 35.7 + 10.7, $p=0.04$) at 16 weeks post-treatment.

Conclusions: Providing an adjunctive treatment to MOVE! that addresses psychological distress has potential benefits for psychological symptom reduction, engagement in healthy dietary habits, and greater physical activity for individuals who traditionally experience barriers to making positive weight management changes.

CHANGE THAT MATTERS: TRAINING PRIMARY CARE PHYSICIANS IN BRIEF, EVIDENCE-BASED HEALTH BEHAVIOR CHANGE INTERVENTIONS

Stephanie A. Hooker, PhD, MPH¹, Michelle D. Sherman, PhD LP ABPP², Katie A. Loth, PhD, MPH, RD, LD³, Kathryn Justesen, MD⁴, Jean Moon, Pharm.D.⁵, Samantha M. Ngaw, MD⁶, Marc James A. Uy, MPH²

¹HealthPartners Institute, Minneapolis, MN; ²University of Minnesota, Minneapolis, MN; ³University of Minnesota, Saint Paul, MN; ⁴University of Minnesota, Minneapolis, MN; ⁵University of Minnesota College of Pharmacy, Plymouth, MN; ⁶Entira Family Clinics, Shoreview, MN

Primary care is an ideal setting in which to address health behavior change (HBC) because of easy access, continuity, and the development of trusting, collaborative relationships between patients and primary care providers (PCPs). Despite the fact that several brief HBC interventions have been found to be effective when delivered by physicians, PCPs spend less than 1% of their time addressing lifestyle in visits. Further, when PCPs do address HBC, they rarely go beyond a simple explanation of risk. PCP barriers to addressing HBC may include lack of training, low confidence, and a dearth of easily accessible, evidence-based tools to use with patients. Our interdisciplinary team developed the *Change that Matters* curriculum to train PCPs in brief, evidence-based interventions for six health behaviors (sleep, physical activity, alcohol reduction, smoking cessation, healthy eating, and medication adherence) and includes three parts: didactic training (5 90-minute sessions), templates for the electronic medical record to guide the discussion, and interactive patient handouts. This study's purpose was to determine if the curriculum (a) is acceptable to PCPs and (b) increases PCP confidence in, perceived efficacy of, and frequency of delivering HBC interventions. A mixed-methods pilot study design was used to evaluate the implementation of the curriculum in a family medicine residency clinic. Resident PCPs ($N = 15$) completed pre- and post-implementation surveys (follow-up time = 15 months), and 10 PCPs completed a post implementation qualitative interview. Content analysis was used to extract qualitative themes using Nvivo software. Hierarchical linear models revealed moderate to large increases in PCP confidence in and perceived effectiveness of delivering HBC interventions (for all except physical activity) from pre-post intervention ($ps < .05$, Cohen's $ds = .70$ – 1.34). Frequency of using HBC interventions did not change (with the exception of smoking cessation which increased). Qualitative themes indicated that the curriculum gave PCPs concrete tools to address HBC, helped structure their discussions with patients, and increased their confidence. Results suggest that the *Change that Matters* curriculum is acceptable to PCPs and improves their confidence in and perceived effectiveness of delivering HBC interventions. Future studies are needed to explore the impact of the curriculum on patient behavior.

DEVELOPING HEALTHY LIFE HABITS IN UNRUPTURED INTRACRANIAL ANEURYSMS PATIENTS: A PROOF OF CONCEPT

Mariantonia Lemos, PhD¹, Ana Maria Torres, n/a², Susana Larrea, n/a², Juliana Londoño, n/a², Gabriela Calle, n/a¹, Santiago Correa, n/a¹, Carlos M. Jimenez, Neurosurgeon and MSc in Epidemiology³

¹Universidad EAFIT, Medellín, Antioquia, Colombia; ²Universidad EAFIT, Medellín, Antioquia, Colombia; ³University of Antioquia, Medellín, Antioquia, Colombia

Background: The prevalence of Unruptured Intracranial Aneurysms (UIAs) has been rising over the last years, due to increasing usage of neurovascular imaging. Considering that the rupture of an aneurysm is associated with mortality or disability, and that smoking and hypertension are risk factors for this, it is important to enhance healthy habits in these patients.

Objective: To determine the effectiveness of a workshop, based in the Health Belief Model, oriented to provide strategies that could enhance healthy habits in UIAs patients.

Method: We designed a 3-hour workshop oriented to increase understanding of the relation between healthy habits and the risk of rupture. Additionally, we sought to provide them with strategies for developing and maintaining healthier life habits. Afterwards, we developed a proof of concept with 28 UIA patients (mean age: 64.6 years, ranging from 43 to 82, 18% male). At the end of the workshop patients were requested to specify a goal behavior and reinforcements for performing it. Participants were contacted at 1 and 3 months for follow-up.

Results: 92.9% and 64.3% of the sample was contacted at the 1 and 3 month follow-up, respectively. On average, there was a 60% and 77% rate of goal achievement at these two points in time. Using the Matrix Method to analyze results, we found there were four main categories that affected behavior change in participants. Those who reported enablers for creating and maintaining the behavior achieved their goal by over 80%, except for one participant (70%). Contributing factors were reported by nine participants as very important for maintaining behaviors. Within said factors better health perception and social support were the most important. As for barriers, participants with higher achievement rates reported fewer obstacles for performing behaviors, and reported more restraining barriers such as illness, in contrast to lower achievement rates' participants which reported less restraining barriers such as being on vacation or not keeping track of the behavior. Finally, all participants with goal achievement over 80% reported feeling more rested, healthier and calmer.

Conclusion: We concluded that the workshop enables patients to create strategies for acquiring and maintaining healthy habits. It is important to highlight the relevance of planning, tracking and reinforcing behaviors for goal achievement. A better strategy for following up with patients is necessary for better attrition rates.

PREDICTORS OF CHANGE IN HEALTH BEHAVIORS DURING THE COLLEGE TRANSITION: THE ROLE OF SELF-COMPASSION

Katherine Gnall, B.A.¹, Crystal L. Park, PhD², Lucy Finkelstein-Fox, M.S.¹, Sharon Y. Lee, M.S., M.A.¹¹University of Connecticut, Storrs, CT; ²University of Connecticut, Storrs Mansfield, CT

Background: The transition to college represents a stressful time in a young adult's life and has been associated with adverse changes in diet and physical activity levels. Thus, there is need to enhance our understanding of factors that predict health behavior change during this transitional period. Recent research has demonstrated associations between self-compassion and engagement in health behaviors, explained at least in part by self-compassion's enhancement of self-regulatory processes. However, these relationships have yet to be tested longitudinally. The present study aimed to enhance our understanding of the relationship between self-compassion and health-promoting behaviors during the college transition as well as the potential mechanisms underlying this relationship. Specifically, we examined lower perceived stress, higher positive affect, and lower negative affect as potential mediators.

Methods: Participants were 157 first-year undergraduate students (mean age = 17.83; 79% female) who were administered self-report surveys of self-compassion at the beginning (T1) and end (T3) of their first semester of college, as well as daily diary questionnaires regarding stress appraisals and affect for one week during the first semester (T2).

Results: Results demonstrate that fruit and vegetable consumption increased from the beginning to the end of the first semester; $t(127) = -5.99, p < .01$. Higher self-compassion at the beginning of the semester predicted increased fruit and vegetable consumption at the end of the semester ($\beta = .20, p < .05$), controlling for fruit and vegetable consumption at the beginning of semester. Self-compassion was not, however, associated with end-of-semester physical activity. Further analyses revealed that the relationship between self-compassion and fruit/vegetable intake was not mediated by T2 average levels of stress appraisal, positive affect, or negative affect, as has been previously hypothesized.

Conclusion: These findings suggest that higher self-compassion predicts more engagement in some aspects of health-promoting behavior (but not all) over the transition to college. Further, the mechanisms underlying this relationship remain unclear. Future research to further examine these relationships are needed. Interventions that target enhanced self-compassion may increase engagement in health behaviors over the transition to college.

CORRELATES OF SKIN SELF-EXAMINATION AND SUN PROTECTION BEHAVIORS AMONG MELANOMA SURVIVORS

Zhaomeng Niu, PhD¹, Trishnee Bhurosy, PhD², Sharon L. Manne, PhD³, Deborah A. Kashy, PhD⁴, Carolyn Heckman, PhD⁵, Lee M. Ritterband, Professor⁶, Elliot J. Coups, PhD⁷¹Rutgers Cancer Institute of New Jersey, Edison, NJ; ²Rutgers Cancer Institute of New Jersey, Somerset, NJ; ³Rutgers Cancer Institute, New York, NY; ⁴Michigan State University, East Lansing, MI; ⁵Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; ⁶University of Virginia Center for Behavioral Health & Technology, Charlottesville, VA; ⁷Rutgers Cancer Institute of New Jersey, South Orange, NJ

Introduction: Melanoma survivors are at increased risk for cancer recurrence and second primary melanomas. Regular skin self-examination (SSE) could reduce melanoma morbidity and mortality. Engaging in sun protection (e.g., shade seeking) is also recommended for melanoma survivors.

Aims: To examine the prevalence and correlates of SSE and sun protection among melanoma survivors.

Methods: Patients (N=441) with stages 0-III melanoma who were 3–24 months post-surgery and non-adherent to either SSE or sun protection recommendations completed an online survey measuring demographics, medical, skin cancer risk and psychological factors, knowledge and attitudes about melanoma, social influence, attitudes toward sun protection behaviors and SSE, and sun protection behaviors. Patients reported whether they checked any part of their body for skin cancer in the last two months. SSE comprehensiveness was assessed based on the number of body parts examined out of 15. The sun protection index was the mean of the following items with responses from 1–5: using sunscreen with a sun protection factor of ≥ 30 , wearing a long-sleeved shirt, wearing a wide-brimmed hat, and staying in the shade when outside on a sunny day. Multiple regression analyses were conducted to evaluate correlates of SSE (performance and thoroughness) and sun protection.

Results: About 66% of participants reported conducting SSE in the past two months; however, only 7.5% reported examining all 15 body parts. Greater worry about recurrence, fewer perceived barriers to SSE, more planning, and higher SSE self-efficacy were positively associated with both SSE performance and SSE comprehensiveness ($ps < .01$). Higher perceived risk of recurrence and physician influence were associated with greater SSE performance, and education and sex were associated with SSE comprehensiveness ($ps < .05$). Education was also positively associated with sun protection behaviors ($p < .01$). Greater physician's recommendation, higher injunctive norms, fewer perceived barriers, and higher protection self-efficacy were associated with sun protection behaviors ($ps < .05$).

Conclusions: Many melanoma survivors do not engage in comprehensive SSE or sun protection. By identifying the correlates of these behaviors in melanoma survivors, this study provides insights for improving SSE and sun protection by targeting specific constructs (e.g., barriers and self-efficacy) in future skin cancer interventions.

CLASSIFICATION OF TECHNIQUES USED IN SELF-DETERMINATION THEORY BASED BEHAVIOR CHANGE INTERVENTIONS IN HEALTH CONTEXTS

Martin S. Hagger, PhD¹, Marta Marques, PhD², Marlene N. Silva, PhD³, Pedro Teixeira, PhD⁴¹University of California, Merced, Merced, CA; ²Trinity College Dublin, Dublin, Dublin, Ireland; ³Universidade de Lisboa, Lisbon, Lisboa, Portugal; ⁴University of Lisbon, Lisbon, Lisboa, Portugal

While evidence suggests that interventions based on self-determination theory can be effective in motivating adoption and maintenance of health-related behaviors, and in promoting adaptive psychological outcomes, the motivational techniques that comprise the content of these interventions have not been comprehensively identified or described. The aim of the present study was to develop a classification system of the techniques that comprise self-determination theory interventions, with satisfaction of psychological needs as an organizing principle. Candidate techniques were identified through a comprehensive review of self-determination theory interventions and nomination by experts. The study team developed a preliminary list of candidate techniques accompanied by labels, definitions, and function descriptions of each. Each technique was aligned with the most closely-related psychological need satisfaction construct (autonomy, competence, or relatedness). Using an iterative expert consensus procedure, participating experts (N=18) judged each technique on the preliminary list for redundancy, essentiality, uniqueness, and the proposed link between the technique and basic psychological need. The procedure produced a final classification of 21 motivation and behavior change techniques (MBCTs). Redundancies between final MBCTs against techniques from existing behavior change technique taxonomies were also checked. The classification system is the first formal attempt to systematize self-determination theory intervention techniques. The classification is expected to enhance consistency in descriptions of self-determination theory-based interventions in health contexts, and assist in facilitating synthesis of evidence on interventions based on the theory. The classification is also expected to guide future efforts to identify, describe, and classify the techniques that comprise self-determination theory-based interventions in multiple domains.

EFFECTS OF SOCIAL COMPARISON ORIENTATION ON OUTCOMES IN ADULTS ENROLLED IN A GROUP-BASED BEHAVIORAL WEIGHT LOSS INTERVENTION

Christiana M. Field, B.A.¹, Andrea Grenga, B.A.², Zeely Denmat, B.A.³, Amy A. Gorin, Ph.D.⁴, Tricia M. Leahey, Ph.D.⁴¹University of Connecticut, Hartford, CT; ²Weight Control and Diabetes Research Center, Cranston, RI; ³UConn Weight Management Lab, Hartford, CT; ⁴University of Connecticut, Storrs, CT

Risks associated with obesity are great. As such, it is crucial to understand factors that may affect weight loss. *Social Comparison Theory* suggests that individuals compare themselves with others to learn about, and therefore improve, the self. Group-based behavioral weight loss (GBWL) interventions afford a unique opportunity for social comparison among group members. Previous studies have shown that weight-focused social comparisons are associated with treatment outcomes in GBWL interventions, though the direction of such findings vary across outcomes. Likewise, it remains unclear how individual variation in one's *trait-like* tendency to socially compare (Social Comparison Orientation; SCO) may impact treatment adherence and weight loss outcomes. This study examined the association between baseline SCO and treatment adherence and outcomes in a GBWL intervention. It was hypothesized that a stronger SCO at baseline would be associated with physical activity adherence, self-monitoring, group attendance, assessment completion, and weight loss at end of treatment (12 months).

This study was a secondary data analysis of a trial testing the efficacy of lay health coaches in GBWL. Participants (N=278, 75.90% female, age 51.83±5.61 years, BMI 34.70±3.34 kg/m²) completed a 12 month GBWL intervention. The Iowa–Netherlands Comparison Orientation Measure and the Paffenbarger Questionnaire measured SCO and physical activity, respectively. Self-monitoring, group attendance, assessment completion, and weight were objectively assessed.

SCO findings were mixed. Stronger SCO at baseline was associated with worse physical activity outcomes during treatment (p=.04). However, stronger SCO also predicted better group attendance (p=.05) and assessment completion at 12 months (p=.03). SCO did not predict self-monitoring or weight loss.

Findings indicate that individual differences in SCO may differentially influence treatment outcomes. While stronger SCO may improve socially salient behaviors (e.g., group attendance and assessment completion), SCO may have no effect, or even a detrimental effect, on behaviors that are more individually motivated (e.g., physical activity, self-monitoring, and weight loss). Future research may consider how best to capitalize on variations in SCO early in treatment to improve critical weight loss behaviors over the course of the intervention.

DELIBERATE IGNORANCE: PEOPLE AVOID MONITORING THEIR WEIGHT-LOSS PROGRESS

Rachel Forsyth, BA¹, James A. Shepperd, PhD.¹¹University of Florida, Gainesville, FL

Background: Self-weighing, a monitoring behavior common in many weight-loss interventions, entails daily, weekly, or monthly tracking of one's body weight. Compared to tracking diet or physical activity, frequent self-weighing is more predictive of successful weight-loss. Despite its effectiveness for weight-loss, we predicted that some people will avoid self-weighing even when trying to lose weight because they anticipate negative information—the scale will reveal that they have not lost weight.

Purpose: In two experiments with people trying to lose weight ($n = 774$), we assessed how negative expectations relate to avoiding the scale.

Methods: In Study 1, participants recalled a time they thought about stepping on a scale and either stepped on the scale (seeking condition) or avoided the scale (avoidance condition). Then they answered a question about their expectation about their weight-loss at that time. In Study 2, we directly assessed avoidance by asking participants to imagine either expecting that they had lost weight (positive expectations condition) or gained weight (negative expectations condition).

Results: Avoidance was common, with 81% of participants in Study 1 ($n = 408$) reporting that they had avoided the scale at some point, and 27.5% of participants ($n = 112$) avoided the scale more than 15 times in the last six months. In addition, negative expectations were linked to avoidance. In Study 1, participants who recalled avoiding self-weighing, compared with people in the seeking condition, expected to receive more negative information about their weight-loss progress (adjusted Welch's $t(480.90) = 7.90, p < .001$; Cohen's $d = .70$). In Study 2, participants reported lower intentions to step on the scale if they imagined that they expected to receive negative feedback about their weight-loss progress than if they imagined that they expected to receive positive feedback about their weight-loss progress (adjusted Welch's $t(209.40) = 4.83, p < .001$; Cohen's $d = .69$).

Conclusions: Avoiding self-weighing appears commonplace even among people trying to lose weight, and stems from negative expectations about one's weight-loss progress.

THE ROLE OF EXECUTIVE FUNCTIONS IN A BEHAVIORAL WEIGHT LOSS INTERVENTION DESIGNED FOR EMERGING ADULTS

Autumn Lanoye, PhD¹, Jessica G. LaRose, Ph.D.²¹Virginia Commonwealth University, Richmond, VA; ²VCU School of Medicine, Richmond, VA

Executive functions encompass higher-order cognitive processes such as working memory, cognitive flexibility, and inhibitory control. Such abilities represent critical underpinnings of behavior change, which requires complex cognition in the form of goal-setting, implementation planning, problem-solving, and self-regulation. Further, weight loss requires behavior change across multiple domains; thus, attempting to lose weight places a high demand on executive functions. Executive functions develop with maturation of the frontal lobe, continuing throughout emerging adulthood. Historically, emerging adults (EA) fare worse than other adults in behavioral weight loss (BWL)—perhaps due in part to still-developing executive functions. The aims of this secondary analysis were to assess rates of executive dysfunction in a sample of EA presenting for BWL treatment and to determine whether executive dysfunction predicted 6-month outcomes. The Behavior Rating Inventory of Executive Function-Adult (BRIEF-A) was administered at baseline to participants (ages 18–25; BMI 25–45 kg/m²) enrolled in a 6-month BWL program. Weight, waist circumference, and body fat percentage were assessed in clinic at baseline and 6-months. Participants ($N=72$, 84.7% female, 68.1% racial/ethnic minority, baseline BMI=32.9 + 4.4) attended 1 in-person group session and 1 in-person individual session, followed by a technology-mediated program with semi-automated e-coaching. Number of clinically-elevated subscales (T-score >65) on the BRIEF-A ranged from 1 to 9, with 27.8% of participants endorsing executive dysfunction in at least 1 domain. The most commonly elevated subscale was planning/organization ($n=9$; 12.5%). Endorsement of one or more clinically elevated subscales on the BRIEF-A did not predict percent weight change ($F=0.00, p=.99$), change in body fat percentage ($F=0.15, p=.70$), or change in waist circumference ($F=0.24, p=.63$) at 6-month follow-up. More than one quarter of EA presenting for a BWL program endorsed clinically significant executive dysfunction in at least one domain. However, this does not appear to have influenced their success with respect to 6-month outcomes. Interpretation of these findings is limited by small sample size and lack of performance-based executive function assessment. While the BRIEF-A may hold greater external validity because it assesses executive functions in daily life, performance-based assessments may better capture EA capacity for executive functioning.

BASELINE PSYCHOSOCIAL AND DEMOGRAPHIC FACTORS ASSOCIATED WITH STUDY ATTRITION AND 12-MONTH WEIGHT GAIN IN THE DIETFITS TRIAL

Priya Fielding-Singh, PhD¹¹Stanford Prevention Research Center, Menlo Park, CA**Objective:** The purpose of this study was to examine correlates of failure—trial attrition and weight gain—in a randomized clinical weight loss trial.**Methods:** The Diet Intervention Examining The Factors Interacting with Treatment Success (DIETFITS) trial included 609 adults (18–50 years; BMI 28–40). Participants were randomized to a 12-month Healthy Low-Fat or Healthy Low-Carbohydrate diet for weight loss. At baseline, participants completed psychosocial, demographic, and anthropometric measures. Stepwise logistic regressions identified baseline factors associated with 1) study attrition and 2) among trial completers, weight gain at 12 months.**Results:** Having higher baseline food addiction and self-efficacy were linked to treatment failure. Being younger, not having a college education, having higher outcome expectations and quality of life, and lower social functioning and self-control increased the odds of trial attrition. Identifying as other than non-Hispanic White, not being married or cohabitating, having higher cognitive restraint and self-control, and lower amotivation, family encouragement, and physical limitations increased the odds of gaining weight by treatment's end.**Conclusions:** Participants' baseline psychosocial and demographic factors may support or impede successful weight loss. Trialists should attend to these factors when designing treatments in order to promote participants' likelihood of completing the trial and achieving their weight loss goals.

SOCIOECONOMIC CONTRIBUTORS TO UNDERGOING BARIATRIC SURGERY AND POST-SURGICAL WEIGHT LOSS

Leah Hecht, PhD¹, Bethany D. Pester, MA², Jordan M. Braciszewski, PhD¹, Amy E. Graham, Doctoral Candidate³, Kara J. Mayer, M.A. Clinical Psychology⁴, Kellie Martens, Ph.D.¹, Aaron Hamann, PsyD¹, Arthur M. Carlin, MD, FACS, FASMBS, DABS⁵, Lisa R. Miller-Matero, PhD, ABPP¹¹Henry Ford Health System, Detroit, MI; ²Wayne State University, Detroit, MI; ³Henry Ford Hospital, Royal Oak, MI; ⁴Henry Ford Health System, Royal Oak, MI; ⁵Henry Ford Health System, Clinton Township, MI**Introduction:** Although there has been an association between insurance coverage and income with undergoing bariatric surgery, further research is needed to understand which socioeconomic factors impact patient outcomes. This study seeks to elucidate whether socioeconomic variables, including receiving social security disability (SSD), insurance type, and median income are associated with undergoing bariatric surgery and post-surgical weight loss. This may explain disparities observed in obtaining surgery and lead to developing appropriate psychosocial interventions to promote optimal weight loss.**Methods:** Data were collected from retrospective chart reviews of patients (N = 314) who completed a required pre-surgical psychosocial assessment for bariatric surgery at a major metropolitan hospital system. Median household income was derived from the patient's zip code. Insurance type was coded as private or government. Post-surgical weight data were collected from patient's charts 1-year after surgery.**Results:** Patients were predominantly female (83%), African American (49%), and middle aged (M = 46.51) with an average BMI of 46.95. The majority (79%) had private insurance and were not receiving social security disability (87%). Univariate logistic regression analyses revealed receiving SSD, insurance type, and median income were associated with undergoing surgery. A multivariate binary logistic regression of these predictors was significant ($\chi^2 = 18.36$, $p = .001$), with insurance type as the strongest predictor of undergoing surgery ($p = .03$) after controlling for pre-surgical BMI. Individuals with private insurance were 2.24 times more likely to undergo bariatric surgery than those with government insurance. Higher median income predicted a greater percentage of excess weight loss at 1-year post-surgery ($F = 6.26$, $p = .013$).**Discussion:** Socioeconomic variables, specifically insurance type and income, may influence whether patients undergo bariatric surgery and their success with post-surgical weight loss. Results suggest that it may be beneficial to review socioeconomic factors during pre-surgical psychological evaluations to identify patients who may be at risk for poorer outcomes. Future investigation is needed to determine whether resources targeting socioeconomic factors, such as offering food vouchers for farmer's markets, contribute to better outcomes and decrease disparities among those who undergo surgery.

SMALL CHANGES FOR WEIGHT LOSS IN AFRICAN AMERICAN CHURCHES: A SUCCESSFUL TRANSLATION

Melissa M. Crane, PhD¹, Joselyn Williams, MPH², Chasidy K. Garcia, BS¹, Kandice Jones, MA³, Inita N. Callaway, MA³, Christy C. Tangney, PhD, FACN, CNS⁴, Laura Zimmermann, MD, MS, FACP¹, Elizabeth B. Lynch, PhD²

¹Rush University Medical Center, CHICAGO, IL; ²Rush University Medical Center, Chicago, IL; ³Hope Community Church, Chicago, IL; ⁴Rush University Medical Center, Arlington Heights, IL

Background: African American churches have been identified as a promising venue to deliver weight management and other health promotion programs to reach underserved congregants and reduce disparities between racial groups. Few programs have tested a participant-centered “small changes” approach to weight loss to engage congregants in lifestyle changes that could be sustained long-term. This “small changes” approach has previously been successful in other difficult-to-reach populations. The purpose of this study was to test whether a previously-successful small changes weight loss program could be translated for use in African American churches.

Methods: The HEAL (Healthy Eating & Active Living) program was delivered via 12 face-to-face group sessions held weekly at a partner church in Chicago's West Side: a segregated, predominately African American region. Sessions were co-led by a researcher and a church partner. The program encouraged participants to make a minimum of six small 100-calorie changes per day to their usual eating habits while also increasing their physical activity. The program was evaluated in a one-group design including assessments at baseline, after program completion (3-month), and after three additional months with no contact (6-month). Wilcoxon signed rank sum tests were used to assess change in weight, waist circumference, hemoglobin A1c, and blood pressure between baseline and the follow up assessments. Significance was set at $p < 0.01$ due to the small sample size.

Results: Seventeen African American congregants from five partner churches participated in the study (16 women, age 57.5 ± 12.1 years, BMI $36.5 \text{ kg/m}^2 \pm 5.4$, A1c 6.3 ± 0.5 , blood pressure $132 \pm 14/82 \pm 7$). Participants attended an average of 77% (mdn=9 of 12) of treatment sessions and 94% and 100% completed the 3 and 6-month assessment visits. Reductions (all p 's < 0.01) were observed during the 3- and 6-month assessments for weight (3 mo. mdn=-2.6 kg; 6 mo. mdn=-2.6 kg), waist circumference (3 mo. mdn=-3.8; 6 mo. mdn=-5.1), and A1c (3mo. mdn=-0.5; 6 mo. Mdn=-0.3). Among those with elevated blood pressure at baseline, there were significant reductions in systolic (3 mo. mdn=-10.7 mmHg) and diastolic blood pressure (3 mo. mdn=-8.0) but at 3 months but not at 6 months. The program was well received by participants with 100% reporting they “definitely would” recommend the program to others at their church and 94% reporting they were “somewhat” or “very satisfied” with the program.

Conclusion: The small changes approach to weight loss was successful in producing moderate sustained weight loss and was well received by participants. This translation study suggests that programs emphasizing small changes is a promising approach for use in African American churches and is appropriate for testing with a larger sample.

EXPLORING FEMALE CANCER SURVIVORS' IDEAS FOR A MULTI-GENERATIONAL DIGITAL LIFESTYLE INTERVENTION

Blanca Noriega Esquivas, MD, MSPH¹, Rafael Leite, BA², Yaray Agosto, MPH³, Marissa Kobayashi, MHS⁴, Dario Vanegas, BS³, Carmen I. Calfa, MD⁵, Matthew P. Schlumbrecht, MD⁶, Joyce M. Slingerland, MD, PhD⁶, Alejandra T. Perez, MD⁵, Frank Penedo, PhD⁶, Sara M. St. George, PhD⁷

¹University of Miami - Miller School of Medicine, Doral, FL; ²University of Miami, Boca Raton, FL; ³University of Miami, Miami, FL; ⁴University of Miami, Coral Gables, FL; ⁵Sylvester Comprehensive Cancer Center, Plantation, FL; ⁶Sylvester Comprehensive Cancer Center, Miami, FL; ⁷University of Miami Miller School of Medicine, Miami, FL

Background: Given the high rates of obesity, an established risk factor for at least 13 cancers, promoting healthy lifestyle behaviors is imperative to reducing the risk of cancer. Our long-term goal is to develop a multigenerational digital health intervention aimed at helping overweight/obese female cancer survivors improve their diet, increase physical activity, and manage their weight by empowering them to promote healthy lifestyle behaviors in their at-risk (e.g., physically inactive) adult children and grandchildren. The Integrate, Design, Assess, and Share (IDEAS) framework was used to guide our intervention development process. The purpose of our iterative study was to explore the ideas of racially/ethnically diverse female cancer survivors regarding a multigenerational lifestyle intervention.

Methods: Participants were 21 randomly selected racially/ethnically diverse overweight/obese grandmothers with breast, endometrial, or ovarian cancers from a larger sample that had previously participated in a psychosocial survey regarding their lifestyle behaviors, family structure, and mobile device use (7 Hispanics, 7 non-Hispanic blacks, 7 non-Hispanic whites; 65.5 ± 1.2 years old; BMI = 31.2 ± 1.0). Participants completed semi-structured interviews either in Spanish ($n=5$) or English ($n=16$). The interview guide was designed to: (a) better understand their family relationships, weight-related challenges, motivation to prevent obesity and/or cancer in their family members, and (b) elicit feedback on preliminary intervention paper mockups developed using behavioral, motivational, and family systems theories. Interviews were audio-recorded, transcribed, and analyzed using a general inductive approach.

Results: Seven key themes emerged: (1) importance of familial support; (2) preference for local family members involvement; (3) survivors' internal strengths and positive mindset; (4) weight loss struggles and successes; (5) barriers and facilitators to maintaining healthy lifestyle behaviors; (6) access to reliable information on cancer risk; and (7) family motivation through reinforcing activities. Participants also expressed their openness to using technology, their excitement about the intervention, and several suggestions related to intervention topics and aesthetic features (e.g. general child health, ways to strengthen family relationships, enhancing icon aesthetics, adding/removing some features).

Conclusions: Understanding end users' needs and preferences to inform the development of a digital health intervention is fundamental. Input from female cancer survivors in the present study is being used to outline intervention content, develop a fully functioning prototype, and conduct a feasibility randomized pilot trial that addresses health behaviors in at-risk multigenerational families from diverse racial/ethnic backgrounds.

IS SLEEP THE ANSWER TO CHILD OBESITY? COST-EFFECTIVENESS OF A SLEEP INTERVENTION IN INFANCY

Rachael Taylor, PhD¹, Eng Joo Tan, PhD², Barry J. Taylor, FRACP¹, Victoria Brown, PhD MPH BEcon(Hons)³, Alison Hayes, BSc PhD²¹University of Otago, Dunedin, Otago, New Zealand; ²University of Sydney, Sydney, New South Wales, Australia; ³Deakin Health Economics, Institute for Health Transformation, Deakin University, Geelong, Victoria, Australia

Our recent randomised controlled trial (RCT) demonstrated that children who received a brief sleep intervention during the first two years of life had just half the risk of obesity at 5 years of age as those who did not receive the sleep intervention. The aim of this analysis was to determine whether early sleep intervention provides a cost-effective option to reducing the burden of child obesity. The RCT included 192 mother/infant dyads randomised to the sleep intervention and 209 control dyads who received usual care. The sleep intervention involved one antenatal group-based education session aiming to set realistic expectations around sleep, and one individualised home visit when infants were around 3 weeks of age, which encouraged parents to help their child learn how to self-settle themselves to sleep, and to avoid using feeding as the first response to infant distress. Those who identified their child as having problems with their sleep were offered additional help. Measures of body mass index (BMI) were obtained at 2 and 5 years of age. Economic evaluation from a health funder perspective was undertaken with intervention costs per child valued in 2018 Australian dollars. The primary effectiveness outcome was difference in quality-adjusted life years (QALYs) between intervention and control, modelled to age 15 years. Cost and QALYs were used to calculate an incremental cost-effectiveness ratio (ICER). ICERs were also determined for the difference in BMI at age 5 years and modelled to age 15 years. The intervention cost was \$186 per child. The ICER was \$18,204 per QALY gained (95% CI \$4,126 to \$536, 527). Group differences in BMI were -0.18 kg/m² (-0.37 to 0.05) at 5 years (measured), and -0.26 kg/m² (-0.52 to 0.03) at 15 years (modelled). ICERs were \$1,021 (\$482 to \$9,430) and \$536 (\$156 to \$8,040) per BMI unit avoided, respectively. The sleep intervention demonstrated long-term benefits to BMI and was deemed cost-effective at accepted cost/QALY thresholds (< \$50,000) suggesting that early sleep intervention offers a viable approach to obesity prevention in young children.

PSYCHOLOGICAL PREDICTORS OF OUTCOMES FOLLOWING 12-MONTH PRIMARY CARE BEHAVIORAL WEIGHT LOSS INTERVENTION

Rachel Goetze, PhD¹, Michael Jensen, MD¹, Allison Holgerson, PhD², Todd Wade, MD¹, Dalia Mikhail, PhD¹, Teresa Jensen, MD¹, Jennifer Geske, MS¹, Matthew M. Clark, Prof. LP PhD³, Karen Grothe, PhD¹¹Mayo Clinic, Rochester, MN; ²University of Florida, Gainesville, FL;³Department of Psychiatry & Psychology / Obesity, Bariatric Surgery & Eating Disord. Program, Mayo Clinic, Rochester, MN

Background: Obesity is prevalent in primary care settings (PC), and novel approaches are needed to help address this significant health problem. Current research findings for predictors of weight loss (WL) and treatment attrition are inconsistent and treatment guidelines are lacking. Therefore the aim of this study was to identify possible multivariate predictors of WL and attrition in PC patients participating in a 12-month behavioral weight loss intervention.

Methods: PC patients with obesity ($N = 166$, $M_{age} = 50$ years, 81.3% female, $M_{BMI} = 35.3$) completed baseline measures of demographic and psychological variables before attending weekly weight loss intervention groups for three months, biweekly groups for three months, then monthly groups for six months. Percent total WL (%WL) was assessed at 12-months for intervention completers ($n = 106$, 62.6%). Early attrition was defined as less than 3-month completion ($n = 61$, 37.4%). Confirmatory factor analysis (CFA) was conducted to examine underlying structure of predictors and reduce the number of variables before using multivariable models. CFA was utilized to test four psychological factors based on baseline self-report psychological questionnaires. Sample independent model fit statistics revealed good fit for four factors with a Root Mean Square Error of Approximation (RMSEA) of 0.09: Eating Behaviors (e.g., food addiction, binge eating), Mood (e.g., depression, anxiety), Social Support (e.g., frequency, helpfulness), and Psychosocial (e.g., alcohol use, childhood abuse).

Findings: Average weight loss at 3-months was 2.9 kg ($sd = 3.3$) and 3.5 kg ($sd = 6.5$) at 12-months. Of the four constructed factors, only Social Support significantly predicted 3-month weight loss ($p = .01$) while Eating Behaviors, Mood, and Psychosocial were not predictive of weight loss at 3- or 12-months ($ps > .05$). No factors significantly predicted treatment attrition ($ps > .05$).

Discussion: Results suggest that baseline eating behaviors, mood, and history of psychosocial factors may not significantly impact WL outcomes or risk of early attrition in individuals seeking intensive behavioral weight loss intervention in the primary care setting. However, perceived helpfulness and frequency of social support for weight loss may impact behavioral weight loss outcomes. Future research is needed to continue tailoring weight loss interventions for individuals at high risk for poor outcomes and early attrition.

ADOLESCENT SELF-MONITORING IS ASSOCIATED WITH WEIGHT LOSS WITHOUT INCREASING DISORDERED EATING IN OBESITY TREATMENT

Laura Caccavale, PhD¹, Elizabeth L. Adams, PhD¹, Hollie Raynor, PhD, RD², Melanie K. Bean, PhD¹¹Virginia Commonwealth University, Richmond, VA; ²University of Tennessee, Knoxville, TN

Self-monitoring of dietary intake is a key component of behavioral weight loss (BWL) treatment, as it helps to inform the self-regulation process. Although adherence to self-monitoring is associated with greater weight loss in adults, recent pediatric guidelines highlighted that there is insufficient evidence determine the effectiveness for adolescents. Further, it is unknown if logging calories might increase disordered eating symptoms among high-risk adolescents. This study examined self-monitoring behaviors of adolescents with obesity enrolled in a 4-month(m) BWL intervention (TEENS+) and the relations to treatment outcomes and eating disorder symptoms. Adolescents ($N = 81$; M age = 13.7; 63% female; 55% racial/ethnic minority; M baseline body mass index [BMI] = 34.8 kg/m²) attended weekly group treatment sessions that taught strategies to achieve weight loss via adherence to dietary and exercise goals. Adolescents were taught to self-monitor weekly (via paper log or app) and reinforced for completion (4/7 days). Coaches provided feedback and taught adolescents how to use the log data and weight change to engage in self-regulation to reach weight loss goals. Out of 15 possible weeks to self-monitor, participants completed a log ~67% of the time ($SD = .29$). Greater adherence to self-monitoring was associated with greater BMIΔ from baseline to 2m ($r = -.46$; $p = .001$), 4m ($r = -.37$; $p = .002$), and 7m (no-contact maintenance phase; $r = -.26$; $p = .042$). Self-monitoring was not associated with changes in disordered eating (Eating Disorder Examination Questionnaire; Δ from baseline to 4m; $p = .848$). Most adolescents used an app or website to look up calories (55%). Paper logs were primarily used (78%) but at post, 55% of adolescent reported trying an app to log. At post, 39.1% of participants reported self-monitoring was “hard/very hard” and 35.9% reported that it was “easy/very easy.” There were no differences in perceived difficulty of self-monitoring ($p = .131$) or 4m BMIΔ ($p = .803$) based on type of log (paper vs app). Most parents (52.4%) at least “sometimes” helped their teens log; however, there was association with self-monitoring frequency ($p = .07$). Consistent with self-regulation theory, self-monitoring was associated with greater adolescent BMI decreases and was not associated with increased disordered eating. Self-monitoring appears important for adolescent weight loss, but more research is needed to better understand how to optimize use of this strategy within BWL treatment.

COLLEGE STUDENTS' MEAL PLAN USE IS ASSOCIATED WITH WEIGHT GAIN

Irene van Woerden, PhD¹, Daniel Hruschka, PhD², Meg Bruening, PhD³¹Idaho State University, Pocatello, ID; ²Arizona State University, Tempe, AZ; ³Arizona State University, Phoenix, AZ

Background: In the US, first year university students are typically required to live on campus and purchase a meal plan. Students' meal plans typically include either a set number of entries, or unlimited entries, to an all-you-can-eat dining hall. First year students typically gain 1–2 kg during their first year, however the reasons for this weight gain are still unclear. This study examined if the number of meals students used from their meal plan was associated with weight gain, and if students with higher dietary quality gained less weight.

Design: Students' objective meal plan use was obtained from the university. Students' Body Mass Index (BMI) was measured by trained research assistants at the start and end of the Fall and Spring semesters. Students fruit and vegetable intake, and added sugar intake, were obtained from a Dietary Screener Questionnaire (DSQ) survey completed at the start and end of the Fall and Spring semesters.

Participants/Setting: Students ($n=526$; 46% non-Hispanic White, 38% Pell Grant recipients) from a large, public, southwestern university were recruited during 2015–2016 from on-campus residence halls.

Statistical analyses performed: Linear mixed-effects models were used to examine if meal plan use was associated with students' BMI at the end of the semester, after controlling for students BMI at the start of the semester, semester, student demographics, and multiple responses for some students. A linear mixed-effects model was then used to determine if dietary quality was associated with weight gain. Students BMI at the end of the semester was predicted by students' dietary quality, after controlling for meal plan use and BMI at the start of the semester, semester, student demographics, and multiple responses for some students.

Results: For every 10 meals used during the semester, students were anticipated to gain 0.03 kg/m² (99% CI=0.01, 0.05) during that same semester. There was no indication that dietary quality (fruit and vegetables, added sugar intake) was associated with weight gain or weight loss.

Conclusions: Meal plan use appears to be associated with first year college students' weight gain

INFLUENCE OF RACE, ANXIETY SENSITIVITY, AND BODY FAT ON FEAR RESPONSE DURING EXERCISE AMONG ADULTS WITH OBESITY

Jocelyn D. Shoemaker, M.A., M.P.H.¹, Jacob D. Landers, M.A.², Brian C. Focht, PhD¹, Charles F. Emery, PhD³¹The Ohio State University, Columbus, OH; ²The Ohio State University, Dublin, OH; ³Ohio State University, Columbus, OH

Background: Obesity is a major public health concern especially among African Americans (AAs) who experience disproportionately higher rates of obesity compared to European Americans (EAs). AAs are also less likely than EAs to lose weight in weight loss interventions, possibly due to less interest in physical activity. Anxiety sensitivity (AS; i.e., fear of anxiety and of physiological sensations that occur with heightened arousal) may contribute to reduced physical activity among AA adults who may be especially sensitive to physiological symptoms that accompany anxiety. This study explored the degree to which AS and body fat are associated with fear during exercise; and the extent to which this effect may be more pronounced in AAs than EAs.

Methods: AA (n=30) and EA (n=34) participants (84.4% women; mean age = 43.4 ± 13.9 years) with obesity (BMI ≥ 30) were recruited from the community and from among patients enrolled in a university-based weight loss program. Participants completed the Anxiety Sensitivity Index-3 and height and weight were measured. All participants completed two study conditions (i.e., exercise and reading activity). During the exercise condition participants walked/ran for 20 minutes on a treadmill at an intensity of 70% of age-predicted maximum heart rate reserve. Participants provided ratings every four minutes of current state of distress or fear. Hierarchical regression was used to evaluate the relationship of race, body fat, and AS (total and physical subscale score) on fear response in the exercise condition.

Results: Results indicated a significant three-way interaction of race, the physical subscale of AS, and BMI in predicting fear response to exercise ($\beta = 0.70$, $p=0.040$). Among EAs, higher BMI and physical AS scores predicted greater mean fear during exercise but, surprisingly, for AAs fear scores appeared relatively constant regardless of BMI.

Conclusion: Results confirmed a significant interaction of race, physical AS, and BMI in predicting fear during exercise, but not in the expected direction. There appeared to be no effect of AA race on fear response to exercise, and the effect in EAs was only apparent in participants with more extreme obesity. These preliminary data suggest that racial differences exist in fear response during exercise. Future research should further explore the effects of race and anxiety sensitivity on fear response among individuals with obesity, especially among EAs.

A SYSTEMATIC REVIEW OF THE DOSE-RESPONSE RELATIONSHIP BETWEEN USAGE AND PHYSICAL ACTIVITY IN ONLINE WEIGHT-LOSS INTERVENTIONS

Nicholas Smith, n/a¹, Sam Liu, n/a¹¹University of Victoria, Victoria, BC, Canada

Background: Regular physical activity is critical to managing obesity. Recent studies have shown that online physical activity interventions can be an effective strategy to manage weight loss. However, the dose-response relationship between online intervention usage and improvements in physical activity outcomes is not well studied. Previous studies have shown that only certain usage metrics (e.g. percent of content accessed) were associated with improvements in psychological outcomes. Understanding the dose-response for physical activity intervention will be important for designing and evaluation of future interventions.

Objective: 1) Examine the types of intervention usage metrics for web-based weight loss interventions aimed to promote physical activity; 2) explore which usage metrics of online interventions were reflective of changes in physical activity behaviours.

Methods: We conducted a systematic review following the PRISMA guidelines to examine the dose-response relationship of web-based interventions targeting physical activity. We used the following keywords: web OR internet OR online OR ehealth AND physical activity OR exercise, AND dose OR dose-response OR usage data AND obesity OR weight*. Peer-reviewed articles published between 2006–2019 were included.

Results: A total of five articles met the inclusion criteria. The mean interventions length was 10±6 months (range 2–30 months). The most commonly usage metrics was login rates (n=5; 100%), followed by time per login (n=2; 40%) and percentage of tasks completed (n=1; 20%). The mean login rates, time per login and percentage of tasks completed of high-dose participants were 64±13%, 9±5.6min, 46%, respectively. Increase in intervention usage measured by login rates, timer per login and percentage of tasks completed were all correlated with a greater improvement in physical activity behaviours.

Conclusion: Our findings suggest that capturing login rate, timer per login and percentage of tasks completed were important usage metrics for evaluating dose-response relationships for online weight-loss interventions. More research is needed in this area to better understand the relationship between intervention usage and improvements in physical activity outcomes. Future studies need to examine whether online interventions have a usage saturation point where no further therapeutic benefit may be obtained.

BINGE EATING PREDICTS ADHERENCE TO DIGITAL SELF-MONITORING DURING BEHAVIORAL WEIGHT LOSS

Mary K. Martinelli, MA¹, Laura D'Adamo, B.A.², Meghan L. Butryn, PhD¹¹Drexel University, Philadelphia, PA; ²Drexel University Center for Weight, Eating, and Lifestyle Science, Philadelphia, PA

Consistent self-monitoring (SM) of eating, weight, and physical activity (PA) predicts better outcomes during behavioral weight loss (BWL), but the factors that influence SM adherence are not well understood. Some prior research suggests that disinhibited eating and binge eating predict worse adherence to dietary SM, possibly due to shame or avoidance. However, this previous research was not conducted with digital food logging, which allows for more objective measurement of adherence, and which can differ from analogue SM in important ways, such as convenience, accessibility, and discreetness. Additionally, no prior research has examined how binge eating and related constructs predict SM of weight or PA during BWL.

This study examined predictors of adherence to digital SM during a 12-week BWL program. Adult participants ($N = 77$) were instructed to self-monitor their eating, PA, and weight using digital devices (food log via mobile app, Fitbit Flex, and wireless "smart" scale). Adherence to SM, assessed objectively using data captured from the three devices, was calculated as the percent of days during treatment that SM was completed (SM of eating was considered complete if ≥ 800 calories were logged). Baseline binge eating (BE) severity was assessed using the Binge Eating Scale and uncontrolled eating (UE) and emotional eating (EE) were assessed using the revised Three Factor Eating Questionnaire. Non-parametric correlations were conducted due to non-normal distributions of SM variables. Sex, race, age, and baseline BMI were considered as covariates, and significant covariates were controlled for in subsequent analyses.

Spearman rank correlations controlling for race revealed that greater BE severity at baseline predicted greater adherence to SM of weight, $\rho = 0.25$, $p = .03$, and SM of eating, $\rho = 0.25$, $p = .03$. BE severity did not predict adherence to SM of PA, $\rho = 0.08$, $p = .50$. Baseline UE and EE did not significantly predict SM adherence.

In contrast to previous research, this study found that participants with greater BE severity at the start of BWL had better adherence to SM of eating, and for the first time established a relationship between BE and digital SM of weight in BWL. Future studies should determine if there are features of analogue versus digital dietary SM that may explain this pattern of findings, and also examine these associations over multiple timepoints and in relation to BWL treatment outcomes.

BARIATRIC PATIENT TREATMENT AND TRANSPORT: EMERGENCY MEDICAL WORKERS' ATTITUDES AND CHALLENGES

Jacob Burmeister, PhD¹¹University of Findlay, Findlay, OH

Background: Emergency medical services workers (EMS; e.g., paramedics, firefighters, emergency medical technicians) are frequently tasked with treating and transporting bariatric patients. They are also often the first provider a patient encounters during an emergent medical interaction. Nurses, physicians, medical students, and even obesity experts have been found to hold generally negative attitudes toward patients with obesity (Phelan, Burgess, Yeazel, Hellerstedt, Griffin, & van Ryn, 2015). However, little or no research has assessed EMS workers' experiences with and attitudes toward bariatric patients. Thus, the present study sought to 1) measure EMS workers' attitudes toward bariatric patients and 2) assess whether negative attitudes were associated with demographic variables such as years of experience and level of training.

Methods: Randomized, stratified, cluster sampling was used to recruit EMS workers ($N = 208$) from a diverse range of communities. Their attitudes toward people with obesity were measured with the Universal Measure of Bias questionnaire (UMB; Latner, O'Brien, Durso, Brinkman, & MacDonald, 2008). They reported their experiences with bariatric patients via open-ended questions.

Results: Negative attitudes and beliefs about bariatric patients were found including comments on patients' hygiene, lack of willpower, and inappropriate over-use of emergency medical services. However, a majority of EMS workers reported feeling comfortable (86%) and well-trained (78%) in treating bariatric patients. EMS workers' attitudes toward bariatric patients were not associated with their level of training or years of work experience (all $ps > .05$). EMS workers' attitudes toward people with obesity in general, as measured by the UMB were similar to other healthcare worker samples ($M = 3.22$, $SD = .89$). The most frequent challenges faced by EMS workers included injuries during lifting (28%) and a related lack of appropriate personnel (25%) and equipment (18%). Some negative attitudes and beliefs about bariatric patients were found as represented by comments on patients' hygiene, willpower, and inappropriate over-use of emergency medical services. A majority of EMS workers reported feeling comfortable (86%) and well-trained (78%) in treating bariatric patients. EMS workers' attitudes toward bariatric patients were not associated with their level of training or years of work experience (all $ps > .05$).

Discussion: The findings of this study suggest that 1) improved access to resources for patient care has the potential to help both EMS providers and bariatric patients and 2) EMS workers are similar to other health care providers in terms of their attitudes toward bariatric patients. Future directions include comparative analysis of attitudes toward other groups of patients that present similar transportation challenges such as those with physical disabilities.

A LATENT TRANSITION ANALYSIS OF ECOLOGICAL CHARACTERISTICS OF FAMILIES IN A TRIAL TO PREVENT EXCESS WEIGHT GAIN

Emily Fu, MPH¹, J.D. Smith, PhD¹, Kevin Grimm, PhD², Cady Berkel, PhD³¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Arizona State University, Tempe, AZ; ³REACH Institute, Arizona State University, Tempe, AZ

Introduction: The high prevalence of elevated Body Mass Index (BMI) in childhood poses dangers to children's short and long-term health. Racial/ethnic minority children have significantly higher prevalence of pediatric obesity compared to White children yet little is known about distinct social-ecological differences (e.g., interpersonal relationships, family environment) among children with elevated BMI and their importance as targets for tailored family-based interventions.

Methods: We examined 240 racially diverse children ages 5 to 13 with BMI $\geq 85^{\text{th}}$ percentile, and their caregiver(s) in a randomized trial of the Family Check-Up 4 Health (FCU4Health) for prevention of excess weight gain. A latent profile analysis first identified three unique profiles—Worst Behaviors (WB), Intermediate Behaviors (IB), and Better Behaviors (BB)—that were collectively differentiated on the variables: Family Health Routines (Media, Mealtime, Sleep), Parent Health Behaviors, Parenting Skills, Child Physical Activity, Child Eating Behaviors, and Child Dietary Choices. A latent transition analysis was run to examine whether class membership changed from Baseline (T1) to 6 months post-randomization (T2), and whether intervention assignment predicted transitions. FCU4Health was delivered during this 6-month period.

Results: At T1, there were 116 families in IB, 96 in WB, and 28 in BB. Of the 96 families in WB at T1, 64 stayed, and 32 transitioned to IB at T2. Of the 116 families in IB at T1, 99 stayed, 5 transitioned to WB, and 12 transitioned to BB. Of the 28 families in BB at T1, 23 stayed, 4 transitioned to Class IB, and 1 transitioned to Class WB. In the FCU4Health group, 45% of families in WB at T1 transitioned to IB at T2 (compared to 21% in the control group) and 8% of families transitioned from IB at T1 to BB at T2 (compared to 11% of families in the control group). Overall, 53% of families in FCU4Health transitioned to a healthier class compared to 32% in the control group.

Conclusions: Distinct profiles of child and family health behaviors and home environment variables existed among this largely homogenous sample of children with elevated BMI. FCU4Health was associated with transitioning to a healthier class compared to a services as usual control group, suggesting tailored interventions such as FCU4Health might be targeting salient obesogenic behaviors commensurate with the profiles identified. Research on tailoring is needed to test this hypothesis.

ACCUULTURATION AS A PREDICTOR OF TREATMENT OUTCOME IN A CHILDHOOD OBESITY PREVENTION STUDY

Nana Yaa A. Marfo, M.S.¹, Michelle M. Cloutier, n/a², Dorothy Wakefield, MS³, Dominica Hernandez, PhD⁴, Amy A. Gorin, Ph.D.⁵, James Wiley, DO⁶¹University of Connecticut, Manchester, CT; ²UConn Health, Ellington, CT; ³UConn Health, Manchester, CT; ⁴Leidos, Columbia, CT; ⁵University of Connecticut, Storrs, CT; ⁶University of Connecticut, Rocky Hill, CT

Introduction: Relative to other racial and ethnic groups in the U.S., Latinxs are disproportionately impacted by the obesity epidemic (Hales, Carroll, Fryar, & Ogden, 2017). Research on acculturation and obesity in Latinx children has shown a positive correlation between maternal acculturation toward mainstream U.S. society and obesity in preschool-aged children (Power, O'Connor, Fisher, & Hughes, 2015); however, few studies have explored the relationship between maternal acculturation and Latinx children's responses to obesity intervention (e.g. Fitzgibbon et al., 2011). This study examined this relationship in an early childhood (i.e. ages 2 to 4) obesity prevention study in Hartford, CT. We hypothesized that higher maternal ratings of acculturation toward Latinx heritage would predict greater child response to treatment (i.e. decrease or no change in BMI percentile).

Methods: Prior to the start of the primary care-based intervention program (Cloutier et al., 2015), a sample of predominantly Puerto Rican (i.e. 60%), Latinx caregivers (n=179) completed the *Brief Acculturation Rating Scale for Mexican Americans-II (Brief ARMSA-II)*, a 12-item questionnaire composed of items from the Anglo Oriented Scale (AOS) and Mexican Oriented Scale (MOS) of the ARMSA-II. Overall acculturation scores (i.e. AOS-MOS) as well as individual U.S. and Latinx acculturation scores were each analyzed as a possible predictor of child BMI percentile change from baseline to one-year follow-up.

Results: The low mean of the acculturation scores suggested that Latinx caregivers generally identified more with the Spanish language/their Latinx heritage than with the English language/mainstream U.S. culture ($\bar{x} = 0.76 \pm 2.10$). Overall acculturation significantly predicted BMI change ($\beta = -0.29$, $t = -3.32$, $p = 0.001$). The degree of identification with mainstream U.S. culture appeared to drive this effect ($\beta = -0.25$, $t = -2.30$, $p < 0.05$).

Discussion: Contrary to our hypothesis, caregiver identification with mainstream U.S. culture predicted better child participant response to treatment in the form of a decrease or no change in BMI percentile. These results suggest that the "Latino paradox" may manifest differently amongst Puerto Ricans relative to other Latinx populations with different historical relationships with the U.S. Future studies should include larger, more diverse samples of Latinx child-caregiver dyads to explore differences within this culturally heterogeneous ethnic group.

ASSOCIATIONS OF MATERNAL WEIGHT, FEEDING PRACTICES, AND CHILD SELF-REGULATION OF INTAKE

Camille Schneider-Worthington, RD, PhD¹, Paige K. Berger, RD, PhD², Michael Goran, PhD³, Roshonda Jones, PhD³, Jasmine Plows, PhD³, Sarah-Jeanne Salvy, PhD⁴

¹University of Alabama at Birmingham, Birmingham, AL; ²Saban Research Institute/Children's Hospital Los Angeles, Los Angeles, CA; ³University of Southern California, Los Angeles, CA; ⁴Research Center for Health Equity, Cedars-Sinai Medical Center, West Hollywood, CA

Objective: The continued increase in the prevalence of obesity in young children is concerning, as early obesity tracks into adolescence and beyond. Parental feeding practices are important for shaping children's development of self-regulation and, in turn, weight trajectories. Yet, there is limited research into how maternal weight status may relate to feeding practices and the child's early intake self-regulation. Thus, this observational cohort study examines the relationship of mother's body mass index (BMI) with maternal feeding practices and, in turn, infant food responsiveness (FR), satiety responsiveness (SR), and emotional overeating (EOE).

Methods: Hispanic mothers were recruited during pregnancy for the parent study. At 6 months postpartum, mothers' weight and height were measured and BMI was calculated. Maternal feeding practices (assessed with Infant Feeding Styles Questionnaire) and infant FR and SR (assessed with Baby Eating Behavior Questionnaire) were examined at 6 months. At 12 months, FR, SR, and EOE were assessed using the Child Eating Behavior Questionnaire. Spearman partial correlations were used to examine associations between maternal BMI and infant feeding practices at 6 months, and associations between infant feeding practices and infant FR, SR, and EOE. Models controlled for infant sex, birth BMI z-score, household income, and maternal age.

Results: A total of 153 mothers had complete data and were included in analyses. In separate models for maternal feeding practices at 6 months, higher BMI was associated with higher scores for restricting the amount the infant consumes (Spearman partial $r=0.17$, $P=0.04$), but lower scores for responsivity to infant satiety (Spearman partial $r=-0.21$, $P=0.01$). Restricting the amount the infant consumes was not associated with infant FR or SR at 6 or 12 months, but was associated with infant EOE at 12 months (Spearman partial $r=0.20$, $P=0.01$). Maternal responsivity to infant satiety cues was inversely associated with infant FR at 6 months (Spearman partial $r=-0.17$, $P=0.04$), but not 12 months (Spearman partial $r=-0.10$, $P=0.21$). Greater maternal responsivity to infant satiety cues at 6 months was significantly associated with lower infant EOE at 12 months (Spearman partial $r=-0.21$, $P=0.01$).

Conclusions: Mothers with excess weight may be more likely to engage in more restrictive and less responsive feeding practices which may affect infant self-regulation of intake. Parental feeding practices shape the early feeding environment and may be a potentially modifiable intervention target to improve the child's self-regulation and weight trajectory. Future studies examining the influence of parental weight status on feeding practices and child early self-regulation of intake are needed, as these may be important for shaping the child's future health.

6:15 PM-7:30 PM

ASSOCIATION BETWEEN PAIN CATASTROPHIZING AND FREQUENT CRAVING FOR PRESCRIPTION OPIOIDS IN PATIENTS WITH CHRONIC PAIN

Dokyoung S. You, PhD¹, Maisa Ziadni, PhD², Jennifer Hah, MD, MS², Beth D. Darnall, PhD³, Sean Mackey, MD, PhD²

¹Stanford, San Mateo, CA; ²Stanford, Palo Alto, CA; ³Stanford University School of Medicine, Palo Alto, CA

The primary aim of this study was to characterize the association between pain catastrophizing and frequent opioid craving using a learning healthcare system in a sample of patients with chronic pain because craving is not a easily modifiable, but strong predictor for opioid misuse. Therefore, this study retrospectively reviewed the self-reported health status of adult patients seeking treatment at a tertiary pain clinic and endorsing prescription opioid use at their initial medical visit. The PROMIS® health and misuse item banks and pain catastrophizing scale (PCS) were administered. First, a MANOVA was conducted to compare the PROMIS measures and PCS scores among patients with varying frequencies of craving (never, rarely, and at least sometimes). Second, an ordinal logistic regression was conducted to examine the association between pain catastrophizing and frequent craving, and negative affect as an explanatory covariate for the association. Among a total of 288 patients (62% female), 67.6% endorsed 'no', 14.6% endorsed 'rarely,' and 17.7% endorsed 'sometimes or more frequent' craving. Patients endorsing craving at least sometimes demonstrated poorer functioning for all PROMIS health measures, more opioid misuse, and greater pain catastrophizing compared to patients endorsing 'no' or 'rarely' craving. Compared to the low levels of PCS scores (< 20), the moderate (20–29) and high (> 29) levels were associated with more frequent craving (OR = 2.3 and 2.8, $ps \leq .012$, respectively) above and beyond pain severity ratings. When entering negative affect as a covariate, the initially significant association was abolished ($ps > .288$), suggesting negative affect explained the association. In conclusion, poorer physical and psychosocial health status were evident in patients endorsing more frequent craving, and the positive association between pain catastrophizing and craving frequency was explained by negative affect. Therefore, pain catastrophizing, as a modifiable risk factor, may be a treatment target to reduce craving frequency through the reduction of negative affect.

TRAUMA HISTORY, DEPRESSION, AND PAIN SEVERITY LINKED IN CHRONIC PELVIC PAIN

Bayley J. Taple, MS¹, David J. Klumpp, PhD¹, Catherine S. Bradley, MD², Niloofar Afari, PhD³, James W. Griffith, PhD¹¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²University of Iowa, Iowa City, IA; ³VA Center of Excellence for Stress and Mental Health and Department of Psychiatry UC San Diego, San Diego, CA

This study from the Multi-Disciplinary Approach to the Study of Chronic Pelvic Pain (MAPP) Research Network examines the relationships among baseline pelvic pain severity, baseline level of depression, childhood and recent trauma exposure (i.e., sexual trauma and physical violence) in patients with urologic chronic pelvic pain syndromes (UCPPS). The etiology of UCPPS is unclear and patients present with heterogeneous symptomatology. Previous research has demonstrated that chronic pelvic pain is associated with trauma history. Moreover, patients with UCPPS often have concurrent emotional distress (e.g., depression and anxiety). Psychosocial factors, including trauma exposure and depression, influence pain symptoms and quality of life for individuals with chronic pelvic pain. Therefore, investigating the relationships among psychosocial factors and pain experience is crucial for the care of these patients. Participants ranged from ages 18 to 82 ($M \pm SD = 43.4 \pm 15.1$ years). The sample, $N = 422$, was 54.7% female. Trauma was assessed with the *Childhood Experiences of Trauma Scale (CTES)* and the *Recent Experiences of Trauma Scale (RTES)*. This study is a secondary analysis of observational data. We analyzed the relationships among sexual trauma and experiences of physical violence, depressive symptoms, and pelvic pain severity. We conducted bivariate correlations for men and women separately. In men and women, baseline pelvic pain severity was associated with childhood sexual trauma ($r_M = .16, p < .05$; $r_W = .14, p < .05$) and baseline level of depressive symptoms ($r_M = .39, p < .001$; $r_W = .36, p < .001$). For women, there was also a small but significant relationship between baseline pelvic pain severity and recent physical violence ($r_W = .13, p < .05$). Overall, baseline pelvic pain severity was related to trauma history and symptoms of depression in individuals with chronic pelvic pain. UCPPS likely has multiple causal influences; the associations among pain, depression, and trauma suggest that these patients may benefit from treatment of emotional and trauma-related symptoms. These findings begin to shed light on the potential clinical implications of the integration of mental health screening assessments in urology and gynecology settings. Going forward, we plan to conduct a multivariable regression analysis as well as longitudinal exploratory analyses to further investigate the nature of these relationships (OSF Registration DOI: 10.17605/OSF.IO/K5JUF).

DIMINISHED DISCLOSURE OF CHRONIC ILLNESS STATUS AMONG COLLEGE STUDENTS WITH FUNCTIONAL AND PAINFUL ILLNESSES

Estée C. Feldman, BS¹, Susan T. Tran, PhD², Rachel N. Greenley, PhD¹¹Rosalind Franklin University of Medicine and Science, North Chicago, IL; ²DePaul University, Chicago, IL

Statement of Problem: College students with chronic health conditions may be at risk for lower social support given their health status and their developmental stage. Yet, little is known about how aspects of the chronic health condition (e.g., etiology of illness, extensiveness of pain) may influence the acquisition of social support in this group. This study assessed whether structural (i.e., number of friends disclosed to) and functional (i.e., perceived support following disclosure) social support differed as a function of illness etiology and pain symptomatology in a sample of undergraduates with chronic physical illness.

Subjects & Procedure: 121 students with varying chronic physical illness participated. Participants reported the number of friends to whom they had disclosed their chronic health condition and their perceived level of peer level of support following disclosure (on a 5-point Likert scale, with higher scores reflecting more support). Chronic health conditions were grouped based on etiology (functional v organic) and based on pain (pain present v no pain).

Results: A chi square test revealed no differences in etiology of illness or pain symptomatology as a function of age, race, ethnicity or biological sex, so none of these were included as covariates. Linear regressions revealed that individuals with functional illnesses ($M=7.30, SD=4.84$) disclosed to fewer friends than did those with organic illnesses ($M=13.25, SD=14.21, b = -.19, SE = .07, t = -2.66, p = .009, r^2 = .25$). Those with painful illnesses ($M=8.30, SD=5.82$) disclosed to fewer friends, $b = -.144, SE = .07, t = -2.09, p = .039, r^2 = .20$ than those without pain symptomatology ($M=13.16, SD=14.70$). There were no differences in perceived support following disclosure between those with functional ($M=3.24, SD=.85$) or organic illnesses ($M=3.49, SD=.71, b = .06, SE=.04, t=1.65, p=.102, r^2 = .16$) or between those with painful ($M=3.30, SD=.85$) or pain free illnesses ($M=3.48, SD=.71, b = .04, SE=.04, t=1.1, p=.274, r^2 = .11$).

Conclusion: College students with chronic physical illness of functional etiology and with painful symptomatology disclose their illness status to fewer friends than do those with organic or pain-free illnesses. However, they experience no less social support following the act of disclosure. This suggests that while individuals with functional and painful illnesses may anticipate poorer outcomes and greater stigmatization following disclosure, they receive social support comparable to peers with organic and pain-free illnesses following disclosure, potentially indicating a mismatch between anticipated and enacted stigmatization among this population. Future research is needed to understand the extent to which anticipated stigma may play a role in lower rates of disclosure, and whether lower rates of disclosure pose risks for psychosocial or disease self-management domains.

DSM-5 EMERGING MEASURES USED IN PATIENT EDUCATION TO IMPROVE PAIN CARE AMONG VETERANS

David Cosio, Ph.D./ABPP¹¹Jesse Brown VA Medical Center, Chicago, IL

Objectives: According to the Institute of Medicine report from 2011, people who suffer from chronic pain have substantial unmet educational needs. Past research has also documented a strong association between chronic pain and psychopathology. Individuals who suffer from this comorbidity have been shown to have impaired recovery and experience further deterioration of psychiatric symptoms. Pain education programming has been found to create positive changes on mental health, specifically depression, and decrease functional disability. The purpose of the current pilot study was to determine whether participation in a pain education program would decrease symptoms on psychiatric and functional disability domains as measured by the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM-5) emerging measures.

Methods: A sample of 90 Veterans participated in the Pain Education School program at a Midwestern Department of Veterans Affairs (VA) Medical Center between November 1, 2013–October 31, 2014. All participants completed a pre- and post-education assessment which included the World Health Organization Disability Assessment Schedule and the DSM-5 Self-Rated Level 1 Cross-Cutting Symptom Measure-Adult.

Results: Paired-samples t-tests were conducted to evaluate the impact of the pain education program on Veterans' scores. The current pilot study found a significant difference in depression ($p=.005$) and in mobility ($p=.000$), social participation ($p=.001$), and total functional disability scores ($p=.001$) upon completion of the pain education program.

Discussion: Findings offer support for the use of pain education programming and DSM-5 emerging measures to enhance clinical practice and decision-making in a Veteran population.

A MIXED METHODS EXPLORATION OF ELECTRICAL STIMULATION IN VETERANS WITH FIBROMYALGIA SYMPTOMS & AFFECTIVE DISORDERS

David Cosio, Ph.D./ABPP¹¹Jesse Brown VA Medical Center, Chicago, IL

Introduction: Past research has shown that electrical stimulation has modest beneficial effects on symptoms of fibromyalgia, which is also commonly associated with anxiety and depression. The purpose of the current study was to evaluate the effectiveness and utilization of electrical stimulation at-home by Veterans.

Methods: Sixty Veterans were identified using the Fibromyalgia Symptoms Questionnaire for an electrical stimulation trial during January 1–December 31, 2016 at a Midwestern VA Medical Center. Each patient completed a brief, semi-structured phone interview, which included an inquiry about the benefits of the units on affective symptoms.

Results: Quantitative findings suggest that participants who were given any kind of unit did not have a significant difference in pain level at follow-up. Participants who were given an AID unit reported a significant difference in anxiety symptoms, while those given the M unit reported a significant difference in depressive symptoms at follow-up. Qualitative findings produced three thematic maps: utilization, effectiveness, and satisfaction.

Limitations: This study used a quasi-experimental, one group, pre-/post-test design, and explored the benefits of programming when based on patient self-selection. The instruments used in this study were self-report measures, and some changes may have been the result of outside services and not the treatment delineated in this study. The findings may differ among other Veterans as the current sample had a larger representation of minority groups compared to the typical Veteran profile.

Conclusions: This information is invaluable in helping patients who suffer fibromyalgia symptoms and affective disorders, and for the providers aiding in their treatment.

DOES COGNITIVE BEHAVIORAL THERAPY INCREASE ACCEPTANCE OF CHRONIC PAIN? A PRACTICE-BASED EVALUATION AMONGST VETERANS

David Cosio, Ph.D./ABPP¹¹Jesse Brown VA Medical Center, Chicago, IL

Purpose: Limited existing literature suggest that ACT and CBT for chronic pain result in comparable improvements in distress and functional impairment, yet it is unclear whether CBT also inadvertently reinforces acceptance-based skills and beliefs. The current study aimed to fill a gap in the literature by evaluating whether group CBT for chronic pain results in clinically meaningful changes in pain-related acceptance in a population of Veterans. The current study also examined the effect of CBT on standardized outcomes (i.e., self-efficacy, health locus of control, quality of life, and illness perception).

Methods: A total of 1204 Veterans with mixed, idiopathic, chronic pain voluntarily participated in a 12-week patient pain education program at a Midwestern VA Medical Center between November 13, 2012 and October 23, 2014. Veterans were then given the opportunity to sign-up for either the ACT and/or CBT groups for chronic pain upon learning about the interventions. A total of 84 (7%) Veterans self-selected to participate in the CBT for pain group intervention. Approximately 60% of the sample ($N = 50$) completed both the pre- and post-intervention assessments, and their responses were included in the current study. The outcome were assessed using the Chronic Pain Acceptance Questionnaire – Revised (CPAQ-R), the Pain Self Efficacy Questionnaire, the Multidimensional Health Locus of Control – Form C, the World Health Organization Quality of Life – BREF, and the Brief Illness Perception Questionnaire. Paired-samples t-tests were conducted to evaluate the effect of the intervention on the outcome variables from baseline to post-treatment.

Results: There was no significant change in pain-related willingness, $t(49) = -1.58$, $p = .120$. There was a significant increase in pain-related self-efficacy, $t(49) = -4.13$, $p < .001$, Cohen's $d = .452$. There was a significant increase in internal locus of control, $t(49) = -3.23$, $p = .002$, Cohen's $d = .366$. There was no significant change in chance locus of control, psychological nor environmental quality of life, and in illness perception.

Conclusions: Results of the present study indicated that group CBT for chronic pain in Veterans increased pain-related acceptance, yet this increase was driven by greater engagement in activities (i.e., participating in everyday activities despite the presence of pain) and not by changes in willingness to experience pain (i.e., decreasing the cognitive fight against pain). These outcomes support the notion that CBT's focus on modifying maladaptive behaviors may inadvertently increase acceptance of chronic pain by reducing behavioral avoidance, which is consistent with the goal of acceptance-focused treatments. Results further indicated that CBT increased both self-efficacy for pain management and internal health locus of control.

PERCEIVED INJUSTICE MEDIATES THE RELATIONSHIP BETWEEN CHILDHOOD NEGLECT AND CURRENT FUNCTION IN PATIENTS WITH CHRONIC PAIN

Maisa Ziadni, PhD¹, Dokyoung S. You, PhD¹, Sean Mackey, MD, PhD¹, Beth D. Darnall, PhD²¹Stanford, Palo Alto, CA; ²Stanford University School of Medicine, Palo Alto, CA

Objective: Cumulative evidence supports the association between perceived childhood neglect and adulthood psychological and physical health, but pathways mediating this association remain largely unknown. The current study examined perceived injustice about chronic pain as a possible mediator, given negative appraisals shaped by childhood maltreatment appear to be generalized to health perception, and perceived injustice about chronic pain has emerged as a salient predictor of pain-related outcomes. Additionally, the Perceived Unfairness Model posits that injustice beliefs as a stressor can lead to negative health consequences over time.

Methods: Patients (n = 742) visiting a tertiary pain clinic completed a survey administered via the Collaborative Health Outcomes Information Registry. Path modeling analyses were used to examine perceived injustice as a mediator of the relationships between childhood neglect and psychological function (depression, anxiety, and anger) and physical function, after controlling for well-known covariates like pain intensity ratings and pain catastrophizing.

Results: Patients endorsing childhood neglect reported higher levels of perceived injustice and worse psychological and physical function. As expected, the effects of childhood neglect on psychological and physical function through perceived injustice were significantly different from zero, suggesting perceived injustice was a significant mediator.

Conclusions: Perceived injustice is a possible cognitive pathway linking perceived childhood neglect to worse psychological and physical function in patients with chronic pain. Therefore, perceived injustice may be a determinant of psychological and physical health and a treatment target for patients suffering from chronic pain and endorsing childhood neglect even after adjusting for pain severity ratings and pain catastrophizing.

ANXIETY AND DEPRESSION IN MIGRAINE: THE ROLE OF EXPERIENTIAL AVOIDANCE

Ashley N. Polk, M.A.¹, Traci A. Protti, M.S.¹, Skylar Cochran, n/a¹, Cara Wittig, n/a¹, Todd Smitherman, Ph.D.¹¹University of Mississippi, Oxford, MS

Migraine is a chronic and disabling condition, with prevalence rates peaking in young adulthood. Migraine is often comorbid with depression and anxiety, which compound headache disability. Anxiety and depression can trigger headache and lead to avoidance of valued activities and potential headache triggers. Experiential avoidance (EA), or unwillingness to experience adverse personal events (e.g., thoughts, feelings, physical sensations), contributes to psychological distress and further exacerbates headache disability. A growing body of literature suggests that avoidance of headache stimuli, a common component of routine migraine management in clinical settings, may actually increase sensitivity to these stimuli over time. However, relations between EA and common psychiatric comorbidities have not been explored among individuals with migraine. The aim of the present study thus was to explore this relationship while accounting for relevant headache covariates.

2,003 undergraduate students completed measures assessing headache symptoms (SDIH-3), disability (HIT-6), experiential avoidance (AAQ-II), and psychiatric symptoms (DASS-21). Of these, 153 met ICHD-3 classification criteria for migraine and were included in the present study. Hierarchical regressions were used to assess unique relationships between EA and depression and anxiety symptoms among migraineurs while controlling for severity and disability.

Participants' mean age was 19.0 (2.4) years; 87.6% were female. They reported 9.9 headaches per month (5.9) with an average severity rating of 6 out of 10 (1.5). Participants reported a mean disability score of 61 (6.7), indicating severe headache impact. Participants reported moderate levels of depression (M = 9 [9.9]), anxiety (M = 10 [8.7]), and EA (M = 25 [9.3]). In the first hierarchical regression, EA predicted depression symptomatology ($\beta = .52$, $\Delta R^2 = .22$, $p < .001$) above and beyond headache severity and disability. In a second regression, EA also predicted anxiety symptoms ($\beta = .48$, $\Delta R^2 = .19$, $p < .001$) after controlling for headache variables.

The present study found that EA accounts for a substantial amount of unique variance in migraineurs' depression and anxiety, as the observed effects were of medium size even after controlling for headache severity and disability. These findings suggest that increased EA is associated with worsening psychological symptoms among migraineurs. As such, well-established behavioral treatments (e.g., relaxation training, biofeedback, stress management) may incorporate acceptance and flexibility practices to foster improved engagement with intrapersonal and affective experiences that exacerbate head pain. Treatment studies investigating application of these approaches to reduce risk of headache chronification and comorbid depression and anxiety are warranted.

IMPACT OF OPIOID PRESCRIBING POLICIES ON EARLY HIGH-RISK OPIOID PRESCRIBING PRACTICES FOR INJURED WORKERS IN WASHINGTON STATE

Jeanne M. Sears, PhD, MS, RN¹, John R. Haight, MPH², Deborah L. Fulton-Kehoe, PhD, MPH², Thomas Wickizer, Ph.D., M.P.H.³, Jaymie Mai, PharmD⁴, Gary Franklin, MD, MPH²

¹University of Washington, Kirkland, WA; ²University of Washington, Seattle, WA; ³College of Public Health, Ohio State University, Columbus, OH; ⁴Washington State Department of Labor & Industries, Olympia, WA

Objective: High-risk opioid prescribing practices over the past two decades have contributed to a national opioid overdose epidemic. Injured workers, many of whom experience chronic pain, have been exposed to dramatic temporal changes in opioid prescribing practices. Accumulating evidence suggests that even limited opioid use for acute pain could increase long-term opioid use, as well as long-term disability. State-level opioid prescribing policies may promote prevention goals, but it remains unclear which specific policies are most effective. The aim of this study was to assess the associations between implementation of several opioid prescribing policies and changes in early high-risk opioid prescribing practices.

Methods: This study included 676,118 injured workers with Washington State Fund workers' compensation claims for injuries occurring from January 2008 through June 2015. Several Washington State opioid prescribing guidelines and rules, as well as a prescription monitoring program, were implemented during the study timeframe. We used single-group interrupted time series analysis of monthly pharmacy billing data to test associations between policy interventions and reductions in 5 high-risk opioid prescribing measures during the first 3 months after injury: (1) > 7 days supply of opioids, (2) high dose, (3) concurrent opioids and sedatives, (4) chronic opioids, and (5) a composite indicator (presence of any of the 4 specific indicators).

Results: During the first 3 months after injury, 9% of injured workers were exposed to high-risk opioid prescribing practices, 12% to low-risk opioid prescribing, and 79% did not fill any opioid prescription. Among workers prescribed any opioids during those 3 months (N=138,124), 30% had the > 7 days supply indicator, 18% had the high dose indicator, 3% had the concurrent indicator, and 2% had the chronic indicator (not mutually exclusive). Each policy intervention was associated with significant reductions in certain high-risk prescribing indicators. Over the timeframe of this study, there was a general shift toward more infrequent and lower-risk opioid prescribing.

Conclusions: Washington State has been a national leader in transforming workers' compensation-related health care delivery and promoting safer opioid prescribing practices. This study demonstrated that several different opioid prescribing policies were significantly associated with reductions in particular high-risk opioid prescribing practices.

SYNERGISTIC IMPACT OF PAIN INTERFERENCE AND DEPRESSION ON QUALITY OF LIFE AND FUNCTION OF THE STROKE PATIENTS

Gina Evans-Hudnall, PhD¹, Jafar Bakhshaie, MD PhD¹, Jane Anderson, PhD²

¹Baylor College of Medicine, Houston, TX; ²Michael E. DeBakey VA Medical Center, Houston, TX

In the United States (U.S.), stroke incidence has decreased from the third to the fifth leading cause of death. Physical pain is a common health condition that occurs after having a stroke. In addition, approximately 30 percent of patients experience depression symptoms post stroke. Both physical pain and depression symptoms impact community integration and quality of life in patients who have had a stroke. Using the baseline data from the VSTOP-EPIC program, this study aims to investigate the interactive effects of pain interference and depression in quality of life and community integration outcome in post-stroke patients. The VSTOP-EPIC program of a 6 session behavioral stroke self-management program that provides an additional 6 sessions that target psychological distress for participants with mild to moderate symptoms of depression and anxiety. At baseline, participants completed validated measures of patient activation, depression, pain severity, and community integration. The main and interactive effects of pain interference and depressive symptoms as predictors of three domains of community integration (home, social, work/activity/productivity), after controlling for relevant covariates (gender, age, stroke severity measured by National Institutes of Health Stroke Scale) were examined. Fifty four participants were included in the logistic regression analyses. In terms of home integration, pain interference and depression accounted for a significant amount of variance ($B = 4.03$, $SE = 1.48$, $p = .007$, and $B = -.044$, $SE = .19$, $p = 0.020$; see Table 2). Regarding social and productive activity integration, pain interference and depression were not significant predictors. However, the interaction terms were significant for both of these dependent variables ($B = -.30$, $SE = .12$, $p = .02$, and $B = -.32$, $SE = .10$, $p = .002$ respectively). Simple slope analyses revealed that pain interference was related to lower levels of productive activity integration among individuals with higher but not lower levels of depression ($B = -2.38$, $SE = 1.10$, $p = .03$, and $B = -3.03$, $SE = .87$, $p = .001$ respectively for slope of the relation between pain and social and productive activity integration respectively). Thus, post-stroke patients with comorbid pain interference and depression showed poorer levels of work and social integration. These data highlight the importance of targeted assessment strategies and interventions that seek to reduce pain and depression among post-stroke patients.

“THE BALM OF HURT MINDS”: AN EXAMINATION OF THE EFFECT OF SLEEP ON CHRONIC PAIN

Kimberly O'Leary, PhD¹, Paul A. Sloan, PhD.²¹Michael E DeBakey Veterans Affairs Medical Center, Temple, TX; ²Department of Veteran Affairs, Houston, TX

Background: Sleep disturbances and pain are intimately linked – the field has long recognized that disturbed sleep influences pain management and that pain intrudes on sleep cycles. Sleep disturbance and pain are particularly prevalent in Veteran populations and tend to be manifestations of a cyclical pattern of dual interference. However, recent longitudinal studies suggests that sleep impairment uniquely predicts later chronic pain. The goals of the present study were to characterize the relationship between sleep and pain in veterans who participated in Pain Management Clinic treatment and to assess the impact of sleep in predicting later recovery.

Methods: We conducted a secondary analysis of cross-sectional data to establish basic relationships between variables (e.g. sleep and pain at time of evaluation). Veterans presenting for initial chronic pain evaluations completed study questionnaires (i.e. pain catastrophizing, pain intensity). Correlations between key variables were run to examine baseline associations. Veterans who completed a behavioral treatment for chronic pain management (e.g. Living with Chronic Pain) completed these questionnaires following completion of treatment. Subsequently, multiple regression models were used to examine associations between sleep domains and later measures of chronic pain management.

Results: At Time 1, a total of 1885 Veterans completed measures of pain and sleep as part of their initial evaluation. A significant interaction (all p 's < .05) was found for the relationship between sleep and average pain ($r = .159$), pain interference ($r = .360$), pain catastrophizing ($r = .388$), and perceived stress ($r = .399$) at time of intake. At Time 2, 43 Veterans completed measures following discharge from a Pain Management Class. Importantly, sleep at time of intake predicted pain intensity ($\eta_p^2 = .246$) and pain catastrophizing ($\eta_p^2 = .204$) at time of discharge. Ongoing analyses will provide further evaluation into the predictive power of sleep on pain measures at point of discharge.

Conclusions: Pain and sleep disturbances are of the most frequently reported complaints in a medical setting. Impairments in sleep specifically may be associated with deficiencies in multiple domains of pain management, even following successful behavioral treatment. Our results suggest that chronic sleep problems are an important contributor and maintenance factor for pain domains.

ADHERENCE TO DAILY ASSESSMENT CALLS DURING COGNITIVE BEHAVIORAL THERAPY FOR CHRONIC PAIN

Brett Ankawi, PhD¹, Mary A. Driscoll, PhD², Sara N. Edmond, PhD³, Diana M. Higgins, PhD⁴, R. Ross MacLean, PhD.⁵, Alicia Heapy, PhD³¹VA Connecticut Healthcare System, New Haven, CT; ²VA Connecticut Healthcare System, Newtown, CT; ³VA Connecticut Healthcare System, West Haven, CT; ⁴VA Boston Healthcare System, Jamaica Plain, MA; ⁵VA Connecticut Healthcare System/Yale University, West Haven, CT

Cognitive behavioral therapy for chronic pain (CBT-CP) is effective for reducing pain intensity and improving physical activity and quality of life, but barriers such as time commitment and transportation exist. Interactive voice response (IVR) interventions rely on telephone technology to reduce treatment barriers by allowing patients to participate from home. Despite this, concerns about patient willingness to use interventions relying on frequent automated calls have emerged. In the Cooperative Pain Education and Self-management (COPES) study, a non-inferiority trial, Veterans ($n=119$) with chronic back pain were randomized to receive 10 weeks of CBT-CP, delivered either in-person ($n=58$) or via IVR ($n=61$). Veterans in both groups received daily IVR self-monitoring calls to assess their pain, sleep, activity, and pain coping skill practice. Utilizing secondary COPES data, patient engagement defined as number of calls taken was examined on aggregate and as a function of treatment group. Veteran participants were primarily male (72%) and white (80%) with longstanding pain (median: 11 years) of moderate intensity (mean 5.6/10). Participants who remained in the study for a minimum of three weeks (85.7% of the sample) completed an average of 66.1 out of a possible 77 phone calls (85.8%). Participants in the IVR-CBT-CP group (69.2, 89.9%) took more calls on average than those in the in-person CBT-CP group (62.4, 81.0%), $t = 2.74$, $p < 0.01$. Bivariate correlations were run first on aggregate data to determine relationships between IVR engagement and key demographic and baseline clinical indicators; these were then repeated within each group. Number of calls taken was not related to age, sex, employment, education, or to baseline levels of depression, pain catastrophizing, cognitive ability, pain or functional interference for the full sample and for each group (all p values > 0.05). For participants receiving in-person CBT-CP only, higher mood dysregulation was related to better call adherence. The high call adherence rate suggests that participants found the daily IVR monitoring acceptable and the lack of a relationship with demographic variables suggest that this treatment is acceptable to a wide range of patients. Taken together, these findings support the use of daily IVR technology in behavioral interventions for pain without concern for disproportional engagement by specific groups (e.g., women, older people, etc). Further, although patients in the in-person CBT-CP group took fewer calls than those in the IVR-CBT-CP group, their adherence was fairly high, suggesting IVR symptom monitoring may be an acceptable addition to in-person interventions.

6:15 PM-7:30 PM

ADVERSE CHILDHOOD EXPERIENCES (ACES) IN FIBROMYALGIA: WHAT IS THE ROLE OF RESILIENCE?

Madeleine Allman, MPH¹, Barbara Bruce, PsyD², Shehzad K. Niazi, MD, FRCP, FACLP², Mohit Chauhan, MD², Barbara Bruce, PhD³¹Baylor College of Medicine, Houston, TX; ²Mayo Clinic, Jacksonville, FL; ³Mayo Clinic, Jacksonville Beach, FL

Introduction: Adverse Childhood Experiences (ACES) generally include child maltreatment (i.e., child abuse and neglect) and household environmental challenges (i.e., witnessing intimate partner violence) that occur during the first 18 years of life. A positive relationship exists between the number of ACES a person experiences and the risk of several health outcomes. Adverse childhood experiences (ACES) have been linked to chronic pain disorders and Fibromyalgia. Previous research has shown an association between ACES and increased pain catastrophizing and depression in Fibromyalgia patients. Further research has found that patients with Fibromyalgia may have poor resilience. We hypothesized that resilience would moderate the relationship between childhood adversity and pain catastrophizing and depression in Fibromyalgia patients.

Method: The present study examined the presence of adverse childhood experiences and depression and pain catastrophizing and resilience in a sample of 163 patients diagnosed with Fibromyalgia who were referred for treatment in a multicomponent treatment program at a large tertiary medical center. Demographic and clinical data were collected at program admission. Patients completed the Adverse Childhood Experiences Questionnaire, the Revised Fibromyalgia Impact Questionnaire (FIQR), the Center for Epidemiologic Studies of Depression Scale (CES-D), the Pain Catastrophizing Scale (PCS), and the Connor-Davidson Resilience Scale.

Results: The average pain catastrophizing score was 25.01 (SD= 13.20). The average CES-D score was 27.35 (SD=13.50). Seventy-two percent of the sample reported at least one ACE with an average of 2.5 ACES (SD= 2.45). The average resilience score was 26.15 (SD= 8.04). Analyses revealed that childhood adversity was significantly related to pain catastrophizing ($p < .01$) and depression ($p < .05$). Resilience was not significantly associated with pain catastrophizing or depression ($p > .05$). There was no significant interaction between resilience and childhood adversity ($p > .05$) on pain catastrophizing or depression.

Conclusions: The current study found that childhood adversity was significantly associated with pain catastrophizing and depression. Psychological resilience has been found to play a role in buffering against depression in adults with a history of ACES. While resilience has demonstrated a moderating effect on childhood adversity in various psychosocial factors, this relationship was not seen in this sample. The Fibromyalgia patients in this sample had an average resilience score (CDSR=26.15) similar to the general population scores (CDSR= 29.0). Further research is needed to illuminate the relationship between childhood adversity and the potential protective impact of resilience in Fibromyalgia.

AGE-VARYING ASSOCIATIONS BETWEEN PHYSICAL ACTIVITY, DEPRESSION AND ANXIETY AMONG RURAL CANCER SURVIVORS

Nishat Bhuiyan, M.S.¹, Joshua M. Smyth, PhD², Kathryn H. Schmitz, PhD, MPH, FACSM, FTOS³, Scherezade K. Mama, DrPH⁴¹The Pennsylvania State University, State College, PA; ²Pennsylvania State University, University Park, PA; ³Penn State University, Hershey, PA; ⁴The Pennsylvania State University, University Park, PA

Rural cancer survivors report higher psychological distress (e.g. depression, anxiety) than their urban counterparts. Physical activity (PA) can improve psychological outcomes, but if and how this association varies across the lifespan is unknown. We examined the prevalence of depressive symptoms and anxiety by age, and the age-varying associations between PA and depressive symptoms and anxiety among rural cancer survivors. Rural cancer survivors in the Partnering to Prevent and Control Cancer (PPCC) study completed questionnaires assessing sociodemographics, depressive symptoms, anxiety, and PA. Intercept-only time-varying effect models (TVEM) assessed the prevalence of depressive symptoms and anxiety as a function of age, and additional TVEM assessed the age-varying associations of moderate, vigorous, and total PA with depressive symptoms and anxiety. Most participants ($N=219$) were in their mid-60s (M age=64.3±12.5 years, range 18–93), female (59.7%), and overweight (M BMI=29.5±6.8 kg/m²). Intercept-only TVEM revealed that the prevalence of depressive symptoms and anxiety significantly differed by age. Depressive symptoms and anxiety were progressively lower in persons between ages 20 and 40 and were relatively stable in those older than age 40. Models revealed a significant positive association between vigorous PA and depressive symptoms and anxiety in persons aged 20 to 40, such that greater vigorous PA was associated with higher depressive symptoms and anxiety. In those over age 70, there was a significant negative association between vigorous PA and depressive symptoms, such that greater vigorous PA was associated with lower depressive symptoms. Findings suggest that younger rural cancer survivors may be using physical activity as a coping mechanism for depressive symptoms and anxiety, two known adverse effects of cancer treatment. Furthermore, results suggest that physical activity is inversely associated with psychological distress among older cancer survivors. Thus, using strategies to promote physical activity that are targeted toward rural, older cancer survivors may present an opportunity to protect against adverse mental health outcomes and treatment effects in this underserved population.

EXPLORING AN INTERACTION OF ANTIDEPRESSANTS AND DEPRESSIVE SYMPTOMS ON HEALTH BEHAVIORS IN COLLEGE STUDENTS

Celestial J. Pigart, n/a¹, Matthew C. Whited, Ph.D., Licensed Psychologist¹, Emily P. Midgette, BA¹, Alexander J. Capiaghi, BS¹, John T. Freeman, Ph.D.², Jordan M. Ellis, MA³

¹East Carolina University, Greenville, NC; ²Durham VA Healthcare System, Durham, NC; ³East Carolina University, San Antonio, TX

Introduction: Physical activity and healthy eating are important health behaviors however, maintaining these behaviors is challenging in the context of depressive symptoms. Although antidepressants help reduce depressive symptoms, it is unclear how antidepressants interact with depressive symptoms to impact health behaviors, especially among emerging adult college students.

Method: Across 2 academic years, a comprehensive survey of college student health was administered anonymously online to 4286 students in exchange for extra credit in a course. Separate items examined how many hours of moderate and strenuous activity (operationally defined for the participant) a participant had over the past 7 days. History of strenuous activity while in high school, and since starting college were quantified as number of days in a week of at least 20 minutes of activity. Two by two factorial ANOVAs with self-reported antidepressant status (Yes v. No) and presence of clinically significant depressive symptoms (> 9 on PHQ9) were used to determine if the interaction between these two factors influenced selected health behaviors. Quick Food Scan from the Eating at America's Table study was used to assess intake of specific food items (e.g. potatoes, vegetables, fruit, beans).

Results: Valid responses based on embedded validity checks resulted in an analytic sample of 3547. Significant interactions between depressive symptoms and antidepressant status were not found for moderate activity ($p = 0.145$) but were found for strenuous activity $F(1, 3432) = 6.643, p = 0.01$. Among individuals with clinically significant depressive symptoms, those who were taking antidepressants reported more weekly strenuous activity ($p < 0.001$) than those not taking antidepressants. History of activity was examined through two items, one examining strenuous activity since starting college $F(1, 3438) = 8.107, p = 0.004$ and another during high school $F(1, 3440) = 6.585, p = 0.01$. Among individuals with clinically significant depressive symptoms, those who were taking antidepressants, reported more strenuous activity prior to, and since starting, college than those not taking antidepressants (all p 's < 0.001). Dietary consumption items (QFS) found non-significant effects when examined for an interaction with antidepressants and depression status (all p 's > 0.05).

Discussion: These results suggest that antidepressants may also provide a “protective effect” for maintaining healthy exercise habits in young adults who are still experiencing depressive symptoms. Further research is necessary to determine if this is a consistently observable effect, and to understand mechanisms by which antidepressants enable individuals experiencing depressive symptoms to maintain physical activity.

PARENTAL AND CHILD EXERCISE AVERSION ASSOCIATED WITH CHILD PHYSICAL ACTIVITY

Karolina Zarychta, PhD¹, Monika Boberska, MA², Aleksandra Luszczynska, PhD²

¹SWPS University, Wroclaw, Mazowieckie, Poland; ²SWPS University of Social Sciences and Humanities, Warsaw, Mazowieckie, Poland

Background: Parental and child cognitions explain child behaviors. A lot is already known in the context of the associations between these factors and food aversion. Yet, there are no studies testing physical activity aversion. This study investigates associations between physical activity aversions (self-reported child aversion and self-reported parental aversion), and child physical activity. Moderating role of child body mass was tested.

Methods: Prospective study with the 7-8-month follow-up was conducted among 879 parent-child dyads (52.4% girls, aged 5–11 years old, 83.2% mothers). Participants completed self-report measures on their physical activity aversion and physical activity; body weight and height were measured objectively.

Findings: Across children with low and high body mass, there was no direct association between parental physical activity aversion and child physical activity. However, parents with high levels of physical activity aversion (T1) were more likely to perceive their children as having high levels of physical activity aversion (T1). In turn, their children were more likely to report high levels of physical activity aversion (T2), which in turn predicted low physical activity in children (T2). The results were similar across subgroups children with low and high body mass.

Discussion: Parental aversion may constitute the first determinant in the chain of aversion-related cognitions, and thus, it may need to be targeted in programs aiming to change physical activity behaviors in children.

MIDDLE-AGED ADULTS' EXPECTANCIES PRIOR TO STARTING A COGNITIVE-MOTOR TRAINING AND EXERCISE PROGRAM

Sean P. Mullen, PhD¹, Jason D. Cohen, Ph.D.², Adam P. Taggart, MSc¹, Tiffany Bullard, B.S.¹, Daniel Palac, PhD³, Walter Boot, PhD⁴, Arthur F. Kramer, PhD⁵, Edward McAuley, PhD⁶

¹University of Illinois at Urbana-Champaign, Urbana, IL; ²Washington University in St. Louis, St. Louis, MO; ³Exponent, Urbana, IL; ⁴Florida State University, Tallahassee, FL; ⁵Northeastern University, Boston, MA; ⁶University of Illinois, Urbana, IL

Much interest exists in finding robust interventions for attenuating cognitive aging. In certain circumstances, expected physical and cognitive benefits, as a function of either physical or cognitive exercise, may to some extent, increase one's engagement in such interventions. The extent to which expectancies at the start of a cognitive-motor training program yield any actual benefits is unknown. We hypothesized that baseline expectancies of physical and cognitive enhancement would contribute to greater physical and cognitive effort and subsequent functioning. In this study we conducted correlational and path analyses with data collected from a randomized controlled trial designed to test the efficacy of a cognitive-motor training program (n=68) on subsequent exercise adherence (compared to an attention control video condition; n=65). Cognitive functioning (e.g., Stroop response time, Sternberg memory) and psychosocial assessments (e.g., *Multidimensional Outcome Expectancies for Exercise Scale*, *Exercise Motivation Inventory-2*; *Physical Activity Self-Regulation Questionnaire*, *Multifactorial Memory Questionnaire*) were administered at baseline (M0) and month one (M1) follow-up. Preliminary analyses revealed significant ($p < .05$) positive Pearson r 's between M0 expectancies of physical benefits and relevant physical health-enhancement motives (*positive health and strength*: r 's = .38 and .34, respectively). Similarly, expectancy of cognitive benefit (that exercise will "increase mental alertness") was positively associated with a matching cognitive health-enhancement motive for engaging in exercise (*revitalization*: $r = .34$). Path analyses (*Mplus 8.1*) were then conducted and good model-to-data fit was achieved. Results favored the intervention group and partially supported hypotheses. Specifically, M1 cognitive and behavioral outcomes and exercise motives were regressed on M0 assessments (expectancies, demographics, group). A significant group effect favoring the intervention was found on physical strategy-use at M1 ($\beta = .19$); group's effect on memory strategy-use was in the expected direction ($\beta = .13$). As expected, cognitive performance at M1 favored the intervention (Stroop $\beta = .19$, Sternberg $\beta = .24$) and M0 expectation of increased mental alertness was independently associated with greater M1 memory-strategy use ($\beta = .23$) and faster Sternberg ($\beta = -.29$). Interestingly, higher expectancy of physical benefits was associated with lower memory-strategy use ($\beta = -.20$) and unrelated to physical strategy-use. No effects were found via exercise motives. Altogether, these data suggest that expectancies and training can facilitate greater effort (i.e., physical activity planning, memory-promotion strategies) towards achieving physical and cognitive benefits. In turn, self-directed and supervised engagement may result in greater functioning.

RELATIONSHIP OF CONSISTENCY IN TIMING OF PHYSICAL ACTIVITY (PA) AND OTHER CUES WITH PA PERFORMANCE IN BARIATRIC SURGERY PATIENTS

Leah M. Schumacher, PhD¹, Graham Thomas, Ph.D.², Sivamainthan Vithiananthan, MD, FACS³, Daniel B. Jones, MD, MS⁴, Hollie Raynor, PhD, RD⁵, Ryan E. Rhodes, Ph.D.⁶, Jennifer Webster, Bachelor of Arts in Psychology⁷, Dale Bond, Ph.D.²

¹Weight Control and Diabetes Research Center, The Miriam Hospital/Alpert Medical School of Brown University, Providence, RI; ²Brown Medical School, Providence, RI; ³The Miriam Hospital/Alpert Medical School of Brown University, Providence, RI; ⁴Harvard Medical School, Boston, MA; ⁵University of Tennessee, Knoxville, TN; ⁶University of Victoria, Victoria, BC, Canada; ⁷Lifespan / The Miriam Hospital, Providence, RI

Although bariatric surgery patients, on average, have low physical activity (PA) levels, there is considerable variability in the amounts of PA performed. Understanding factors that underlie this variability can help inform design of PA promotion strategies. There is growing evidence that consistency in temporal PA patterning (e.g., more PA in the morning [AM]) and in other cues (e.g., PA location) underlies PA variability in non-surgical populations. This study is the first to use smartphone-based ecological momentary assessment (EMA) and accelerometry in combination to examine in near real-time whether greater consistency in PA cues (time, type, location) and, specifically, more consistent AM PA, relates to higher PA levels in bariatric surgery patients. Participants (n=76) carried a smartphone synced with an accelerometer via Bluetooth for 10 d preoperatively. When a ≥ 10 -min PA bout was detected via accelerometry, participants were prompted to complete a survey to verify PA (Y/N) and report PA type and location category (e.g., home, work). PA time was automatically recorded and classified as AM (4:00-11:59am), afternoon (12:00-4:59pm), or evening (5:00pm-3:59am). For each participant with >1 verified PA bout, we identified modal type, location, and time of PA; computed % of PA bouts of this type/location/time (to provide indices of cue consistency) and % of AM PA bouts; and classified participants as a consistent AM, afternoon, or evening exerciser ($>50\%$ of bouts in one window) or a temporally inconsistent exerciser ($\leq 50\%$ of bouts in one window). PA outcomes included light (LPA) and moderate-to-vigorous PA (MVPA) min/d. Fifty-five (72%) participants with valid data performed a $M \pm SD$ of 6.8 ± 6.1 PA bouts, 287 ± 75 LPA min/d and 34 ± 23 MVPA min/d. Walking (55%), home (50%) and evening (54%) were the most common PA type, location, and time. Observed high levels of consistency in PA type (81 \pm 19%), location (82 \pm 20%) and time (74 \pm 22%) were unrelated to daily LPA and MVPA (p 's $> .05$). A greater % of AM PA bouts related to greater LPA and MVPA (p 's $< .05$). Consistent AM exercisers also performed more MVPA than evening exercisers ($M \pm SE$: 62 ± 9 vs. 28 ± 4 min/d; $p = .01$). Consistency in AM PA, but not other cues, related to higher PA levels in bariatric patients preoperatively. Future research should identify mechanisms (e.g., habit formation, better time management) underlying the benefits of AM PA and whether targeting increases in AM PA can increase PA in this population.

RECIPROCAL ASSOCIATIONS BETWEEN PHYSICAL ACTIVITY AND DEPRESSION. LONGITUDINAL RESEARCH IN PATIENT-PARTNER DYADS

MAGDALENA KRUK, MA¹, Anna Banik, PhD², Monika Boberska, MA³, Ewa Kulis, MA³, Zofia Szczuka, MA², Karolina Horodyska, PhD², Aleksandra Luszczynska, PhD³

¹SWPS University of Social Sciences and Humanities, WROCLAW, Dolnoslaskie, Poland; ²SWPS University of Social Sciences and Humanities, Wroclaw, Dolnoslaskie, Poland; ³SWPS University of Social Sciences and Humanities, Warsaw, Mazowieckie, Poland

Background: Physical activity (PA) is recommended for boosting mental health and well-being as well as for preventing the development of depression. Although numerous research investigated the associations between moderate-to-vigorous physical activity (MVPA) and depression, the order in which these variables are chained and the dyadic effects remain unclear. Therefore, using a longitudinal dyadic design and cross-lagged analyses, we examined the patterns of associations between MVPA and depression in dyads (patients with a chronic somatic illness and their partners).

Methods: Data were collected twice, with 2-3-month follow-up (Time 2; T2). Participants were 238 dyads of patients with a chronic illness ($M_{age} = 47.03$; 67.2% women) and their partners ($M_{age} = 45.47$; 65.1% women) at Time 1 (T1), whereas at T2 from 176 full patient-partner dyads. Most frequently, patients were diagnosed with cardiovascular diseases (27%) or diabetes (11%). Depression and MVPA scales were filled out by participants at T1 and T2. Path analysis was conducted, accounting for the dyadic interdependence of data, stability of the constructs over time, correlations of all T1 constructs and covariations between all T2 residuals.

Findings: Three dyadic associations were found. More intensive symptoms of depression in patients' (T1) predicted a higher intensity of depression symptoms (T2) among partners and lower levels of partners' MVPA (T2). However more frequent MVPA of patients (T1) explained lower levels of partners' MVPA (T2).

Conclusions: The study provided evidence for the dyadic pattern of associations between depression and MVPA. Accounting for the role of depression may increase the efficiency of MVPA-promoting interventions for patients with chronic diseases and for their partners.

THE EFFECT OF A SEDENTARY BEHAVIOR INTERVENTION ON PHYSICAL FUNCTION AND QUALITY OF LIFE IN AFRICAN AMERICAN OLDER ADULTS

Brianna N. Leitzelar, M.S., M.A.¹, Neda E. Almassi, B.S.¹, Kevin M. Crombie, M.S.¹, Kelli F. Koltyn, Ph.D.¹

¹University of Wisconsin - Madison, Department of Kinesiology, Madison, WI

Sedentary behavior (SB) increases the risk for declines in health and function in older adults, thus it is important to develop effective interventions to reduce SB. "Stand Up and Move More" (SUMM) is a 4-week SB intervention for older adults based in self-regulation theory. Weekly sessions focus on breaking up prolonged bouts of sitting through group discussion, goal setting, action plans, self-monitoring, and problem solving. The purpose of this pilot study was to examine the efficacy of the SUMM intervention for African American older adults. To do so, participants (age: $M=67\pm9$ yrs) completed the SUMM intervention ($n=15$) or a time and attention matched comparison intervention ($n=11$). Primary outcomes were measured at baseline (wk0) and post-intervention (wk4) and included SB (self-report, accelerometry), physical function (Short Physical Performance Battery), and quality of life (SF-36). Perceptions of the workshop were recorded at wk4. Results from repeated measure ANOVAs indicated no significant changes in accelerometer-derived SB or physical function. There was a significant group effect for self-report SB ($p < 0.05$) such that those in the comparison group reported more SB ($M=612.6\pm153.6$ mins/day) than those in the SUMM group ($M=448.2\pm153.5$ mins/day). In addition, there were significant improvements in quality of life (SF-36 subscales: social functioning and role-physical). Specifically, there was a significant group by time interaction for social functioning ($p < 0.05$). Post-hoc analyses revealed increased social functioning from wk0 ($M=60.3\pm30.6$) to wk4 ($M=78.3\pm19.8$, $p < 0.05$) in the SUMM group and no change in the comparison group ($p > 0.05$). Further, both groups reported higher role-physical scores from wk0 ($M=52.9\pm25.1$) to wk4 ($M=61.8\pm21.3$, $p < 0.05$), indicating fewer problems due to physical health. Pearson correlation analysis revealed a negative correlation between the change in SB and the change in vitality (SF-36 subscale) ($R=-.80$, $p=.003$), indicating those with the largest reduction in SB had the largest increase in vitality. Lastly, participants reported the SUMM workshop was beneficial, encouraging, and made them aware of their sitting time. These results indicate there were quality of life benefits from participating in the SUMM workshop. Future work with larger sample sizes is needed to determine the efficacy of the SUMM intervention for reducing SB and improving physical function for African American older adults. DEEP LEARNING AND GOOGLE STREETVIEW: AUTOMATING MICROSCALE AUDITS OF STREET INTERSECTION FEATURES FOR PHYSICAL ACTIVITY

Marc A. Adams, PhD, MPH¹, Akshar D. Patel, n/a², Hannah Hook, MSc Sustainable Cities, MSc GIS Technology³, Tsung-Yen Yu, MCS⁴, Ariane Middel, PhD¹, Ross Maciejewski, PhD⁴, Vincent Berardi, PhD⁵, Christine B. Phillips, PhD⁶

¹Arizona State University, Phoenix, AZ; ²Arizona State University College of Health Solutions, Tempe, AZ; ³Arizona State University, Gilbert, AZ; ⁴Arizona State University, Tempe, AZ; ⁵Chapman University, Long Beach, CA; ⁶Atria Senior Living, Louisville, KY

Background: Microscale built environment (BE) features correlate with physical activity (PA), even after accounting for macro-scale walkability. In-person audits of microscale features are time-intensive, require extensive training, and are susceptible to auditor fatigue. Virtual audits are valid alternatives to in-person audits and effectively eliminate travel, weather, and safety challenges, yet still rely on the limitations of trained human labor. Artificial intelligence could help scale microscale audits for PA research.

Purpose: Deploy a deep-learning model to detect microscale features in Google Street View (GSV) images at street intersections around participant homes and relate features to adults' PA and self-reported intersection safety features.

Methods: Adults (N=728) in the WalkIT Arizona study reported their walking for transportation and leisure (IPAQ) and the combined presence of walk signals and crosswalks (NEWS) at baseline. GSV images (N=113,872) were obtained in four cardinal directions at intersections within 500m of participant homes. Previously trained and validated (against human raters) region-based convolutional neural network models using Google's TensorFlow detected pedestrian walk signals, crosswalks, and curb cuts in street images. Feature-specific prevalence was estimated by dividing the number of features detected in images by the number of images. Mean prevalence of each feature was calculated by participant buffer. Spearman rho (r_s) tested for correlations between model-detected features, PA, and reported safety features.

Results: Models processed all GSV images in 4.5 hours. Model-estimated prevalence was 0.8% for walk signals, 5% for crosswalks, and 48% for curb cuts. Walk signals correlated positively with crosswalks ($r_s=.72$, $p<.001$) and inversely with curb cuts ($r_s=-.11$, $p=.003$). No association was found between crosswalks and curb cuts. Walking for transportation was associated with walk signals ($r_s=.13$, $p<.001$), crosswalks ($r_s=.13$, $p=.001$), but not with curb cuts. Leisure walking was not related to walk signals or crosswalks but was inversely related to curb cuts ($r_s=-.08$, $p=.04$). Self-reported intersection safety features were related to model-inferred walk signals ($r_s=.20$, $p<.001$) and crosswalks ($r_s=.21$, $p<.001$) in participant neighborhoods.

Conclusion: Results support the predictive validity of deep-learning models and their use for automating microscale audits across thousands of intersections for population surveillance or hypothesis testing of built environments for PA research.

DOG FACILITATED PHYSICAL ACTIVITY INTERVENTIONS: A SYSTEMATIC REVIEW

Ryan E. Rhodes, Ph.D.¹, Maria Baranova, Bachelor of Science², Hayley Christian, PhD³, Carri Westgarth, BSc(Hons) MPH PhD⁴

¹University of Victoria, Victoria, BC, Canada; ²University of Victoria, Cumberland, BC, Canada; ³University of Western Australia, West Perth, Western Australia, Australia; ⁴University of Liverpool, Wirral, England, UK

Objective: Regular walking is a critical target of physical activity promotion, and promoting dog walking is a viable physical activity intervention for a large segment of the population. The purpose of this paper was to review intervention approaches to physical activity that have involved canine interactions, and evaluate their effectiveness as well as highlight the populations, settings, designs, and intervention components that have been applied so as to inform future research.

Design: Systematic review.

Data Sources: Literature searches were conducted in May 2019 using five common databases.

Eligibility Criteria: Studies included published papers in peer-reviewed journals and grey literature (theses, dissertations) in the English language that included any physical activity behavior change design (i.e., RCT, quasi experimental) that focused on canine-related intervention. Findings were grouped by population, setting, medium, research design and quality, theory-base, and behavior change techniques applied.

Results: The initial search yielded 22889 publications which was reduced to 13 independent studies of primarily medium quality after screening for eligibility criteria. The approaches to intervene on physical activity were varied and included loaner dogs, new dog owners, and the promotion of walking among established dog owners. Findings were consistent in showing that canine-assisted interventions do increase physical activity. Sub-analyses of intervention effectiveness did not appear to be moderated by population, study quality, dissemination medium, setting or behavior change techniques.

Conclusions: Canine-based physical activity interventions appear effective, but future research should move beyond feasibility and proof of concept studies to increase rigor and quality.

MEDIATORS OF PHYSICAL ACTIVITY BEHAVIOR CHANGE INTERVENTIONS AMONG ADULTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Ryan E. Rhodes, Ph.D.¹, Patrick Boudreau, M.A., B.Ed.², Karin Weman Josefsson, n/a³, Andreas Ivarsson, PhD⁴¹University of Victoria, Victoria, BC, Canada; ²Department of Tourism, University of Otago, New Zealand, Duendin, Otago, New Zealand; ³Halmstad University, Halmstad, Hallands Lan, Sweden; ⁴Halmstad University, Gullbrandstorp, Hallands Lan, Sweden

Background: An understanding of the determinants of physical activity through mediators of behaviour change is important to evaluate the efficacy of interventions. Prior reviews on this topic have been narrow in focus and used vote counting procedures to analyze the results. The purpose of this review is to update these prior reviews with meta-analysis in order to evaluate the state of our understanding of physical activity interventions that include proposed mediators of behaviour change.

Methods: Literature was identified through searching of five key databases. Studies were eligible if they described a published experimental or quasi-experimental trial in English examining the effect of an intervention on physical activity behaviour and mediators in non-clinical adult populations with the necessary statistical information to be included in the analysis. Zero-inflated correlation coefficients were used as effect size estimates with meta-analytic structural equation modelling to yield the indirect and direct paths within a mediation framework. Overall effects, and results by theory and construct were estimated.

Results: Fifty-one articles which comprised 49 unique samples and 20841 participants of medium and high study quality passed the eligibility criteria. Small overall effects were identified for mediation paths a ($r = .13$), b ($r = .17$), and c ($r = .22$) that showed relatively similar findings by theory and construct. Path c' was statistically significant in almost all models, however, and path AB was not statistically significant using any theory overall. Only regulation behaviors (e.g., plans, self-monitoring) and intentions had statistically significant pathways ($ab = .05$ and $.06$).

Conclusion: The small effect sizes seen in physical activity interventions are not explained by our current theories, mainly because of similarly small A and B pathways. Changes in behavioral regulation constructs and intention have the most evidence as mediators of physical activity intervention. Innovation and increased fidelity of interventions is needed and should be a priority for future research.

MY PLANS HELP YOU PLAN YOUR PHYSICAL ACTIVITY: ASSOCIATION BETWEEN INDIVIDUAL, DYADIC AND COLLABORATIVE PLANS IN ADULT DYADS

Ewa Kulis, MA¹, Monika Boberska, MA¹, Karolina Horodyska, PhD², MAGDALENA KRUK, MA³, Anna Banik, PhD², Zofia Szczuka, MA², Aleksandra Luszczynska, PhD¹¹SWPS University of Social Sciences and Humanities, Warsaw, Mazowieckie, Poland; ²SWPS University of Social Sciences and Humanities, Wrocław, Dolnoslaskie, Poland; ³SWPS University of Social Sciences and Humanities, WROCLAW, Dolnoslaskie, Poland

Background: Existing evidence supports the assumption that action planning is associated with physical activity. However, research focused mostly on forming individual plans and on within-person associations. It is unclear if plans formed by one person may prompt their partner to form plans. The associations between individual, dyadic (i.e., where a target person is setting plans together with a partner on when, where, and how the target person will individually engage in behavior change), and collaborative plans (i.e., where two individuals make plans on when, where, and how to enact a behavior together) are rarely investigated. Therefore, this study tested the associations between three types planning of physical activity (dyadic, collaborative, and individual plans) in sedentary adult-partner dyads.

Methods: Participants were 299 sedentary adult—partner dyads. Sedentary adults were 18–90 years old ($M = 44.43$; $SD = 16.72$), 64.9% were women. Partners were 18–84 years old ($M = 42.87$; $SD = 16.31$), 64.9% were women. Data were collected twice, with one week between Time 1 [T1] and Time 2 [T2] measurements.

Results: Analyses explaining sedentary adult's and partner's planning showed that the frequent use of dyadic and collaborative planning [T1] by the partner was related to more frequent dyadic and collaborative planning [T2] by the sedentary adult. Also more frequent use of collaborative planning [T1] by the sedentary adult was related to more frequent dyadic and collaborative planning [T2] by the partner. Other longitudinal dyadic effects were not significant.

Conclusions: Collaborative planning of one person in the dyad turned out to be significant predictor of planning formed by the other person in a dyad. When developing physical activity promotion interventions researchers and practitioners may consider including collaborative planning training to enhance the probability of dyadic transfer of planning skills.

THE INFLUENCE OF NEIGHBORHOOD ENVIRONMENT ON PHYSICAL ACTIVITY PATTERNS OF FIRST GENERATION LATINA IMMIGRANTS

Rodney P. Joseph, PhD¹, Sonia Vega-López, PhD¹, SeungYong Han, Ph.D.¹¹Arizona State University, Phoenix, AZ

Background: This study explored physical activity (PA) patterns of first generation US Latina immigrants and examined how neighborhood environment factors influence these PA patterns. This research was conducted to inform development of a culturally tailored PA intervention for first generation Latina immigrants.

Methods: Using a cross-sectional study design, 39 first generation Latina immigrants completed the International Physical Activity Questionnaire and the Neighborhood Scales Questionnaire, which assessed 6 perceived neighborhood factors: walking environment, aesthetic quality, safety, violence, social cohesion, and activities with neighbors. Median self-reported MET-minutes/week of PA were used to summarize domain- and intensity-specific PA patterns. Logistic regression examined associations between neighborhood factors and engaging in leisure-time PA (i.e., dichotomous outcome of some vs. no leisure-time PA) and meeting national PA guidelines (i.e., dichotomous outcome of meeting vs. not meeting guidelines).

Results: Participants (age = 40.5 ± 4.3 years; length of US residency = 4.6 ± 1.0 years) reported engaging in a median of 4512 MET-minutes/week of total PA. The majority of their PA was acquired through domestic activities (2160 MET-minutes/week), followed by leisure-time (396 MET-minutes/week), transportation (198 MET-minutes/week), and work PA (0 MET-minutes/week). Intensity-specific PA patterns showed that participants engaged in a median of 594 MET-minutes/week of walking activity and 3500 MET-minutes/week of moderate-to-vigorous PA. Logistic regression models showed that neighborhood factors of walking environment, aesthetic quality, and safety were significantly associated with engaging in leisure-time PA (odds ratios of 5.95 [95% CI:1.49; 23.74], 2.45 [95% CI:1.01; 5.93] and 3.30 [95% CI:1.26; 8.67], respectively) and meeting national PA guidelines (odds ratios of 8.44 [95% CI: 1.63; 43.69] 11.99 [95% CI: 1.79; 80.29], and 3.54 [95% CI:1.21; 10.29], respectively). Neighborhood factors of violence, social cohesion, and activities with neighbors were not significantly associated with PA outcomes.

Discussion: Although most participants engaged in PA at levels that met national guidelines, the majority of their PA was achieved through domestic activity, with limited leisure-time, transportation, and work PA. Given leisure-time PA, in particular, plays a significant role in improving health outcomes, findings suggest that many Latina immigrants could benefit from a leisure-time PA intervention. Such interventions should consider neighborhood environmental influences, as our data suggest these factors can serve as determinants to PA.

“I NOW FEEL THE NEED TO EXERCISE”: A QUALITATIVE STUDY OF PHYSICAL ACTIVITY MAINTENANCE AMONG LATINAS

Andrea S. Mendoza-Vasquez, MPH, PhD¹, Nathaniel Z. Badii, N/A², Noe Crespo, PhD³, Samantha Hurst, PhD, MA⁴, Britta DeMartini, PhD⁵, Bess H. Marcus, Ph.D.⁶, Esther Solis Becerra, B.S. in Public Health⁷, Elva Arredondo, Ph.D.³

¹UC San Diego/San Diego State University, San Diego, CA; ²UC San Diego, La Jolla, CA; ³San Diego State University, San Diego, CA; ⁴University of California, San Diego, La Jolla, CA; ⁵University of California, San Diego, SAN DIEGO, CA; ⁶Brown University, Sharon, MA; ⁷Brown University School of Public Health, East Providence, RI

Background: The impact of physical activity (PA) interventions can be enhanced by identifying and implementing effective strategies to help Latina women begin exercising and achieve long-term maintenance. Because most PA promotion research has focused on helping individuals initiate PA, little is known on individual, interpersonal, or environmental factors that influence PA maintenance.

Purpose: This qualitative study aimed to explore factors associated with maintenance and non-maintenance of PA among Latinas.

Methods: Semi-structured individual interviews were conducted with 21 Latina women who increased their PA as a result of an intervention, and who completed a subsequent 3-month maintenance period without any contact from research staff. Data were analyzed using structural coding procedures under a thematic analysis framework.

Results: Among the most important facilitators of PA maintenance identified by participants were: having made PA a habit or part of their lifestyle; the ability to proactively overcome obstacles to engaging in PA; having specific sources of motivation such as satisfaction with outcomes obtained; having the knowledge and skills to maintain PA; and having a supportive social and built environment. Alternatively, non-maintainers reported obstacles including self imposed barriers (e.g. being embarrassed to exercise in public), an environment that was not conducive to exercise, and lack of social support or accountability. Moreover, non-maintainers seemed dissatisfied with their weight loss outcomes.

Conclusions: Teaching intervention participants skills to proactively overcome obstacles, and guiding them to form habits and set realistic expectations, could help participants to independently continue engaging in PA upon completion of PA interventions.

ASSOCIATION BETWEEN THE BUILT ENVIRONMENT AND ACTIVE TRANSPORTATION AMONG U.S. ADOLESCENTS

Selam Tewahade, BS¹, Kaigang Li, PhD², Risë B. Goldstein, Ph.D., M.P.H.³, Denise Haynie, Ph.D., M.P.H.⁴, Ronald J. Iannotti, PhD⁵, Bruce Simons-Morton, EdD, MPH⁴

¹Colorado School of Public Health, Fort Collins, CO; ²Colorado State University, Fort Collins, CO; ³Social and Behavioral Sciences Branch, Division of Intramural Population Health Research, Eunice Kennedy Shriver NICHD, Bethesda, MD; ⁴NICHD, Bethesda, MD; ⁵CDM Group Inc, Bethesda, MD

Because low physical activity (PA) is a major determinant of obesity and cardiovascular disease in the U.S., interest is increasing in factors influencing PA. One opportunity for increasing daily PA is using it as transportation to and from school and/or work. We examined associations between characteristics of the built environment of home neighborhoods and transportation-related PA to and from school and/or work among youth and emerging adults. The data were drawn from Waves 1 (high school) and 4 (post high school) of the NEXT Generation Health Study (n = 2780), which enrolled a nationally representative, longitudinal cohort of U.S. students starting in 10th grade (Wave 1) in the 2009–10 school year. Participants' modes of travel were categorized into three groups: active (walking/cycling, AT), public (PubT), and passive transportation (being driven or chauffeured/driving, PT). Neighborhood characteristics included land use mix, street connectivity, residence density, park density, recreational density, and walkability. Multinomial logistic regressions were used to examine adjusted associations between modes of travel to and from school and/or work and neighborhood characteristics for Waves 1 and 4 separately. Analyses accounted for complex survey features including stratification, clustering and sampling weights and covariates (ethnicity, sex, education, and socioeconomic status). The weighted percentages of AT, PubT, and PT were 22%, 29%, and 49% in Wave 1 and 35%, 11%, 54% in Wave 4, respectively. The multivariable multinomial logistic models show that compared to PT group, residence density (standardized adjusted odds ratios [sAORs]: 3.01 in Wave 1 and 11.46 in Wave 4) and walkability (sAORs: 2.86 in Wave 1 and 2.75 in Wave 4) show the strongest associations with transportation-related PA in AT group in both Wave 1 and Wave 4. Similarly, residence density (sAOR = 16.91) and walkability (sAOR = 4.72) show the strongest association with transportation-related PA in PubT compared to PT in Wave 4, whereas residence density (sAOR = 4.72) is the only built-environmental characteristic that is significantly associated with PubT in Wave 1. More mixed land use, greater street connectivity, and higher walkability and density of residence, parks and recreational facilities were associated with AT, suggesting that city planners may need to consider creating more walkable communities with mixed land use to promote daily transportation-related PA.

ADDING AUTOMATED AND HUMAN COACHING TO AN M-HEALTH PHYSICAL ACTIVITY APP FOR US VETERANS: RESULTS OF THE STAY STRONG TRIAL

Jennifer M. Gierisch, PhD, MPH¹, Lorraine R. Buis, PhD², H. Myra Kim, ScD², Richard R. Evans, M.S. Biostatistics³, Lori Bastian, MD., MPH⁴, Felicia McCant, MSSW⁵, Gwendolyn C. Hooks, MA⁶, Laura Damschroder, MS, MPH⁷

¹Duke School of Medicine Department of Population Health Sciences and Durham VA ADAPT, Durham, NC; ²University of Michigan, Ann Arbor, MI; ³US Dept. of Veterans Affairs Center for Clinical Management Research, Ann Arbor, MI; ⁴Yale School of Medicine, West Haven, CT; ⁵ADAPT HSRD, Durham VA Health Care System, Durham, NC; ⁶VA Ann Arbor Healthcare, Ann Arbor, MI; ⁷VA Ann Arbor Center for Clinical Management Research (CCMR), Ann Arbor, MI

Many military servicemembers rapidly decrease physical activity (PA) levels as they enter civilian life. Mobile health (mHealth) devices with personalized health coaching may help veterans sustain PA levels and increase effectiveness of mHealth interventions. Stay Strong (SS), a mobile app tailored for veterans of recent wars, was developed to augment PA monitoring device outputs by providing individualized health coaching, tailored automated messaging, and personalized goal-setting. The objective of this study was to determine whether a mobile PA sensor combined with health coaching would improve PA levels as measured by *active minutes* recorded by Fitbit Charge 2, at 12 months versus a mobile PA sensor alone among Afghanistan/Iraq Veterans.

Invitation letters were sent to a random sample of 2286 US Afghanistan and Iraq War Veterans; 357 completed online enrollment process and were randomized to either SS with health coaching (SS+Coaching; n = 178) or SS-alone (SS-Alone; n = 179). SS-Alone provided app-based dashboard showing PA levels and weight from a Bluetooth scale. SS+Coaching added up to 3 coaching calls, standard and tailored messaging and weekly personalized PA-based goals. Primary outcome was change in PA level (assessed via Fitbit "active minutes") from baseline to 12-months. Primary analytic cohort was an intent-to-treat, with outcomes compared using 6- and 12-months measures and longitudinal data mixed-effects models.

Active minutes at baseline averaged 247.9, with no difference between groups (p = 0.90). Compared to baseline, both groups exhibited declines in PA at 12 months (65.78 vs. 41.01). Participation in SS-Alone versus SS+Coaching resulted in no significant differences in active minutes at 12 months (p = 0.92 for ANCOVA; p = 0.84 for mixed-effects model). Engagement in both programs declined after 6 months (57% of SS-alone vs 70% of SS+Coaching synced valid active minutes at 12-months), though SS-Alone experienced a steeper decline (OR = 0.98 (95% CI: 0.94, 1.02)). In both groups, 12-month follow-up participation exhibited declines, with 33% of SS-Alone and 38% of SS+Coaching participants remaining in the study.

Compared to SS-Alone, adding low-intensity health coaching in the first 12 weeks of a PA mHealth program, to tailored and standard motivational messages and personalized goals, was not enough to prevent PA decline. High response to "cold" invitation letters indicated high enthusiasm for study though the attraction of free equipment (e.g., Fitbit) may have contributed to both high initial excitement and increased baseline PA. Longer, more intense coaching may be needed to sustain engagement and increase PA.

PHYSICAL ACTIVITY IMPROVEMENTS AMONG PEER MENTORS ENGAGED IN A BEHAVIORAL INTERVENTION TRIAL OF LATINO ADULTS.

Ines Campero, BA¹, German Blanco, MPH, MCHES², Patricia Rodriguez Espinosa, Ph.D., M.P.H.³, Jylana L. Sheats, PhD, MPH⁴, Abby C. King, PhD⁵

¹Stanford University School of Medicine, Palo Alto, CA; ²Stanford University, San Jose, CA; ³Stanford School of Medicine, Palo Alto, CA; ⁴Johnson & Johnson, New Brunswick, NJ; ⁵Stanford University School of Medicine, Stanford, CA

Studies have shown that regular physical activity (PA) improves overall health and wellbeing. However, maintaining nationally recommended levels of PA becomes challenging with increasing age. PA support from trained peer mentors has been shown to increase moderate to vigorous physical activity (MVPA) among aging populations, yet little is known about the effects of such support on mentors' own PA. The purpose of this secondary analysis of a successful trial using physically active peer mentors was to determine if the mentors maintained or increased their own MVPA and motivation to be active. As part of the COMPASS2 trial, physically active mid-life and older adults were recruited to serve as PA mentors to sedentary Latino adults living in their community. After a systematic screening process, eligible peer mentors were consented and trained in intervention delivery, which was based on Social Cognitive Theory and the Transtheoretical Model. Each mentor was assigned at least one mentee (mean number of mentees/mentor=4), and met in-person with each mentee for ~20 minutes/session during a one-year period (session schedule=weekly for 8 weeks; bimonthly afterwards). Peer mentors were required to attend monthly 2-hour group meetings with research staff and other mentors to receive additional training and share and learn from one another. The validated CHAMPS PA survey was orally administered at baseline and at the end of mentors' study participation along with a qualitative exit interview. Quantitative survey results indicated that peer mentors ($N=25$; mean age= 61 ± 13.8 years; 80% Latino ethnicity; 80% women) were able to a) maintain >250 average weekly minutes of MVPA; b) increase average weekly minutes of moderate-intensity walking (e.g., brisk walking, uphill walking) by 40%; and c) increase mean minutes of aerobic machine use by two-fold (i.e., from 55 mins to 120 mins, on average). Peer mentors also reported that their study participation motivated them to be more physically active, become more conscious of their PA levels, and better understand the connection between PA and their overall health. This study represents a potential "stealth" intervention model for promoting PA maintenance among already active aging adults. The findings suggest that peer mentors may improve their own motivation for PA and PA behaviors, providing a "dual" benefit from such interventions beyond participant successes in improving their PA.

PHYSICAL ACTIVITY CO-PARTICIPATION AMONG PARENT-PRESCHOOL CHILD DYADS

Deirdre Dlugonski, PhD¹, Katrina D. DuBose, PhD², Christine Habeeb, PhD², Patrick Rider, MS²

¹University of Kentucky, Lexington, KY; ²East Carolina University, Greenville, NC

Purpose: Family-based physical activity interventions are recommended by the Community Preventive Services Task Force to achieve small, statistically significant increases in child physical activity. These interventions often encourage families to engage in physical activity together, yet little is known about parent-child physical activity co-participation. The specific goals of this study were to: compare patterns of physical activity co-participation for parent and 2–5 year old child dyads by parent sex, examine relationships between parent-child physical activity co-participation and child physical activity (total and moderate-to-vigorous; MVPA), and examine the relationship between self-reported and objective measures of physical activity co-participation.

Method: Parent-child dyads ($N = 45$; 49% mother-child) wore Bluetooth-enabled accelerometers for 8 days to measure individual physical activity and physical activity co-participation. Parents completed demographic and self-reported family physical activity questionnaires.

Results: Parent-child dyads spent 136 ± 68 minutes per day in-proximity according to the Bluetooth-enabled accelerometers. The majority (90%) of parent-child in-proximity time was spent in sedentary and/or light activities. Child total physical activity (light and MVPA) was not associated with parent light activity ($r = .23, p=.12$) or MVPA ($r = -.07, p = .64$). Partial correlations, controlling for daily in-proximity time, showed a positive, statistically significant relationship between child total physical activity and parent-child in-proximity active minutes ($r = .48, p=.001$). A one-way ANOVA was used to compare individual child physical activity by parent-child physical activity co-participation tertiles. Children in the highest tertile of parent-child co-activity participated in significantly more MVPA per day (75.5 minutes) compared to children in the lowest tertile (50.3 minutes) ($p = .03$). There was no association between self-reported and objective measures of physical activity co-participation.

Conclusion: Parents and their young children spent most of their time together engaged in sedentary and light activities. Children who engaged in the most physical activity with their parent had the highest levels of individual MVPA. Future studies are needed to assess the validity and reliability of self-reported physical activity co-participation measures and to provide contextual information about how parents and children spend their time together to enhance family-based physical activity interventions.

A QUALITATIVE EVALUATION OF A PILOT BEHAVIORAL INTERVENTION TECHNOLOGY PROGRAM TO PROMOTE WALKING AMONG UNDERSERVED PATIENTS

Mary H. Smart, PharmD, MS¹, Nadia A. Nabulsi, MPH², Ben Gerber, MD, MPH³, Lisa K. Sharp, PhD¹¹University of Illinois at Chicago, Chicago, IL; ²University of Illinois at Chicago College of Pharmacy, Chicago, IL; ³University of Illinois at Chicago - Department of Medicine, Chicago, IL

Introduction: Sedentary lifestyles are prevalent among patients from ethnic minorities and a lower socioeconomic status. Behavioral intervention technologies (BITs) using smartphones and wearable devices may provide these vulnerable populations access to health technologies that encourage walking and promote increase in physical activity. However, these populations are often under-represented in BIT research.

Objective: To identify major themes from patient reported experiences with the pilot program set in an ambulatory care setting that emerged during the study exit-interviews.

Methods: Thirty sedentary, overweight (BMI >25 kg/m²) patients recruited from an inner-city academic medical center participated in an 8-week pilot BIT program. A health coach (HC) encouraged walking and helped patients establish step goals each week. Patients wore Fitbit devices and received text messages from the HC. Step goals were SMART: Specific, Measurable, Achievable, Relevant, and Time-bound. Texting and Fitbit activities were managed with mytapp, a secure, low-cost, custom app. After 8 weeks, audio-recorded interviews were conducted to assess patients' experiences. Using thematic analysis, two independent reviews analyzed the responses to identify relevant themes. QDA Miner Lite (version 5) was used to manage data and coding.

Results: Of the 30 who enrolled, 23 (79%) were female and were on average 47 (SD = 9.5) years old. The majority were African American (80%), followed by Hispanic/Latino (17%), with 6 (20%) who reported a yearly household income < \$20,000, and 11 (37%) reported high school as their highest level of education. At baseline, the BMI was on average 39.6 kg/m² (SD = 9.2 kg/m²), and 9 (30%) of the participants self-rated their health as either "fair" or "poor." The following eight themes emerged through a BIT framework: (1) Texting convenience, (2) Personal HC, (3) Goal Setting, (4) Fitbit feedback, (5) Patient self-motivation, (6) Challenges, (7) Habit formation, and (8) Other changes.

Conclusion: Patients' feedback provided rich data for future iterative program development. Findings showed that the pilot program was well accepted among participants. Preliminary results of a BIT walking program integrated into primary care supported further development and testing for a highly vulnerable group.

ACUTE PSYCHOLOGICAL EFFECTS OF RESISTANCE EXERCISE IN MEN WITH SYMPTOMS OF MUSCLE DYSMORPHIA: A PILOT STUDY

Nicholas SantaBarbara, PhD¹, Sanaz Nosrat, PhD², James W. Whitworth, PhD³, Joseph T. Ciccolo, PhD⁴¹UCLA, Marina Del Rey, CA; ²Lehman College, New York, NY; ³Boston University, Jamaica Plain, MA; ⁴Teachers College, Columbia University, NEW YORK, NY

Background: Muscle dysmorphia (MD) reflects a pathological preoccupation with increasing muscle size and it disproportionately affects men. Men with MD have poor mental health and engage in risky behaviors to increase muscle size, including excessive resistance exercise (RE) despite the risk of injury. Research has identified various psychological and behavioral correlates of MD, but few studies have examined factors that may reinforce RE behavior.

Method: Using a within-subjects design, 21 men aged 18–35 years with MD symptoms completed several MD assessments and both an acute bout of moderate (70% of 10-repetition maximum; 10-RM) and high (100% of 10-RM) intensity RE in a counter-balanced manner separated by at least 48-hours. State body image, perceived muscle size, exercise enjoyment, and ratings of perceived exertion (RPE) were assessed before (PRE), during (MID), immediately after (POST), and 15 and 30 minutes after (DELAY 15 and 30, respectively) RE.

Results: 95.2% of the sample reported being stressed about their body size in social, occupational, or other situations, and 90.5% indicated that they exercise when they are sick or injured, despite any risk of injury. The majority also perceived their current muscle size to be significantly less muscular than what they would ideally want to look like; what other people would choose as ideal; and what their current or future romantic partner would find most attractive ($p < .001$). Other results showed that body image improved from PRE to POST during both conditions ($F = 6.54, p < .01$), with greater effect sizes for high ($d = 0.57$; 95% CI -6.82, -1.46) compared to moderate ($d = 0.39$; 95% CI -4.12, -0.18) intensity. Perceived muscle size improved from PRE to POST during the high intensity condition only ($F = 5.98, p < .01, d = 0.66$, 95% CI -0.76, -0.29). Participants also enjoyed the high intensity condition more than the moderate intensity ($t = 3.21, p < .01, d = 0.35$, 95% CI -0.77, -0.17), despite higher perceived exertion at each timepoint ($p < .01$). None of the changes were sustained during the DELAY period.

Conclusion: This pilot study suggests that high intensity RE can enhance body image and perceived muscle size more than moderate intensity RE. These effects are acute and attenuate within a short period of time. Future studies that test different RE variables, such as session duration and weekly session frequency, are needed to further examine factors that reinforce RE behavior.

A COMPARISON OF TOTAL AND DOMAIN-SPECIFIC SEDENTARY TIME IN BREAST CANCER SURVIVORS AND HEALTHY CONTROLS

Allyson Tabaczynski, BSc¹, Edward McAuley, PhD², Linda Trinh, PhD³¹University of Toronto, TORONTO, ON, Canada; ²University of Illinois, Urbana, IL; ³University of Toronto, Toronto, ON, Canada

Background: Sedentary behavior is associated with many negative health outcomes for breast cancer survivors (BCS) including mortality risk and poorer quality of life. Cancer survivors engage in more sedentary behavior than those with no history of cancer, with 66% of their day spent sedentary. However, little is known regarding the context in which sedentary behaviors are performed, which is imperative for successful behavior change.

Purpose: To examine differences in total and domain-specific sedentary time of BCS and healthy, age-matched controls.

Methods: 20 BCS and 20 age-matched, healthy controls wore ActiGraph GT3X+ accelerometers to measure time spent physically active and sedentary. Participants also completed surveys assessing demographic, medical and behavioral factors (i.e., smoking, drinking). Self-reported sedentary behavior performed across numerous domains (i.e., transport, work, screen time and leisure) on work and non-workdays was measured using the Domain-Specific Sitting Time Questionnaire. Analysis of covariance (ANCOVA) was conducted to explore between-group differences in sedentary behavior adjusting for significant between-group differences in demographic, medical or behavioral factors.

Results: BCS were 55.3±9.8 years old, had a BMI of 28.8±5.6 kg/m², and were 77.9±42.7 months since diagnosis. Healthy controls were 53.8±9.6 years old and had a BMI of 26.2±7.3. BCS and healthy controls spent a total of 661.8±88.4 and 727.6±135.5 minutes/day sedentary, respectively. BCS reported significantly more time spent watching TV (152.4 vs. 60.3 minutes/day; $F(1, 36)=7.60$; $p=.009$) and significantly less sedentary time in leisure activities (57.6 vs. 106.9 minutes/day; $F(1,36)=8.19$; $p=.007$) than their healthy counterparts. No significant differences were found for total volume of sedentary time between the groups.

Conclusion: BCS spend the majority of their waking hours sedentary. Despite no differences in total volume of sedentary time, domain-specific sedentary time varied between BCS and controls. BCS engaged in more TV watching and less sedentary time in other leisure activities (e.g., socializing) than controls, thus interventionists should focus on reducing or breaking up time spent watching TV in BCS. Further investigation into the factors contributing to TV viewing is warranted to determine specific intervention targets.

WHEN OUTCOMES MATTER: A TEMPORAL ANALYSIS OF BELIEFS IN THE EXERCISE DOMAIN

Jessica A. Emerson, PhD¹¹Miriam Hospital, Lifespan, East Providence, RI

Presently there is insufficient evidence to support the complex capabilities of interventions that employ mHealth technology and can reach a person at any time. An understanding of what beliefs predict behavior from day to day and how temporal context influences these associations will inform interventionists about the types of beliefs to target and when. The present research defines and examines two distinct measurement issues regarding temporal context related to attitudes and outcome expectancies for exercise behavior. An ecological momentary assessment (EMA) study was conducted among 50 previously inactive adults participating in an exercise study who reported their beliefs and behavior over 12 weeks. Attitudes are likely to be sensitive to the timing of their assessment given that attitudes are conceptualized to integrate outcome expectancy with subjective value; as the value of an outcome changes, attitudes may also change. Using EMA to examine daily processes addresses previously unanswered questions about whether prior evidence supporting long-term (over weeks or months) between-subject associations hold for day to day within-subject processes. A more positive affective attitude was associated with a 22% greater chance of exercise later that same day ($OR = 1.22$, $p = .002$). Outcome expectancies are beliefs about specific consequences of behavior that can occur immediately or in the long-term. Given that people differ in how much they discount future rewards, perceptions about outcome timing may influence the predictive strength of the belief on behavior. In prior work examining affective versus instrumental beliefs, outcome type may be confounded with temporal proximity given that affect-related outcomes tend to be more immediate consequences than instrumental outcomes. To our knowledge no validated assessments for outcome timing existed prior to this study, thus we piloted a questionnaire for this purpose. Affective outcome expectancies predicted more min/week of exercise ($b = 38.61$, $p = .045$) and participants believed affective outcomes would occur 48.6 days sooner ($p < .001$) than instrumental outcomes. Temporal differences in outcome timing may underlie stronger associations commonly found between affective outcome expectancies and exercise. Taken together, this research highlights the importance of temporal context when targeting these social cognitive beliefs.

6:15 PM-7:30 PM

MEANING IN LIFE: A BUFFER AGAINST THE EFFECTS OF ANXIETY ON SUBJECTIVE PHYSICAL HEALTH

Jessica Morse, MS¹, Maeve O'Donnell, Ph.D.², Mark A. Prince, PhD³, Michael Steger, MS; PhD³¹Colorado State University, Denver, CO; ²Seattle Children's Research Institute, Seattle, WA; ³Colorado State University, Fort Collins, CO

Presence of meaning in life (PM) is a core component of well-being that aids people in coping with anxiety and the everyday life stressors that provoke worry, uncertainty, and distress (e.g., Hill et al., 2018). Research suggests that people who report their lives as highly meaningful tend to experience better mental and physical health than those who experience their lives as low in meaning or purpose (e.g., Roepke, Jayawickreme, & Riffle, 2014). People who experience a strong sense of purpose have lower levels of inflammation, report better physical health, and live longer than those with low levels of PM (e.g., Hooker, Masters, & Park, 2018). Unlike meaning in life, high levels of anxiety tend to detract from people's physical health (e.g. Charles & Almeida, 2006). Empirical research indicates that highly anxious people tend to experience increased risk for myriad diseases (e.g., Roest, Martens, de Jonge, & Denollet, 2010) and report worse overall physical health (e.g. Watson, 1988).

In this study, we sought to explore mechanisms by which meaning might influence the effects of anxiety on physical health perceptions day-to-day. We hypothesized that participants with high PM would report less anxiety and better physical health at the trait level than those low in PM. We also expected that anxiety would not have as detrimental of an effect on people's perceptions of their physical health if they experienced high levels of meaning in life. In other words, on days when people experience anxiety, they will likely report lower subjective physical health; however, participants with low PM will report significantly worse health when anxious than those with high PM.

We conducted a three-week daily diary study with an undergraduate student sample (n=66; 76% women, 76% Caucasian). Participants completed a baseline measure of PM and a set of daily measures, including anxiety and physical health. Data were analyzed in MPlus using MSEM with PM as a trait-level moderator of the daily anxiety-health relationship.

Results aligned with our hypotheses. First, we found that participants high in PM (1 SD above the mean) reported significantly less anxiety and better overall health than those low in PM (1 SD below the mean). Second, we found that PM significantly moderated the effects of anxiety on health such that people who were low in PM experienced a greater decline in physical health on days when they reported more anxiety than participants high in PM (Slope = .36 (SD = .19), $p = .020$, Bootstrapped CI [.007, .72]. On days when participants reported minimal anxiety, they reported similar physical health. Thus, PM seems to serve as a buffer when people experience high levels of anxiety on a day, such that those high in PM do not seem to experience a perceived worsening of their physical health as do people low in PM. Results support the important role of PM in protecting against physical and psychological distress.

HEALTH BEHAVIOR PROFILES AND QUALITY OF LIFE AMONG ALASKA NATIVE MEN AND WOMEN

Kathleen Gali, PhD¹, Marily Oppezzo, PhD, MS, RDN², Mariah A. Knox, BA³, Jordan D. Skan, M.S.⁴, Maria Crouch, MS⁵, Matthew Schnellbaeche, MD³, Judith J. Prochaska, PhD, MPH⁶¹Stanford Prevention Research Center, Stanford University, Stanford, CA; ²Stanford University, Mountain View, CA; ³Alaska Native Tribal Health Consortium, Anchorage, AK; ⁴Alaska Native Tribal Health Consortium, Anchorage, AK; ⁵ANTHC, Wasilla, AK; ⁶Stanford University, Stanford, CA

Introduction: Indigenous populations, including Alaska Native men and women, have long experienced substantial health inequity and have a lower life expectancy relative to other US racial/ethnic groups. While the contributing factors are multiple and complex, the health behaviors in which people engage, such as smoking and exercise, relate to both quantity and quality of life. In this study we examined various health behaviors and their relation to health-related quality of life (HRQoL) and depressive symptoms among Alaska Native men and women in the Norton Sound Region.

Methods: The Centers for Disease Control and Prevention's "Healthy Days Measure" assessed HRQoL in the past 30 days. Used with diverse populations, the measure yields the number of days when a person was physically and mentally unhealthy (categorized as none, infrequent [1–13 days], and frequent [14+ days]) and provides a subjective overall health rating. The 10-item CESD assessed depressive symptoms. Health behaviors examined were physical activity, dietary habits, past month use of cannabis, heavy episodic use of alcohol (4+ drinks for women, 5+ drinks for men), and cigarette dependence based on time to first cigarette upon waking and cigarettes per day. Univariate regressions tested the association of each behavioral risk factor with the HRQoL subscales and CESD. Analyses were adjusted for age, sex, and community connectedness, as a socioeconomic indicator.

Results: The sample (N=299, 49% female, age M=46, SD=14) were current smokers who averaged 12 cigarettes per day (SD=10) for M=30 years (SD=14), and 65% smoked within 30 minutes of waking. Adjusting for covariates, frequent unhealthy days was associated with cannabis use (OR=2.95, $p=.001$) and smoking cigarettes sooner upon waking (OR=2.10, $p=.02$). Overall subjective good health was associated with being physically active (OR=1.82, $p=.02$) and not engaging in heavy episodic alcohol use (OR=0.54, $p=.02$). Depressive symptoms were associated with heavy episodic alcohol use (B=0.19, $p=.001$) and cannabis use (B=0.16, $p=.008$). Diet was unrelated to the HRQoL subscales and CESD.

Conclusions: Use of substances (alcohol, tobacco, cannabis) and engagement in physical activity are related to health-related quality of life and depressive symptoms in a sample of Alaska Native people of the Norton Sound Region. Study of lifestyle interventions to optimize quality of life and reduce depressive symptoms in Alaska Native populations is encouraged.

A PILOT STUDY TO EXAMINE NURSES' PERCEPTIONS OF SEXUALLY TRANSMITTED DISEASE (STD) EDUCATION IN LONG-TERM CARE FACILITIES

Lauren Maziarz, PhD, RN¹, Nikki Sorgi, n/a², Nicole Bowsher, n/a², Courtney Wagner, n/a²¹Bowling Green State University, Toledo, OH; ²Bowling Green State University, Bowling Green, OH

Background: Many older adults (40%) in the US aged 65–80 are sexually active (American Association of Retired People [AARP], 2018) yet report less condom use, fewer STD screenings, and lower risk perceptions of STDs than their younger counterparts (Syme, Cohn, & Barnack-Tavalaris, 2017). Since more than 1.5 million nurse employees work in LTCFs in the US (CDC, 2013), examining perceptions of STD education from the nurses' perspective allows for insight into why STD education in long-term care facilities (LTCFs) remains rare among this vulnerable population.

Methods: As a pilot study to examine both current STD education practices and perceptions of STD education, a four-page mailed survey was sent to all LTCF Directors of Nursing (DONs) in Northwest Ohio (n=99) with a response rate of 29% (n=29). DONs were the target population as they are the most likely employee to hold Registered Nurse licensure. The Health Belief Model formed the basis for the 21-item survey.

Results: Respondents were predominately female (97%), Caucasian/White (83%), over 40 years of age (76%), with an Associate degree as their highest level of education (52%). Only 2 nurses stated their LTCF provides STD education to their residents while 4 nurses stated their LTCF provides condoms. Almost all nurses were supportive of STD education at their facility (97%) but previous education on how to address STDs among residents was rare, with 86% of nurses having had no formal training. Overwhelmingly, nurses did not see STDs or human immunodeficiency virus (HIV) as problems among their residents (100% and 96%, respectively) yet support for sex in LTCFs was high. All (100%) agreed sex among married residents should be supported while 75% agreed sex among non-married residents should be supported. Furthermore, 89% believed LTCFs should provide private spaces for intimate partner visits. Most nurses stated they were comfortable discussing HIV risk (86%), STD risk (86%), erectile dysfunction (76%), sexual desire and intimacy (68%), and correct condom use (66%). The most commonly perceived barriers to providing STD education were family opposition (62%), resident embarrassment (52%), limited time (48%), and lack of education on STD prevalence among older adults (48%). The most commonly perceived benefits were being seen as a leading LTCF within the community (66%), promotion of healthy sexual relationships (55%), improved health of residents (45%), and improved knowledge of STDs among residents (45%).

Conclusions: There is a clear disconnect between what the evidence says in terms of STD risk among older adults and what nurses are perceiving as problems among their residents. There was strong support for STD education among nurses in our study though implementation remains rare. Addressing the most commonly perceived barriers and benefits may prove beneficial in increasing the number of LTCFs that provide STD education to residents.

PILOTING AN EXPRESSIVE WRITING INTERVENTION TO ADDRESS SEXUAL HEALTH AND SUBSTANCE USE IN EMERGING ADULT GAY AND BISEXUAL MEN

Steven Samrock, MA¹, Tyrel J. Starks, PhD², Brooke Wells, PhD³¹PRIDE Health Research Consortium / Hunter College / City University New York, New York, NY; ²Hunter College, New York, NY; ³Widener University, Chester, PA

Background: Emerging adult (EA) gay and bisexual men (GBM) are consistently among those facing the highest HIV prevalence. Expressive Writing (EW) interventions have demonstrated efficacy to reduce drinking and improve psychosocial functioning. The hypothesized mechanism of EW is exposure. Writing provides an opportunity to experience emotions that might otherwise be avoided, allowing one to re-organize these experiences more adaptively. The learning objectives of this study were (a) to evaluate the feasibility and effectiveness of Express Yourself (EY): an EW intervention addressing condomless anal sex (CAS) and substance use (SU) related problems in EA GBM; and (b) to examine linguistic mechanisms by which EW may exert effects of CAS and SU among EA GBM.

Methods: EA GBM (n=78) from New York City were enrolled into a pilot randomized controlled trial. Eligible participants age 18–29 had at least one incident of SU (e.g. cocaine, crack, ecstasy, methamphetamine, heroin) in the past 60 days; and at least one incident of CAS with a casual male partner in the past 60 days.

Participants completed a baseline survey and interview before random assignment to one of two conditions. Both conditions involved three 15-minute writing sessions with breaks between each session. Those in EY (n=39) were instructed to write about their deepest emotions and thoughts about sexuality and sex life. Control participants (n=39) wrote about their day. Using Linguistic Inquiry and Word Count (LIWC) software, writing content was analyzed to calculate degree to which various categories of words were used. Outcome variables were assessed using a count outcome of CAS and the Comprehensive International Diagnostic Instrument – Substance Abuse Module (CIDI-SAM).

Results: The direct effect of condition on CIDI scores and CAS was non-significant for both outcomes. Significant indirect effects through the linguistic content of writing samples were detected. PATH models indicated the participants in the EY condition used significantly more positive and negative emotion words. Indirect effect tests indicated Treatment condition accounted for significant reductions in CIDI scores through increases in positive emotion words. Similarly, results of indirect effects testing indicated treatment accounted for significant decreases in CAS through its association with positive emotion words and significant increases in CAS through its association with negative emotion words.

Conclusions: These findings reinforce the premise that EW operates, in part, through mechanisms related to emotional exposure. They further suggest that EW may constitute a low-cost and scalable intervention to reduce SU and CAS among EA GBM. Benefits appear to be associated with the presence of positive emotion words. Future studies might benefit from the experimental manipulation of writing prompts to maximize writing content for therapeutic benefits.

ACCELERATING EHEALTH BEHAVIORAL INTERVENTIONS INTO PRACTICE: THE KEEP IT UP! HYBRID EFFECTIVENESS-IMPLEMENTATION TRIAL

Brian Mustanski, PhD¹, Kathryn Macapagal, PhD¹, J.D. Smith, PhD²¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Despite substantial NIH investment in developing eHealth HIV interventions, little implementation research has examined strategies to effectively scale up these programs. To advance eHealth intervention implementation, we are conducting a county-randomized comparative implementation trial of two delivery approaches for Keep It Up! (KIU!), an online, CDC-best-evidence HIV prevention program for young men who have sex with men (YMSM) that just tested HIV negative. Strategy 1 is a traditional approach of community-based organizations (CBOs) integrating the program into their ongoing HIV testing operations. Strategy 2 is direct-to-consumer (DTC) strategy with home-based HIV/STI testing. This presentation describes the protocol for target county selection and outcome measures in the trial as an illustration of implementation research for behavioral interventions.

Methods: We reviewed geographic clustering of counties with 1,500+ YMSM. Standalone counties were automatically selected for inclusion. Among clustered counties, we selected the one with the most Black and Latino 18–29-year-olds and removed those directly adjacent, repeating this procedure until 64 counties were selected. Two adjacent counties were added based on topography.

Selected counties were stratified and randomized 2:1 to receive KIU! via the CBO or DTC strategy. Funding proposals were solicited from CBOs in the 44 CBO-strategy counties. Counties with successful CBO applicants were checked against the DTC counties to ensure balance. Outcomes for this type III hybrid trial follow RE-AIM, with the primary outcomes being impact (reach x effectiveness) and cost per infection averted. We also capture various metrics of adoption and implementation from YMSM self-report, KIU! meta-data, and CBO and DTC staff reports and interviews.

Findings: The CBO-strategy arm selected 14 CBOs for funding in the first round. A second funding announcement was released Fall 2019, with the goal of selecting another 8 CBOs, resulting in 22 counties per arm. The subsequent panel presentations will discuss the pragmatic design of each arm as well as the refreshing of the intervention technology to meet the demands of scalability.

Implications for Behavioral Interventions: Given the national urgency to end the HIV epidemic, understanding the best strategies to implement eHealth HIV interventions to reach the most people is critical to realizing the cost-effective scalability promised by such interventions. Careful selection of research targets and unobtrusive measures is critical to maintaining scientific rigor while remaining pragmatic in these studies.

EAT. SLEEP. PLAY. PROSPECTIVE ASSOCIATIONS AMONG HEALTH BEHAVIORS IN A SAMPLE OF US ADOLESCENTS

Denise L. Haynie, PhD, MPH¹, Leah M. Lipsky, Ph.D.², Kaigang Li, PhD³, Katherine D. Maultsby, B.S.⁴, Rajeshwari Sundaram, M.Stat., Ph.D.⁵, DANIEL S. LEWIN, Ph.D.⁶¹NICHD/NIH, Bethesda, MD; ²Social and Behavioral Sciences Branch, Division of Intramural Population Health Research, Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; ³Colorado State University, Fort Collins, CO; ⁴NICHD DIPHR, Bethesda, MD; ⁵Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; ⁶Children's National Health System, Washington, DC

Healthful patterns of sleep, nutrition, and physical activity during adolescence are important for later adult health. We examined associations of sleep duration, timing (chronotype, social jetlag), and problems with food intake and physical activity (PA) from 10th to 12th grade in the NEXT Generation Health Study, a diverse, nationally representative prospective cohort of U.S. adolescents (N=2569, 57% female, 45% White). Participants reported previous-week daily servings of fruits and vegetables, whole grains, sugar sweetened beverages (soda), sweet and savory snacks; days/week they ate fast food and engaged in PA; and hours/week of vigorous PA (VPA). Participants reported usual sleep period for school/work days (SD) and free-days (FD), from which duration, chronotype (midpoint of FD sleep period, adjusted for weekend oversleeping) and social jetlag (absolute difference between SD and FD sleep period midpoints) were derived. Sleep problems was a count of reported problems falling asleep, staying asleep and snoring. Separate multilevel linear regression models, using residual maximum likelihood method and accounting for the repeated measures, examined each food and PA type as outcomes and included demographics, survey weights, time, and BMI. Over time, adolescents consumed significantly less fruits, vegetables and fast food, and more whole grains, soda and snacks, and engaged in less PA. Later chronotype was associated with less healthful behavior and more discretionary food intake and was included in models for sleep duration and problems, but not social jetlag due to collinearity. Longer SD sleep duration was associated with less fast food (FEB=-.03, SE=.01). Longer FD sleep duration was associated with less intake of fruit/vegetables (FEB=-.08, SE=.05), and whole grains (FEB=-.04, SE=.01), more soda (FEB=.03, SE=.01), and less PA (FEB=-.08, SE=.02) and VPA (FEB=-.08, SE=.02). Greater social jetlag was associated with less intake of fruit/vegetables (FEB=-.10, SE=.04) and whole grains (FEB=-.08, SE=.02), more snacks (FEB=.04, SE=.02) and less VPA (FEB=-.12, SE=.02). More sleep problems were associated with less intake of fruit/vegetables (FEB=-.14, SE=.05) and more fast food (FEB=.03, SE=.02) and soda (FEB=.07, SE=.02). The pattern of results suggests that greater desynchronization of adolescent sleep period with biologic preferences and sleep problems are associated with less optimal patterns of dietary intake and PA.

NIGHTLY SLEEP QUALITY IS ASSOCIATED WITH DAILY COGNITION IN LATE-LIFE

Emily K. Donovan, B.A.¹, Joseph M. Dzierzewski, Ph.D.¹, Constance H. Fung, MD, MSHS², Karen Camacho, MPH³, Cathy A. Alessi, M.D.⁴, Jennifer L. Martin, Ph.D.⁵

¹Virginia Commonwealth University, Richmond, VA; ²VA Greater Los Angeles Healthcare System/David Geffen School of Medicine at University of California, Los Angeles, North Hills, CA; ³VA Greater Los Angeles Healthcare System, North Hills, CA; ⁴David Geffen School of Medicine, University of California, Los Angeles // Geriatric Research, Education and Clinical Center, VA Greater Los Angeles Healthcare System, North Hills, CA; ⁵UCLA/VA Greater Los Angeles, North Hills, CA

Introduction: While some changes in sleep and cognition are considered part of normal aging, older adults often experience poor sleep quality and cognitive decline that goes beyond the scope of normal aging. Attention is a cognitive domain that may be particularly sensitive to alterations in sleep quality. One explanation for this relationship is that poor sleep quality impacts an individual's ability to filter or suppress stimuli. The present study examined between-persons (mean-level) and within-persons (day-to-day) relationships between self-reported nighttime sleep quality and self-reported daytime attention in a community-dwelling sample of older men without neurocognitive disorder.

Methods: Participants included 38 community-dwelling men aged ≥ 65 years ($M_{age} = 75.36$ years, $SD_{age} = 7.51$ years, range = 66–90 years) without a diagnosis of neurocognitive disorder. Participants completed a sleep diary twice daily for one week (7 days). The sleep diary included questions about sleep habits as well as 0–10 rating scales about sleep quality and attention. Sleep quality was assessed using a single item from the morning sleep diary which asked, "How was the quality of your sleep last night?" (0 = "very poor" and 10 = "excellent"). Attention was assessed using a single item from the evening sleep diary which asked, "How was your attention today?" (0 = "poor" and 10 = "excellent"). A two-level multilevel model was parameterized with days (level 1) nested within individuals (level 2) to examine whether nightly sleep quality predicts an individual's daily attention rating.

Results: A single multilevel model predicting self-reported attention revealed the following: (1) older individuals who reported better sleep quality (on average) also reported having better daily attention (on average) [$\beta = 0.64$, $t(248.15) = 10.12$, $p < 0.001$], and (2) following a day of above-average sleep quality, older individuals reported above-average attention [$\beta = 0.16$, $t(259.79) = 2.75$, $p = .006$].

Conclusion: Not only was overall sleep quality associated with self-reported attention, but a night of good sleep was associated with better self-reported attention the following day. Results point to the potential importance of nightly fluctuations in sleep quality for daytime functioning and suggest that interventions aimed at achieving consistent sleep quality are worth exploring as possible methods for improving daytime cognitive functioning in older adults. Given known sex differences in sleep and cognition in aging, studies are also needed to explore this relationship among older women.

THE ASSOCIATION BETWEEN ADOLESCENT SLEEP QUANTITY AND SUGARY BEVERAGE CONSUMPTION: CONSIDERING THE NEIGHBORHOOD CONTEXT

Chan L. Thai, PhD, MPH¹, Sonia Rubens, PhD¹

¹Santa Clara University, Santa Clara, CA

Background: Research suggests that poor sleep is associated with sugary beverage consumption. Little is known, however, about whether the neighborhood context, such as ease of access to different types of beverages, may impact this association. The current study examined the association between sleep quantity and sugary beverage consumption while accounting for neighborhood availability of these drinks among a national sample of adolescents.

Methods: Data on adolescents aged 12–17 were drawn from the National Cancer Institute's Family Life, Activity, Sun, Health, and Eating (FLASHE) survey (N=1700), a web-based survey administered to parent-adolescent dyads in 2014. Multivariable regression models were used to examine associations between sleep (< 8 hrs, 8–10hrs, >10hrs) and frequency of sugary beverage consumption in the past week (soda, energy drinks, sports drinks; not at all to 3+ times/day) while controlling for the presence of a convenience store (yes/no) and supermarket (yes/no) in the neighborhood and standard sociodemographic variables (age, sex, parent education level, race).

Results: Approximately 35% of participants slept less than the recommended 8–10 hours of sleep ($n = 646$) while 58% reported sleeping the recommended amount of time ($n = 1075$). Sleep is consistently associated with frequency of consumption of soda and energy drinks, such that adolescents who sleep the recommended number of hours (8–10) are less likely to consume soda ($\beta = -.06$, $p = .02$) and energy drinks ($\beta = -.08$, $p = .004$) compared to those who sleep less than 8 hours, controlling for sociodemographic factors. When accounting for the presence of a convenience store and a supermarket in the neighborhood, this relationship remains stable for frequency of both soda ($\beta = -.06$, $p = .01$) and energy drink ($\beta = -.07$, $p = .005$) consumption. We did not find a relationship between sleep and frequency of sports drink consumption in unadjusted and adjusted models.

Conclusions: While effect sizes are small, findings from the current study show a consistent relationship between sleep and *caffeinated* sugary beverage consumption over and above neighborhood access to beverages. Exploring interventions that address sleep and caffeinated sugary beverage consumption may lead to greater success in influencing sleep and sugary beverage consumption behaviors.

LOW HEART RATE VARIABILITY IS A MARKER OF SUBJECTIVE SLEEP REACTIVITY TO STRESS AMONG INDIVIDUALS WITH AN INSOMNIA DISORDER.

Jean-Philippe Gouin, PhD¹, Margaret A. McCarthy, BSc², Dylan Smith, PhD³, Aurore A. Perrault, n/a⁴, Florence Pomaes, PhD¹, Jennifer Suliteanu, Bachelor of Science in Psychology (progress)¹, Kazem Habibi, BSc (Honours)⁵, Thien Thanh Dang-Vu, MD PhD¹

¹Concordia University, Montreal, PQ, Canada; ²Concordia University, Hampstead, PQ, Canada; ³University of Ottawa, Ottawa, ON, Canada; ⁴SCN lab / Concordia University, Montreal, PQ, Canada; ⁵Concordia University, Pierrefonds, PQ, Canada

Introduction: Greater exposure to life stressors is associated with higher risk for insomnia. However, there are significant individual differences in sleep reactivity to stress. Heart rate variability (HRV), an index of vagal-dependent parasympathetic activity to the heart, is conceptualized as a marker of emotional and physiological arousal. In our prior work on three different samples of good sleepers, low HRV was associated with greater risk for insomnia symptoms in response to both acute and chronic stressors. The goal of the current study was to examine whether HRV would predict both subjective and objective sleep reactivity to stress among individuals with an insomnia disorder.

Methods: Fifty-five adult participants with an insomnia disorder completed a 14-day stress diary, an overnight polysomnography (PSG), an HRV assessment during resting wakefulness, as well as 2 self-report questionnaires, i.e., the Insomnia Severity Index (ISI) and the Pittsburgh Sleep Quality Index (PSQI).

Results: Resting HRV moderated the association between daily stress exposure and subjective insomnia severity, as assessed by the ISI, $p = .005$, $R^2 = .14$, and PSQI, $p = .02$, $R^2 = .09$. Individuals with lower HRV exhibited greater sleep reactivity to stress than their counterparts with higher HRV. However, HRV did not moderate the association between daily stress exposure and objective (PSG) measures of sleep duration, $p = .27$, $R^2 = .02$, or sleep efficiency, $p = .36$, $R^2 = .01$.

Conclusion: These results indicate that HRV is associated with subjective, but not objective sleep reactivity to stress among individuals with an insomnia disorder.

DAY-LEVEL RECIPROCAL ANALYSIS OF SLEEP AND EATING IN ADULTS WITH UNHEALTHY LIFESTYLE

Samuel Battalio, B.S.¹, Donald Hedeker, PhD², Annie W. Lin, PhD, RD¹, Bonnie Spring, PhD³

¹Northwestern University, Chicago, IL; ²University of Chicago, Chicago, IL; ³Northwestern University Feinberg School of Medicine, CHICAGO, IL

Poor sleep health has been causally linked to obesity and is among the modifiable health risk factors implicated in the obesity epidemic. Sleep health is posited to impact weight and cardiometabolic health through multiple pathways, spanning biological, cognitive, and behavioral domains. A primary pathway through which sleep is posited to influence weight and cardiometabolic health is via a tendency for those with poor sleep health to eat more calories and eat a greater proportion of calories from energy dense foods. Research also suggests that the association between sleep health and diet is reciprocal, such that diet can also influence one's sleep. Although compelling, this research has tended to rely upon either tightly-controlled laboratory experiments, which lack ecological validity, or large-scale observational designs using long-term recall, which lack granularity. Research using ecologically valid and granular assessment to evaluate both directions of the relationship between sleep and diet is necessary. Here, we conducted a secondary analysis of baseline data from the Make Better Choices 2 (MBC2) trial to evaluate the reciprocal associations between sleep health and diet. Participants were 212 adults with low physical activity, high sedentary time, and poor-quality diet. Participants monitored and self-reported sleep health and diet daily for approximately seven days through a custom smartphone application. From these daily self-reports, we computed sleep health (quality, duration) and diet (total calories, proportion of calories from saturated fat, fruit and vegetable servings) domains. For each domain and time lag (last night's sleep predicting today's eating, and today's eating predicting tonight's sleep), we computed linear mixed models with a random person-level intercept, controlling for sex, age and BMI. We decomposed predictors into a person-level mean across observations and a deviation from the mean at each observation. Participants were 76% female, 59% non-white minority, mean age = 40.8 years, and 65% obese. None of the models, evaluating either lag or any particular domain combination, provided evidence of a statistically significant association between sleep health and diet (P s > .102, $|Z|$ s < 1.63). These findings suggest that, in adults who eat a poor-quality diet, sleep and diet are not associated at the day level. The results are contrary to past research that has found between-person associations between sleep health and diet. Further research that evaluates various components of diet and sleep using diverse methodologies is necessary to replicate these findings and to clarify these dynamics. Specifically, research should evaluate diet nutritional composition in greater detail, and evaluate various person-level characteristics posited to act as moderators.

DEVELOPING AND TESTING A WEB-BASED PROVIDER TRAINING FOR COGNITIVE BEHAVIORAL THERAPY OF INSOMNIA

Daniel J. Taylor, Ph.D.¹, Allison Wilkerson, PhD², Brian E. Bunnell, PhD³, Jessica Dietch, PhD⁴, Kristi M. Pruiksmas, PhD⁵, Casey D. Calhoun, Ph.D.⁶, Melissa E. Milanak, PhD⁷, Sophie Wardle-Pinkston, M.S.⁸

¹University of Arizona, Tucson, AZ; ²Medical University of South Carolina, Mount Pleasant, SC; ³University of South Florida, Tampa, FL; ⁴VA Palo Alto Health Care System, War Related Illness and Injury Study Center (WRIISC CA), Sunnyvale, CA; ⁵University of Texas Health Science Center at San Antonio, Cedar Park, TX; ⁶Medical University of South Carolina, Charleston, SC; ⁷Medical University of South Carolina (MUSC), Charleston, SC; ⁸University of Arizona, TUCSON, AZ

Introduction: Chronic insomnia is a common and debilitating disease and a risk factor for significant medical morbidity, mental health problems, and workplace difficulties. Cognitive behavior therapy for insomnia (CBT-I) is the current gold standard treatment for insomnia. However, there is a critical lack of providers trained in CBT-I, in part due to a bottleneck in training availability and the time and cost associated with the current training platforms. Our team developed and evaluated CBTiweb.org, a web-based provider training course for CBT-I.

Methods: To develop an effective training platform, CBTiweb.org first underwent alpha- and beta-testing. Feedback from alpha- and beta-testers was used to optimize the course for use in the feasibility comparison study. The comparison study recruited licensed providers (n=44) to be randomly assigned to complete the online CBT-iweb.org course (n=21) or in-person training (n=23) of the same materials and information. Comparison study participants completed a Computer System Usability Questionnaire (CUSQ) as well as investigator developed Continuing Education (CEU) type pre/post-questionnaires to assess knowledge acquisition.

Results: Linear mixed-effects modeling revealed within-subjects effects ($F(24.55) = 135.16$, $p < 0.001$) where there was a significant increase in knowledge acquisition (baseline = 59% correct, post-training = 78% correct) when collapsed across both groups. The interaction effects were non-significant ($F(24.55) = 0.10$, $p = 0.760$), which indicated similar gains (20%) in knowledge across both groups and demonstrated equivalence between the in-person and the CBTiweb.org training formats.

Conclusion: Alpha and beta testers of CBTiweb.org reported high levels of satisfaction with the site and provided feedback on several areas for improvement. Based on their feedback, appropriate updates were made to the website platform. These results suggest the final CBTiweb.org product was successful in training clinicians given the success of licensed providers on knowledge assessments following completion of the web-based training. CBTiweb.org is an efficient and effective training platform for clinicians to gain knowledge and competence in the most effective treatment for insomnia.

NIH-FUNDED CBPR: SELF-REPORTED COMMUNITY PARTNER AND INVESTIGATOR PERSPECTIVES

WILLIAM N. ELWOOD, Ph.D.¹, James N. Corrigan, Ph.D.², Kathryn A. Morris, MPH¹

¹National Institutes of Health, BETHESDA, MD; ²National Cancer Institute, BETHESDA, MD

The community-based participatory research (CBPR) approach across health contexts has matured greatly over the last 20 years. Though contributions to the literature on the development and effectiveness of CBPR interventions have grown, the number of publications on the function and evaluation of actual community research partnerships has not kept pace. To help address that gap, we searched National Institutes of Health archival data and identified a set of 489 CBPR projects including collaboration-building, exploratory/pilot, research, and program project grants.

We saw a need to understand the experiences of researchers and community members to understand whether and how they value this approach. Literature reviews in CBPR are plentiful; some CBPR reviews suggest that there is insufficient literature on the organizational capacities associated with ongoing successful CBPR partnerships. To help resolve that disparity, we proposed two research questions:

RQ1: What are the perceptions of researchers who have conducted NIH-funded CBPR projects?

RQ2: What are the perceptions of community members who have been partners in NIH-funded CBPR projects?

More specifically, perceptions of the following were assessed: (1) prior history of collaboration between researchers and community members, (2) funding sufficiency, (3) prior history of collaborations among community organizations, (4) researcher views of community engagement, and (5) community partner views of community engagement.

We found community partner contact information commonly was absent from grant records and contacted principal investigators (PIs) for community-partner contact information. Subsequently, we built upon established measures to ask principal investigators and community partners for their perceptions of participation in NIH-funded CBPR projects. Many principal investigators and community partners reported existing collaborations—between academicians and community organizations as well as among community organizations. Partners tended to agree on the appropriateness of funding levels to accomplish projects and on the community partners' ability to recruit and retain participants, collect data, and implement interventions. Partners differed in perceptions of participation in research design, data analyses, manuscript and presentation production, and dissemination of findings. Suggestions include collection of lead community partner information without undue burden and increased standard education and involvement of community organizations in research vocabulary and practices.

PHYSICIAN CHARACTERISTICS ASSOCIATED WITH HEALTHCARE UTILIZATION AMONG 1.5- AND SECOND-GENERATION CAMBODIAN AMERICAN WOMEN

Ivy K. Ho, PhD¹¹University of Massachusetts Lowell, Lowell, MA

Cambodian Americans face significant psychosocial challenges, including low educational attainment, poverty, and mental health problems. Furthermore, health problems such as cardiovascular diseases and cancer are prevalent in this population. Yet, little is known about the social influences of healthcare utilization among Cambodian Americans. The present study focused on healthcare utilization among younger-generation Cambodian American women. Specifically, this study examined the how provider characteristics are associated with healthcare utilization. This qualitative study was based on data from individual interviews of 19 Cambodian American women who were either US-born or who were foreign-born and arrived in the US by age six years. Results indicated that 1) feeling comfortable with the provider, 2) provider having a “nice” personality, 3) feeling valued by one’s provider, 4) provider’s cultural competence, and 5) provider gender were important factors to Cambodian American women. These results are described and interpreted within social, cultural and historical contexts of racism, sexism, cultural stereotypes, refugee experience, legacy of trauma, and healthcare policy. Practitioners can draw from the results of this study to enhance treatment delivery. Based on the study’s results, researchers may identify directions for further investigation.

BULLYING EXPERIENCES, BODY ESTEEM, AND THE MODERATING ROLE OF WEIGHT STATUS AMONG ADOLESCENTS

Lauren A. Fowler, PhD¹, Chelsea Kracht, PhD², Kara D. Denstel, MPH², Tiffany M. Stewart, PhD², Amanda E. Staiano, PhD, MPP, MSc²¹Washington University in St Louis, St Louis, MO; ²Pennington Biomedical Research Center, Baton Rouge, LA

Introduction: Adolescents with overweight or obesity (OW/O) are more likely to be victims of verbal, physical, and relational bullying than their average-weight peers. Adolescents with OW/O may also have lower body esteem and body dissatisfaction. The relationship between bullying, body esteem, and body dissatisfaction is unclear, and may differ based on adolescent weight status.

Methods: Adolescents between 10 and 16 years of age reported demographic characteristics and completed surveys. Anthropometrics were objectively assessed. Bullying was assessed using the Personal Experiences Checklist, which includes four subscales of bullying (cultural, cyber, relational, and physical) and a total score (total bullying). Body esteem was assessed using total score on the Body Esteem Scale, and body dissatisfaction was assessed using the Body Image Assessment for Pre-Adolescents, operationalized as the discrepancy between current figure and ideal body figure. Linear regression models were used to examine the relationships between bullying, body esteem, and body dissatisfaction, and an interaction term (alpha level for significance of interaction = .10) was included to test whether total bullying and weight status (normal vs. OW/O) moderated these relationships, adjusting for confounders.

Results: In total, 338 adolescents provided complete measures. On average, adolescents were 12.5 ± 1.9 years old, 59.0% were White, 35.1% were African American, and 5.9% were other; also 50.3% had OW/O. Total bullying was inversely associated with body esteem ($p = 0.002$) and positively associated with body dissatisfaction ($p = 0.04$). OW/O status was related to lower body esteem ($p = 0.001$) and greater body dissatisfaction ($p = 0.01$). The interaction term (total bullying and weight status) was significant for body esteem and body dissatisfaction ($ps < .08$). Models stratified by weight status tested all bullying subscales in the same model. Among adolescents with normal weight, relational bullying was related to lower body esteem, while physical bullying was related to greater body esteem. In adolescents with OW/O, relational bullying was related to lower body esteem. For body dissatisfaction, cyberbullying was significantly related to less body dissatisfaction among adolescents with normal weight but was not related to body dissatisfaction among adolescents with OW/O.

Conclusions: In this sample, the relationship between bullying experiences, body esteem, and body dissatisfaction differed by adolescent weight status. Cyberbullying was related to less body dissatisfaction among adolescents with normal weight but not those with OW/O, whereas relational bullying was negatively related to body esteem for adolescents regardless of weight status. Additional investigation into differential bullying experiences by weight status is warranted to find tailored solutions for adolescent health.

IMPACT OF EGOCENTRIC NETWORKS ON PHYSICAL, EMOTIONAL, AND SEXUAL VIOLENCE AMONG A SAMPLE OF COLLEGE STUDENTS

Meg Patterson, PhD, MPH¹, Tyler Prochnow, MEd², Jordan L. Nelson, MPH¹, Mandy N. Spadine, MPH, CPH, CHES®¹, Sydney E. Brown, BSPH³, Beth A. Lanning, PhD, MCHES²

¹Texas A&M University, College Station, TX; ²Baylor University, Waco, TX; ³Texas A&M University, Bryan, TX

Introduction: Intimate partner violence (IPV) is an increasing concern on college campuses. While research has identified individual-level risk factors related to IPV among college students (e.g., hooking up, alcohol use, gender), less has investigated interpersonal relationships and IPV. The purpose of this study was to use social network analysis, an innovative approach to exploring social connections in relation to behaviors and outcomes, to understand how social connections relate to the odds of a college student experiencing IPV.

Methods: 697 students provided demographic and behavioral data (individual-level variables) as well as information regarding up to 5 individuals they felt closest to in their life (egocentric network variables) via an online survey. Hierarchical logistic regression analyses were conducted using individual-level variables and network variables to predict a history of physical, emotional, and sexual violence among this sample.

Results: Egocentric network variables added 8.8% - 11.4% of explained variance in predicting the odds of sexual (Nagelkerke $R^2 = .303$, $p < .001$), physical (Nagelkerke $R^2 = .280$, $p < .001$), and emotional violence (Nagelkerke $R^2 = .203$, $p < .001$). Being connected to people who have a history of IPV significantly increased a student's odds of indicating a history of physical (OR = 1.034, $p < .001$), emotional (OR = 1.023, $p < .001$), and sexual violence victimization (OR = 2.879, $p < .010$) themselves. Having more disconnected egonetworks was related to sexual violence victimization (OR = 1.305, $p = .017$), while being connected to more people of the same gender was related to emotional violence victimization (OR = 1.988, $p = .043$). Gender and hooking up were related to all types of IPV.

Conclusion: Egocentric networks were important in explaining history of IPV in this sample. Notably, people with a history of violence tend to populate one another's personal networks. These findings add to the current literature that largely focuses on individual-level risk factors related to IPV. The way college students' close networks are composed and structured help in understanding IPV in this population, and should be considered in prevention and reactionary efforts on college campuses.

NEIGHBORHOOD WALKABILITY IS RELATED TO SOCIAL HEALTH AMONG ADULTS

Jacob Carson, BSPH¹, Terry L. Conway, PhD², Brian Saelens, Ph.D.³, Lawrence Frank, PhD⁴, Kelli L. Cain, MA⁵, James F. Sallis, PhD¹

¹UC San Diego, San Diego, CA; ²University of California San Diego, La Mesa, CA; ³University of Washington / Seattle Children's Research Institute, Seattle, WA; ⁴University of British Columbia, Vancouver, BC, Canada; ⁵University California San Diego, SAN DIEGO, CA

Objectives: Neighborhood walkability is related to multiple health behaviors. Present analyses examined how neighborhood walkability was related to three social health outcomes.

Methods: Using cross-sectional data from the Neighborhood Quality and Life Study (NQLS), we analyzed 1,745 adults, ages 20-66, recruited from Seattle and Baltimore regions. Social outcomes of Social Interaction (with neighbors), Sense of Community (social cohesion) and Informal Social Control (social capital) were measured by survey, and walkability around each participant's home (1km buffer) was based on a GIS index of residential density, street intersection density, and mixed land use. Two mixed models were conducted for each outcome, with and without adjusting for walkability-related reasons for selecting the neighborhood (self-selection). Covariates included sex, age, socioeconomic status, white/nonwhite ethnicity, marital status, and time living in the neighborhood.

Results: Neighborhood walkability was positively related to Social Interaction both with adjusting for self-selection ($p = .008$) and without ($p < .001$). Sense of Community was positively associated with walkability only without adjusting for self-selection ($p = .009$). Informal social control had a negative association with walkability when self-selection was included in the model ($p = .036$).

Conclusions: Walkability may facilitate social interaction with neighbors. Adults may choose walkable neighborhoods because of social cohesion. The "negative" nature of the Social Control items (e.g., take action if children are skipping school) may account for the inverse association with walkability. In addition to facilitating physical activity, neighborhood walkability may benefit some aspects of social health.

ASSESSMENT STRATEGY TRENDS IN SOCIAL DETERMINANTS OF HEALTH

Irina Kolobova, PhD, LMFT¹, Samantha L. Wronski, MS², David Wamble, PhD³, Heather L. Black, PhD¹¹Merck & Co., Inc, North Wales, PA; ²RTI-Health Solutions, Research Triangle Park, NC; ³RTI Health Solutions, Durham, NC

The Centers for Disease Control and Prevention reported that social and environmental factors (20%) and behavior (40%) contribute to premature death more than inadequate clinical care (10%) and genetics (20%-30%) (Adler & Prather, 2015). Despite the limited contribution of clinical care, healthcare payers, systems, and providers are increasingly responsible for the overall health of their patients and the associated costs (Santilli & Vogenberg, 2015). As a result, these stakeholders are progressively utilizing social determinants of health (SDoH) assessment strategies to understand patients' social needs and to assess intervention effectiveness.

To identify which assessment strategies and interventions payers, healthcare systems, and providers use to assess and address patient SDoH, the authors conducted a systematic literature review of 6,611 unique studies identified through MEDLINE, MEDLINE in-Process, EMBASE, PsycINFO, and CINAHL (published between January 2011 and June 2019). Included studies had an SDoH assessment or intervention that was facilitated by a US healthcare payer, system or provider. SDoH was defined using the Office of Disease Prevention and Health Promotion's Healthy People 2020 framework and included five key areas: Economic stability, Education, Social and community context, Health and health care, and Neighborhood.

This poster focuses on the 261 studies identified that included a relevant SDoH assessment used in patient screening or an intervention. Additional information on SDoH interventions identified in the review are presented elsewhere. A variety of assessment strategies, including brief questionnaires and lengthy structured scales, in both cross-sectional and interventional studies were identified. Assessments were used with general clinical populations and in indications such as cancer, depression, diabetes, heart failure, HIV, and pregnancy. Assessment strategies tended to focus on one SDoH domain; the health and health care domain was most represented, with frequent use of health literacy assessments such as the Newest Vital Sign and REALM. Social support and health-related knowledge were also commonly assessed. The majority of studies were from a health-care systems or provider perspective, which may be related to a publishing bias for this stakeholder type. Future efforts to increase accessibility of non-published information on SDoH assessments being used in practice will improve collaboration across stakeholders.

CASCADING EFFECTS OF CHILDHOOD ABUSE ON PHYSICAL HEALTH ISSUES IN LATER ADULTHOOD THROUGH ANXIETY AND POOR DAILY SLEEP QUALITY

Eunjin L. Tracy, Ph.D.¹, Cory Tracy, B.S.², Jichan J. Kim, Ph.D.³, Rumei Yang, Ph.D.⁴, Eunjung kim, M.A.⁵¹University of Utah, SALT LAKE CITY, UT; ²Independent researcher, Salt Lake City, UT; ³Liberty University, Lynchburg, VA; ⁴Nanjing Medical University School of Nursing, Nanjing, Jiangsu, China; ⁵Arizona State University, Tempe, AZ

Childhood abuse is a prevalent and serious public health issue worldwide and an important type of early life stress to consider given its lasting effect on the individual's mental and physical health throughout the life-course. Childhood abuse is one of the main environmental risk factors in the development of trait anxiety. Also, the effect of childhood abuse on sleep quality in adulthood is well documented. Furthermore, while sleep, as a process that restores the body's ability to self-regulate and keeps the body's hormones in balance, plays a vital role in physical health over the lifespan, individuals with higher anxiety were found to experience poorer daily sleep quality. Given the link between childhood abuse, trait anxiety, daily sleep quality, and physical health issues, we examined whether childhood abuse affected physical health issues in later adult life and then explored the potential, sequential mediating roles of trait anxiety and daily sleep quality in these relations. This study utilized the Midlife in the United States Study (MIDUS) 2 (wave 2) project 4: Biomarkers (data collected 2004-2009) to measure childhood abuse, trait anxiety, and daily sleep quality; and MIDUS 3 (wave 3) project 1: survey (data collected 2013-2014) to measure physical health issues in later adult life ($n=281$, $M_{age} = 56.38$ in wave 2). In the current analysis, childhood abuse was treated as a latent variable with three indicators including emotional abuse, physical abuse, and sexual abuse. Physical health was also treated as a latent variable with three indicators including functional limitations in activities of daily living, functional limitations in instrumental activities of daily living, and self-rated physical health. To test mediation effects, Mplus (version 8) was used with 5000 bootstrap samples for significance testing. Individuals who reported a higher level of childhood abuse reported a higher level of physical health issues in later adulthood. Furthermore, individuals who reported a higher level of childhood abuse reported a higher level of trait anxiety and a lower level of daily sleep quality leading to an increase in physical health issues. The results highlight the cascading effects of childhood abuse on serious health consequences over the lifespan through trait anxiety and poor daily sleep quality. The current study suggests that it is critical to raise public awareness that recognizes the seriousness of childhood abuse due to its lasting impact later in life by creating a vicious cycle of repeated health issues. Preventions and intervention programs targeting childhood abuse are recommended. Potential clinical implications of our findings could be that adults may benefit from intervention efforts that minimize the effect of childhood abuse and break the vicious cycle of health issues created by adverse childhood experience.

DAILY ASSOCIATION BETWEEN PRESENTEEISM AND MOMENTARY MOOD, PHYSICAL SYMPTOMS, AND PAIN

Kaori Suwa, BS¹, Akifumi Kishi, PhD¹, Kazuhiro Yoshiuchi, MD, PhD², Yoshiharu Yamamoto, PhD³¹Educational Physiology Laboratory, Graduate School of Education, The University of Tokyo, Bunkyo-ku, Tokyo, Japan; ²The University of Tokyo, Graduate School of Medicine, Department of Stress Sciences and Psychosomatic Medicine, Bunkyo-ku, Tokyo, Japan; ³Educational Physiology Laboratory, Graduate School of Education, The University of Tokyo, Bunkyo-ku, Tokyo, Japan**Background:** Presenteeism refers to the decrease in productivity in employees who are present at work but not functioning at full capacity due to health conditions. The majority of studies on presenteeism to date have used health and productivity data collected through questionnaires, with a recall period between a week and a month, and have focused on between-individual differences. Presenteeism, however, may change from day to day and reflect momentary changes in health conditions, which may be captured by daily subjective symptoms. Utilizing a smartphone-based Ecological Momentary Assessment (EMA) technique, this study investigated the daily associations between presenteeism and mood, physical symptoms, and pain within individuals.**Methods:** Twenty-five employees from nursing and health care (35.9 ± 9.0 years; mean \pm SD) completed EMA on their mood, physical symptoms, and pain 5 times per day over a two week period. Daily presenteeism was additionally evaluated once a day at the end of their workday, using questions extracted from the Health and Work Performance Questionnaire (HPQ). Recalled presenteeism was assessed using the original HPQ, with a recalled period of one month. We first calculated intraclass correlation coefficients between recalled presenteeism and the mean of daily presenteeism in the whole study population. Secondly, we used two level hierarchical linear models (HLM) to examine the effect of the mean level of the mood, physical symptoms or pain for a day on presenteeism of the day adjusted by sex and age. Given the known relevance of depression and lower back pain with presenteeism, we further applied multivariate HLM to examine the effect of these factors on daily presenteeism.**Results:** Consistency and agreement between recalled and the mean of daily presenteeism were both 0.58 ($p < 0.01$). Greater daily presenteeism (i.e., less productivity) was significantly associated with increased levels of depression ($p < 0.01$), anxiety ($p < 0.01$), and lower back pain ($p < 0.05$) and with decreased levels of motivation ($p < 0.01$) and concentration ($p < 0.01$). Multivariate HLM revealed that only depression remained to have a significant influence on presenteeism ($p < 0.05$).**Conclusion:** This study confirmed a fluctuation of presenteeism on a daily basis. Daily presenteeism may be specifically influenced by negative aspects of mood rather than physical symptoms including pain, suggesting that mood status may be an effective target to improve productivity in the workplace.

EXPERIENCES WITH STRESS AMONG AFRICAN AMERICAN MEN LIVING WITH TYPE 2 DIABETES: A QUALITATIVE INQUIRY.

Ledric Sherman, Ph.D., M.A.¹¹Texas A&M University, College Station, TX**Introduction:** Self-managing type 2 diabetes (T2D) is critical but often presents a challenge among African American men. Stress may exacerbate both mental and physical problems, which can lead to poor self-management; however, the evidence is sparse. The purpose of this study is to examine the relationship the role of stress in type 2 diabetes management among a prospective group of African American men living in the southern United States.**Methods:** Nineteen African American men with T2D were recruited from barbershops and churches. Interviews were conducted using a semi structured interview guide. Transcripts were analyzed using a phenomenological approach and focused on identifying common themes describing the responses regarding any stress that the participants have pertaining to living with and managing type 2 diabetes.**Results:** The themes that emerged from the participant responses are: (1) experiencing less stress, (2) stress not attributed from diabetes, (3) avoid thinking about stress, and (4) some stress is prevalent. Overall, participants expressed either that diabetes was not attributing to the stress that they have or that they have less stress than they did prior to being diagnosed with type 2 diabetes.**Discussion & Conclusion:** In this sample of African American men, stress became a factor for some participants when considering the complications that can occur from diabetes. These findings suggest the need for key considerations to only incorporate general information about diabetes and stress management, but should be gender and culturally relevant to African American men.

EXPLORING PERCEPTIONS OF SELF-CARE AMONG UNDERGRADUATES AT A MIDWESTERN UNIVERSITY

Lauren Maziarz, PhD, RN¹, Sherry Grone, MFN¹, Caylie Shover, B.S.¹¹Bowling Green State University, Toledo, OH

Background: College counselors are reporting record numbers of student visits for a variety of mental health problems, with noted rises in depression, anxiety, and overall distress (Center for Collegiate Mental Health [CCMH], 2016). Since a student's overall wellbeing ultimately impacts academic success, health professionals need to better understand the perceptions of and barriers to engaging in protective self-care activities among this population.

Methods: An electronic survey was sent to a random sample of 4,997 undergraduate students at a public, mid-size university in the Midwest with a response rate of 7% (n=370). The 26-item survey included both Likert-scale and open-ended questions to solicit perceived barriers. Barriers were then coded and categorized during post-hoc analysis.

Results: *Nutrition:* Only 31% of respondents said they ate at least 3 servings of vegetables while 41% said they ate 2 servings of fruit on most days of the week. The majority (61%) also agreed they eat more processed, junk foods when feeling stressed. The most common barriers to eating healthfully were lack of time (n=155), lack of money (n=137), lack of accessibility (n=117), and personal preference for unhealthy foods (n=46). *Exercise:* When asked about current exercise, 43% agreed they exercised at least 30 minutes, 5 days a week. The most common barriers to exercise were lack of time (n=193), school work (n=101), lack of motivation (n=78), and no energy (n=31). *Sleep:* While not the majority, 39% agreed they regularly drink caffeine to maintain alertness and 37% agreed they regularly take naps to function. The most common barriers to sleep were school work (n=215), lack of time (n=123), social obligations (n=61), stress (n=59), and digital distractions (n=50). *Spirituality:* Only 38% agreed spiritual or religious beliefs were important to their overall health. The most common barriers to feeling connected spiritually were time (n=97), not identifying as being religious or spiritual (n=90), not feeling like religion or spirituality was a priority (n=40), and not feeling comfortable practicing their religion at school (n=31).

Conclusions: There are numerous perceived barriers to engaging in self-care activities among undergraduate participants in this study. While the low response rate limits generalizability, we suggest that addressing self-care perceptions should be an important part of future prevention programs among this increasingly vulnerable population.

ASSESSING WOMEN'S SEXUAL MINORITY STRESSORS IN DAILY LIFE: DOES THE WAY WE ASK THE QUESTION MATTER?

Kristin E. Heron, Ph.D.¹, Charlotte A. Dawson, B.A.², Cassidy M. Sandoval, M.A.², Lauren Butler, n/a¹, Jazmine Craig, n/a³, Abby L. Braitman, Ph.D.¹, Robin J. Lewis, Ph.D.¹¹Old Dominion University, Norfolk, VA; ²Virginia Consortium Program in Clinical Psychology, Norfolk, VA; ³Norfolk State University, Norfolk, VA

Researchers are often interested in using ecological momentary assessment (EMA) to assess real-world, naturally occurring experiences. However, there are few well-validated measures to assess constructs via EMA, and thus, researchers are often left to create items for individual studies. One area lacking well-validated EMA measures is the daily assessment of sexual minority stressors (SMS), or the unique stressors sexual minority individuals (e.g., lesbian, gay, bisexual) experience due to their marginalized status. Previous research suggests the way researchers ask EMA questions about general stressors is important. Therefore, the aim of this study was to describe rates of reported SMS using different question formats. As part of a study of same-sex female couples, 321 sexual minority women ages 18-35 completed daily surveys for 14 consecutive days regarding their experiences and health behaviors. To assess daily SMS, two question types used in previous research were asked each morning. Participants were first asked a general question about if any negative events related to being a sexual minority occurred the previous day (yes/no). Then, a published 8-item daily SMS measure that inquired about specific experiences (e.g., hearing anti-LGBT talk, being made fun of) was administered. In total, participants provided data on 4,008 days. Results indicated that in response to the general dichotomous question, participants reported experiencing negative events on 5.2% of days (209 days). In contrast, in response to the 8 specific experiences, participants reported at least one on 19.5% of days (788 days). Specific experiences ranged in occurrence from 1.2% of days (49 days; being explicitly threatened) to 10.2% of days (411 days; hearing anti-LGBT talk). Instances when participants denied a negative event in the general item but subsequently endorsed a specific experience were explored. Given the discrepant reports among the two question types, these data suggest sexual minority women will report more SMS experiences in response to questions about specific events or experiences as compared to a single general question inquiring about negative events or stressors. These findings have methodological implications for future studies that assess daily SMS. Given that SMS may contribute to health disparities, accurate assessment of real-world experiences of SMS is essential to further our understanding of health disparities among sexual minority individuals.

RISK AND SOCIODEMOGRAPHIC FACTORS ASSOCIATED WITH OPIOID USE AMONG AFRICAN AMERICAN FAITH-BASED POPULATIONS

Kelsey Christensen, MA¹, Alexandria Bauer, MA², Carole Bowe Thompson, BS³, Sheila Lister, B.S.⁴, Jannette Berkley-Patton, PhD⁵¹University of Missouri - Kansas City School of Medicine, Kansas City, MO; ²University of Missouri-Kansas City, North Charleston, SC; ³University of Missouri-Kansas City/ School of Medicine, Kansas City, MO; ⁴University of Missouri, Kansas City Missouri, Kansas City, MO; ⁵University of Missouri-Kansas City, Kansas City, MO

An estimated 1.7 million people suffer from an opioid overdose each year. Rates of opioid abuse/overdose tend to be higher in Whites. However, in the Midwest, which has observed some of the most rapid increases in opioid abuse/overdose, African Americans (AAs) are more likely to die from an opioid overdose compared to Whites (e.g., in Missouri, 31.5 per 100,000 versus 15.5 per 100,000, respectively) despite lower rates of use. Given that AAs are also disproportionately burdened by opioid abuse risk factors (e.g., low income, rural residence) and are less likely to seek substance abuse treatment, culturally-appropriate interventions that address opioid use should be considered. AA churches may be an ideal setting for opioid prevention and treatment efforts since it is a highly trusted institution, and AAs have the highest rate of church attendance among all racial/ethnic groups. This study examined traditional and religiosity predictors (e.g., insurance status, gender, history of pain, other substance use behaviors, religious behaviors) of self-reported lifetime opioid use using survey data from 4 AA churches (N = 250 church members and community members using church outreach ministry services) that participated in the Taking It to the Pews (TIPS) study, a faith-based HIV/STD/Hepatitis C education and testing intervention in the Kansas City metropolitan area. This is the first study to examine opioid use in an AA church-affiliated population. Participants were predominantly female (71%, N=178) and church members (74%, N = 184), with an average age of 47 (SD = 12.03). 79% of participants attended church weekly or more. 53% of participants reported prescription opioid use (ever), 11% reported crack/cocaine/heroin use (ever), and 60% reported marijuana use (ever). 74% reported a lifetime history of severe pain (e.g., from injury, medical procedure, illness) requiring medical intervention. Preliminary analyses indicated that there were significant relationships between lifetime opioid use and Medicaid status, church attendance, pain history, history of crack/cocaine/heroin use, history of marijuana use, and a history of binge drinking. Gender was not related to lifetime opioid use. Logistic regression analyses indicated that those who reported lifetime opioid use were less likely to have Medicaid (OR = .22, p = .004). They also attended church more frequently (OR = 1.29, p = .02), had a history of severe pain (OR = 24.17, p < .001), a history of crack/cocaine/heroin use (OR = 4.42, p = .03), and a history of marijuana use (OR = 2.70, p = .01). These findings suggest that AA churches have great potential to reach church-affiliated populations, especially church members, living with chronic/acute pain with lifestyle interventions (e.g., physical activity and stress management classes) for pain management and opioid abuse recovery programs appropriately tailored for faith-based settings.

CANNABIS USE THROUGH E-CIGARETTES, INCLUDING JUUL

Alison F. Cuccia, MSPH¹, Minal Patel, PhD, MPH¹, Elexis C. Kierstead, MPH¹, Yitong Zhou, MS¹, Barbara Schillo, PhD¹, Donna Vallone, PhD, MPH²¹Truth Initiative Schroeder Institute, Washington, DC; ²Truth Initiative, Washington, DC

Introduction: Cannabis and tobacco use have been correlated for years. Electronic cigarettes (e-cigarettes) are an increasingly popular tobacco product, particularly among youth and young adults, largely due to the popularity of the device JUUL. Though JUUL is a closed system, JUUL and other e-cigarettes can be modified and used with cannabis. E-cigarettes may appeal to those who otherwise may not have used cannabis, putting them at risk for poor academic/professional performance, interpersonal problems, and risk-taking behaviors. Little research has explored e-cigarette use with cannabis, particularly with the emergence of JUUL.

Methods: Data were collected from a nationally representative panel of U.S. adults aged 18-64, with an oversample of JUUL users (n=3415). Ever e-cigarette users were asked about ever and current (past 30-day) e-cigarette use with cannabis (marijuana or liquid THC oil). Past 12-month JUUL users were asked about ever JUUL use with cannabis. Weighted multivariate logistic models examined differences in e-cigarette cannabis use controlling for age, gender, education, race/ethnicity, smoking status, and current e-cigarette use.

Results: Among all adults who ever used e-cigarettes (n=892), 31% ever used e-cigarettes with cannabis. Compared to those 45-64 years old, e-cigarette users aged 25-34 had greater odds of ever using e-cigarettes with cannabis [adjusted odds ratio (aOR)=2.51; 95% confidence interval (CI): 1.43-4.42]. Compared to non-current users, current e-cigarette users also had greater odds of ever using e-cigarettes with cannabis (aOR=2.36, CI: 1.56-3.57). Among adult ever e-cigarette with cannabis users (n=360), almost half (49%) currently used e-cigarettes with cannabis. Compared to non-current e-cigarette users, current e-cigarette users had greater odds of current e-cigarette use with cannabis (aOR=5.13; CI: 2.47-10.67). Among past 12-month JUUL users (n=472), 21% ever used JUUL specifically with cannabis, which did not differ by current tobacco use status or demographics.

Conclusion: These data suggest that nearly a third of adults ever using e-cigarettes have used them with cannabis. Current e-cigarette users may be more likely to use e-cigarettes with cannabis, though not necessarily JUUL with cannabis. As the e-cigarette market evolves, innovative policy and programs are needed to reduce the uptake of cannabis with these products to protect against co-use with tobacco and other cannabis behavioral health outcomes.

CONFIRMATORY FACTOR ANALYSIS OF THE DRINKING CONTEXT SCALE FOR USE WITH AFRICAN AMERICAN YOUNG WOMEN WHO USE ALCOHOL

Anthony Hitch, M.A.¹, Jennifer L. Brown, PhD², Ralph J. DiClemente, PhD³¹University of Cincinnati, Cincinnati, OH; ²University of Cincinnati, College of Medicine, Cincinnati, OH; ³NYU College of Global Public Health, New York, NY

The Drinking Context Scale (DCS; O'Hare, 1997) was developed to measure one's expectancies concerning the likelihood of excessive alcohol use across various situational contexts. This 9-item questionnaire was validated in a majority White (93.3%) undergraduate sample, which yielded three subscales: a) convivial drinking, b) negative coping, and c) intimate drinking. While high prevalence of heavy alcohol consumption is a major health concern among young women, alcohol use behaviors among African American women differ from women with different racial identities. The aims of the current study were to a) confirm the factor structure of the DCS in a community-based sample of African American young women who drink alcohol and b) assess concurrent validity with a measure of heavy alcohol consumption (AUDIT-C; Saunders et al., 1993). This study analyzed baseline data from the N-LITEN study, an STI/HIV prevention intervention for African American young women. Participants were women who self-identified as African American ($N = 560$), were 18-24 years old (M age = 20.58, $SD = 1.89$), consumed alcohol ($\geq 3x$) in the past 90 days, and reported condomless vaginal or anal sex with a male partner in the past 90 days. Confirmatory factor analysis assessed the goodness of fit of the three-factor model. Normed-fit index (NFI), Tucker Lewis index (TLI), comparative fit index (CFI), root-mean-square error of the approximation (RMSEA), and standardized root-mean-square residual (SRMR) were employed. AUDIT-C total score was included as a dependent variable in the final structural equation model (SEM) to determine concurrent validity. A one-, two-, and three-factor model were fitted to the data in the same manner as the original validation study. The three-factor model showed the best model fit, $\chi^2 (25, N = 560) = 103.13$, $p < .001$, NFI = 0.97, TLI = 0.96, CFI = 0.98, RMSEA = 0.07, SRMR = 0.04. The SEM model displayed good model fit, $\chi^2 (51, N = 560) = 150.40$, $p < .001$, NFI = 0.96, TLI = 0.97, CFI = 0.97, RMSEA = 0.06, SRMR = 0.04, such that higher DCS scores were associated with greater heavy alcohol consumption, $B = 0.56$, $SE = 0.04$, $p < .001$, accounting for 61.6% of the variance in AUDIT-C scores. This study confirmed the three-factor structure of the DCS and moderate concurrent validity with the AUDIT-C was found within this sample suggesting appropriateness for use among African American young women.

6:15 PM-7:30 PM

PROTECTIVE AND RISK FACTORS FOR INCREASED ALCOHOL USE IN COLLEGE STUDENTS ON THE U.S./MEXICO BORDER

Claudia J. Woloshchuk, B.A.¹, Carlos Portillo, B.S.¹, Daniel Hill, n/a¹, Christopher S. Marquez, n/a¹, Alex Trejo, n/a¹, Theodore V. Cooper, PhD¹¹University of Texas at El Paso, El Paso, TX

Problematic alcohol use among college students continues to be a problem in the U.S. and has previously been found to be a possible coping mechanism for underlying psychological illnesses (Metzger et al. 2017). However, parental behavior associated risk factors for problematic alcohol use during young adulthood have yet to be thoroughly investigated in young adults on the U.S./Mexico border. The present study assessed the relationships between participants' past month alcohol consumption and the likelihood of having alcoholic parents, adverse childhood experiences, reported symptoms of depression, anxiety and stress, participants aggressive behaviors, resiliency, self-efficacy and coping skills in primarily Latinx college students. College students ($N=179$; M age=21.56 years, $SD=4.62$; 76% female; 83.5% Hispanic/Latinx, 9.3% White) provided consent and completed the following assessments: demographics, The Children of Alcoholics Screening Test (CAST), The Depression, Anxiety and Stress Scale (DASS), the Adverse Childhood Experiences Scale (ACES), The Buss-Perry Aggression Questionnaire (BPAQ), The Brief Resilience Scale (BRS), The General Self-Efficacy Scale (GSE), The Collectivistic Coping Styles Measure (CCSM), reported if their parents have used alcohol, and reported the number of times they used alcohol within the past month. Linear regression models were used to test the association between Past Month Alcohol Usage ($F(24, 154) = 1.94$, $p < .01$) and the reported protective and risk factors. Holding other predictors constant, increased past month alcohol consumption was positively associated with physical abuse ($\beta=4.00$, $p < .01$), feelings of being unloved ($\beta=4.95$, $p < .01$), mother being physically abused ($\beta=3.76$, $p < .05$), and anger ($\beta=.65$, $p < .05$), and negatively associated with having a house member go to prison ($\beta=-4.45$, $p < .05$). That adverse childhood experiences, specifically of physical abuse, feeling unloved/unsupported, and mothers being physically abused, and feelings of anger, are associated with increased alcohol intake suggests that students may benefit from trauma intervention efforts. These efforts should include parents and occur prior to the onset of drinking related problems. Additionally, that having a house member go to prison is associated with reduced alcohol consumption, suggests students may learn from familial mistakes while under the influence. Future studies should be prospective in nature and include multiple familial perspectives.

A TRANSFORMATIVE JOURNEY: NURSES WITH SUBSTANCE USE DISORDER WHO COMPLETE AN ALTERNATIVE TO DISCIPLINE PROGRAM

Susan Ervin, PhD¹¹University of Nevada, Reno, Reno, NV

Substance use disorder (SUD), defined as the misuse of drugs and/or alcohol, affects approximately 10% of the three million Registered Nurses (RNs) in the US. In addition to general risk factors (for example, family history, history of physical, sexual abuse), RNs have specific risk factors. These include easy access to controlled substances, stressful work environments, and lack of education about SUD in nurses. SUD in nurses is a significant issue because of the potential for impaired practice and patient endangerment. State nursing regulatory agencies have developed programs, called Alternative to Discipline Programs (ADPs) to address this issue. ADPs remove impaired RNs from practice, facilitate treatment during the acute phase of SUD, and return RNs to practice in a structured, monitored work environment.

Research related to RNs in ADPs has addressed characteristics of nurses in ADPs, impact of ADPs on stress and life-burden, and the self-integration that occurs during participation in an ADP. Little research addresses the actual lived experience of nurses who complete an ADP. This phenomenological study was conducted to explore that lived experience. The question that guided this research was: What is the meaning and significance of the lived experience of RNs with SUD who complete an ADP? Van Manen's six research activities guided this inquiry and Colaizzi's seven step method was used for analysis.

Three RNs participated. Findings resulted in five main themes and four subthemes that provide a rich description of these RNs experiences. Findings, validated through participant review, provided the essence of completing an ADP. This essence was *A Transformative Journey*. Themes common to the participants' journeys were 1) Leap of Faith, 2) Pain of Surrender, 3) Feelings of Drowning, 4) Structured Sobriety, and 5) Nurse Affiliations. Themes represent the transformation participants underwent during the ADP and the importance of other nurses in the journey. Subthemes included 1) Future Nurses at Risk, 2) Hidden Pain, 3) Tell Me Why, and 4) Protecting One Another.

Understanding the meaning and significance of the lived experience of RNs who complete an ADP has implications for nursing practice, education, and research. Implications for practice include provision of a voice for nurses who complete ADPs and creation of a supportive practice culture. Implications for nursing education include increased curricular content related to risk factors for SUD that are specific to nurses, and recognition of SUD in students and graduates. Implications for research include expansion of this study and studying risk factors for nursing students. This was a small, homogenous group of participants. Research with more, and diverse, participants would expand knowledge about RNs who complete ADPs. SUD in nurses can begin in nursing school and more knowledge about student risk factors is needed.

STRATEGIES TO IMPROVE TREATMENT UTILIZATION FOR SUBSTANCE USE DISORDERS: A SYSTEMATIC REVIEW OF INTERVENTION STUDIES

Jason Satterfield, PhD¹, Erin A. Vogel, PhD¹¹UCSF, San Francisco, CA

Background: Despite a growing body of research on screening and brief interventions, very little is known about how to efficiently and effectively make treatment referrals. The efficacy of clinical interventions to improve referrals and promote treatment utilization for substance use disorders (SUD) remains unclear.

Objective: The present study systematically reviewed the literature on interventions to improve referrals and promote treatment utilization.

Methods: We conducted a systematic review of clinical intervention studies (published in English between 2000-2017) reporting outcomes relevant to the utilization of specialty substance use treatment. We excluded studies that did not report treatment utilization outcomes (i.e., treatment initiation, attendance, engagement). Results of randomized controlled trials (RCTs) were synthesized. Risk of bias was assessed using Cochrane guidelines. Proportions of positive to negative utilization outcomes were calculated for each low-bias RCT. Interventions were categorized by theory-based approach. Within each intervention category, we report the number of studies with positive effects for at least half of relevant outcomes.

Results: Fifty-two RCTs were identified, with 35 (67.3%) measuring treatment initiation, 39 (75.0%) measuring attendance, and 4 (7.7%) measuring engagement. Twenty-three RCTs (44.2%) had low risk of bias and were synthesized. Strongest effects were found on treatment utilization with 35% overall positive studies and most consistent findings in collaborative care (67%) and cognitive-behavioral (100%) intervention categories. Overall, 29% of treatment attendance studies were positive with twelve-step promotion showing the strongest results (50%). Only one low risk study looked at engagement, finding strong results (75% of outcomes) for twelve-step promotion.

Conclusions: Interventions focused on collaborative/coordinated care and CBT were most effective at increasing SUD treatment initiation, while twelve-step promotion interventions were more effective at increasing sustained attendance and engagement. Interventions and outcomes were largely heterogeneous and often poorly defined. Further research is needed to develop, define, and test robust models of treatment utilization to improve the efficacy of referrals to treatment and to identify precisely which intervention components are most effective in promoting treatment utilization at each step of the treatment continuum.

BLACK FIRST-YEAR COLLEGE STUDENTS' ALCOHOL OUTCOME EXPECTANCIES: IMPLICATIONS FOR INTERSECTIONAL ALCOHOL INTERVENTIONS

Shemeka Thorpe, MS¹, Amanda E. Tanner, PhD, MPH¹, Samuella Ware, MPH, CHES¹, David L. Wyrick, PhD, MPH¹, Jeffrey J. Milroy, DrPH, MPH¹, Kate Guastaferro, PhD, MPH²

¹The University of North Carolina Greensboro, Greensboro, NC; ²Pennsylvania State University, University Park, PA

First-year college students are a risk group for heavy episodic drinking. On average, more than 42% of first-year college students reported one or more episodes of heavy episodic drinking in the past month. Alcohol outcome expectancies (AOEs), such as tension reduction, disinhibition, social assertiveness, and physical and sexual enhancement, are the greatest predictors of alcohol use during the first year of college. Given the lower rates of alcohol use among Black students, understanding their AOE may be useful in informing culturally relevant interventions. The purpose of this study was to examine the AOE of Black first-year college students and how these expectancies vary by gender, sexual orientation, sexual behavior, and previous alcohol use. Exploratory moderation analyses were conducted. Data was collected in 2017 from first-year students from four geographically diverse universities in the United States via an online baseline survey. In this analysis, students had to identify as Black, male or female, and a first-year student (N=307). The majority of the sample was heterosexual (92%), 18 years old (88.3%), and attended a predominately white institution (93.8%). Around one-quarter used alcohol in the last 30 days. Examining the AOE indicated that participants had low endorsement of positive outcomes of alcohol use such as tension reduction and sexual enhancement and higher endorsement of negative expectancies such as behavioral and cognitive impairment. There were significant moderation effects. Sexual minority males and females were more likely to endorse risk and sociability expectancies which had significant positive associations with alcohol use. Heterosexual women were significantly more likely to endorse cognitive and behavioral impairment expectancies which were significantly associated with never consuming alcohol. All women endorsed sexuality expectancies which were significantly associated with alcohol use. Addressing alcohol expectancies can help re-correct the misguided positive expectancies for alcohol use, reframe the negative expectancies as an opportunity to reduce alcohol use, and provide suggestions on alcohol-free activities that elicit similar positive expectancies. Mandating first-year college students to participate in alcohol interventions that include an intersectional framework (e.g. focusing on the intersection of race, gender, and sexual orientation) would be useful in supporting Black first-year college students overall health.

ARE DRUG COURTS AN OPPORTUNITY TO INTERVENE IN THE WELL-BEING IN CHILDREN AND FAMILIES OF SUBSTANCE-USING PARENTS?

Kate Guastaferro, PhD, MPH¹, Wendy P. Guastaferro, PhD², Daniel J. Whitaker, PhD³

¹Pennsylvania State University, University Park, PA; ²Florida Atlantic University, Boca Raton, FL; ³Georgia State University, Atlanta, GA

More than 60% of people involved in the criminal justice system have a substance use disorder. Adult drug courts are effective community-based interventions for individuals with substance use disorder facing criminal charges; currently more than 3,400 adult drug courts provide services to 150,000 people annually. Individuals considered for and enrolled in drug courts often present with myriad needs that extend beyond substance misuse and criminal behavior. While drug courts must attend to these primary objectives, to maximize effectiveness, drug court programs must also consider treatments and services for needs that could interfere with successfully engaging in, and completing, treatment and supervision requirements.

Among adult drug court participants, it is estimated more than half are parents to at least one child under 18. Though we know justice-involved parents typically do not parent minor children alone, little is known about the family environment surrounding the drug court parent, their child, and other caregivers of that child. A parents' criminal justice involvement and substance use may create a suboptimal environment for children including trauma, poor mental health, and an increase in the risk for child maltreatment. Thus, given the negative effects parental substance use and criminal justice involvement may have on child well-being, we sought to examine characteristics of drug court parents that affect the well-being of their children and families, specifically parenting and mental health, and to compare these characteristics to the other caregiver.

In a cross-sectional sample of 100 drug court parents, we collected data on caregiver characteristics that may affect child and family wellbeing including the family environment, substance use and addiction severity, criminogenic risk and needs, parenting, adult mental health and child mental health. Statistical analyses were employed to differentiate parenting behaviors and mental health needs from drug court parents and other caregivers. As expected we found that the drug court parents were at moderate to high risk for recidivism and presented with multiple and significant criminogenic and psychosocial functioning needs. Risk for potential child maltreatment and poor parenting behaviors were elevated, and significantly higher compared to the other caregivers. DCP demonstrated clinically elevated mental health needs, and were significantly different across all indicators of mental health compared to other caregivers. Our findings confirm that there are additional needs of drug court clients that necessitate intervention. Adult drug courts may be a viable intervention point to address issues of parenting and mental health to improve the wellbeing of criminal justice-involved individuals, their children, and families.

COMMUNITY VIOLENCE AND RISK FOR SUBSEQUENT SUBSTANCE USE IN ADOLESCENTS: ROLE OF SLEEP PROBLEMS

Övgü Kaynak, PhD¹, Christopher R. Whipple, PhD¹, Wendy Kliever, PhD², Stephen J. Lepore, PhD³¹Penn State Harrisburg, Middletown, PA; ²Virginia Commonwealth University, Richmond, VA; ³Temple University, Philadelphia, PA

Introduction: Exposure to community violence (ECV) can trigger a host of internalizing and externalizing symptoms in youth (Fowler et al., 2009). Specifically, witnessing or experiencing victimization within the community is associated with increased substance use (Sanders-Phillips & Kliever, 2019). What is less understood are the underlying mechanisms that might explain this association. Sleep problems have been linked to both ECV (Bagely et al., 2016) and substance use (Wong, Brower, Zucker, 2009) and may be a pathway to consider in the relation between ECV and substance use. The current longitudinal study examines how sleep problems in the context of ECV may affect subsequent substance use in youth.

Methods: Data for the study came from a sample (n=985) of middle school students collected during their participation in a randomized trial on the efficacy of an intervention designed to promote psychosocial adjustment among youth exposed to violence. A longitudinal mediation model tested the indirect effect of 9-month (T2) sleep problems on the relation between baseline (T1) ECV and 12-month (T3) substance use (alcohol, tobacco, and other drugs). The outcome did not differ by sex and inclusion in the model resulted in unacceptable fit, so it was excluded from the final model. The final model controlled for study condition, depressive symptoms, intrusive thoughts, and substance use at T1.

Results: The fit of this model was adequate, $\chi^2(3) = 17.73, p < .001$; CFI=0.951; RMSEA=.074 [90% CI=0.043, 0.110]; SRMR=0.031. There was a significant positive association between ECV at T1 and sleep problems at T2 ($b=0.284, p < .001, 90\% \text{ CI}=0.236, 0.333$), and a significant positive association between sleep problems on substance use at T3 ($b=.006, p < .01, 90\% \text{ CI}=.003, .009$). Depressive symptoms were positively associated with sleep problems. Substance use at T1 was positively associated with substance use at T3. The indirect effect of sleep as a mediator in the relation between community violence exposure and substance use at T3 was significant ($b=.002, p < .001, \text{ CI}=.001, .003$). The proposed direct and indirect relations between ECV and substance use accounted for 14.4% of the variance in substance use at T3.

Conclusions: Consistent with expectations, higher levels of ECV was significantly associated with subsequent poorer sleep which, in turn, was associated with subsequently more substance use among middle school students. The structural model showed that ECV was significantly associated with more substance use directly and indirectly through sleep problems. These longitudinal findings suggest that ECV can increase risk for substance use in youth and suggest that sleep problems may account for how ECV might influence substance use. Recognizing and addressing sleep problems in students may be an effective way to target children who need clinical intervention related to their exposure to violence.

MEDICAID-INSURED CALLER CHARACTERISTICS AND QUIT OUTCOMES AT THE ARIZONA SMOKERS' HELPLINE

Uma Nair, PhD¹, Benjamin Brady, DrPH², Patrick O'Connor, n/a³, Taylor Grogg, n/a³, Mark Martz, PhD, MPA⁴¹University of Arizona, Tucson, AZ; ²University of Arizona, Sahuarita, AZ; ³Arizona Smokers' Helpline, Tucson, AZ; ⁴University of Arizona, Phoenix, AZ

Background: Despite historic reductions in tobacco use, disparities in use still exist. Racial and ethnic minority groups, gender and sexual minorities, low socioeconomic status individuals, those with a mental health condition, pregnant women, youth, and Medicaid enrollees have been identified as priority populations. Among these, Medicaid-insured tobacco users are a uniquely disparate group. In the last 15 years, the decline in smoking among Medicaid beneficiaries was one-third the national average. In some states, there has been no detectable reduction in smoking among enrollees. For tobacco cessation quitlines, it is important to identify whether insurance type represents a barrier to quitting that needs to be addressed in treatment.

Purpose: To examine whether insurance type is associated with quit status among tobacco users enrolled in a quitline service. We hypothesized that after controlling for factors known to be associated with quit outcomes, there would not be a difference in quit outcomes by insurance type.

Methods: We included clients who enrolled at the Arizona Smokers' Helpline (ASHLine) from Jan 2014 – Nov 2018 who had complete data for analysis (N=8,606). Data including insurance type, demographic characteristics, and history of tobacco use were collected at the time of intake. Tobacco quit status is self-reported, 30-day point prevalence measured 7-months post enrollment.

Results: Compared to all other clients, those with Medicaid (41%) were statistically more likely to be female, smoke in the home, and have a mental or chronic health condition. They were less likely to be educated, receive social support, or use cessation medication. Controlling for these and other theoretically relevant variables, the adjusted odds of quitting for Medicaid enrollees was 0.87 (95% CI: 0.79-0.96) when compared to clients not enrolled in Medicaid. We also found that clients with 7 or more coaching sessions were three times more likely to quit compared to those with 1 or 2 sessions (OR 3.25, 95% CI: 2.87-3.69).

Discussion: The association between Medicaid and tobacco cessation was significant, but less impactful than many other controlling factors. This suggests that insurance status alone represents a less meaningful barrier to quitting than other factors. Research has shown that despite making similar efforts in quitting, socioeconomically disadvantaged tobacco users are about half as likely to quit compared to high socioeconomic groups. Thus, the factors that contribute to initiating a quit attempt are different than those required for maintaining abstinence. Given its importance, additional coaching sessions might focus on assisting Medicaid-insured clients to connect with resources that address upstream determinants of health in general, and smoking behavior specifically.

PREFERENCES FOR FINANCIAL INTERVENTIONS AMONG CURRENT SMOKERS

Jaimee L. Heffner, PhD¹, Paul Litwin, MS¹, Salene M. Jones, PhD, MA, LP¹¹Fred Hutchinson Cancer Research Center, Seattle, WA

Background: The prevalence of smoking is 4 times higher among people of low socioeconomic status. Although financial stress is a barrier to smoking cessation, current cessation approaches do not address financial concerns as a means of improving the likelihood of successful quitting. To identify financial interventions that would be engaging to smokers as a component of a smoking cessation program, we asked current smokers what interventions would be helpful and through what modalities they would prefer to receive them.

Methods: Current smokers (n=89) were recruited through Prolific Academic and completed a web-based survey as part of a broader study on financial health. The survey included the Financial Anxiety Scale (FAS) and a measure of financial well-being. Participants reported their past and current cigarette smoking and their preference for nine different financial interventions and three options regarding how to receive the interventions (in-person, phone, web/app).

Results: Mean FAS was 29.24 and mean financial well-being was 44.31, indicating moderate financial stress. A substantial majority of current smokers reported at least some interest in basic needs assistance (74%), medical bills assistance (78%), a database of financial services (80%), or information on specific financial services that apply to the participant's situation (83%). They were also interested in debt/loan repayment programs (67%), employment programs (52%) and help with financial anxiety (56%). Legal assistance (35%) and budget planning (38%) were of less interest. Regarding modality, they overwhelmingly wanted to receive financial services online or by mobile app rather than by phone or in person.

Conclusions: Current smokers were most interested in interventions that helped them identify direct financial aid. Reflecting the extent to which financial health impacts mental health, the majority also reported interest in receiving assistance to help with financial anxiety. There is high interest among current smokers in receiving financial interventions, particularly when delivered digitally. Including financial interventions in smoking cessation programs could help engage smokers and assist them by addressing poor financial health and its consequences as barriers to cessation.

CO-USE OF CIGARETTES AND CANNABIS ON THE SAME OCCASION AMONG YOUNG ADULT SMOKERS

NHUNG NGUYEN, PhD¹, Pamela M. Ling, MD, MPH², Johannes Thrul, PhD³

¹Center for Tobacco Control Research and Education, Alameda, CA; ²UCSF Center for Tobacco Control Research and Education, San Francisco, CA; ³Johns Hopkins University, Baltimore, MD

Background: Cannabis is commonly used by young adult smokers. Prior research has predominantly described cigarettes and cannabis co-use as any use of both substances in the last 30 days using retrospective self-reports. Existing studies suggest that closer temporally related co-use (e.g., on the same occasion vs. on separate occasions) is associated with worse physical and mental functioning. Here, we examine co-use on the same occasion and identify factors associated with this co-use pattern.

Methods: A smartphone-based study collected 2891 consecutive daily assessments during 30 days among 147 young adult smokers (Mean age=22.7, 52% female) in the San Francisco Bay Area in 2016-2017. Daily reports on use of cigarette and/or cannabis were aggregated over the study period for each participant. Frequencies (i.e., number of days) of same-occasion co-use were computed for each participant. Multivariate linear regression examined the associations between frequency of same-occasion co-use with numbers of days using cigarettes, numbers of days using cannabis, and perceived general health, controlling for age, sex, race, and education.

Results: Overall, 92 participants (63%) reported any co-use of cigarettes and cannabis over the 30-day study period. Among these 30-day co-users, 98% (n=90) reported any co-use on the same day, and 85% (n=78) participants reported any co-use on the same occasion. Co-users with a greater number of same-occasion co-use episodes reported more days of smoking cigarettes ($\beta=0.54$, $p<0.01$) and using cannabis ($\beta=0.86$, $p<0.01$). A greater number of same-occasion co-use episodes was significantly associated with lower perceived general health in bivariate analysis ($\beta=-.03$, $p=0.04$), but this association was attenuated after controlling for demographics ($\beta=-.03$, $p=0.07$).

Conclusions: Given that same-occasion co-users more frequently used cigarettes and cannabis, interventions should address timeframes of co-use and tailor to different co-user profiles. Future research should measure co-use more accurately, such as on the same occasion, rather than in the last 30 days.

CIGARETTE BRAND USE AND SEXUAL ORIENTATION: RESULTS FROM THE NATIONAL SURVEY ON DRUG USE AND HEALTH (NSDUH)

Alexandra Budenz, MA, DrPH¹, Yvonne A. Prutzman, PhD, MPH¹¹National Cancer Institute, Rockville, MD

Background: Gay, lesbian, and bisexual populations have a higher prevalence of cigarette smoking than heterosexuals, resulting in increased mortality from tobacco-related illness. There is extensive evidence that tobacco companies have targeted marketing towards these populations, which can influence tobacco-related perceptions and brand preference. The purpose of this study was to measure differences in cigarette brand use by sexual orientation.

Methods: Using the 2015-2017 cycles of the National Survey on Drug Use and Health (Sample N=24,310), we conducted survey weighted univariate and bivariate analyses of the most commonly-used cigarette brands (N=5) among adult smokers by sexual orientation. We then conducted survey weighted logistic regression analyses for each cigarette brand to test relationships between sexual orientation and brand use while controlling for sociodemographic characteristics.

Results: Adult smokers who identified as bisexual or gay/lesbian (vs. heterosexual) had higher odds of American Spirit (AOR=3.22, 2.86, respectively) and Camel cigarette use (AOR=1.78, 1.70, respectively). Identifying as gay/lesbian was associated with significantly increased odds of Marlboro use (AOR=1.23), while identifying as bisexual was associated with increased odds of Newport (menthol) use (AOR=1.71). Prevalence of American Spirit use was particularly pronounced in bisexual (17.6%) and gay (12.7%) men (vs. 5.71% heterosexual men), and Newport use was most prevalent among bisexual (29.3%) and gay/lesbian women (26.2%, vs. 21.4% heterosexual women).

Conclusions: Adult smokers who identify as bisexual or gay/lesbian may be more likely to prefer certain popular cigarette brands compared to heterosexuals. Specifically, identifying as bisexual or gay/lesbian was associated with approximately three times the odds of American Spirit use, and gay/lesbian and bisexual women also had elevated prevalence of Newport use. Health claims and other characteristics of these cigarette brands may influence risk perceptions and tobacco-related health outcomes in this population. Therefore, marketing and promotion practices of these brands must be examined to improve tobacco-related public education and targeted risk communication.

ASSOCIATION OF NICOTINE HARM PERCEPTIONS AND SUBSEQUENT SMOKING ABSTINENCE AMONG SMOKERS WHO USED THE NICOTINE SALT POD SYSTEM

Nicholas I. Goldenson, PhD¹, Shivaani Prakash, PhD¹, Erik Augustson, PhD, MPH¹¹JUUL Labs, Inc., San Francisco, CA

Objective: Previous research has not found an independent association between nicotine and tobacco-related diseases, including cancer. Yet recent evidence suggests that misperceptions regarding the harmfulness of nicotine are widespread. There is little data on nicotine harm perceptions among smokers who use electronic nicotine delivery systems (ENDS), and it is unknown if nicotine harm perceptions are prospectively associated with future abstinence from cigarette smoking.

Methods: Adult past 30-day smokers (N=26,187) who recently purchased a nicotine salt pod system (NSPS; JUUL Labs, Inc.) were invited to participate in a behavioral study and completed baseline, 30-, 60-, 90-, 180- and 270-day follow-up assessments online. At baseline, participants completed two measures assessing nicotine harm perceptions ("How large a part of the health risks caused by cigarette smoking comes from the nicotine itself?" and, "How large a part of the cancer caused by cigarette smoking comes from the nicotine itself?") with 4-level response options ("A very large part or all of the health risks [VLP]," "A relatively large part [RLP]," "A relatively small part [RSP]," "None or a very small part [VSP]"). At each follow-up, participants reported if they had smoked combustible cigarettes in the past 30-days (yes/no). Repeated-measure logistic regressions adjusted for sociodemographic and smoking characteristics were used to assess associations of nicotine harm perceptions and subsequent smoking across follow-ups.

Results: 12.5% of smokers responded that VSP of the health risks caused by smoking comes from nicotine, 46.7% RSP, 28.4% RLP, and 12.4% VLP of the health risks. Similarly, 17.3% responded that VSP of the cancer risks caused by smoking comes from nicotine, 44.4% RSP, 24.7% RLP, and 13.5% VLP of the cancer risks. Compared to smokers who stated VSP of the health risks caused by smoking comes from the nicotine, those who stated a RSP (aOR[95% CI]=0.87[0.81, 0.92]) and RLP (aOR[95% CI]=0.92[0.86, 0.98]) had significantly reduced odds of abstaining from smoking across all follow-ups; odds were not significant for those who stated VLP of the health risks (aOR[95% CI]=1.03[0.96, 1.13]). Models of nicotine cancer risk perceptions and future smoking demonstrated a similar pattern of findings.

Conclusions: Among adult past 30-day smokers, misperceptions regarding the harm of nicotine were common. Beliefs that nicotine caused a relatively large part of the health risk of smoking (vs. none or a very small part) were prospectively associated with reduced odds of subsequent past 30-day abstinence from combustible cigarette smoking across a 9-month period. Accurately communicating the independent cancer and disease risk of nicotine is important for supporting smokers' efforts to switch away from combustible tobacco products.

DISCRETIONARY SPENDING PRIORITIES AMONG JOB-SEEKING SMOKERS

Amy Chieng, BA¹, Sarah A. Stinson, B.A.², Judith J. Prochaska, PhD, MPH³¹Stanford University, Palo Alto, CA; ²California Northstate University College of Medicine, Elk Grove, CA; ³Stanford University, Stanford, CA

Significance: Tobacco use is costly for physical and financial wellbeing. Smoking is associated with unemployment and greater difficulty finding re-employment. The current study examined job-seeking smokers' prioritization of smoking over other basic life needs.

Methods: Data were collected at baseline in a clinical trial testing a smoking cessation intervention for job-seeking smokers. Participants (N=290) ranked items from 1 (highest priority) to 13 (lowest priority) for prioritization of their discretionary spending. The online survey randomly ordered presentation of the items.

Results: With a mean score of 4.7 (SD=3.1), cigarettes ranked #2 in importance behind only food (M=2.5, SD=2.7); 45% of the sample ranked tobacco in their top 3 spending priorities. Nicotine replacement therapy (NRT) was ranked the lowest. On average, job-seeking resources (e.g., cell phone, transportation, grooming, new clothing) were prioritized less than food and cigarettes, but higher than other items (e.g. medical treatment, alcohol). Those in precontemplation for quitting smoking were more likely to rank cigarettes in their top 3 (55%), compared to those in contemplation (37%) and preparation (44%), $X^2=2.69$, $df=2$, $p=.032$. Those who smoked within 30 minutes upon waking (50%) were more likely to rank cigarettes in their top 3, compared to those who smoked after 30 minutes (33%), $p<.05$. Smoking more cigarettes/day correlated with a greater prioritization of cigarettes ($r=-0.21$, $p<.01$) and lower prioritization of food ($r=0.16$, $p<.01$). Spending more on cigarettes also was associated with lower prioritization of food ($r=0.15$, $p<.05$). More past year quit attempts was significantly associated with less prioritization of cigarettes ($r=0.16$, $p<.01$). Non-Hispanic whites gave higher priority to cigarettes (M=4, SD=2.8) than did other racial/ethnic groups (M=5, SD=3.2, $F(1,289)=6.11$, $p=.014$). Prioritization of cigarettes did not differ by gender nor significantly correlate with age, education, income, or amount spent on cigarettes ($p's>.10$). The April 2017 California cigarette tax hike was not associated with prioritization of cigarettes or NRT ($p's>.300$). Cigarettes/day, stage of change, and time to first use upon waking were not significantly associated with prioritization of NRT.

Conclusions: Findings indicate cigarettes are highly prioritized, second only to food in discretionary spending, among job-seeking unemployed smokers. Cigarettes were prioritized over job-seeking and healthcare needs, particularly among more heavily addicted smokers. Helping job-seekers quit smoking would increase resources for job-seeking and other basic life needs.

DIFFERENCES IN SMOKING PATTERNS AMONG PUERTO RICANS COMPARED TO OTHER LATINO SUBGROUPS

Evelyn Arana-Chicas, DrPH¹, Delwyn Catley, PhD², Francisco Cartujano Barrera, MD¹, Ciara A. Torres, PhD³, Eida M. Castro, PsyD, MS⁴, Kristi Graves, PhD⁵, Ana Paula Cupertino, Ph.D.¹¹John Theurer Cancer Center, Hackensack Meridian Health, Hackensack, NJ; ²Children's Mercy Kansas City, Kansas City, MO; ³Hackensack University Medical Center, Hackensack, NJ; ⁴Ponce Health Sciences University, Ponce, N/A, Puerto Rico; ⁵Georgetown University, Washington, DC

Introduction: Puerto Ricans have the highest smoking prevalence rate and are less likely to quit when compared to other Latino sub-group in the U.S. Smoking prevalence varies between 19-35% for Puerto Ricans in the U.S. mainland vs. 13-17% in Puerto Rico (PR). Puerto Rican smokers are understudied and underserved with respect to access to smoking cessation treatment resources.

Objective: The objective of this study is 1) to compare smoking patterns of Puerto Ricans in the US with other Latino subgroups and 2) to compare smoking patterns of Puerto Ricans born in the US vs Puerto Rico.

Methods: Participants (N=279) were drawn from an ongoing smoking cessation trial for Latinos in the U.S. As part of the baseline survey we assessed smoking patterns (cigarettes per day (CPD), nicotine dependence, use of menthol cigarettes, use of pharmacotherapy to quit, e-cigarettes use, and past quit attempts), and country of origin. Participants represent 21 Latin American countries which were collapsed into two groups: Puerto Ricans and Non-Puerto Rican Latinos.

Results: A total of 19.4% of participants (n=54) self-identified as Puerto Ricans. Within the Puerto Rican sample, 42.6% (n=23) were born in Puerto Rico and 57.4% (n=31) were born in the U.S. When comparing Puerto Ricans vs non-Puerto Rican Latinos, Puerto Ricans were significantly less likely to have made a past quit attempt ($p=0.029$) and significantly more likely to smoke menthol cigarettes ($p<.001$). When comparing Puerto Ricans born in the U.S. and Puerto Rico, Puerto Ricans born in the U.S. had higher nicotine dependence (28.1% vs 17.4%), higher use of menthol cigarettes (84.4% vs 65.2%), and more past quit attempts (3.44 M vs 1.7 M) compared to Puerto Ricans born in the island, although these differences were not significant. There were no differences in CPD or in using e-cigarettes or pharmacotherapy in the past to quit smoking.

Conclusion: Consistent with prior research Puerto Ricans differed in their smoking patterns from other Latino smokers. They had strikingly lower rates of past quit attempts and higher use of menthol cigarettes compared to other Latino sub-groups. Although the sample size is small, results were similar when comparing Puerto Ricans born in the U.S. with those born in Puerto Rico. These differences suggest that targeted intervention efforts may be warranted for Puerto Rican smokers.

ASSOCIATIONS OVER TIME OF CIGARETTE SMOKING, FOOD INSECURITY, AND PSYCHOLOGICAL DISTRESS

Jin Kim-Mozeleski, PhD¹, Janice Y. Tsoh, PhD², Krishna Poudel, PhD³¹Case Western Reserve University, Shutesbury, MA; ²University of California, San Francisco, San Francisco, CA; ³University of Massachusetts Amherst, Amherst, MA

Introduction: In the U.S., tobacco use is concentrated in disadvantaged and vulnerable populations, such as populations with lower income and with mental health needs. Food insecurity—a stressful condition due to problems in food access—is linked with psychological distress and is an independent risk factor for tobacco use. It is not well understood how these variables influence one another over time. We examined how tobacco use (cigarette smoking), food insecurity, and psychological distress operate as risk factors for one another in a 2-year longitudinal analysis.

Methods: We analyzed data from the 2015 and 2017 waves (T1 and T2, respectively) of the Panel Study of Income Dynamics, a nationally representative household survey. The sample included 7,946 heads of households who provided data in both T1 and T2 on current cigarette smoking status (yes/no), food insecurity (USDA Food Security Survey Module), and psychological distress (K6 Psychological Distress Scale). Reciprocal effects of smoking, food insecurity, and psychological distress were examined using cross-lagged panel analysis. In a saturated model, cross-lagged regression coefficients were estimated simultaneously with direct-effect paths from T1 to T2, controlling for age, sex, education, and poverty. Analyses were conducted in Mplus using survey weights, accounting for the complex survey design.

Results: Results showed significant bidirectional associations between smoking status and food insecurity. Cigarette use at T1 positively influenced food insecurity at T2; conversely, food insecurity at T1 positively influenced cigarette use at T2. Food insecurity and psychological distress also had significant, positive bidirectional associations. However, the association between cigarette use and psychological distress was unidirectional. Psychological distress at T1 influenced cigarette use at T2, but cigarette use at T1 did not influence psychological distress at T2. Rather, cigarette use and psychological distress were concurrently associated at T2 only.

Conclusions: The current findings show that smoking, food insecurity, and psychological distress operate as risk factors for one another, although the relationships were nuanced. There is a need to replicate with more timepoints, towards understanding the overlapping health and mental health burden of smoking, food insecurity, and psychological distress. These findings have treatment implications for working with vulnerable populations experiencing high burden of health disparities.

ASSOCIATIONS BETWEEN E-CIGARETTE ABSOLUTE VERSUS RELATIVE HARM PERCEPTIONS AND INFORMATION SEEKING BEHAVIORS AMONG US ADULTS

Irina Iles, PhD, MPH¹, Arielle S. Gillman, PhD, MPH², William Klein, PhD³, Rebecca Ferrer, PhD⁴, Annette Kaufman, PhD, MPH²¹National Cancer Institute, Hyattsville, MD; ²National Cancer Institute, Rockville, MD; ³National Cancer Institute, NIH, Bethesda, MD; ⁴National Cancer Institute, Pittsburgh, PA

Background: The use of e-cigarettes (e-cigs), an innovative alternative tobacco product, has increased considerably in the US in recent years. Although vaping e-cigs is not without health risks, e-cigs have been framed in some contexts either as “not harmful” (an absolute judgment) or as “less harmful than combusted cigarettes” (a relative judgment). We assessed how absolute vs. relative harm perceptions of e-cigs were associated with e-cig information seeking in a sample of current cigarette smokers and non-smokers.

Method: We analyzed data on US adults 18 years or older from two cycles of the National Cancer Institute’s Health Information National Trends Survey (HINTS-FDA 2015, $N = 3,738$ and 2017, $N = 1,736$). We used weighted logistic regression models to explore associations between harm perceptions and information seeking behaviors (controlling for demographics and survey cycle).

Results: When information seeking behaviors were regressed separately on absolute and relative harm perceptions, higher absolute harm perceptions were significantly associated with lower odds of having looked up information on where to buy e-cigs ($aOR = 0.46$, $p = .01$) and on e-cigs cost ($aOR = 0.47$, $p = .01$). Higher relative harm perceptions were significantly associated with higher odds of having looked up information on e-cigs health effects ($aOR = 1.78$, $p = .04$); and lower odds of having looked up information on using e-cigs to quit/reduce smoking ($aOR = 0.64$, $p = .03$) and on e-cigs cost ($aOR = 0.59$, $p = .02$). When information seeking behaviors were regressed simultaneously on both harm perceptions, only relative harm perceptions continued to be significantly associated with having looked up information on using e-cigs to quit/reduce smoking ($aOR = 0.54$, $p = 0.01$). Additionally, current smokers vs. non-smokers had significantly higher odds of having looked up information on using e-cigs to quit/reduce smoking ($aOR = 2.75$, $p = .01$); and on how to get free e-cigs samples ($aOR = 4.89$, $p = 0.03$). Interactions between harm perceptions and smoking status were not significant.

Conclusion: Although e-cigs may pose unique harms to health, information seeking behaviors indicate that individuals may primarily consider e-cig risk as it compares with that of combusted cigarettes when seeking e-cig information, an approach that aligns with e-cig marketing strategies. Given the cross-sectional nature of the data, it is also possible that information seeking drives relative harm perceptions and replication with longitudinal data is necessary.

DIETARY INTAKES AMONG HEAVY VS. LIGHT SMOKERS FROM THE ALPHA-TOCOPHEROL, BETA-CAROTENE CANCER PREVENTION STUDY COHORT

Mandeep Virk-Baker, PhD, MPH, MSc, RD¹, Mark Parascandola, PhD, MPH²¹University of Maryland, Lutherville-Timonium, MD; ²National Cancer Institute, Rockville, MD

Background: Smokers tend to have less adequate diet as compared to non-smokers. Less is known about dietary differences between light vs. heavy smokers. The purpose of this study was to evaluate dietary intake by the level of smoking.

Methods: We evaluated dietary intake among light vs. heavy smokers in Finnish male smokers, aged 50 - 69 years, in the Alpha-Tocopherol, Beta-Carotene Cancer Prevention (ATBC) Study. Out of 27,111 participants, 17,300 (63.8%) reported smoking ≥ 20 cigarettes/day and were classified as heavy-smokers, and 9,811 (36.2%) reported smoking < 20 cigarettes/day and were classified as light-smokers.

Results: Baseline mean serum alpha-tocopherol (11.86 ± 0.03 vs. 12.13 ± 0.04 mg/l; $p < 0.00001$) and beta-carotene (201.90 ± 1.38 vs. 233.48 ± 1.93 ug/l; $p < 0.00001$) were significantly lower among heavy-smokers. Intakes of cereal (212.13 ± 0.67 vs. 221.78 ± 0.84 g/day; $p < 0.00001$), vegetables (110.91 ± 0.54 vs. 118.29 ± 0.71 g/day; $p < 0.00001$), fruits (209.91 ± 1.48 vs. 232.44 ± 1.98 g/day; $p < 0.00001$), and total dietary fiber (18.44 ± 19.29 g/day; $p < 0.00001$) were significantly lower among heavy-smokers as compared to light-smokers. However, intakes of red meat (73.14 ± 0.27 vs. 68.04 ± 0.32 g/day; $p < 0.00001$), processed meat (78.10 ± 0.47 vs. 69.44 ± 0.54 g/day; $p < 0.00001$), dairy products (737.23 ± 3.06 vs. 719.42 ± 3.74 g/day; $p < 0.00001$), coffee (640.56 ± 2.80 vs. 549.23 ± 3.13 g/day; $p < 0.00001$), and alcohol (20.55 ± 0.18 vs. 13.50 g/day; $p < 0.00001$) were significantly higher among heavy-smokers as compared to light-smokers.

Conclusions: Dietary intake vary significantly by the level of smoking and heavy-smokers have poorer intakes as compared to light-smokers. The observed dietary differences have important implications for cancer prevention and control efforts, suggesting a need to incorporate dietary components into tobacco cessation interventions.

Funding: This research was supported in part by the Intramural Research Program of the NIH and the National Cancer Institute. BEHAVIORAL CESSATION INTERVENTION MAY MITIGATE ADVERSE EFFECTS OF POOR SLEEP ON LONG-TERM ABSTINENCE IN LOW-INCOME SMOKERS

Stephen J. Lepore, PhD¹, David W. Sosnowski, PhD², Collins N. Bradley, PhD¹¹Temple University, Philadelphia, PA; ²Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD

Significance: Most treatment-seeking smokers relapse within a year of a quit attempt. Evidence suggests that inadequate sleep is a modifiable risk factor for treatment relapse. Using data from a randomized controlled trial, Kids Safe & Smoke-Free (KiSS; $n = 327$), we examined whether an evidence-based behavioral cessation intervention mitigated the effects of inadequate sleep on relapse at 12-month follow-up. The primary aim of KiSS was to address child tobacco smoke exposure in a sample of predominantly low-income, female, African American smokers. KiSS randomized parents to either a multilevel pediatric clinic intervention (Ask, Advise, Refer; AAR) combined with telephone counseling (AAR+Counseling) or the AAR intervention plus attention control (AAR+Control).

Methods: Data included 12-month, post-treatment bioverified 7-day point-prevalence smoking abstinence, self-reported sleep duration (average hours sleep per night in prior month), sleep medication use, and current depressive symptoms. Participants with missing abstinence data were coded as "not abstinent," and other missing data were imputed using multiple imputation. Logistic regression was used to predict bioverified quit from condition, sleep duration, and the condition x sleep interaction, controlling for depressive symptoms and sleep medication use.

Results: Independent of depressive symptoms and sleep medication use, there were significant effects of condition, sleep duration, and condition x sleep duration (all p 's $< .05$). The odds of being abstinent were higher in the AAR+Counseling condition than in the AAR+Control condition ($OR = 3.45$, $SE = .49$, $p = .01$), and smokers who slept more hours also had higher odds of being abstinent ($OR = 1.77$, $SE = .23$, $p = .01$). The condition x sleep interaction showed that among those in the AAR+Control group, more sleep hours were associated with higher odds of being quit, yet among those in the AAR+Counseling condition, there was no relation between sleep duration and abstinence.

Conclusions: Inadequate sleep appears to reduce the odds of quitting among smokers receiving minimal intervention but does not appear to be a risk factor among smokers receiving more intensive intervention.

MINORITY STRESSORS AND POOR MENTAL HEALTH ARE ASSOCIATED WITH INCREASED RISK OF BINGE EATING BEHAVIORS IN SEXUAL MINORITY WOMEN

Billy Caceres, PhD, RN¹, Kristin E. Heron, Ph.D.², April J. Ancheta, BSN¹, Cindy B. Veldhuis, PhD¹, Tonda L. Hughes, PhD, RN, FAAN³¹Columbia University, New York, NY; ²Old Dominion University, Norfolk, VA; ³Columbia University School of Nursing, New York, NY

Despite evidence suggesting that sexual minority women (SMW; e.g., lesbian, bisexual) have higher rates of binge eating behaviors than heterosexual women, factors that contribute to this disparity are still not well understood. It is theorized that minority stress – or the unique stressors associated with being a member of a stigmatized group – may contribute to health disparities and to higher rates of some unhealthy behaviors. Therefore, we used data from the Chicago Health and Life Experiences of Women (CHLEW) study to examine binge eating in a community sample of SMW. We tested the cross-sectional associations of minority stressors (stigma consciousness, perceived discrimination, and internalized homophobia) and symptoms of poor mental health (depressive and posttraumatic stress [PTSD]) on any/no reports of past-three-month overeating episodes and binge eating episodes (overeating with loss of control). We used multiple logistic regression adjusted for demographics and social support to investigate the association of minority stressors with binge eating behaviors. Logistic regression models examining the associations of mental health symptoms with binge eating behaviors also adjusted for minority stressors. The analytic sample included 662 SMW: mean age 39.8 years, 245 (37.0%) were White, 239 (36.1%) were Black, 156 (23.6%) were Latina and 22 (3.3%) were “other race”, and 610 (92.2%) had a high school education or greater. A total of 114 (17.9%) reported overeating and 60 (9.1%) reported binge eating in the past 3 months. After covariate adjustment, higher levels of stigma consciousness (adjusted odds ratio [AOR] 1.44, 95% CI = 1.15-1.79) and perceived discrimination (AOR 1.28, 95% CI = 1.10-1.50) were associated with higher odds of overeating. There was no significant association between internalized homophobia and overeating (AOR 1.02, 95% CI = 0.98-1.07). Minority stressors were not associated with binge eating. Higher levels of depressive (AOR 1.07, 95% CI = 1.02-1.12), but not PTSD (AOR 1.09, 95% CI = 0.99-1.20) symptoms, were associated with higher odds of overeating. However, both depressive (AOR 1.14, 95% CI = 1.08-1.21) and PTSD (AOR 1.17, 95% CI = 1.03-1.33) symptoms were associated with higher odds of binge eating. It appears that minority stressors may increase the likelihood of overeating, whereas mental health symptoms were associated with higher likelihood of binge eating. Given the association of binge eating behaviors with chronic conditions (e.g., obesity and cardiovascular disease), these findings suggest that interventions targeting both minority stressors and mental health symptoms are needed to reduce risk of binge eating behaviors among SMW.

INTIMATE PARTNER VIOLENCE AND ITS RELATED FACTORS AMONG CHINESE IMMIGRANT WOMEN: AN ONLINE SURVEY STUDY

Yang Li, PhD¹¹University of Missouri, Columbia, MO

Background: Intimate partner violence (IPV) is a serious social and health issue that affects women around the world. Extensive research on IPV has been conducted with Whites, African Americans, and Hispanic Americans. However, there are only a small body of IPV research on Asian immigrants, even less research has been conducted in the context of IPV specifically for Chinese immigrants. The purpose of the study is to investigate the prevalence of IPV and its multiple related factors among Chinese immigrant women.

Methods: This is a cross-sectional descriptive study using the online survey approach. A total of 475 Chinese immigrant women were recruited via Chinese social network sites. Past year IPV, sociodemographic, partners' sociodemographic, relationship-related, and immigration-related factors, religion, social support, acculturation, adverse childhood experiences (ACE), and gender role beliefs were measured. Binomial logistic regression models were conducted to test the relationships between multilevel factors and the occurrence of past year IPV, with those multilevel factors included as explanatory variables and past year IPV included as the response variable.

Results: We found approximately 21% of women experienced past year IPV, 19% had emotional violence, 4% had physical violence, and 3.2% had sexual violence. Relatively young age, cohabiting relationship, lower levels of relationship satisfaction, relatively old age of arrival, longer length of stay, ACE, and lower levels of social support were found in relation to increased risk of IPV among this sample of Chinese immigrant women recruited online.

Conclusion: The study added to our understanding of IPV among this ethnic group of women. Future research is still needed to explore abused Chinese immigrant women's perceptions of IPV, safety strategies, help-seeking behaviors, availability of personal and institutional resources, and special needs for services. Culturally-tailored IPV prevention and intervention programs specific to Chinese immigrant women are also needed.

LESSONS LEARNED IN MODIFYING A HEALTH PROMOTION BEHAVIORAL CHANGE TOOL FOR MOTHERS WITH DISABILITIES

Lorraine O. Walker, EdD, MPH¹, Heather Becker, Ph.D.², Erin E. Andrews, PsyD, ABPP³¹University of Texas at Austin, Austin, TX; ²The University of Texas at Austin, Austin, TX; ³University of Texas at Austin, Manchaca, TX

Women with disabilities are a historically unrecognized health disparities group, who increasingly choose to have children. Maintaining healthy behaviors postpartum is challenging as infant care adds to existing demands, especially for mothers with physical disabilities (MPDs). However, self-report tools measuring health behaviors and behavior change are typically not designed with women with physical disabilities in mind. To understand key considerations in modifying such tools, we recruited mothers on a social media group dedicated to parents with disabilities, a listserv related to disabilities and through other personal contacts, and then interviewed them via teleconference using open-ended questions. Interview questions elicited feedback about an existing toolkit (health behavior assessment, profile of results, and behavior change decision aid) designed for nondisabled mothers. The (a) assessment covered 6 domains (diet, physical activity, smoking, alcohol use, body image, and depressive symptoms) and was followed by (b) a graphical profile of results. Finally, a (c) behavioral decision aid facilitated setting behavioral change goals. Interviewees were 11 MPDs (mean age 29; 9 white, 2 other races) who parented biological children up to age 3. Their physical disabilities included spinal cord injury, spinal bifida, amputation, and neuromuscular and other disorders. Audio-recorded interviews were transcribed and analyzed by quantitative and qualitative content analysis. Two researchers independently coded the interviews and then compared themes. Most mothers rated the 3 toolkit components as very or moderately easy to understand and very or moderately useful. Still, themes emerged on how to adapt this toolkit as well as other self-report tools when used with MPDs. These include: Use non-judgmental language and tone in assessments because MPDs face frequent comparisons with nondisabled ideals for behavior and parenting; be aware that body image (and challenges of body acceptance) may have different meanings to MPDs; ensure that exercise items contain examples applicable to MPDs (e.g., wheeling or swimming); include strengths and supports not just risks; consider motivation in design of behavior change tools; allow women choice in setting goals for change; use alternate formats (paper or electronic) as different ones may work for different MPDs; include methods for accessing social support especially from others MPDs; and identify resources for adaptive parenting tools. An overarching conclusion is that needs and preferences vary among MPDs because they have differing strengths and abilities, so flexibility is needed in modifying self-report tools. However, MPDs repeatedly stressed the importance of considering their specific needs because they are so often neglected in services and research.

THE ASSOCIATION BETWEEN SELF-CARE BEHAVIOR AND WELL-BEING IN MOTHERS OF TODDLERS

Elizabeth S. Weinstein, M.A.¹, Sarah A. Novak, PhD²¹Hofstra University, Long Island City, NY; ²Hofstra University, Hempstead, NY

The vulnerability of postpartum women to emotional, physical, and psychological distress is a well-developed area of research, but the role of self-care is less understood. It is important to examine mothers' inability to engage in self-care behavior because recent research highlights its effect on mental health (Elliott, Powell, & Brenton, 2015; Gunderson & Barrett, 2015; Rizzo et al., 2012). The current pilot study adapted a detailed self-care measure that was developed for a different population, the Self-Care Assessment Worksheet (SCAW; Saakvitne & Pearlman, 1996), to examine the association between self-care behaviors and well-being of mothers. We administered an online survey to 65 mothers of toddlers born in 2017 to investigate specific categories of behaviors they engage in to take care of themselves. The SCAW is comprised of physical, psychological, emotional, spiritual, workplace/professional, and balance self-care subscales. Interestingly, out of the six self-care subscales, the most consistent associations were found for the physical, emotional, and work self-care domains. Reports of engaging in more of these types of self-care were associated with lower levels of depression, anxiety, and stress, as well as higher levels of self-efficacy and perceived emotional and instrumental support. In contrast, the dimensions of spiritual, psychological, and balance were less consistently correlated with psychosocial well-being. In addition, anecdotal feedback about the measure from our participants suggests that the SCAW may have some treatment benefits worth investigating in the future. Participants expressed that the measure gave them insight into the various ways they were taking care of themselves and where there was room for improvement. Thus, these preliminary results highlight that the SCAW appears to be a useful instrument to measure specific self-care behaviors in a sample of new mothers, and many of the expected links with well-being were found. Of course, because this is a cross-sectional design, it is not possible to determine whether self-care contributes to well-being, having superior psychological and social resources makes self-care possible, or if the associations are truly bidirectional. Longitudinal studies will be especially valuable to help establish directionality as well as the potential for change over time. Future studies could further examine the potential clinical utility of the SCAW to guide treatment with mothers.

EFFECT OF INTIMATE PARTNER VIOLENCE EXPOSURE ON HIV VIRAL LOADS IN A PERINATAL COHORT IN SOUTH AFRICA

Abigail M. Hatcher, PhD¹, Kirsty Brittain, PhD², Tamsin Phillips, PhD², Allison Buba, PhD³, Elaine Abrams, MD⁴, Landon Myer, MD²¹University the Witwatersrand, JOHANNESBURG, Gauteng, South Africa; ²University of Cape Town, Cape Town, Western Cape, South Africa; ³ICAP, Columbia University, New York, NY; ⁴Columbia University, New York, NY

Introduction: While antiretroviral therapy (ART) in pregnancy can ensure infant and maternal health, ART adherence postpartum is often poor. One-third of HIV-positive women who achieved viral control during pregnancy virally rebound in the first year after giving birth. Intimate partner violence (IPV) worsens ART adherence and viral suppression among non-pregnant women in cross-sectional studies. However, less is known about how IPV alters viral response longitudinally or around the time of pregnancy.

Methods: We conducted secondary analysis of a prospective cohort of women in a public sector antenatal clinic in Gugulethu, a township near Cape Town, South Africa. Viral loads assessed at each of ten clinic visits (Abbott RealTime HIV-1) indicated viral suppression (< 50 copies/mL) and were assessed continuously as log copies/mL. IPV was measured at three time points using behaviorally-specific items on physical, sexual, and psychological violence (WHO instrument). Covariates were maternal age, gestation at enrolment, socio-economic status, timing of HIV diagnosis and ART initiation, relationship status, depressive symptoms (Edinburgh Postnatal Depression Scale), and alcohol use (AUDIT). We used dynamic panel modeling to estimate the longitudinal impact of IPV on viral loads.

Results: Of 471 women followed for a median of 23 months, a majority (84%) achieved viral suppression by 6 weeks postpartum, but only two-thirds (62%) were virally suppressed by 18 months postpartum. Nearly one in three women (29%) reported some form of IPV in pregnancy or during the study period. IPV victimization at any time point was associated with 64% reduced odds of achieving viral suppression 12 months postpartum (aOR=0.36, 95%CI 0.22-0.60). In longitudinal models, lagged IPV exposure was associated with higher viral loads after controlling for fixed effects, past viral control, and duration on ART. Model fit was improved by adding depressive symptoms and alcohol use, as these partially mediate the effect of IPV on viral suppression. In the final model, each standardized increase in IPV was associated with higher viral loads (coef=0.09, 95%CI 0.02-0.17). The effect of IPV was greater in magnitude than depressive symptoms (coef=0.05, 95%CI -0.03-0.12) or alcohol (coef=0.05, 95%CI -0.01-0.11). Model fit was acceptable (RMSEA=0.058, CFI=0.930).

Discussion: These findings from a perinatal South African cohort suggest exposure to IPV leads to higher viral loads postpartum. Compared with other comorbidities commonly addressed in the health setting (depression, alcohol use), IPV demonstrates a robust association with later viremia. Perinatal programs to address IPV may have positive outcomes for HIV-related health, and will be crucial for ensuring wellbeing of mothers and infants.

DISCONTINUING CANNABIS USE DURING PREGNANCY: AN EXPLORATORY STUDY OF WOMEN'S MOTIVATIONS AND EXPERIENCES

Cynthia L. Battle, Ph.D.¹, Samantha Ernst, BS², Jane Metrik, Ph.D.³, Ana M. Abrantes, PhD⁴¹Alpert Medical School of Brown University, Providence, RI; ²Butler Hospital, Providence, RI; ³Brown School of Public Health, Providence, RI; ⁴Brown University / Butler Hospital, Providence, RI

Background: A growing proportion of US women smoke marijuana during pregnancy, with epidemiologic data suggesting rates of use increasing 62% between 2002 and 2014. Recent changes in legalization may lead to greater access to cannabis, as well as a perception of lower prenatal risk. Although rising rates of prenatal use have been documented, little is known regarding why women use cannabis during pregnancy, as well as what motivates them to quit, and what the process of prenatal discontinuation is like. Documenting the experience of pregnant women who are attempting to discontinue cannabis use will be a useful first step in the development of new interventions and services.

Methods: In this exploratory study pregnant women were screened for cannabis use prior to and during pregnancy, and asked about reasons for using or discontinuing cannabis during the current pregnancy. Participants who reported discontinuation of cannabis during pregnancy were invited to take part in an interview regarding motivations for discontinuation, their process of quitting including barriers and facilitators, and emotional and physical symptoms. Participants included pregnant women seeking enrollment in two randomized clinical trials testing prenatal wellness interventions.

Results: To date, 1031 pregnant women were screened for cannabis use, and 230 of these women reporting used cannabis in the 6 months immediately before the pregnancy. We conducted a structured interview with 14 women who reported prenatal cannabis discontinuation and found that concerns about fetal exposure were highly salient. Many women voiced concerns about lack of support in the process of quitting, as well as difficulties accessing accurate information about the impact of prenatal cannabis use. Prenatal physical symptoms added challenges for some women during the process of quitting. Other specific barriers and facilitators to discontinuation were identified.

Conclusion: These findings provide an initial picture regarding motivations for discontinuing use of cannabis prenatally, and what the process is like for women who are trying to quit during the perinatal period. Many women reported insufficient supports in their process of quitting. Further research is needed to more fully elucidate motives for discontinuation and intervention approaches to support women who are interested in quitting during and after pregnancy.

Symposium 1 8:00 AM-9:15 AM

PRESIDENTIAL SYMPOSIUM: FROM IDEAS TO INTERVENTIONS: A REVIEW OF FRAMEWORKS FOR DESIGNING AND OPTIMIZING HEALTH-RELATED BEHAVIORAL INTERVENTIONS

Susan M. Czajkowski, Ph.D.¹, Kate Guastaferro, PhD, MPH², Tianchen Qian, PhD, Bonnie Spring, PhD³

¹Division of Cancer Control and Population Sciences, National Cancer Institute, NIH, Bethesda, MD; ²Pennsylvania State University, University Park, PA; ³Northwestern University Feinberg School of Medicine, CHICAGO, IL

Behavioral risk factors (e.g., tobacco use, adverse diet, sedentary lifestyles, overweight and obesity) are major contributors to chronic diseases such as cancer, cardiovascular disease, and diabetes. Designing more effective interventions for these risk factors is critical to accelerating the impact of behavioral medicine on disease incidence, progression and recovery. While there exist a number of frameworks and process models aimed at promoting the careful, systematic design and optimization of behavioral interventions, little guidance is available to compare key aspects of these models, understand their common and unique features, and aid in selecting the best approach for a specific research question. In this symposium, several approaches to designing and optimizing interventions for behavioral risk factors will be reviewed to promote greater knowledge of each individual framework, advance our understanding of commonalities and synergies between the frameworks, and allow for an informed choice on the part of investigators interested in developing and testing health-related behavioral interventions. The panel will include three speakers. The first speaker will discuss the Science of Behavior Change (SOBC) experimental medicine approach and the Obesity-Related Behavioral Intervention Trials (ORBIT) model for developing treatments for chronic diseases. The second speaker will then describe the Multiphase Optimization Strategy (MOST), and the third speaker will discuss an experimental design for informing the design of just-in-time adaptive interventions: Micro-Randomized Trials (MRTs). Finally, the discussant will identify commonalities and synergies among these frameworks as well as key differences that can help researchers choose which approach most benefits their research goals.

DEVELOPING BETTER BEHAVIORAL INTERVENTIONS USING THE SOBC EXPERIMENTAL MEDICINE APPROACH AND ORBIT MODEL

Susan M. Czajkowski, Ph.D.¹

¹Division of Cancer Control and Population Sciences, National Cancer Institute, NIH, Bethesda, MD

The ability to translate basic behavioral and social science discoveries into effective health-related behavioral interventions is essential for accelerating our science and increasing the impact of behavioral medicine research. As with the translation of biomedical discoveries into efficacious preventive and therapeutic interventions, identifying and assessing the mechanisms or “drivers” of behavior and using a well-defined framework to guide the process of designing and testing interventions can encourage the development of well-characterized, precisely targeted & optimized behavioral treatments, improving the likelihood they will have more robust and sustainable effects on the ultimate health outcomes of interest. In this talk, two approaches or frameworks used for developing health-related behavioral interventions – the Science of Behavior Change (SOBC) experimental medicine approach and the Obesity-Related Behavioral Intervention Trials (ORBIT) model – will be described. The key features of each of these frameworks will be discussed, with commonalities as well as differences emphasized to enable the audience to understand how and when each approach is best used, and how the approaches can be combined within a program of research designed to produce effective and sustainable health-related behavioral interventions.

2 8:00 AM-9:15 AM

A BRIEF OVERVIEW OF THE MULTIPHASE OPTIMIZATION STRATEGY: OPPORTUNITIES FOR INTERVENTION SCIENCE

Kate Guastaferro, PhD, MPH¹

¹Pennsylvania State University, University Park, PA

Traditionally the evaluation of a behavioral intervention utilizes a two-arm randomized controlled trial. While the RCT is able to demonstrate effectiveness, the design leaves important questions regarding efficacy, economy, and scalability unanswered and thereby potentially hindering the public health impact of an intervention.

This presentation will provide a brief overview of an innovative methodological framework for optimizing behavioral interventions, the multiphase optimization strategy (MOST). Inspired by principles of engineering, interventions developed using MOST are designed to produce the best expected outcome obtainable given key constraints, a process called optimization. MOST can be used to develop, refine, or adapt interventions to make them more efficient, effective, economical, and/or scalable. The presentation will give a brief overview of the three phases of MOST (preparation, optimization, and evaluation); highlight diverse applied examples to demonstrate the utility of MOST across a number of public health priorities; and describe potential to improve the impact on public health.

3 8:00 AM-9:15 AM

OPTIMIZING BEHAVIORAL MOBILE HEALTH INTERVENTIONS: THE ROLE OF MICRO-RANDOMIZED TRIALS

Susan Murphy, Ph.D.¹

¹Harvard University, Cambridge, MA

Mobile devices along with wearable sensors facilitate our ability to deliver supportive behavioral interventions to individuals anytime and anywhere. These interventions are being developed and employed across a variety of health fields, including to improve medication adherence, encourage physical activity and healthier eating as well as to support recovery in addictions. Most mobile health interventions involve notifications such as reminders or suggestions or supportive messages, delivered as an individual goes about their everyday life. Yet repeated notifications can lead to disengagement. To reduce disengagement, it is critical to only deliver notifications when they are most likely to be effective. Thus critical questions in the optimization of these mobile health intervention components include not only, “Are the notifications useful?” but also “Does the individual’s current context such as location, time, mood impact the usefulness of the mobile health notification?” These questions concern the optimization of the mobile health intervention. In this talk we discuss the micro-randomized trial design for use in optimizing mobile health interventions. We illustrate the ideas with the micro-randomized trials across a variety of fields.

Symposium 2

8:00 AM-9:15 AM

UNDERSTANDING, PLANNING, AND EVALUATING IMPLEMENTATION STRATEGIES FOR SCHOOL-BASED PHYSICAL ACTIVITY APPROACHES

Jacob Szeszulski, PhD¹, Paul Estabrooks, PhD², Maria E. Fernandez, PhD³, Rebecca E. Lee, PhD⁴, Timothy Walker, PhD¹¹University of Texas Health Science Center at Houston, Houston, TX; ²University of Nebraska Medical Center, Omaha, NE; ³University of Texas Health Science Center, Houston, TX; ⁴Arizona State University, Phoenix, AZ

Introduction: Children spend a large portion of their days in school, which provide physical activity opportunities that lead to positive health benefits. Despite their positive impact, school staff often face barriers when implementing physical activity approaches in schools (e.g., competing academic priorities, implementation by multiple stakeholders, stringent resource constraints), which can decrease their effectiveness. Therefore, there is an important need to understand the current implementation strategies being used in schools and ways to develop and evaluate them. In this symposium, we provide examples of how implementation science methods can be used for understanding, planning, and evaluating implementation strategies, within the context of school-based physical activity approaches.

Studies: The first study will discuss how a qualitative approach was used in a Houston, Texas school district to identify implementation strategies that schools already use to administer physical activity programs. The second study will describe how the Implementation Mapping process can aid in the identification or development of implementation strategies, based on theory, evidence, and new data. The third study will describe the process for evaluating implementation strategies used in the delivery of an early care and education center-based physical activity program, which is currently underway in Phoenix, Arizona. Taken together these three studies will serve as diverse examples of comprehensive and important processes for understanding, planning and evaluating implementation strategies in school-based physical activity research.

Discussion: Discussion from this symposium will focus on how different strategies can be applied across the research continuum (i.e., development, planning, and assessment), and how different research questions may warrant the use of different methodological approaches. In addition, this symposium discusses implementation strategies commonly used in the delivery of school-based physical activity research, and discusses how researchers and practitioners can use various implementation strategies to improve the effectiveness of approaches. Finally, this symposium will highlight multiple implementation science processes and provide context for choosing and applying these processes based on the specific implementation challenge. Overall, this symposium will provide researchers and practitioners some insight in how to use of implementation strategies and provide guidance on how implementation science is critical for improving the delivery process of school-based physical activity approaches.

8:00 AM-9:15 AM

IMPLEMENTATION MAPPING: A PROCESS FOR IMPROVING THE DELIVERY OF SCHOOL-BASED PHYSICAL ACTIVITY PROGRAMS

Maria E. Fernandez, PhD¹, Jacob Szeszulski, PhD², Timothy Walker, PhD², Gil ten Hoor, PhD³, Christine M. Markham, PhD⁴¹University of Texas Health Science Center, Houston, TX; ²University of Texas Health Science Center at Houston, Houston, TX; ³Maastricht University; ⁴University of Texas Health Science Center at Houston

Background: Inefficient implementation processes can weaken the impact of school-based physical activity programs, leading to poor reach, effectiveness, and maintenance. Implementation Mapping, a systematic, theory-driven process for planning implementation strategies can improve the delivery of physical activity approaches. Implementation Mapping is a part of the broader Intervention Mapping protocol for planning, implementing and evaluating health promotion programs that is used worldwide (>1000 publications). This abstract provides an example of how users applied Implementation Mapping for the “Focus on Strength” program that used strength exercises to help overweight children build self-efficacy.

Methods: Implementation Mapping uses the Intervention Mapping protocol and theory/frameworks from the field of implementation science to inform strategy selection and/or development. In step one, users conducted an implementation needs assessment to identify “Focus on Strength” program adopters (e.g., principals) and implementers (e.g. teachers). In step two, users created implementation outcomes (e.g., physical education teachers include strength exercises 3x per week for 15 minutes per class) and performance objectives (implementation sub-behaviors) to reach those implementation outcomes (e.g., teachers reflect on implementation of strength exercises). In addition, users identified determinants of implementation behavior, which were found in the literature, theoretical models, or school specific (e.g., lack of time). Finally, in step two, users crossed determinants with performance objectives to create matrices of change objectives that articulated what needed to change in a determinant of implementation behavior to enable the implementation action (e.g., teachers schedule time weekly to implement the program). In step three, users chose theoretical methods (e.g., participatory problem solving), that guided the selection or design of strategies (e.g., workshops). In step four, users produced implementation protocols and products (e.g., training manual) to improve the delivery process and contextual factors influencing implementation. Finally, in step five, users evaluated the program’s success in reaching implementation goals (e.g., implementation of strength exercises), performance and change objectives, and influencing determinants.

Discussion: Implementation is important to the delivery of school-based health promotion programs, yet implementation strategies are rarely applied systematically. Implementation Mapping, an evidenced-based, theory driven approach to develop/select implementation strategies, protocols and materials can accelerate and improve the delivery of school based physical activity interventions and allow users to tailor program delivery to the specific needs of their school’s setting.

8:00 AM-9:15 AM

SUSTAINABILITY VIA ACTIVE GARDEN EDUCATION (SAGE): IMPLEMENTATION STRATEGIES IN EARLY CARE AND EDUCATION CENTERS

Rebecca E. Lee, PhD¹, Jacob Szeszulski, PhD², Elizabeth Lorenzo, BSN¹, Jennie Hill, PhD³, Teresia O'Connor, MD⁴, Meg Bruening, PhD¹, Gabriel Shaibi, PhD⁵, Michael Todd, PhD¹, Paul Estabrooks, PhD³

¹Arizona State University, Phoenix, AZ; ²University of Texas Health Science Center at Houston, Houston, TX; ³University of Nebraska Medical Center, Omaha, NE; ⁴Baylor College of Medicine, Houston, TX; ⁵Center for Health Promotion and Disease Prevention, Phoenix, AZ

Introduction: Strategies that enhance adoption, implementation, and/or sustainability of school-based programs to improve health are critical. Sustainability via Active Garden Education (SAGE) is a garden-based program to improve preschool-aged children's physical activity and nutrition in early care and education centers (ECEC). SAGE uses multiple implementation strategies including teacher trainings, training others for leadership roles, creating program champions, and building community coalitions to improve delivery and sustainability processes. Here we describe the evaluation of SAGE's implementation strategies and preliminary results.

Methods: SAGE uses a "see one, do one, teach one," approach to implement semi-weekly 1-hour SAGE sessions in ECEC ($N=15$), develop ECEC staff for leadership roles, and identify program champions via a 1 initial teacher training, 11 train-the-trainer sessions (6 weeks), 1 booster training, and 12 ad hoc support sessions (6 weeks). Teachers completed surveys at pre-training, after the booster and post-training to assess implementation self-efficacy (5 items) and behaviors (20 items). ECEC directors completed a sustainability needs assessment (SNA) near the end of training. A SAGE community advisory board (CAB) completed the Wilder Collaboration Inventory.

Preliminary Results: Teachers had high levels of self-efficacy at pre-training, which peaked at the booster training and returned to baseline at post-training. Self-efficacy was higher for garden maintenance and taste testing activities, and lower for other curriculum elements (games, songs, discussions) and parent engagement. Teachers reported that booster training improved their abilities to manage the room during SAGE programming and to model appropriate behaviors for their class. SNA results showed that SAGE scored moderately (3.8 of 5) on training others for leadership roles and creating program champions. The CAB reported having strong purpose (4.4 of 5), but felt there were fewer resources (3.6 of 5) available to complete that Purpose.

Discussion: Implementation self-efficacy was sensitive to hands-on implementation experience. Engaging implementers in immersive and multi-sensory tasks (e.g., garden, taste tests) may enhance determinants of program delivery (i.e., self-efficacy). Programs like SAGE that enhance leadership roles and foster program champions could increase the potential for sustainable improvements in ECEC health programming in under-resourced areas.

8:00 AM-9:15 AM

IMPLEMENTATION STRATEGIES USED TO SUPPORT PHYSICAL ACTIVITY APPROACHES IN ELEMENTARY SCHOOLS: A QUALITATIVE STUDY

Timothy Walker, PhD¹, Jacob Szeszulski, PhD¹, Michael Robertson, Doctoral Student², Paula Cuccaro, PhD³, Maria E. Fernandez, PhD⁴

¹University of Texas Health Science Center at Houston, Houston, TX; ²MD Anderson Cancer Center; ³University of Texas Health Science Center at Houston; ⁴University of Texas Health Science Center, Houston, TX

Background: Various school-based approaches can improve children's physical activity before, during, and after school. However, the implementation of these approaches remains a challenge. Few studies have used qualitative methods to examine implementation strategies to support the delivery of physical activity approaches in schools. The purpose of this study is to gain a better understanding of these implementation strategies from stakeholders' perspectives.

Methods: We conducted individual interviews with elementary school staff from a mid-sized school district in Texas. Interviews lasted approximately 60 minutes and were audio recorded and transcribed for analyses. We used directed content analysis and an iterative categorization approach to systematically code and analyze the qualitative data. We identified emerging themes related to implementation strategies.

Results: We interviewed a total of 15 participants (4 classroom teachers, 4 physical education teachers, 3 assistant principals, and 4 principals). Participants discussed numerous implementation strategies supporting adoption, implementation, and maintenance of school-based physical activity approaches (e.g. before and after-school programs, classroom-based activity approaches, structured recess programs). Schools were commonly using a combination of discrete implementation strategies to support the delivery of physical activity approaches. Two of the most prominent strategies were training and program champions. Schools supported offsite and onsite training opportunities to help educate and motivate staff about specific physical activity approaches. Onsite trainings were held at the start of, and sometimes throughout, implementation. Participants frequently emphasized the important role that program champions play and the advantages of having a group of passionate individuals to drive the use of school-based physical activity approaches. Program champions often had many different responsibilities, including obtaining materials, helping train and motivate staff, checking/replacing equipment, and monitoring progress. Other commonly cited strategies included strategic scheduling, small-scale testing, and monitoring.

Discussion: Recent research efforts have set out to gain a better understanding of school-based implementation strategies. Findings from this study complement these efforts by contributing to a better understanding of implementation strategies specific to school-based physical activity approaches and including stakeholders' perspectives. In addition, results highlight potential mechanisms through which commonly used strategies operate to improve implementation. This information can be used to optimize future efforts centered on developing and testing implementation strategies for physical activity promotion in schools.

Symposium 3

8:00 AM-9:15 AM

NOVEL SLEEP AND CIRCADIAN HEALTH INTERVENTIONS FOR CANCER PATIENTS/SURVIVORS: WHERE DO WE GO FROM HERE?

Eric S. Zhou, PhD¹, William H. Redd, PhD², Rina S. Fox, PhD, MPH³, Qian Lu, MD, PhD⁴, Brian D. Gonzalez, PhD⁵¹Harvard Medical School, Boston, MA; ²Icahn School of Medicine, New York, NY; ³Northwestern University Feinberg School of Medicine, Chicago, IL; ⁴MD Anderson Cancer Center, Houston, TX; ⁵Moffitt Cancer Center, Tampa, FL

Background: Sleep and circadian health are becoming increasingly recognized as critical elements impacting a cancer patient's/survivor's disease-specific and overall health and well-being. Despite the prevalence of sleep/circadian disruptions in this population, there are few interventions tailored to their unique medical and psychosocial needs. Finding ways in which we can effectively manage the burden of disrupted sleep/circadian function using intervention strategies adapted to their needs is essential to patient engagement and integration into routine clinical care.

Method: This symposium presents the work of four investigators who developed novel sleep/circadian health interventions for cancer patients/survivors and evaluated their efficacy. The interventions are characterized by important elements that improve the likelihood of future integration into oncology care: (1) use of portable consumer technology; (2) fully automated web-based delivery; and (3) a culturally sensitive program.

Results: As described in the individual abstracts, the novel interventions were delivered in a range of cancer patient/survivor populations (e.g., adolescents/young adults, ovarian/endometrial survivors, an ethnic minority group). They evaluated light exposure therapy for disrupted circadian rhythms, a tailored online intervention for insomnia, and an expressive writing intervention. Each of these programs helped to ameliorate a range of symptoms including sleep disruption, psychological distress, and impaired quality-of-life.

Conclusions: These novel interventions are suited to meeting the sleep/circadian health needs of cancer patients/survivors as they were all tailored to some aspect of their distinctive cancer experience. All of the programs were designed in a way to reduce the demand on healthcare systems, requiring fewer financial and/or staff resources, which can help to increase the likelihood of adoption in clinical practice. Future research should determine how such programming can be disseminated in more cancer centers across the country.

AN ONLINE INSOMNIA INTERVENTION TAILORED FOR ADOLESCENT AND YOUNG ADULT CANCER SURVIVORS IMPROVES SLEEP AND QUALITY OF LIFE

Eric S. Zhou, PhD¹, Elizabeth Fine, BS², Christopher Recklitis, Ph.D, MPH³¹Harvard Medical School, Boston, MA; ²Dana-Farber Cancer Institute; ³Dana-Farber Cancer Institute, Boston, MA

Background: Cognitive-behavioral therapy for insomnia (CBT-I) is highly effective and considered the gold standard treatment. Unfortunately, cancer survivors are unlikely to receive CBT-I, even in centers delivering specialized cancer survivorship care due to a lack of qualified providers. One way in which this major treatment barrier has been addressed has been through the use of online insomnia programs, including SHUTi (Sleep Healthy Using the Internet). However, SHUTi was designed for healthy adults, with limited content relevant to the specific developmental, psychosocial, and medical challenges experienced by adolescent and young adult (AYA) cancer survivors.

Methods: 17 AYA survivors (mean age=19.8 years; range=14-25 years) with insomnia enrolled in a 6-module, automated CBT-I program that was tailored to their unique sleep-impairing issues (e.g., delayed sleep phase, cancer-related fatigue). They were blood cancer (52.9%) and solid tumor (47.1%) survivors an average of 9.3 years post-diagnosis. Participants completed assessments at Baseline, and at 8- and 16-weeks post-intervention. We assessed insomnia severity (Insomnia Severity Index; ISI) and quality of life (PedsQL Physical Health and Psychosocial Health summary scores).

Results: Thirteen participants (76%) completed their 8-week follow-up and 11 (65%) completed 16-week follow-up. Significant, and positive, pre/post-intervention changes were reported at both follow-up timepoints in insomnia severity (Baseline=15.0; 8-week=11.1; 16-week=6.8), Physical Health (Baseline=67.8; 8-week=71.9; 16-week=75.6), and Psychosocial Health (Baseline=61.2; 8-week=66.8; 16-week=68.0). The majority (82%) of participants did not complete all 6 CBT-I modules, with a mean completion rate of 3.2 modules.

Conclusions: A novel online insomnia intervention is efficacious at treating AYA cancer survivors' insomnia and has the secondary benefit of improving quality of life. This has important implications for access to evidence-based clinical care for this growing population. However, it is worth noting that despite the significant improvements experienced by participants, most AYA cancer survivors failed to complete the entire program. Further research must explore ways to better engage the AYA population in insomnia treatments.

2

8:00 AM-9:15 AM

LIGHTING INTERVENTION FOR CANCER-RELATED SLEEP PROBLEMS

William H. Redd, PhD¹, Lisa Wu, PhD², Mariana Figueiro, Ph.D.³, Heiddis Valdimarsdottir, Ph.D.¹

¹Icahn School of Medicine, New York, NY; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³Rensselaer Polytechnic Institute, Troy, NY

Background: Cancer-related fatigue, depression, and sleep disturbance typically develop early in the disease course and treatment. 23 to 44% of survivors suffer from these sequelae up to 5 years post-treatment. The hypothesized mechanism is disruption of the Circadian Rhythm (CR) (i.e., disruption in 24-hour cycles of hormone secretion, body temperature, and sleep-wake activity cycles which respond to environmental cues, such as light and darkness). CR disruption is evidenced by impaired sleep-wake phases, flat diurnal cortisol rhythms, and lower evening melatonin. Such CR disruption has even been shown to affect survival. Our research investigates how light can be used to promote circadian entrainment (i.e., synchronization) to alleviate suffering. In the absence of external cues, the circadian system runs with a period length slightly greater than 24 hours. Morning light, especially daylight, is the most effective synchronizer of the circadian system to local time. The circadian system is maximally sensitive to short-wavelength blue light (i.e., circadian-effective light, CEL).

Methods: We deliver CEL to cancer patients in the morning for a minimum of 30 minutes in order to entrain their circadian system and alleviate aforementioned cancer-related sequelae. We have used two light delivery procedures: systematic light exposure (sLE) in which CEL is projected directly to the eyes from small portable light glasses. The other is programmed environmental illumination (PEI), which provides indirect, circadian-effective illumination of the entire hospital room. Both procedures are comparable in CR synchronization, but differ in ease of delivery and cost. PEI places no demands on the patient as the light is received passively; whereas sLE – the less expensive and portable light source – requires patient involvement (i.e., patients must wear the glasses).

Results: Repeated-measures linear mixed models indicated a statistically significant time × treatment group interaction effect with sleep efficiency improving more with CEL over time compared with circadian ineffective light ($F_{3,42} = 5.55$; $P = .003$) with a large effect size (partial $\eta^2 = 0.28$). By the end of the intervention and 3 weeks post-intervention, medium to large effects were seen for sleep efficiency with CEL. Medium to large effect sizes were also seen in sleep quality, total sleep time, and wake after sleep onset for participants with CEL. Indeed, data analysis revealed significant improvements in sleep efficiency for patients receiving CEL with their sleep efficiency being within the clinically normal range at the end of intervention and at follow-up.

Conclusions: Light delivery interventions with cancer patients are noninvasive and cost-effective. These interventions also yield positive improvements in cancer-related fatigue and depression.

3

8:00 AM-9:15 AM

FEASIBILITY AND PRELIMINARY EFFICACY OF SYSTEMATIC BRIGHT LIGHT EXPOSURE AMONG GYNECOLOGIC CANCER SURVIVORS

Rina S. Fox, PhD, MPH¹, Heather McGinty, PhD², Sofia Garcia, PhD³, Kathryn Reid, PhD⁴, Katrin Bovbjerg, BA⁵, Precilla Fajardo, BA⁵, Lisa Wu, PhD¹, Shohreh Shahabi, MD⁵, Jason Ong, PhD⁵, Phyllis Zee, MD, PhD⁴, Frank Penedo, PhD⁶

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²OSU Comprehensive Cancer Center, OH; ³Northwestern University, Chicago, IL; ⁴Northwestern University Feinberg School of Medicine, Chicago, IL, Canada; ⁵Northwestern University Feinberg School of Medicine; ⁶Sylvester Comprehensive Cancer Center, Miami, FL

Background: Cancer-related sleep disturbance is highly prevalent and adversely impacts physical and emotional well-being. Emerging evidence shows that bright light exposure can improve sleep disturbance by enhancing circadian regulation. This pilot study assessed the feasibility and preliminary efficacy of systematic bright light exposure on sleep among women with a history of gynecologic cancer.

Methods: Women aged 18-75 with a history of non-metastatic ovarian or endometrial cancer who completed primary chemotherapy and endorsed current sleep disturbance (Pittsburgh Sleep Quality Index (PSQI) global score ≥ 5) were randomized 1:1 to receive 45 minutes of bright white light (BWL; $n = 9$) or dim red light (DRL; $n = 9$) every morning for 4 weeks via Re-Timer® glasses. Participants wore wrist actigraphs and completed sleep diaries for one week before the intervention, during the intervention, and for one week before a 3-month follow-up appointment. Participants also completed assessments of subjective sleep quality at baseline (T1), post-intervention (T2), and 3-month follow-up (T3).

Results: Of the 211 women with whom in-person or telephone contact was made, 62 (29.4%) completed telephone screening, of whom 35 (56.5%) were deemed eligible and 25 (17.7%) agreed to complete an in-person screening. Of those who completed in-person screening, 22 (88%) were deemed fully eligible and enrolled. One participant withdrew after consent but before randomization, leaving a randomized sample of 21. The retention rate at 3-month follow-up was 85.7%, and protocol adherence was >85%. Mixed model ANOVAs demonstrated that the number of nighttime awakenings, per actigraphy, increased over time for the DRL condition, while it decreased from T1 to T2 before returning to baseline at T3 for the BWL condition ($F_{2,30} = 2.70$, $p = 0.08$, $\eta_p^2 = .025$). Additionally, women in the BWL group reported significant improvements over time on the PSQI global score ($F_{2,16} = 2.90$, $p = 0.08$, $\eta_p^2 = 0.27$) compared to participants in the DRL group. The percentage of DRL participants with healthy sleep (i.e., PSQI score < 5) was 0% at T1, 11.1% at T2, and 0% at T3. For BWL participants these percentages were 11.1% at T1, 44.4% at T2, and 11.1% at T3. These percentages were statistically significantly different at T2 ($\chi^2(1) = 3.88$, $p = 0.05$).

Conclusions: Results suggest that BWL can be feasibly implemented among women with a history of ovarian or endometrial cancer, and may be an effective strategy to diminish sleep disturbance in this population.

4

8:00 AM-9:15 AM

OPTIMIZING EXPRESSIVE WRITING INTERVENTION TO IMPROVE SLEEP QUALITY AMONG CHINESE BREAST CANCER SURVIVORS

Qian Lu, MD, PhD¹, Ivan Wu, Ph. D.¹¹MD Anderson Cancer Center, Houston, TX

Background: Sleep problems are common among Chinese American breast cancer survivors, however, few studies have tested interventions to improve sleep quality among this population.

Purpose: The study evaluated whether a culturally sensitive expressive writing intervention improved sleep quality.

Methods: Chinese-speaking breast cancer survivors ($N=136$) in the U.S. were randomly assigned to one of three conditions to write three 30-minute weekly essays: a cancer-fact condition to write about facts relevant to the cancer experience for three weeks; a self-regulation condition to write about deepest feelings at week 1, stress and coping at week 2, and finding benefits at week 3; or an enhanced self-regulation condition to write about stress and coping at week 1, deepest feelings at week 2, and finding benefits at week 3. Sleep quality was assessed using one item from the Pittsburgh Sleep Quality Index (PSQI) at baseline, 1-, 3-, and 6-month follow-up.

Results: A linear mixed effect model regressed sleep quality on condition, time (i.e., study week), and a condition by time interaction with relevant covariates. Adjusted results showed no main effects of condition, yet a significant condition by time interaction ($b = -.11$, $SE = .05$, $p = .034$). Specifically, sleep quality improved significantly more in the enhanced self-regulation condition compared to the control.

Conclusion: This pilot study shows that expressive writing has the potential to improve sleep quality for Chinese American cancer survivors. Future efforts are warranted to replicate the study in a larger trial, disseminate, and implement this low-dose and brief intervention in community and clinical settings.

Symposium 4

8:00 AM-9:15 AM

PRIMARY CARE PATIENTS' PERSPECTIVE IN THE MODERN ERA: DIGITAL TECHNOLOGY, POLICY CHANGES, AND SHIFTING PERSPECTIVES.

Dara Steinberg, Ph.D.¹, Nathalie Moise, n/a¹, Andrea T. Duran, PhD², Molly L. Tanenbaum, PhD³, Nataliya Pilipenko, Ph.D./ABPP⁴

¹Columbia University Medical Center, New York, NY; ²Columbia University Irving Medical Center, New York, NY; ³Stanford University School of Medicine, Palo Alto, CA; ⁴Columbia University, College of Physicians and Surgeons, New York, NY

Patient centered care has become the cornerstone of modern medicine, prompting primary care settings to foster opportunities for engaging patients in their health care. While approaches like shared-decision making (Stacey et al., 2017) and motivational interviewing (Miller & Rollnick, 2002) have been shown to be beneficial, these approaches remain underutilized in primary care. Leveraging technology has been proposed to foster shared decision making in physical and mental health care but also faces challenges. For instance, the Internet provides increased access to information for patients yet the quality of the information available has been found to be variable in various medical subject areas (e.g., Fuzzell et al., 2019; Hargrave et al., 2006; Wiley et al., 2017).

This symposium will focus on the interplay between patient-centered care, decision-making, and technology in the domains that are particularly salient for the primary care setting. Presentations will include: beliefs about vaccinations and how that drives decisions regarding vaccination choices; beliefs about collaborative care and use of technology to more effectively engage patients in and integrate mental health care into the primary care setting and overcoming barriers and obstacles to adopting diabetes management devices. The diversity in topics will help present how underlying principles regarding understanding patients, their beliefs, and choices, as well as considering the role of technology can be applied across diverse clinical situations, populations, and settings.

PATIENT PERCEPTIONS OF A SELF-DELIVERED ELECTRONIC DEPRESSION SCREENING, ACTIVATION AND EDUCATION TOOL: ARE BRIEF, BEHAVIORAL INTERVENTIONS FEASIBLE IN WAITING ROOMS OF PRIMARY CARE SETTINGS?

Nathalie Moise, n/a¹, Andrea T. Duran, PhD²

¹Columbia University Medical Center, New York, NY; ²Columbia University Irving Medical Center, New York, NY

Introduction: Although collaborative care (CC) for depression is among the most well studied, effective programs for treating depression in the primary care setting, suboptimal patient-provider communication at the critical time of referral may contribute to high initial no show rates limiting program effectiveness in real world settings. Primary care settings are increasingly incorporating digital health technology into clinical workflows (screening with tablets), but few interventions have sought to use technology to deliver brief, behavioral interventions in the waiting room. We sought to assess acceptability and perceptions of an electronic web-based tablet-delivered tool that delivers depression screening, patient activation, psychoeducation and direct referral to CC.

Methodology: The candidate interface (depression screening, video-assisted patient activation, treatment preference assessment, psychoeducation) was designed and revised based on semi-structured interviews with 10 national experts, 12 patients, and 32 providers as well as a depression treatment initiation systematic review. We recruited 29 (planned 60 patients) end-users from an academic primary care clinic and observed, recorded and guided participants through a usability protocol where they completed goal-oriented tasks and pre/post-questionnaires to assess acceptability, usability (System Usability Scale [SUS]) and overall satisfaction with the tool. We employed descriptive statistics for quantitative responses and content analyses to code qualitative responses for themes.

Results: The average age of 29 participants was 61.8±11.8 years; 72.4% were female, 44.8% Hispanic/Latino and primarily Spanish speakers, 31.0% Black/African American. We found that at least 55.2% had at least mildly elevated depressive symptoms. For the final version of the tool, 86.6% would be comfortable using the tool in the waiting room; 77% were likely to talk to their PCP about depression after using the tool; 61% felt questions about pros and cons were addressed; 83% felt helpful in deciding which medication to choose but 72% still felt that they wanted to discuss with their PCP before making a final decision about depression care.

Discussion: We demonstrate high acceptability and interest in using self-administered, enhanced screening and activation technology in waiting rooms. Our preliminary results suggest that meeting patients “where they are” may be one approach to enhancing use of digital behavioral health technology as well as engagement in depression treatment in collaborative care settings, particularly among patients with low literacy or sub optimal access/adherence to digital health interventions at home.

GETTING ONBOARD (OVERCOMING BARRIERS & OBSTACLES TO ADOPTING DIABETES DEVICES): A PILOT STUDY TO SUPPORT USE OF CONTINUOUS GLUCOSE MONITORING (CGM)

Molly L. Tanenbaum, PhD¹, Christine Wu, BA², Sarah Hanes, BA¹, Korey Hood, PhD¹

¹Stanford University School of Medicine, Palo Alto, CA; ²PGSP-Stanford PsyD Consortium

Type 1 diabetes (T1D) is a burdensome disease with demanding self-management tasks to optimize glycemic control and prevent short- and long-term complications. Advances in diabetes devices such as CGM have enabled improved glycemic control, reduced risk of complications, and improved quality of life. However, a minority of adults (18-50) with T1D currently use CGM and a sizeable proportion quit CGM within the first year due to several known barriers including cost; being bothered by alerts and alarms from the device; and other factors. The American Diabetes Association's 2019 Standards of Care state that CGM use “requires robust and ongoing diabetes education, training and support”; there is a great need for new research to determine what programs would best provide this support. Our goal is to provide the necessary education and support so that adults with T1D can adopt CGM and obtain optimal benefit from this technology. To that end, we are piloting and iteratively refining a behavioral intervention package, ONBOARD, in a small sample of adults with T1D (20 in their first year of CGM use and 20 not currently using CGM). The intervention is delivered during four 60-minute videoconference sessions over the course of 12 weeks. Intervention content includes a social learning component (first-person narratives from adults with T1D who use CGM) and reinforces problem-solving skills related to CGM use. We will obtain participant feedback on intervention content from focus groups and use this feedback to refine the intervention. This presentation will focus on describing the aims, design and methods of this pilot study and will present preliminary data. We will also discuss next steps for this research, including plans for a larger randomized controlled trial of ONBOARD. Finally, we will discuss implications for adapting these efforts for future diabetes technologies (e.g. closed loop systems in which an insulin pump and CGM use an algorithm to determine insulin dosing and have potential to reduce self-management burden) and relevance of a diabetes device adoption intervention such as this in other clinical settings (e.g. type 2 diabetes; primary care).

8:00 AM-9:15 AM

PATIENT VACCINATION PERCEPTIONS: IMPROVING UNDERSTANDING OF EARLY LIFE VACCINATION PRACTICES AND CAREGIVER PERCEPTIONS. DOES VACCINATION TYPE PLAY A ROLE?

Nataliya Pilipenko, Ph.D./ABPP¹¹Columbia University, College of Physicians and Surgeons, New York, NY

Introduction: Although pediatric vaccinations are regarded among the most successful public health achievements, immunization rates are subject to imperfect uptake (WHO, 2017). Moreover, Latino children in the US are under immunized despite ongoing research and programmatic interventions (Adorador et al., 2011). Caregivers are among the 'key players' in pediatric health, but to date, study of pediatric vaccination perceptions received limited research attention within Family Medicine (FM) settings in primary care. This project aims to improve understanding of caregivers' decision-making process related to routine age-based pediatric vaccinations, as compared to annual seasonal influenza vaccinations. This research is especially important given recent rise in anti-vaccination movement (Azhar et al., 2018).

Methods: Survey incorporating modified Parent Attitudes about Childhood Vaccines (PACV) questionnaire (Opel et al., 2013) and items examining vaccination-related beliefs based on the Cognitive Model of Empowerment (Vallee-Tourangeau et al. 2017) was developed and culturally adopted for English and Spanish. Participant (N=100) adult caregivers of children 0-24 months old are recruited during clinic visits, asked to complete the survey and provide consent for child's vaccination records review.

Results: Data collection in currently underway (n = 42, 57.14% Spanish speakers). Data will be analyzed to understand connections between caregivers' beliefs and vaccination-related behaviors. Differences in behaviors and beliefs between routine and influenza vaccinations will also be examined. It is anticipated that the results of this study will allow improved understanding of caregiver factors implicated pediatric vaccination decisions.

Symposium 5

8:00 AM-9:15 AM

INTERDISCIPLINARY CHRONIC PAIN MANAGEMENT - BEST PRACTICES IN ASSESSMENT, TREATMENT, AND TRAINEE EDUCATION

Amy M. Goetzinger, PhD¹, Seema M. Patidar, PhD², Skye Ochsner Margolies, PhD³, Maryam Jowza, MD², Dominika James, MD¹UNC - Chapel Hill, Chapel Hill, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³UNC-Chapel Hill, Chapel Hill, NC

Comprehensive and successful chronic pain management hinges on an interdisciplinary care model that recognizes the complexities of chronic pain and the importance of treating individuals struggling with chronic pain in the context of the biopsychosocial model. The proposed symposium provides a snapshot into four different facets of an interdisciplinary approach currently practiced and taught at an academic medical center. It is our goal that this symposium will both educate and spark discussion with our behavioral medicine peers.

The first presentation, given by a pain psychologist, will review concurrence of substance abuse and mental health disorders in patients with chronic pain and the consequent barriers to treatment. Based on clinical experience, data, and lessons learned in both the inpatient and outpatient medical setting, her discussion will explore how assessment and treatment planning by pain psychologists can assist with these challenges and contribute to improved functioning, quality of life, pain control, psychological adjustment, and treatment adherence. She will expand this discussion to highlight how this approach can be best incorporated into an interdisciplinary model of care.

The second presentation, given by a pain psychologist, will outline the assessment and treatment of sleep disturbance in the context of chronic pain. The complex relationship between pain and sleep will be reviewed with an emphasis on pain catastrophizing and sleep-related cognitive arousal. Current cognitive behavioral and acceptance based interventions practiced in the outpatient setting will be discussed and illustrated with case reports.

The third presentation, given by a pain psychologist, will present on the important role that pain psychologists play in perioperative pain management. She will discuss Enhanced Recovery After Surgery (ERAS) pathways and a novel protocol implemented at an academic medical center for women undergoing benign laparoscopic gynecologic surgery, including psychoeducation and brief behavioral intervention via phone consultation with pain psychology. Data will be presented and discussed in the broader context of feasibility, other treatment models, and future considerations.

The last presentation is from a pain physician and will review an innovative, interdisciplinary simulation curriculum utilizing standardized patients to assist medical trainees specializing in pain management in navigating challenging patient encounters. Her presentation will outline the goal of the pilot program in improving medical trainee confidence and the model for inter-professional feedback utilizing pain psychology expertise. Data will also be presented examining trainee evaluations of the learning experience and expectations for future training.

ASSESSMENT AND TREATMENT OF CHRONIC PAIN, MENTAL HEALTH AND SUBSTANCE ABUSE COMORBIDITIES - BEST PRACTICES AND LESSONS LEARNED FROM OUTPATIENT AND INPATIENT ACADEMIC MEDICAL SETTINGS

Amy M. Goetzinger, PhD¹

¹UNC - Chapel Hill, Chapel Hill, NC

Mental health (MH) and substance abuse (SA) comorbidities are common among chronic pain patients and can significantly impact treatment adherence, as well as progress towards therapeutic goals and outcomes. Assessment and treatment planning by pain psychologists can assist with these challenges and contribute to improved functioning, quality of life, pain control, psychological adjustment, and treatment adherence. This discussion focuses on a review of best practices in the assessment and treatment planning for patients with chronic pain and MH/SA comorbidities in the outpatient and inpatient medical settings.

Clinically informative and appropriate screening and assessment psychometrics will be presented, both for outpatient and inpatient use, for brief screening as well as comprehensive psychological assessment. Common behavioral treatment recommendations will be reviewed, along with discussion of how to address patient barriers related to access and follow through with treatment recommendations. Data have been collected as part of clinical research from patients treated at an academic medical center.

Data pertaining to patients with chronic pain in the outpatient setting will be presented related to prevalence of psychological comorbidities (trauma history, depression and anxiety disorders, in particular), prevalence of Opioid Use Disorder (OUD) and other SA comorbidities, and adherence to treatment recommendations. Best practices related to appropriate follow up and treatment planning in the outpatient setting will be discussed, with particular focus on medically and psychologically complex, challenging cases.

Data pertaining to patients with chronic in the inpatient medical setting also will be presented, along with recommendations for best practices in addressing chronic pain and associated MH and SA comorbidities as part of an acute pain medical service. Care transition from inpatient to outpatient treatment will also be reviewed, along with strategies to address barriers to transitioning care.

In addition, data from a new initiative aimed at better understanding and improving multidisciplinary treatment for patients with comorbid chronic pain and OUD in the inpatient medical setting also will be presented. The latter program was developed systematically using "test cases" as part of a pilot feasibility study. Methodological considerations, barriers to treatment, screening and assessment refinement process, optimization of care coordination with other treatment providers, and transition to outpatient methadone maintenance or Suboxone treatment along with psychological therapy will be discussed.

OPPORTUNITIES FOR IMPROVING THE PERIOPERATIVE PAIN EXPERIENCE: UTILIZATION OF A BRIEF PSYCHOLOGICAL INTERVENTION AS PART OF INTERDISCIPLINARY ENHANCED RECOVERY AFTER SURGERY (ERAS) PATHWAYS

Seema M. Patidar, PhD¹

¹University of North Carolina at Chapel Hill, Chapel Hill, NC

Enhanced Recovery After Surgery (ERAS) pathways are interdisciplinary, patient-centered, evidence-based protocols intended to improve perioperative patient experiences and surgical outcomes. Surgeons, anesthesiologists and nursing staff are primarily involved in developing and implementing ERAS pathways, targeting both physical and psychological factors. In the context of more thoughtful perioperative opioid prescribing practices, there has been more attention to alternative strategies for improving the perioperative pain experience. One strategy for improving pain related outcomes is addressing patient expectations prior to surgery through psychoeducation regarding upcoming surgery, related pain, and pain management. Additionally, providers may consider more comprehensive risk assessment and inclusion of pain psychology interventions, which can target pain related distress and substance use behaviors.

Providers at our institution chose to include an elective psychological intervention delivered by pain psychologists as part of the ERAS pathway for benign laparoscopic gynecologic surgeries, such as hysterectomy and myomectomy. Many women seeking gynecologic surgery have comorbid chronic pain, such as pelvic pain, and psychological distress, including symptoms of anxiety and depression. Psychological factors can have notable influence on the pain experience and relevant clinical outcomes. Coping skills interventions have been shown to reduce pain, anxiety and depression in different settings.

In this study, all patients pursuing surgery received additional psychoeducation (pain coping skills workbook) and were offered phone consultation with a pain psychologist. The phone calls included assessment of pain, expectations for surgery, risk assessment for poor outcomes, review of psychoeducation and introduction to diaphragmatic breathing as a coping skill. Majority of women in this sample had chronic pain at the time of surgery, and over 40% had clinically significant levels of psychological distress (anxiety or depression). Data suggests that psychoeducation and participation in pain psychology consultations may add an additional level of benefit to patients during the perioperative time period, but more research is necessary to further explore these relationships.

Feasibility of implementing perioperative interventions and future considerations for improving pain related surgical outcomes will be reviewed. Other ERAS targets will be presented for discussion. Interdisciplinary models to promote adaptive coping with perioperative pain and the surgical experience will be introduced for comparison, including postoperative intervention in an inpatient setting and utilization of telehealth.

8:00 AM-9:15 AM

ASSESSMENT AND TREATMENT OF CHRONIC PAIN AND SLEEP DISTURBANCE USING A HYBRID COGNITIVE BEHAVIOR THERAPY FOR INSOMNIA (CBT-I) AND ACCEPTANCE AND COMMITMENT THERAPY (ACT) TREATMENT MODEL

Skye Ochsner Margolies, PhD¹¹UNC-Chapel Hill, Chapel Hill, NC

Chronic pain, a common and costly disorder, affects approximately 1.5 billion people worldwide. Current treatment approaches focus increasingly more on pain reduction and increased functioning in the context of chronic pain rather than pain elimination. Sleep is a critical component of functioning and quality of life and the presence of clinical insomnia among chronic pain patients has been well established with an estimated 50–70% of chronic pain patients reporting pain-related insomnia. Consequences of chronic pain and insomnia, both as independent syndromes and comorbid with each other, include mood disturbances, medication habituation, memory impairment, daytime fatigue, vocational and interpersonal difficulties, increased healthcare utilization, impaired health status, and accidents. As we look to different approaches to improve the quality of life of our patients with chronic pain, the treatment of sleep has become an important area of clinical and research interest.

Although the impact of insomnia on pain has historically been considered bidirectional, recent research demonstrates that this relationship is more complex and driven in large part by pain catastrophizing and sleep related cognitive arousal. Psychological flexibility has naturally emerged as an area of interest in the non-pharmacological treatment of chronic pain and insomnia as independent syndromes. More recently, this exploration has expanded to the concurrence of chronic pain and insomnia with an emphasis on third-wave cognitive-behavioral approaches emphasizing mindfulness and acceptance as means of increasing psychological flexibility in this setting.

The proposed presentation will outline the current research on the interplay of chronic pain and sleep disturbance and discuss assessment and treatment of these frequent concurrent disorders. Case reports from our outpatient pain management clinic will be presented outlining sessions and treatment components of a hybrid CBT-I/ACT treatment approach delivered for patients with comorbid chronic pain and insomnia in both individual and group formats. Data will also be presented focusing on associations between changes in processes of psychological flexibility (pain interference, pain acceptance) with changes in sleep outcomes (insomnia severity, beliefs about pain and sleep, sleep efficiency) in the context of chronic pain and psychological comorbidities.

8:00 AM-9:15 AM

INTERDISCIPLINARY EDUCATION OF PAIN MEDICAL FELLOWS IN TREATMENT OF CHRONIC PAIN, PSYCHOPATHOLOGY AND SAFETY CONCERNS USING SIMULATION TECHNIQUES IN THE CLINIC SETTING - HOW CAN PSYCHOLOGISTS ASSIST?

Maryam Jowza, MD¹¹University of North Carolina at Chapel Hill, Chapel Hill, NC

In light of the current “opioid epidemic, interaction with patients who present with chronic pain have become increasingly challenging, even for pain physicians. Medical trainees in pain management programs report discomfort with patient encounters especially when addressing comorbid psychiatric illness. As a result, we developed a pilot multidisciplinary simulation curriculum utilizing standardized patients to assist with navigating difficult patient encounters. The goal of our program is to improve trainee confidence in addressing difficult patient encounters while maintaining an enjoyable learning environment

This curriculum takes place in our outpatient clinic where clinical scenarios developed with input from both pain physicians and clinical pain psychologists are played out with assistance of trained actors. One medical trainee is assigned to each case, and the interactions are recorded and played remotely to other trainees with board certified pain physicians and clinical pain psychologists present. After each scenario, the multidisciplinary team debriefs learners.

The debriefing session is used as an opportunity to assess the scenario, review pertinent psychopathology, and explore implications of treatment decisions. As part of the debriefing, the clinical psychologists may also engage with “role play” and enter the scenario with the standardized patient while the trainees observe the interaction.

At the conclusion of all scenarios, learners are asked to complete a survey to assess if educational objectives were met. This curriculum is used to teach, rather than evaluate trainees. Trainee evaluation of the curriculum indicated that all (n=15) 100% noted the experience was enjoyable and educational with 93% stating they would strongly prefer more multidisciplinary simulation in their fellowship training. Further when asked if after the session, they felt more comfortable with approaching challenging patients 15/15 agreed or strongly agreed. When asked if they would change their current practice/approach because after the session, 13/15 strongly agreed and 2/15 agreed.

High-fidelity scenarios developed and debriefed with input from clinical psychologists provides invaluable training for future and current pain clinicians. Of the trainees who completed our simulation curriculum, all agreed it was beneficial, with nearly all trainees preferring more multidisciplinary simulation in the future.

Symposium 6

8:00 AM-9:15 AM

ACCELERATING BEHAVIORAL HEALTH RESEARCH WITH BIOMARKERS: CHALLENGES AND OPPORTUNITIES

Nancy Jallo, PhD¹, Patricia A. Kinser, PhD, WHNP-BC, RN², Lana Sargent, PhD³¹Virginia Commonwealth University, Williamsburg, VA; ²Virginia Commonwealth University School of Nursing, Richmond, VA; ³Virginia Commonwealth University, Ashland, VA

The importance of behavioral research using interviews, surveys, experimental designs, and observation research methods is well-established. However, researchers are often faced with the enduring questions of: do the significant results impact health outcomes and what mechanism or pathway may mediate these results and outcomes? Behavioral research that incorporates biomarkers is, by nature, multidisciplinary and may accelerate our understanding of the challenges and inherent complexities in human behavior change and health outcomes across a broad range of health and development states throughout the lifespan. However, incorporating biomarkers as an objective measure of health outcomes is not without challenges. Researchers are confronted with issues related to making theoretical and conceptual connections, assessing analytic validity, analyzing data, and interpreting the results. In this symposium, three research teams will present research integrating behavioral and biomarker measures in populations across the lifespan and provide examples of challenges faced and addressed to accelerate behavioral health research. Drs. Brown and Jallo will discuss integrating inflammatory and microbiota biomarkers in research focused on infants and pregnant women and provides a foundation for understanding the role of microbiota and preterm infant growth as well as the biologic pathways linking negative and positive emotions to health outcomes and well-being. Drs. Kinser and Lapato will discuss challenges and opportunities related to the use of DNA methylation as a biomarker to predict and categorize individuals at risk of complex disorders, such as perinatal depression, preterm birth, and substance use. Dr. Sargent will discuss the benefits and challenges of using “big data” to identify biological markers for disease prediction of complex diseases of aging such as cognitive impairment and physical frailty.

Learning Objectives.

1. Explore how behavioral health research may be accelerated by the integration of biomarkers into a research design in various populations across the lifespan.
2. Discuss possible challenges researchers may encounter and potential strategies to address those concerns.

8:00 AM-9:15 AM

THE USE OF BIOMARKERS IN MATERNAL AND CHILD HEALTH

Nancy Jallo, PhD¹, Lisa Brown, PhD², Jamie Sturgill, PhD³¹Virginia Commonwealth University, Williamsburg, VA; ²Virginia Commonwealth University; ³University of Kentucky Internal Medicine, Microbiology, Immunology & Molecular genetics

Objective: The psychophysiological state of a woman impacts not only her health but potentially the health of her infant as well. While stress is a pervasive phenomenon experienced by women throughout their lifespan, pregnancy is an essentially a vulnerable period. Psychosocial stress is associated with anxiety, fatigue, and depressive symptoms, which are risk factor for negative health outcomes for both the woman and the infant. It is proposed these factors influence health through a behavioral as well as an inflammatory pathway. The use of psychometric measures of stress and associated symptoms are well-known. The challenge is to integrate a physiologic or biomarker to examine the inflammatory pathway to provide a deeper understanding of this problem. In fact, this inflammatory pathway has been linked to preterm birth which is another source of stress for the mother and health challenges for the infant born preterm. Care of the preterm infant is complex, due in part to highly recognized and frequently studied behaviors of the preterm infant and the lesser-studied physiological challenges. A newer and less well-known physiological consideration is the infant's microbiome, the community of microorganisms, both helpful and harmful, that inhabit the human body. The infant's microbiome is influenced by the maternal microbiome and various aspects of NICU care such as feeding. One way the maternal microbiome influences the infants is through kangaroo care (KC) or skin-to-skin care. KC increases the chance of the infant being colonized with the mother's flora. The composition and diversity of the microbiome is thought to influence the physical growth of the preterm infant. In this talk, we will discuss the following: 1) key concepts about using inflammatory and microbiota biomarkers to study health outcomes in women and infants; 2) to examine the relationships between psychometric and biologic measures of stress related symptoms and well-being in pregnant women; and 3) challenges and opportunities for developing a predictive model for intervention development and testing. Recent biobehavioral research on maternal stress, associated symptoms and resiliency, as well as the microbiome and preterm infant growth will be used to inform the discussion and highlight opportunities to advance our research and future work.

8:00 AM-9:15 AM

DNA METHYLATION AS A BIOMARKER IN RESEARCH STUDIES: CHALLENGES AND OPPORTUNITIES

Patricia A. Kinser, PhD, WHNP-BC, RN¹, Dana Lapato, PhD², Roxann Roberson-Nay, PhD³, Tim York, PhD⁴, Colleen Jackson-Cook, PhD⁵¹Virginia Commonwealth University School of Nursing, Richmond, VA; ²Virginia Commonwealth University; ³VCU School of Medicine, Virginia Institute for Psychiatric and Behavioral Genetics, Richmond, VA; ⁴VCU School of Medicine, Virginia Institute for Psychiatric and Behavioral Genetics; ⁵Virginia Commonwealth University School of Medicine Division of Molecular Diagnostics

Objective: Both genetic and environmental factors contribute to inter-individual variation in risk for complex disorders like depression, cancer, and substance misuse. The ability to predict disorder risk and severity from personal and/or family history is limited. As a result, there is considerable interest in identifying and using biological markers (i.e., biomarkers) in both clinical and research applications. Biomarkers offer an opportunity to identify and classify individuals by risk for developing a complex disorder. Recently, DNA methylation has gained attention as a potential measure for understanding not only complex trait pathoetiology but also for serving as a biomarker to predict and categorize individuals by risk for complex disorders. In this talk, we will discuss the following: (1) key concepts about DNA methylation in general; (2) whether/how DNA methylation might be used as a biomarker for identifying risk for complex traits; (3) the potential for using DNA methylation markers to impute information about individual behaviors like tobacco smoking history or alcohol consumption; (4) challenges and opportunities for the use of DNA methylation in behavioral health research. Recent DNA methylation studies of perinatal depression by this research team will be used to inform the discussion and highlight opportunities for future work.

3

8:00 AM-9:15 AM

SHARED MECHANISMS FOR COMPLEX DISEASES: A MODEL FOR USING BIG DATA TO STUDY COMPLEX SYSTEMS

Lana Sargent, PhD¹, Mike Nalls, PhD², Martina Mueller, PhD³, Stefania Bandinelli, MD, PhD⁴, Sarah Lageman, Ph.D., ABPP-CN⁵, Andrew Singleton, PhD⁶

¹Virginia Commonwealth University, Ashland, VA; ²Data Tecnica International; ³Medical University of South Carolina School of Nursing; ⁴Laboratory of Clinical Epidemiology, InCHIANTI Study Group; ⁵VCU Department of Neurology; ⁶Laboratory of Neurogenetics, National Institute on Aging, National Institutes of Health

There is an emerging understanding for the shared clinical and biological mechanisms for many diseases of aging. These include clinical and biological factors that contribute risk for the development of complex diseases of aging such as physical frailty and cognitive impairment. As a result, there is considerable interest in using “big data” and innovative machine learning statistical techniques to predict diseases before they occur. Machine learning statistics has the ability to combine large numbers of clinical and biological markers (i.e. protein, genomic) to identify and classify individuals by risk for developing a complex disorder. These methods can uncover the potential clinical and biological factors for understanding not only complex traits but can also serve as a model to predict and categorize individuals by risk for complex diseases of aging. In this talk, we will discuss the following: (1) key concepts about using “big data” to study disease of aging; (2) whether/how clinical, protein, and genomic markers might be used for identifying risk for complex diseases; (3) the potential for using machine learning statistics to develop predictive models for the detection of disease in the clinical setting; (4) challenges and opportunities for developing predictive models using biological data from multiple “big data” repositories/longitudinal studies of aging. Recent predictive models developed by this research team using clinical and biological data will be used to inform the discussion and highlight opportunities for future research.

Symposium 7

8:00 AM-9:15 AM

COUPLE COMMUNICATION IN CANCER: NOVEL APPROACHES TO EXAMINING PROCESSES AND MECHANISMS

Laura S. Porter, PhD¹, Shelby Langer, PhD², Katherine Ramos, Ph.D.¹, Joan M. Romano, Ph.D.³, Tracey A. Revenson, PhD⁴

¹Duke University Medical Center, Durham, NC; ²Arizona State University, Phoenix, AZ; ³University of Washington, Seattle, WA; ⁴Hunter College, City University of New York, New York, NY

For patients and their intimate partners, cancer poses significant challenges that can negatively impact both individuals and their relationship. Evidence suggests that couples' ability to communicate effectively plays a major role in the psychological adjustment of both individuals, their relationship quality, and their ability to cope with the effects of cancer and its treatment. However, research on couple communication in cancer has been limited by reliance on global self-report measures of communication, cross-sectional designs, samples limited to a single cancer type, and lack of attention to mechanisms by which communication influences outcomes. This symposium will present data from an ongoing multi-site, multi-method longitudinal study of couple communication in patients with breast, colorectal, and lung cancer and their partners. To date, 232 couples have completed the first phase of the study which includes (a) baseline global self-report measures of communication, psychological adjustment, and relationship functioning, (b) ecological momentary assessment (EMA) of communication, mood, and relationship functioning collected twice/day via smartphone for two weeks, and (c) a lab-based video-recorded couple conversation from which we derived objective measures of communicative behavior and a vocal measure of emotional arousal, fundamental frequency (f_0). The first speaker will present findings from the EMA data to evaluate the relationship intimacy model in explaining links between communicative behavior and patient and partner psychological and relationship adjustment. The second speaker will focus on objective indicators of couples' communicative behavior during a cancer-related discussion using a novel coding scheme to measure positive and negative approach and distancing behaviors. She will present data on reliability, factor structure, and construct validity through associations of the behavioral scales with self-report measures of communication and adjustment. The third speaker will focus on f_0 as an innovative method of assessing emotional arousal, the unique advantages of measuring f_0 in couple conversations, and associations between f_0 and self-report measures of communication. The discussant will summarize findings and discuss their implications for measurement, theory, and content of efficacious interventions to improve couples' communication and adjustment.

THE RELATIONSHIP INTIMACY MODEL OF COUPLE ADAPTATION TO CANCER: SUPPORT FROM A PROSPECTIVE, LONGITUDINAL, SMARTPHONE-ENABLED ECOLOGICAL MOMENTARY ASSESSMENT STUDY

Shelby Langer, PhD¹, Michael Todd, PhD¹, Joan M. Romano, Ph.D.², Niall Bolger, PhD³, Jonathan Bricker, PhD⁴, Karen L. Syrjala, PhD⁵, John Burns, PhD⁶, Francis J. Keefe, Ph.D.⁷, Timothy Strauman, PhD⁷, Julie Gralow, MC², Kelly Westbrook, MD⁷, Veena Shankaran, MD⁸, S Yousuf Zafar, MD⁹, Renato Martins, MD¹⁰, Neeta Ghosh, MA, MPH⁵, Laura S. Porter, PhD¹¹

¹Arizona State University, Phoenix, AZ; ²University of Washington, Seattle, WA; ³Columbia University, New York, NY; ⁴Fred Hutchinson Cancer Research Center/University of Washington, Seattle, WA; ⁵Fred Hutchinson Cancer Research Center, Seattle, WA; ⁶Rush University, Chicago, IL; ⁷Duke University, Durham, NC; ⁸Hutchinson Institute for Cancer Outcomes Research, Seattle, WA; ⁹Duke University; ¹⁰University of Washington; ¹¹Duke University Medical Center, Durham, NC

Avoidant communication has been linked to poor psychosocial adjustment among persons with cancer and their partners. The relationship intimacy model of couples' adaptation to cancer (Manne & Badr, 2008) posits that the mechanism by which compromising behaviors such as avoidance are linked to maladjustment is through reduced feelings of closeness (i.e., intimacy). Prior studies testing this model have been limited by cross-sectional designs and retrospective measures. We used ecological momentary assessment to test this model in real time. Patients and caregivers completed assessments via smartphone between 12 and 2pm (afternoon) and 8 and 10pm (evening) for 14 days (87% completion). Items assessed the extent to which they held back from expressing feelings in conversation with their partner, intimacy (relationship closeness and connectedness), distress (9 items from the POMS), and relationship satisfaction (1 item). Actor-partner interdependence mediation models were used to examine afternoon intimacy as a mediator of associations of concurrent holding back with same-day evening distress and relationship satisfaction. Participants were 232 patients with stage 2-4 breast, colorectal, or lung cancer and their caregivers: M (SD) age = 53 (12); 83% white; 68% female patients and 34% female caregivers. In analyses involving distress, significant actor indirect effects (IEs) emerged for both patients (IE = .015, CI = .005, .025) and caregivers (IE = .008, CI = .000, .015). On afternoons when patients and caregivers held back, they also reported less intimacy, which in turn was associated with their own greater distress that evening. A partner effect also emerged for caregivers such that on afternoons when caregivers held back, the patient reported less intimacy at that time, and reduced intimacy was associated with greater patient distress that evening (IE = .006, CI = .001, .012). In analyses involving relationship satisfaction, significant actor and partner IEs emerged for both patients and caregivers. On afternoons when patients and caregivers held back, they also reported less intimacy, as did their partners; less intimacy that afternoon, in turn, was associated with lower ratings of one's own relationship satisfaction that evening. These findings lend support for the relationship intimacy model and suggest that interventions designed to reduce holding back and boost intimacy (e.g., through shared positive experiences) may lead to better adjustment.

8:00 AM-9:15 AM

ASSOCIATIONS BETWEEN COMMUNICATION AND EMOTIONAL CO-REGULATION (FUNDAMENTAL FREQUENCY) IN COUPLES COPING WITH CANCER

Katherine Ramos, Ph.D.¹, Danielle Weber, M.A.², Melanie Fischer, Ph.D.³, Neeta Ghosh, MA, MPH⁴, Shelby L. Langer, Ph.D.⁵, Michael Todd, PhD⁶, Donald H. Baucom, Ph.D.⁷, Laura S. Porter, Ph.D.⁸

¹Duke University Medical Center, Durham, NC; ²UNC-Chapel Hill; ³Universität Heidelberg; ⁴Fred Hutchinson Cancer Research Center, Seattle, WA; ⁵Arizona State University; ⁶Arizona State University, Phoenix, AZ; ⁷UNC-Chapel Hill; ⁸Duke University

The assessment of fundamental frequency (f0)—the perceived pitch of a human voice—presents a novel and innovative approach to study couples' communication in the context of cancer. F0 carries information about a person's internal emotional arousal, thus measuring f0 in couple conversations can capture communication of emotional information between partners. This presentation discusses the assessment of f0 as an innovative method to assess emotional arousal and summarizes preliminary findings about associations between f0 and individuals' emotional adjustment and emotional disclosure in the context of cancer.

Couples (n = 77 dyads) who are part of a larger observational study examining couples' communication in cancer completed measures of emotional disclosure and depression and then engaged in a 15-minute audio-recorded conversation about a cancer topic of their choosing, during which participants' f0 was measured. Patients were 69% female and 92% White, with a mean age 53.7 (SD = 12.0). Partners were 68% male and 88% White with a mean age 53.7 (SD = 13.6).

Patients' and partners' f0 were each averaged to capture overall levels of emotional arousal across the conversation. A two-intercept actor-partner interdependence model (APIM) was used to test within-individual and cross-partner associations of f0 with self-report measures. Patient-reported depression was negatively related to partner's average emotional arousal during their conversation about cancer (i.e., higher patient depression was associated with lower partner f0), $b = -9.85$ (SE = 4.21), $p < .01$. Partners' depression scores were not associated with patients' emotional arousal. A similar pattern emerged for holding back from disclosing emotions, with patient-reported holding back being negatively related to partner arousal, $b = -5.74$ (SE = 2.75), $p < .05$. Partners' holding back scores were not associated with patients' emotional arousal. No within-individual associations between questionnaire measures and f0 were found.

Results suggest that partners' f0 is associated with patients' depression and communication behavior. Partners' lower emotional arousal might be an unplanned response influenced by either a patient's depressive affect or hesitation to share concerns about difficult issues with cancer; in essence, the couple develops a system of discussing cancer at a less emotional level. Alternatively, a partner might knowingly hold back about cancer-related topics to not "push the issue" emotionally when patients are more depressed and holding back emotionally. We see this pattern in the context of when patients are more depressed. Most importantly, combining these findings with other results about communication behaviors will be needed to clarify whether this pattern is adaptive or maladaptive for the couple in this context.

8:00 AM-9:15 AM

OBSERVATIONAL ASSESSMENT OF COMMUNICATION AMONG PERSONS WITH CANCER AND THEIR CAREGIVING PARTNERS

Joan M. Romano, Ph.D.¹, Brian Baucom, Ph.D.², Donald Baucom, Ph.D.³, Laura S. Porter, Ph.D.⁴, Sara Bybee, L.C.S.W.², Blair Puleo, B.A.⁵, Alex Leger, B.A.², Rachel Hagan, B.S.⁶, Brandon Moncur, B.A.², Elizabeth Suggs, B.A.², Bin Suh, B.S.N.⁷, Neeta Ghosh, MA, MPH⁸, Shelby Langer, PhD⁵

¹University of Washington, Seattle, WA; ²University of Utah; ³University of North Carolina, Chapel Hill; ⁴Duke University Medical Center, Durham, NC; ⁵Arizona State University, Phoenix, AZ; ⁶Arizona State University, Tempe, AZ; ⁷Arizona State University; ⁸Fred Hutchinson Cancer Research Center, Seattle, WA

To understand couple communication in the context of cancer, it is crucial to assess behaviors that foster or discourage disclosure and intimacy, which have been linked to adjustment in patients and partners. However, few studies in this area have utilized direct observation, which provides unique information beyond that obtainable from self-report. The purpose of this study was to apply for the first time the Asymmetric Behavior Coding System (ABCS), a novel observational system that measures positive and negative approach and distancing behaviors, and to evaluate its psychometric properties in a large sample of couples coping with cancer. We examined reliability, factor structure, and construct validity through associations of the behavioral scales with self-report measures of communication (disclosure, holding back, protective buffering), intimacy, and relationship adjustment. Participants were 134 patients with stage 2-4 breast, colorectal, or lung cancer and their partners: M (SD) age = 54 (13); 86% white; 4.5% Latinx; 66% female patients and 36% female partners. Patients and partners completed self-report measures and engaged in a 15-minute video-recorded discussion about the patient's cancer and treatment. Six coders rated 22 behaviors on a 7-point scale separately for patients and partners for each 3-minute segment. Items loaded onto four factor-analytically derived scales: positive approach (6 items, e.g., disclosure, validation), positive distancing (4 items, e.g., minimization), negative approach (7 items, e.g., blame, defensiveness), and negative distancing (5 items, e.g., withdrawal, avoidance). Inter-rater reliabilities ranged from .82 to .99. Internal scale reliabilities ranged from .78 to .93. Positive approach was associated with self-reported disclosure ($r = .14$, $p = .022$), intimacy ($r = .18$, $p = .003$), and relationship adjustment ($r = .15$, $p = .019$). Negative approach was positively associated with holding back ($r = .17$, $p = .005$) and protective buffering ($r = .19$, $p = .002$), and inversely associated with intimacy ($r = -.32$, $p < .001$) and relationship adjustment ($r = -.36$, $p < .001$). Negative distancing was associated with protective buffering ($r = .16$, $p = .008$). Findings support the reliability and construct validity of the ABCS scales. Objective assessment of behaviors that enhance disclosure and intimacy has the potential to inform interventions to improve communication in couples coping with cancer.

Symposium 8

8:00 AM-9:15 AM

USING TECHNOLOGY TO BYPASS BARRIERS TO MIND-BODY CARE FOR HETEROGENEOUS MEDICAL POPULATIONS

Giselle K. Perez, PhD¹, Lunthita M. Duthely, Ed.D., M.S., B.A., RYT-200², Ethan G. Lester, PhD³, Sharon L. Lo, PhD⁴, Ana-Maria Vranceanu, PhD¹, Stephanie J. Sohl, PhD⁵

¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²University of Miami Miller School of Medicine, Miami, FL; ³Massachusetts General Hospital, Boston, MA; ⁴University of Michigan, Ann Arbor, MI; ⁵Wake Forest School of Medicine, Winston-Salem, NC

Although mind-body treatments are associated with substantial emotional and physical health benefits, novel technology-based approaches to delivery (e.g., videoconferencing, web-based, smart phone apps, Computer Adapted Real Time; i.e., CART) are needed in order to overcome barriers to participation. Delivering mind-body interventions through technology requires careful adaptation that includes feedback from participants, proof of concept testing, and rigorous randomized controlled trials (RCTs). In line with SBM's 2020 theme of "Accelerating Our Science: Addressing Tomorrow's Health Challenges", this symposium brings together 4 examples of how mind-body interventions can be developed and delivered through a variety of technological means. First, *Giselle Perez* will describe a mixed methods approach to developing and piloting a video-based mind-body group program aimed at improving psychosocial coping and resilience among adolescent and young adult (AYA) cancer patients. Next, *Lunthita Duthely* will present on the feasibility and acceptability of a pilot mHealth intervention targeting internalized stigma to improve resilience and clinic appointment attendance for women living with HIV. *Ethan Lester* will then present results of three pilot RCTs of virtual mind-body groups aimed to improve resiliency among internationally diverse patients with neurofibromatosis (adolescents, adults, and adults who are deaf). Last, *Sharon Lo* will next present the results of an RCT of a self-regulation focused mind-body (e.g., mindfulness, deep breathing, biofeedback) intervention (*Heart Math*) against usual care for adolescents with Type 1 Diabetes. She will specifically examine changes in heart rate variability, and emotion regulation for this population. Dr. *Stephanie Sohl* will place these studies within the larger context of technology-based mind-body research and will discuss future directions for clinical research programs.

⁶Dana-Farber Cancer Institute, Boston, MA; ⁷MGH/HMS, Boston, MA;

⁸Massachusetts General Hospital, Boston, MA

Background: Adolescent and young adult cancer survivors (AYAs) are susceptible to experiencing chronic stress and adverse health outcomes. Physical effects of treatment may exacerbate typical adjustment problems and lead to functional impairments that interfere with educational, professional and social pursuits. AYAs thus often express feeling alone in their experiences. Despite these vulnerabilities, there is a lack of psychosocial programs that help AYAs cope with life after treatment. This talk will highlight our process to develop a virtual mind-body resiliency program for AYAs to improve coping and adjustment.

Methods: We adapted the program over 3 phases using an iterative design process. First, we conducted in-depth, individual and group interviews via video-conferencing with 18 AYAs to understand their posttreatment stressors, coping strategies, programmatic needs, and obstacles to participating in psychosocial services. We identified key themes, which we used to adapt the manual (Bounce Back). Second, we conducted two pilot test groups (n=3/group) to inform additional program refinements. Participants provided written and verbal qualitative feedback on the helpfulness, relevance, and acceptability following each session. Iterative manual revisions were made to incorporate this feedback. We finalized the program after reviewing qualitative findings with a diverse team of stakeholders (clinician, researchers, and AYAs).

Results: From 3/18-10/18, we conducted group interviews with 18 AYAs (mean age=21.43; 67% female). Themes reflected challenges with interpersonal relationships and self-confidence. Specifically, AYAs expressed a desire for 1) feeling understood, 2) developing a peer survivor network, and 3) learning tools to manage stress and process changes in the self. Participants in the test group (mean age=21.43; 33% female) reported that the program was helpful, enjoyable, convenient, and relevant to their survivorship experiences. In particular, participants noted that social support and validation offered by the peer group, exercises centered on self-concept/identity changes after cancer treatment, cognitive reframing methods, and the use of multiple relaxation response exercises were helpful treatment components.

Conclusions: Qualitative findings from key stakeholders were instrumental to adapting a virtual resiliency program that has the potential to connect and support a young cancer population who is otherwise widely geographically dispersed. We are currently examining the feasibility and efficacy of this program in a pilot RCT.

MEASUREMENTS, MONITORING, AND ME: DESIGNING AN MHEALTH INTERVENTION FOR WOMEN LIVING WITH HIV

Lunthita M. Duthely, Ed.D., M.S., B.A., RYT-200¹, Alex Sanchez Covarrubias, M.D.², Megan Brown, M.P.H.², Tanya Thomas, B.S.², Samantha Waddell, B.S. (c)³, JoNell Potter, Ph.D.²

¹University of Miami Miller School of Medicine, Miami, FL; ²University of Miami, Miller School of Medicine; ³University of Miami

Individual-level barriers to HIV care (care) adherence are often interrelated. In the literature, HIV stigma is linked to depression, and directly affects HIV health outcomes among minorities (Earnshaw, Bogart, Dovidio, & Williams, 2013). A significant correlation exists between barriers to care, such as depression, and adherence to care; furthermore, endorsing multiple barriers to care was related to detectable viral load (Wawrzyniak, 2015). Resilience mitigates these barriers—resulting in positive health outcome such as increased medication adherence and HIV viral load suppression, among minority WLWH (Dale et al., 2014). Specifically, ethnic minorities living with stigmatized conditions, like cancer and HIV, deal with additional, multiple stressors, including racism, low health literacy, language barriers, and immigration challenges. For HIV treatment adherence, mHealth interventions are rapidly increasing. Modes of delivery range from telephonic delivery, text messaging, and full-blown apps (Cole-Lewis & Kershaw, 2010). Data permit real-time signaling and assessments, but the potential benefits of these technologies must be leveraged by individual considerations (Labrique et al, 2013; Pérez et al, 2015; Jack & Mars, 2014; Marent et al., 2018)—particularly for special populations, such as undocumented individuals or persons who have not disclosed their health status to others. Here we describe a feasibility/acceptability RCT of a short-term, longitudinal, mixed-methods, pilot mHealth intervention for WLWH (KL2TR002737). The qualitative arm informed the study design. Representative of the regional linguistic profile, data collection and interviews were conducted in three languages. Primary outcomes included study feasibility (enrollment) and acceptability (opened messages), and secondary outcomes (3 and 6 months) included resiliency (CD-RISC25), HIV stigma (HSS), medical mistrust (GBMM), HIV medication adherence, depressive symptomatology (PHQ-9), clinic attendance and HIV viral load suppression. Details about the methodology using technology, as well as case study results and future directions for women living with HIV will be discussed.

8:00 AM-9:15 AM

VIRTUAL MIND-BODY GROUPS IMPROVE RESILIENCY FACTORS IN INTERNATIONALLY DIVERSE PATIENTS WITH NF1, NF2 AND SCHWANNOMATOSIS: RESULTS OF THREE RANDOMIZED CONTROLLED TRIALS (RCTS) IN ADULTS, ADOLESCENTS AND PATIENTS WHO ARE DEAF

Ethan G. Lester, PhD¹, Jonathan Greenberg, PhD², Ana-Maria Vranceanu, PhD²

¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital/Harvard Medical School, Boston, MA

Background: Patients with NF have lower quality of life (QoL) relative to the general population and cancer patients. Although biomedical treatments have greatly improved outcomes across NF patients an enormous need remains for interventions to increase resiliency in patients with NF across the lifespan. Our team has adapted a mind body program - The Relaxation Response Resiliency Program (3RP) - to be delivered via live videoconferencing groups for the specific needs of: 1) adults with NF1, NF2 and schwannomatosis (3RP-NF); 2) adolescents with NF1 and NF2 (Resilient Youth with NF; RY-NF); 3) adults with NF2 who are deaf (d3RP-NF-CART). The three programs teach the same core resiliency skills (i.e., gratitude, mindfulness, coping, optimism and social support) but have been iteratively tailored to each population through direct qualitative feedback and prior research. The programs are highly feasible, accepted and efficacious in improving QoL when tested individually against an attention placebo control via three separate RCTs. The use of technology also provides more access and eliminates barriers to participation/treatment. Here we report data on the efficacy of the three programs in improving resiliency factors over and above the attention placebo control.

Methods: Patients (63 adults, 51 adolescents, 45 patients who are deaf) were recruited through an international NF registry. Screening and consent occurred via live video, with CART for patients who were deaf. Data was collected electronically. The intervention programs and control (8 sessions; 90 minutes for adults, 45 for adolescents, and 60 for deaf adults) were delivered by a clinical psychologist. Participants in the intervention received a patient manual and age/symptom tailored meditation recordings for home practice.

Results: Although specific outcomes varied by population, participants in all three interventions experienced significant improvements ($p < .05$) in one or more resiliency factors over and above their respective attention placebo controls, with many of these improvements maintained at six months.

Conclusions: A virtual mind-body program adapted for the needs of adults, adolescents and patients with NF2 who are deaf was associated with sustained improvement in resiliency factors. Promoting resiliency may be particularly important for individuals with NF who are living with a chronic incurable condition with an unpredictable trajectory. Details and lessons learned on virtual mind body program adaptations, results compared by patient populations, future directions and implications for NF care will be discussed.

8:00 AM-9:15 AM

DEVELOPMENT OF A TECHNOLOGY MEDIATED INTERVENTION TARGETING EMOTION REGULATION SKILLS IN ADOLESCENTS WITH TYPE 1 DIABETES

Sharon L. Lo, PhD¹, Kiren Chaudhry, BA², Emily Fredericks, PhD³, Dana Albright, PhD³, Niko Kaciroti, PhD¹, Christine M. Hunter, PhD⁴, Alison L. Miller, PhD⁵

¹University of Michigan, Ann Arbor, MI; ²University of Michigan School of Public Health, Canton, MI; ³University of Michigan; ⁴Office of Behavioral and Social Sciences Research, National Institutes of Health, Bethesda, MD; ⁵University of Michigan, School of Public Health, Ann Arbor, MI

Adolescence marks a time of heightened emotional reactivity and intensity as well as changes in one's ability to regulate thoughts, feelings, and behaviors. Therefore, adolescence serves as a period of risk for those with chronic medical conditions such as Type 1 Diabetes (T1D) in terms of medical adherence. Teens with poorer emotional awareness and ability to process emotions, skills that are critical to emotion regulation (ER), predict poorer metabolic control and adherence. Mindfulness-based strategies that act on ER processes have been suggested as important for improving adherence and health outcomes for youth with T1D (Salmoirago-Blotcher et al., 2018).

As part of an ongoing clinical trial (NCT03688919), we developed a technology-mediated intervention based on prior work that uses biofeedback to improve ER (Miller et al., 2018). Participants were adolescents aged 13-17 years who have been diagnosed with T1D for at least six months and have hemoglobin A1c (HbA1c) ≥ 7.0 . Teens were recruited from a hospital-wide registry of patients with T1D. Teens engaged in relaxation and biofeedback activities using a commercially-available program (HeartMath; McCraty et al., 2006) to learn diaphragmatic breathing and improve physiological coherence, as indexed by heart rate variability. Participants were randomly assigned to intervention group at enrollment. Teens were shown how to practice breathing and relaxation skills at home using a commercially-available mobile app (Insight Timer) that was downloaded on the participant's smartphone. They were asked to practice at least five minutes of guided breathing per day using the mobile app across a period of eight weeks. An incentive structure was designed to improve engagement in the technologically-based home practice: teens were asked to text a screenshot of Insight Timer use every day. For each screenshot, they were awarded with an entry into a raffle for a \$100 gift card. Additionally, if participants sent at least 4 screenshots per week, they had the opportunity to earn \$10 each week.

Here we describe the feasibility of delivering a biofeedback-mediated intervention with mobile-app based home practice to target emotion regulation skills. Outcomes included measures of heart rate variability that were collected at pre- and post-intervention as well as measures of ER, which included the Children's Emotion Management Scales (Zeman et al., 2000), Positive and Negative Affect Schedule for children (Ebesutani et al., 2011), and the parent-reported Perceived Stress Scale (Kupst et al., 2015). Results on intervention dosage and changes in heart rate variability and ER outcomes will be presented.

Symposium 9

8:00 AM-9:15 AM

NOVEL METHODS FOR CAPTURING SUBJECTIVE INTENSIVE LONGITUDINAL DATA WITHIN LONG TERM EPIDEMIOLOGICAL AND INTERVENTION STUDIES

Genevieve F. Dunton, PhD, MPH¹, Inbal Nahum-Shani, PhD², Donna Spruijt-Metz, MFA, PhD¹, Dana Wolff-Hughes, PhD³¹University of Southern California, Los Angeles, CA; ²University of Michigan, Ann Arbor, MI; ³National Institutes of Health, Bethesda, MD

Health behavior theories and interventions have been criticized for their failure to incorporate dynamic within-person changes and fluctuations in psychosocial and emotional states. Fortunately, advancements in mobile smartwatch and smartphone technologies now can facilitate frequent and real-time assessments of subjective constructs (e.g., stress, pain) in individuals' daily lives. The first generation of these intensive longitudinal data (ILD) studies involved temporally-dense self-report assessments (e.g., every few hours) across limited time spans (e.g., 7-14 days). However, this approach does not tell us how within-subject processes themselves evolve or change across longer time periods such as months or years, nor does it help link momentary changes to processes that ebb and fold at slower time scales. For example, does the strength of the association between momentary stress levels and subsequent smoking change across the course of an intervention? This symposium will showcase how the next generation of ILD studies are implementing innovative methods to assess intensive subjective data across longer timescales. Three studies from NIH's Intensive Longitudinal Health Behavior Network (ILHBN) will be presented that are each capturing and modeling ILD nested within long-term epidemiological and intervention studies lasting months to years. The first presentation will describe how the TIME (Temporal Influences on Movement and Exercise) Study is implementing four types of Ecological Momentary Assessment (EMA): microinteraction-EMA, burst-EMA, daily diary-EMA, and context sensitive-EMA approaches to assess micro-temporal changes in psychosocial factors contributing the adoption and maintenance of physical activity, limited sitting, and sufficient sleep across one year in young adults. The second presentation will discuss how HeartSteps, a year-long physical activity Just-in-Time-Adaptive Intervention (JITAI) for adults with histories of cardiovascular disease and/or obesity, is combining daily, weekly, and intra-day self-report measurements to gather high-granularity data while minimizing participant burden. The third presentation will share how the MARS (Mobile Assistance for Regulating Smoking) study is using intensive longitudinal self-reported assessments from five studies of smokers attempting to quit to investigate how the temporal dynamics of psychosocial factors can detect states of vulnerability to a lapse and states of receptivity to engaging in self-regulatory activities. Collectively, these presentations will demonstrate how innovative approaches to capturing ILD across long-term studies, when combined with state-of-the-art modeling techniques, can yield critical insights into the prediction and modeling of health behaviors that will lead to innovations in health behavior theories and theory-based interventions.

CORRESPONDING AUTHOR: Genevieve F. Dunton, PhD, MPH, University of Southern California, Los Angeles, CA; dunton@usc.edu

INNOVATIVE ECOLOGICAL MOMENTARY ASSESSMENT STRATEGIES TO CAPTURE MICRO-TEMPORAL PROCESSES UNDERLYING LONG-TERM CHANGES IN PHYSICAL ACTIVITY, SEDENTARY BEHAVIOR, AND SLEEP

Genevieve F. Dunton, PhD, MPH¹, Shirlene D. Wang, BA¹, Aditya Ponnada, B. Des², Rebecca Campo, PhD³, Sy-Miin Chow, PhD⁴, Stephen Intille, PhD²¹University of Southern California, Los Angeles, CA; ²Northeastern University, Boston, MA; ³NHLBI; ⁴Pennsylvania State University

Engaging in sufficient levels of physical activity and sleep, and limiting sitting time are important contributors to the prevention of weight gain. Interventions typically focus on the adoption of these behaviors. Yet, success at maintaining behaviors is low. Sustaining these behaviors over time may be challenging due to daily and within-daily fluctuations in how people feel, who they interact with, and obstacles they encounter. Thus, factors influencing the maintenance of health behaviors may become more apparent when assessed on a *micro-timescale* (i.e., across minutes, hours, or days). Part of NIH's Intensive Longitudinal Health Behavior Network (ILHBN), the Temporal Influences on Movement and Exercise (TIME) Study, uses real-time mobile technologies to collect intensive longitudinal data to examine the processes underlying the maintenance of physical activity, low sedentary time, and sufficient sleep duration in ethnically-diverse, emerging adults (ages 18-24). The TIME Study nests Ecological Momentary Assessment (EMA) within a 12-month longitudinal epidemiological design to provide insight into how psychological and health behavior variables change across micro- (e.g., minutes/hours), meso- (e.g., days/weeks), and macro- (e.g., months/years) timescales. Through self-report surveys delivered on smartphones and smartwatches, EMA captures real-time information on affective states, physical feeling states, self-control, attention, intentions, goal-setting, and tracking. Several innovative strategies are used in order to encourage participant engagement and limit burden. First, smartphone-based EMA occurs in twice-monthly "bursts" with 1-2 minute surveys delivered hourly across four days. Second, smartwatch-based one-item "microinteraction-EMA" occurs multiple times per hour during non-burst periods. Third, a smartphone-based "daily diary" EMA survey is prompted near the end of each day. Fourth, sensor-informed "context-sensitive" EMA will prompt surveys when activity behaviors and geographical locations are detected by built-in phone sensors. This presentation will discuss the challenges and trade-offs in designing this study and the technology to collect high-volume self-report data across a 12-month period. EMA prompt compliance data will be compared across the different types of sampling approaches. Strategies to combine the various forms of EMA data in joint analyses will be discussed. Data from this project will be used to examine how changes in within-subject means (i.e., usual levels), variances (i.e., fluctuations), and covariances (i.e., associations) for time-varying psychological and health behavior variables across micro-, meso-, and macro-timescales contribute to long-term health behavior change. Findings will contribute to building more predictive models and efficacious interventions for health behavior maintenance.

8:00 AM-9:15 AM

NOVEL USE OF MHEALTH DATA TO IDENTIFY STATES OF VULNERABILITY AND RECEPTIVITY TO JITAIS

Inbal Nahum-Shani, PhD¹, Alexander Moreno, MS², Zhenke Wu, PhD³, Jamie Yap, MS³, Cho Lam, PhD⁴, James Rehg, PhD⁵, Susan Murphy, Ph.D.⁵, Santosh Kumar, PhD⁶, David Wetter, PhD⁷

¹University of Michigan, Ann Arbor, MI; ²Georgia Institute of Technology; ³University of Michigan; ⁴University of Utah, Salt Lake City, UT; ⁵Harvard University, Cambridge, MA; ⁶University of Memphis; ⁷Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Smoking cessation decreases morbidity and mortality and is a cornerstone of cancer prevention. The ability to impact current and future vulnerability (e.g., high risk for a lapse) in real-time via engagement in self-regulatory activities (e.g., behavioral substitution, mindful attention) is considered an important pathway to quitting success. However, poor engagement represents a major barrier to maximizing the impact of self-regulatory activities. Hence, enhancing real-time, real-world engagement in evidence-based self-regulatory activities has the potential to improve the effectiveness of smoking cessation interventions. Just-In-Time Adaptive Interventions (JITAI) delivered via mobile devices have been developed for preventing and treating addictions. JITAI adapt over time to an individual's changing status and are optimized to provide appropriate intervention strategies based on real time, real world context. Organizing frameworks on JITAI emphasize minimizing disruptions to the daily lives and routines of the individual, by tailoring strategies not only to vulnerability, but also to receptivity (i.e., an individual's ability and willingness to utilize a particular intervention). Although both vulnerability and receptivity are considered latent states that are dynamically and constantly changing based on the constellation and temporal dynamics of emotions, context, and other factors, no attempt has been made to systematically investigate the nature of these states, as well as how knowledge of these states can be used to optimize real-time engagement in self-regulatory activities. The MARS (Mobile Assistance for Regulating Smoking) study focuses on closing this gap by applying innovative computational approaches to one of the most extensive and racially/ethnically diverse collection of real time, real world data on smoking cessation. The data includes intensive longitudinal self-reported and sensor-based assessments from five studies (three completed and two ongoing) of ~1,500 smokers attempting to quit. The goal is to use these data to investigate whether and how the temporal dynamics and interactions of emotions, self-regulatory capacity (SRC), context, and other factors can detect states of vulnerability to a lapse and states of receptivity to engaging in self-regulatory activities. We will discuss challenges and opportunities relating to the curation, integration and modeling of these intensive longitudinal data. We will also discuss the planning of a Micro-Randomized Trial (MRT) designed to investigate how knowledge of states of vulnerability and opportunity gained from the analysis of existing data can be used to optimize real-time engagement in self-regulatory activities.

8:00 AM-9:15 AM

ADVANCING NEW APPROACHES TO ECOLOGICAL MOMENTARY ASSESSMENT TO ENABLE MODELING OF GRANULAR DYNAMICS ON PHYSICAL ACTIVITY

Donna Spruijt-Metz, MFA, PhD¹, Predrag Klasnja, PhD², Benjamin Marlin, PhD³, Misha Pavel, PhD⁴, Daniel E. Rivera, PhD⁵, Natalie M. Golaszewski, PhD⁶, Guillaume Chevance, PhD⁷, Eric B. Hekler, PhD⁸

¹University of Southern California, Los Angeles, CA; ²University of Michigan, Ann Arbor, MI; ³University of Massachusetts Amherst, Worcester, MA; ⁴Northeastern University; ⁵Arizona State University, Tempe, AZ; ⁶University of California, San Diego, SAN DIEGO, CA; ⁷University of California, San Diego, San Diego, CA; ⁸UC San Diego, San Diego, CA

Over the last two decades, a key tool for studying the relationships between health behaviors and psychosocial and contextual variables that influence them has been ecological momentary assessment (EMA). In traditional EMA studies, participants are paid or receive goods or services for a few days to several weeks in exchange for participation in intensive data-collection protocols that require frequent responses to EMA each day and other requests for data. With the emergence of mobile technology and just-in-time adaptive interventions (JITAI), researchers are increasingly focusing on questions of how health behaviors—and factors that influence them—evolve over time, and the dynamics of these processes over different time scales. Studying such questions requires long-term studies for which traditional EMA protocols are poorly suited. The traditional EMA approach is not sustainable financially in long-term studies, and participants typically are unwilling to participate for more than a few days/weeks due to high burden. Consequently, understanding fine-grained dynamics of health behaviors over time requires not just new modeling approaches but new assessment approaches as well.

In this talk, we will discuss the approach we have taken to gather psychosocial data in order to model granular dynamics of influences on physical activity. Our work was done in the context of the development of HeartSteps, a physical activity JITAI that is currently deployed in a year-long study with adults with histories of cardiovascular disease and/or obesity. We will discuss how we are combining daily, weekly, and intra-day self-report measurements to gather data that enables modeling at a high level of granularity while minimizing participant burden, as well as how we are attempting to use sensor data as passively collected indicators of psychosocial constructs we are assessing in the study. We will describe decisions about what to measure, when to measure, how frequently to measure, as well as the tradeoffs of these decisions. Throughout, our assessment needs were in conversation with—and sometimes in conflict with—modeling needs, as well as with the need to maintain the usability of the intervention and keep participant burden to a minimum. Key aspects of our assessment strategy involve judicious selection of constructs to assess daily and weekly, use of EMA bursts to understand intraday variation of most important constructs, ongoing checks on the usefulness of the constructs we are assessing for predicting physical activity, and leveraging passively collected data to build detectors and predictors of psychosocial constructs that are repeatedly re-grounded via self-report.

Symposium 10

DEVELOPING DIGITAL CIGARETTE SMOKING CESSATION INTERVENTIONS FOR HIGH RISK POPULATIONS: CROSS CUTTING METHODS TO CLOSE THE GAP

Megan Kelly, Ph.D.¹, Diana M. Kwon, BA², Jonathan Bricker, PhD³, Roger Vilardaga, PhD⁴, Judith J. Prochaska, PhD, MPH⁵

¹Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA; ²Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA; ³Fred Hutchinson Cancer Research Center/University of Washington, Seattle, WA; ⁴Duke University, Durham, NC; ⁵Stanford University, Stanford, CA

The cigarette smoking rate among US adults has reached an all-time low of 14 percent. However, this great progress has not equally benefited everyone—especially those who are the most vulnerable. For example, 32 to 88 percent of people with serious mental illness are current smokers and consume 40 percent of all cigarettes in the US. Fifteen to fifty-four percent of cancer patients are current smokers at the time of their diagnosis and at least half of them will remain smokers following diagnosis. And Black smokers are half as likely to quit smoking than White smokers. These populations' smoking trends provide prominent illustrations of the tremendous need to develop smoking cessation interventions for high risk populations of smokers, with the overarching goals of reducing disparities and making further progress in reducing the overall US adult smoking rate.

Digital interventions (e.g., websites, smartphone apps) are a low-cost, accessible, personalized, and high reach method that have the potential to reduce these disparities in smoking. Website access or smartphone ownership is high, ranging from 60% to 90% depending on the population. There are now over 12 million US adult smokers each year using websites for smoking cessation, and over 3 million adults using smoking cessation apps.

However, a major barrier to progress in digital interventions for high risk populations is the lack of early phase research to shape their development. Early research ensures that interventions are tailored to the user, acceptable to them, engaging, impact hypothesized mechanisms of action, and show preliminary signs of effectiveness. The goal of this symposium is to show cross-cutting methods of early phase intervention development.

Methods: will range from focus groups and secondary analyses of general population cessation trials for the goal of planning a digital intervention to showing mechanisms of action and preliminary effectiveness of pilot randomized trials for interventions specifically designed for certain high risk populations of smokers. Accordingly, Dr. Kelly will first present focus group results for planning a website for Veterans smokers with mental disorders. Ms. Kwon will then present secondary data analyses on mechanisms of action and cessation among Black smokers in a general population web-delivered intervention. Dr. Bricker will present pilot RCT results on acceptability and preliminary effectiveness of a cessation app for cancer patients who smoke. Dr. Vilardaga will present engagement results for a cessation app designed for smokers with serious mental illness. Dr. Prochaska will discuss the presentations in terms of their value and utility for design research on digital interventions to address smoking disparities for high risk populations.

CORRESPONDING AUTHOR: Jonathan Bricker, PhD, Fred Hutchinson Cancer Research Center/University of Washington, Seattle, WA; jbricker@fredhutch.org

ADAPTING WEB-BASED TOBACCO CESSATION TREATMENTS FOR VETERANS WITH MENTAL HEALTH DISORDERS: DESIGN CONSIDERATIONS

Megan Kelly, Ph.D.¹, Beth Ann Petrakis, MPA², Erin D. Reilly, Ph.D.², Karen S. Quigley, Ph.D.³, Jonathan Bricker, PhD⁴, Edit Serfozo, MPH⁵, Jaimee L. Heffner, PhD⁶

¹Edith Nourse Rogers Memorial Veterans Hospital, Bedford, MA; ²Bedford VA Medical Center, Bedford, MA; ³Northeastern University, Needham, MA; ⁴Fred Hutchinson Cancer Research Center/University of Washington, Seattle, WA; ⁵Fred Hutchinson Cancer Research Center; ⁶Fred Hutchinson Cancer Research Center, Seattle, WA

Smoking is the leading preventable cause of death and disability for Veterans with mental health disorders. Veterans with mental health disorders have high rates of smoking (32-68% vs. 15% in the general population) and low lifetime quit rates (17-33% vs. 43% in the general population). One promising treatment for reducing tobacco use among Veterans with mental health disorders is Acceptance and Commitment Therapy (ACT). Several studies show that web-based ACT smoking cessation interventions are efficacious. However, these interventions have not been tailored for use by Veterans (e.g., addressing the Veteran culture that often embraces smoking) or modified for individuals with a broad array of mental health disorders. To tailor a web-based ACT tobacco cessation intervention (WebQuit Plus) for Veterans with mental health disorders (Vet WebQuit), we conducted four focus groups with Veterans with mental health disorders ($n = 20$; $M_{age} = 51.7$, $SD_{age} = 11.2$; 16 men, 4 women, 65% were non-Hispanic/white) to identify useful adaptations for this intervention. We utilized a user-centered design process to understand Veterans' needs and preferences for a web-based tobacco cessation intervention for Veterans with mental health disorders. Veterans suggested avoiding military images that were combat-related and aversive (e.g., images of fighter planes, paratroopers). They preferred images of people engaged in physical activities and images of people with loved ones. They reported a preference for images of the American flag to represent the constructs of freedom and commitment. Veterans discussed their discomfort with self-compassion exercises and suggested replacing this content with more concrete behavioral coping strategies for smoking cravings and smoking lapses/relapses. They also discussed their positive reactions to mindfulness exercises related to thoughts and emotions (e.g., mindful acceptance of anxiety exercise). Results of the focus groups also demonstrated the importance of using gender neutral names in user quit stories and avoiding particular names that have negative connotations in military culture. This feedback will be used to develop Vet WebQuit and we will assess the acceptability of the modified intervention in future usability testing. Overall, results from this project will help identify important elements to consider in adapting web-based interventions, particularly tobacco cessation interventions, for Veterans with mental health disorders.

8:00 AM-9:15 AM

HOW WELL DO BLACK SMOKERS RESPOND TO WEB-BASED SMOKING CESSATION INTERVENTIONS?: CESSATION RATES AND MECHANISMS OF ACTION

Diana M. Kwon, BA¹, Kristin E. Mull, MS², Jonathan Bricker, PhD³¹Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA; ²Fred Hutchinson Cancer Research Center, Seattle, WA; ³Fred Hutchinson Cancer Research Center/University of Washington, Seattle, WA

Background: The smoking rate for Black adults in the U.S. remains high at 15%. Furthermore, even though Black smokers want and try to quit more than White smokers, they still are significantly less likely to quit and more likely to die from a smoking-related disease. A critical barrier to smoking cessation for Black adult smokers is access to low-cost and effective smoking cessation treatment. Self-help web-delivered cessation interventions could overcome this major barrier to care. To date, no published studies have reported on the effectiveness or mechanisms of action of websites for smoking cessation among Black adult smokers. Thus, the purpose of this study was to compare Black adult smokers, versus White adult smokers, on: (1) cessation rates and (2) mechanisms of action for two web-delivered smoking cessation interventions in a large RCT.

Methods: A secondary analysis of a large RCT (N=2637) comparing two web-delivered interventions for smoking cessation: Acceptance and Commitment Therapy (ACT) vs. NCI's Smokefree.gov. Both websites were designed for a general population of smokers. Black adult smokers (n=281) were compared with White adults smokers (n=1914) on the following: (1) self-reported 30-day point prevalence abstinence at the 12-month follow-up (88% retention) and (2) mechanisms of action defined as engagement (i.e., number of logins, number of unique days logged in) and acceptance of physical cravings to smoke as measured in the first 3 months post-randomization.

Results: In the ACT arm, Black participants had 1.71 times higher odds of 12-month abstinence as compared to White participants (36% vs. 21%; OR=1.71; CI: 1.12, 2.62; p=.013). By contrast, in the Smokefree.gov arm, there was no difference in quit rates between Black and White smokers (27% vs. 25%; OR=.97; CI: 0.62, 1.48; p=.875). Regarding mechanisms of action, number of logins (p=.020) and number of unique days logged in (p=.021) both partially mediated the difference in cessation rates between Black and White smokers; acceptance of physical cravings did not mediate the difference in cessation rates (p=.075).

Conclusions: Web-delivered ACT for smoking cessation appears to be more effective for Black smokers than White smokers. This result may be explained by their level of engagement with the intervention. Development and testing of a web-delivered ACT intervention specifically tailored to Black smokers is now needed.

3

8:00 AM-9:15 AM

DEVELOPING A SMARTPHONE APP FOR CANCER PATIENT SMOKING CESSATION: PILOT RCT RESULTS ON ACCEPTABILITY AND EFFECTIVENESS

Jonathan Bricker, PhD¹, Noreen L. Watson, PhD², Jaimee L. Heffner, PhD², Brie Sullivan, MS³, Kristin E. Mull, MS², Jamie Ostroff, PhD⁴¹Fred Hutchinson Cancer Research Center/University of Washington, Seattle, WA; ²Fred Hutchinson Cancer Research Center, Seattle, WA; ³Fred Hutchinson Cancer Research Center; ⁴Memorial Sloan Kettering Cancer Center, New York, NY

Background: Persistent smoking after a cancer diagnosis predicts poor outcomes including decreased treatment effectiveness, increased risk of disease recurrence and second primary cancers, and worse survival rates. Unfortunately, 50-64% of smokers with cancer continue to smoke after their diagnosis. Limited access to effective tobacco cessation interventions is widely recognized as a key barrier for promoting cessation in the context of cancer care. Smartphone applications ("apps") can address this problem by providing a highly accessible, low-cost smoking cessation intervention tailored to patients with a recent cancer diagnosis.

Objective: Determine the participant acceptability and potential effectiveness of a smartphone app for smoking cessation among cancer patients.

Methods: We used an agile, user-centered design framework to develop a smartphone app (called "Quit2Heal"), specifically designed to help cancer patients stop smoking by providing skills training and stories from cancer survivors that focus on coping with internalized shame, cancer stigma, depression, and anxiety as core triggers of smoking. Quit2Heal was compared with NCI's QuitGuide, a widely used stop smoking app, in a pilot randomized trial with a 2-month follow-up period. Participants were 59 adult smokers diagnosed with cancer within the past 12 months recruited through 2 cancer center networks and social media over a 12-month period. Participants were 75% female, 78% white. The most common types of primary cancers were lung (36%) and breast (17%). The 2-month follow-up survey retention rate was 92% (54/59) and did not differ by study arm (p=.15).

Results: Compared to QuitGuide participants, Quit2Heal participants reported being more satisfied with their assigned app overall (90% vs. 65%; p=.047), found their app's overall approach for quitting a good fit (86% vs. 62%; p=.043), and opened their app descriptively more times [M = 10.0 (SD = 14.40) vs. 6.1 (SD = 5.3); p=.332]. The self-reported 30-day point prevalence quit rate at the 2-month follow-up was 20% for Quit2Heal vs. 7% for QuitGuide (OR=5.16; 95% CI: 0.71, 37.29; p=.104). Quit2Heal participants also showed descriptively greater improvement in internalized shame, cancer stigma, depression and anxiety.

Conclusion: In a pilot trial with a high short-term retention rate, Quit2Heal had promising acceptability and effectiveness for helping cancer patients stop smoking. Testing in a full scale RCT is now needed.

4

8:00 AM-9:15 AM

DOSE-RESPONSE EFFECTS OF A NOVEL SMOKING CESSATION APP DEVELOPED FOR PATIENTS WITH TOBACCO USE DISORDER AND SERIOUS MENTAL ILLNESS

Roger Vilardaga, PhD¹¹Duke University, Durham, NC

Background: Examining dose-response effects with smoking cessation apps is key to understanding the mechanisms of action of these digital technologies.

Methods: Learn to Quit (LTQ) is a theory-based smoking cessation app that contains 28 learning and skills modules designed and adapted for individuals with serious mental illness (SMI). This app showed promising preliminary efficacy in a pilot randomized controlled trial among 62 patients with tobacco use disorder and SMI. Using app background analytics, we measured engagement with LTQ and its comparator -- QuitGuide, a standard of care smoking cessation app -- by collecting number of daily interactions with each technology. Smoking outcomes included reductions in number of cigarettes per day (CPD) from baseline to week 16.

Results: Background: analytics of the LTQ app measured a total of 27,955 total interactions (vs. 5,956 for QuitGuide). LTQ users had a smoking reduction of 10.5 CPD (vs 5.6 for QuitGuide). Both visual inspection and regression analysis indicated that participants with large reductions in CPD at trial endpoint (> 5 CPD) displayed consistently higher levels of engagement with the Learn to Quit app throughout the 4-months clinical trial compared to participants who had small reductions (5 or less CPD; $p < 0.001$; R Square = 0.50). This pattern was not replicated in QuitGuide.

Conclusions: LTQ appears to more effectively engage patients with SMI than QuitGuide, which in turn is associated with larger reductions in CPD at trial endpoint. This dose-response analysis suggests that LTQ was effectively designed to engage its target audience.

Symposium 11

8:00 AM-9:15 AM

REACH, ADOPTION, AND IMPLEMENTATION IN PHYSICAL ACTIVITY INTERVENTIONS FOR UNDERSERVED CANCER SURVIVORS

Scherezade K. Mama, DrPH¹, Yue Liao, MPH, PhD², Shawna Doerksen, PhD³, Rachel C. Shelton, ScD, MPH⁴

¹The Pennsylvania State University, University Park, PA; ²The University of Texas MD Anderson Cancer Center, Houston, TX; ³Penn State College of Medicine, State College, PA; ⁴Columbia's Mailman School of Public Health, New York, NY

Nearly 2 million Americans will be diagnosed with cancer in 2019, and the number of cancer survivors is expected to rise to over 20 million by 2026. Engaging in physical activity post-cancer diagnosis is associated with reduced risk of cancer-specific and all-cause mortality. Despite the overwhelming evidence supporting physical activity post-cancer diagnosis, the vast majority of cancer patients and survivors are insufficiently active and at greater risk of cancer recurrence and developing comorbidities. Improved implementation of exercise within cancer care and during survivorship has been shown to reduce adverse treatment effects. However, few studies have explored supportive care across the cancer continuum through an implementation lens. The goals of this symposium are to explore the reach, adoption, implementation and maintenance of supportive care interventions during and post-cancer treatment in diverse, medically underserved cancer survivors. First, we will describe determinants of physical activity in rural cancer survivors. Next, we will identify the characteristics of cancer survivors that predicted class attendance for a community-based, 12-week physical activity intervention. Finally, we will examine techniques to effectively recruit metastatic breast cancer patients to a digitally-delivered supportive care intervention that delivers guidelines-based symptom management, including physical activity. The symposium will conclude with a moderated discussion on implementation science and exercise across the cancer continuum.

8:00 AM-9:15 AM

USING A COMMUNITY-ENGAGED APPROACH TO REACH UNDERSERVED POPULATIONS AND DETERMINANTS OF PHYSICAL ACTIVITY AMONG RURAL CANCER SURVIVORS

Scherezade K. Mama, DrPH¹, Nishat Bhuiyan, MS², Kathryn Schmitz, PhD, MPH, FACS, FTOS³

¹The Pennsylvania State University, University Park, PA; ²The Pennsylvania State University, State College, PA; ³Penn State College of Medicine, Hershey, PA

Rural cancer survivors are more likely to be physically inactive and less likely to do leisure-time physical activity than cancer survivors residing in urban areas with greater access to resources for engaging in healthy behaviors. Yet, few physical activity interventions reach rural cancer survivors or include representative samples of rural cancer survivors. The Partnering to Prevent and Control Cancer (PPCC) study used a community-engaged approach to understand determinants of physical activity in rural, non-metropolitan cancer survivors. An academic-community partnership was used to recruit cancer survivors residing in rural communities to complete questionnaires assessing leisure-time physical activity (LTPA) and sociodemographic determinants, including gender, age, race/ethnicity, marital status, education, income, employment status, and weight status. LTPA was assessed using the Godin Leisure-Time Exercise Questionnaire, and participants were categorized as insufficiently active/sedentary, moderately active, or active. Chi-square tests were used to explore differences in LTPA by sociodemographic characteristics, and multinomial logistic regression was used to explore characteristics of moderately active and active rural cancer survivors compared to insufficiently active/sedentary participants. Through the PPCC partnership, 263 cancer survivors enrolled in the study, representing 18 counties and 84 cities in central Pennsylvania. The two most common types of cancer reported were breast (22.2%) and prostate (21.8%) cancers, and most (89.9%) cancer survivors were at least 12 weeks post-treatment. Participants were mostly women (59.7%), 55-74 years old (60.7%), married (78.6%), and were affected by obesity (39.9%). Over half (50.6%) earned less than a bachelor degree, 20.0% reported an annual household income < \$40,000, and 62.6% were not currently employed. More cancer survivors who were women, 55+ years old, married, overweight or obesity, earned less than a bachelor degree, and reported an annual household income < \$80,000 were categorized as insufficiently active/sedentary ($ps < .05$). Compared to those who were insufficiently active/sedentary, participants who reported being active were more likely to be ≥ 12 weeks post-treatment (OR=1.8), be normal weight (OR=5.261), and have earned a bachelor degree or more (OR=1.7). Findings contribute to our understanding of how to effectively use a community-engaged approach to reach rural cancer survivors. Additionally, we identified sociodemographic characteristics of rural cancer survivors who are most likely to engage in LTPA and who are at greatest risk for not meeting LTPA recommendations. Determinants identified through this study will be used to tailor recruitment and implementation of an evidence-based physical activity intervention for rural cancer survivors.

8:00 AM-9:15 AM

PREDICTORS OF CLASS ATTENDANCE OF A COMMUNITY-BASED EXERCISE PROGRAM FOR CANCER SURVIVORS

Yue Liao, MPH, PhD¹, Leticia A. Gatus, DrPH, MPH², Sara Flores³, Christine Wang³, Karen Basen-Engquist, PhD⁴¹The University of Texas MD Anderson Cancer Center, Houston, TX; ²MD Anderson Cancer Center, Houston, TX; ³University of Texas MD Anderson Cancer Center; ⁴University of Texas MD Anderson Cancer Center, Houston, TX

Background: Regular exercise and physical activity provides many physical and mental health benefits to cancer survivors. However, many cancer survivors are not active enough to achieve these health-promoting effects. Increasing efforts have been made to develop and implement community-based exercise programs for cancer survivors. Yet, few studies examined cancer survivors' characteristics that are associated with the participation in the program.

Methods: The Active Living After Cancer (ALAC) is an ongoing community-based exercise program. It is consisted of 12 weekly group sessions that include training in cognitive and behavioral skills for behavior change, brief practice of moderate-intensity physical activity, and a didactic or discussion session covering a survivorship related topics. The ALAC program works with local community partners to reach cancer survivors. Community partners also provide the health educators for program delivery and locations for conducting the group session. This study analyzed data from participants in the first two years of the ALAC program. Participants reported their demographic and cancer-related information, and answered questions regarding quality of life at baseline. They also reported their physical activity level using the International Physical Activity Questionnaire-Short Form (IPAQ-SF) before and after the program. Linear regression was used to test the association between participants' characteristics and class attendance.

Results: Participants (n=250) averaged 60 years old (SD=10.7), were 95% female, 81% overweight/obese, 55% Hispanic, 28% black, 40% with household income < \$25,001, and 75% with less than a college degree. Majority of the participants had breast cancer as the primary diagnosis (75.8%), followed by colorectal cancer (5.7%) and ovarian cancer (4.1%). Thirty-five percent participants had early stage cancer. Participants on average attended 9 classes (SD=2.4). Class attendance was positively associated with the increase in total weekly activity minutes at the end of the program ($\beta=46.21$, $p=.004$). Older participants attended more classes ($\beta=.03$, $p=.047$). Normal weight participants attended more classes compared to obese participants ($\beta=.99$, $p=.016$). Participants who rated lower on satisfaction with social roles and higher on mental health at baseline attended more classes ($ps < .05$). Class attendance did not differ by gender, racial groups, household income, education level, cancer type (breast vs. all others), cancer stage, or physical health at baseline.

Conclusion: Preliminary results from the ALAC program suggest that a diverse background of cancer survivors participated in this community-based exercise program. Group-based exercise program could be more attractive to cancer survivors who seek more social interactions.

8:00 AM-9:15 AM

REACH, ADOPTION, AND IMPLEMENTATION OF 'NURSE AMIE 2.0': A TABLET-BASED SUPPORTIVE CARE INTERVENTION FOR WOMEN WITH METASTATIC BREAST CANCER

Shawna Doerksen, PhD¹, Erica Schleicher, MS², William A. Calo, PhD, JD, MPH³, Kathryn Schmitz, PhD, MPH, FACS, FTOS³¹Penn State College of Medicine, State College, PA; ²Penn State College of Medicine; ³Penn State College of Medicine, Hershey, PA

Background: Current life expectancies for women with metastatic breast cancer (MBC) are longer now compared with 15 years ago. However, to gain these extended life expectancies, women must undergo continuous treatment, and face significant adverse cancer treatment-related symptoms and decreasing quality of life (QOL). The time spent at clinic appointments is focused on treatment versus symptoms, and traditional methods of addressing QOL require patients to attend even more in-person appointments. Women with MBC residing in medically underserved areas where in-person efforts are nearly impossible face additional barriers to care. Technology-based programs may be a suitable option to improve the reach and adoption of symptom management interventions.

Methods: We developed a tablet-based supportive care program for women with MBC. Nurse AMIE (Addressing Metastatic Individuals Everyday) is an innovative program that has the potential to reach a large proportion of women, including those in medically underserved areas. Participants are given the tablet program and are contacted by a patient navigator throughout the study. In this symposium, we will discuss reach, adoption, and implementation of Nurse AMIE in a pilot study.

Results: We were able to recruit and retain 21 women ($M_{age} = 60.86$ yrs, average 10.52 years since initial breast cancer diagnosis) into our pilot study. This equates to 80% reach, as only 20% of women who we approached declined to participate. Interestingly, all participants live in medically underserved areas. Adoption was high, as evident by the fact that participants interacted with Nurse AMIE 67.12% of days (of the women who had used Nurse AMIE for at least a month at the time of this report). Additionally, implementation of the intervention was excellent as the patient navigator who delivered the program met all weekly calls and intervention activities with nearly 100% fidelity.

Conclusion: Data suggest that women with MBC in medically underserved areas, can be effectively reached and recruited for a technology-based supportive care program, and adoption rates are high. Additionally, Nurse AMIE was implemented successfully at the organization level. These types of mHealth interventions for MBC patients may be a good solution for symptom management.

Symposium 12

8:00 AM-9:15 AM

MISINFORMATION AND MISPERCEPTIONS ABOUT TOBACCO PRODUCTS: FINDING SOLUTIONS FOR COUNTERING TOBACCO INDUSTRY TACTICS

Linda Cameron, Ph.D.¹, Pamela M. Ling, MD, MPH², Marc T. Kiviniemi, PhD CPH³, Joseph N. Cappella, PhD⁴, Geoffrey T. Fong, Ph.D.⁵¹University of California, Merced, Merced, CA; ²UCSF Center for Tobacco Control Research and Education, San Francisco, CA; ³University of Kentucky, Lexington, KY; ⁴Univ of Pennsylvania, Philadelphia, PA; ⁵University of Waterloo, Waterloo, ON, Canada

The spread of misinformation and misperceptions about cigarettes, electronic cigarettes, and other tobacco products through social and other media poses significant threats to tobacco control efforts and public health. This symposium will examine the problem of tobacco misinformation and misperceptions and consider research directions for developing innovative solutions to this growing challenge to tobacco control worldwide. The symposium will present theory and research on how people respond to misinformation about tobacco products, how to inoculate people from tobacco misinformation and misperceptions, and how to impede the spread of misinformation and misperceptions by countering the strategies of the tobacco industry. The speakers will consider these issues from multiple disciplinary perspectives including public health, medicine, social and health psychology, and communications. First, Pamela Ling will present research examining previously secret documents from the tobacco industry that reveals their strategies for fueling misperceptions of tobacco and nicotine in the general public and generating misinformation about tobacco products within the scientific community. She will discuss how these strategies have evolved over past decades and how they are currently implemented to normalize the use of nicotine and promote new products. Marc Kiviniemi will then present theory and research on the powerful role of affective processes in the spread of misinformation and misperceptions of tobacco products. He will describe how tobacco industry messaging directly targets affective processes to create misperceptions of products and how positive affective associations shape misperceptions and promote product use over and above the influence of cognitive or “fact-based” misinformation. Next, Joseph Cappella will describe multiple approaches to creating communications that can counter misinformation about tobacco products and their emotional and motivational effects. He will present research demonstrating the effectiveness of these strategies and describe contexts in which these approaches are best applied. Finally, Geoff Fong will discuss implications of the body of research for tobacco regulations and communications to counter misinformation and misperceptions propagated by the tobacco industry while providing an international perspective based on evidence from the International Tobacco Control Policy Evaluation Project. Taken together, this symposium highlights the approaches of different disciplines and how future, multidisciplinary research can yield further innovative solutions for counteracting misinformation and misperceptions.

8:00 AM-9:15 AM

TOBACCO INDUSTRY EFFORTS TO PROPAGATE MISINFORMATION AND MISPERCEPTIONS

Pamela M. Ling, MD, MPH¹¹UCSF Center for Tobacco Control Research and Education, San Francisco, CA

When faced with the evidence of the health harms of smoking, tobacco companies launched efforts to change perceptions of smoking and nicotine. This presentation will review evidence from analyses of previously secret tobacco industry documents describing tobacco industry strategies to generate misinformation about tobacco in the scientific community and misperceptions of tobacco and nicotine for the public. Tobacco companies used their own scientists and partnerships with academic institutions to generate science suggesting nicotine has benefits and to garner public health endorsement of efforts to develop “safer” cigarettes through product modification. Tobacco companies supported publications in scientific journals and scientific symposia on these topics, and some scientists solicited industry support to generate studies beneficial to the industry. The science was conducted with the public in mind, and experiments were designed (e.g., driving, piloting airplanes) that would readily translate into stories for the press. Scientific efforts were accompanied by public relations campaigns to liken nicotine to caffeine and differentiate it from addictive drugs. Complementary to the efforts to influence the scientific community, tobacco advertising strategies were used to distract and reassure consumers with health concerns. This included images that evoked positive emotions, images of scientific advancement, cleanliness, financial and social success, and positive smoking role models. Some product characteristics (e.g. reduced carcinogens, special filters) were promoted that implied safety without scientific evidence of benefit. Over time, tobacco companies changed their strategy from denial of the harms and addiction of smoking to acknowledge these dangers in order to support the promotion of new tobacco products (e.g. heated tobacco products) and electronic nicotine delivery devices. Strategies similar to past efforts are being deployed to normalize the use of nicotine and promote new tobacco products. Future implications for tobacco regulation, communication and other substances such as legalized cannabis will be discussed.

8:00 AM-9:15 AM

MOVING BEYOND “THE FACTS”: ADDRESSING AFFECTIVE FACTORS IN UNDERSTANDING AND RESPONDING TO TOBACCO INDUSTRY MISINFORMATION

Marc T. Kiviniemi, PhD CPH¹¹University of Kentucky, Lexington, KY

Misinformation presented by the tobacco industry about the risks posted by tobacco product consumption has a long history. There is a similarly long history of public health efforts to correct misperceptions caused by such misinformation and to attenuate its impact on tobacco use. Historically, both research efforts to understand misinformation and intervention efforts to address it have taken a predominantly “fact based”/cognitive lens, defining misinformation as being communication that counters accepted scientific fact about smoking harms. However, an additional core feature of nearly all tobacco industry messaging is a focus on affective associations with tobacco use, creating positive feelings associated with the act. In parallel, much of behavior is guided by affective cues over and above cognitively-based, factual constructs. This presentation will focus on a framework for considering how “mis-affecting”-- creating positive emotional associations with a behavior with substantial health risks like tobacco consumption -- shape responses to tobacco industry communications over and above cognitive misinformation. Data relevant to three core ideas will be presented. First, emotional associations with behaviors, including tobacco use behaviors, are a causal influence on behavioral decisions separate and distinct from cognitions. Second, a variety of intervention strategies can change affective associations with behaviors without the need for concomitant changes in cognitions. Third and finally, affective associations can operate to influence behavior even in situations where an individual lacks relevant domain knowledge. Each of these core ideas has direct implications for public health efforts to address and respond to industry misinformation.

8:00 AM-9:15 AM

APPROACHES TO CORRECTING MISINFORMATION ABOUT TOBACCO PRODUCTS

Joseph N. Cappella, PhD¹¹Univ of Pennsylvania, Philadelphia, PA

Advertising about tobacco products has produced a long history of misinformation about tobacco and its consequences for consumers. This misinformation calls out for correction through regulatory action and through communication campaigns to counter false and misleading beliefs. This presentation will describe approaches to messaging in service of correcting false beliefs and their emotional residue (belief echoes). The approaches considered include (1) simple correction of the misinformation (education) while avoiding repetition of the falsehood; (2) inoculation of targeted audiences in advance against specific appeals; (3) the use of narrative appeals (and testimonial examples) to reframe the misinformation in an alternative (causal) mental model; (4) value affirmation to motivate action and reduce barriers to receipt of threatening information; (5) emotional appeals to counteract residual affect from misinformation; (6) moral appeals especially ones activating moral outrage by citing self-interested deception. This overview will cite key research studies relevant to tobacco products in which each corrective strategy has been successfully deployed including some recent published and unpublished work from our TCORS projects. In addition to an illustrative study, the conditions under which each approach might be best applied will be discussed. For example, emotional appeals must be explicitly tied to the misinformation being corrected or the utility of emotional invocation will be less relevant to belief correction. Combinations of approaches will also be mentioned to describe when two or more elements can work together to enhance the impact on correction. For example, narrative and inoculation can provide engaging messages that forewarn and forearm young people about the addictive character of ENDS products. Although single no approach to correcting misinformation is fully effective in all contexts, understanding the alternatives and their conditions of application, alone and together, can enhance researchers' and regulators' tool box of interventions.

Symposium 13

8:00 AM-9:15 AM

UNDERSTANDING THE LANDSCAPE OF LONELINESS: FROM CAUSES TO DIGITAL INTERVENTIONS

Danielle Ramo, PhD¹, Lena Bertozzi, n/a², Emma Bruehlman-Senecal, PhD¹, Jana Haritatos, PhD¹, Vicky Rideout, MA³, Susannah R. Fox, BA⁴, Julianne Holt-Lunstad, PhD⁵, Kimberly S. Stevens, Clinical Psychology Doctoral Student⁶, Brock Kirwan, PHD⁵, Benjamin F. Miller, PsyD⁷

¹Hopelab, San Francisco, CA; ²Hopelab, BERKELEY, CA; ³VJR Consulting, San Francisco, CA; ⁴Internet Geologist LLC, Washington, DC; ⁵Brigham Young University, Provo, UT; ⁶UNLV, Henderson, NV; ⁷Well Being Trust, Oakland, CA

Loneliness is a prevalent public health risk among all age groups in the U.S. that is related to mental and physical health challenges including anxiety and depression, poor sleep quality, substance use, susceptibility to illness and self-harming behaviors. Now more than ever there is a need to understand contributors to loneliness, and develop innovative solutions that can act to decrease chronic loneliness and its ill effects. This symposium will present the results of three studies across the population and study design spectrum to inform our understanding of the experience of and solutions for loneliness. The first presentation is an analysis of a nationally-representative survey conducted by Hopelab and the Well Being Trust, highlighting nuanced relationships between loneliness and social media use among adolescents. The second presentation is an fMRI study of the relationship between social integration and activation in brain regions implicated in stress reactivity and regulation within a middle-aged community sample. The final talk is an intervention designed by Hopelab and Grit Digital Health called Nod, that addresses loneliness in college students by providing scaffolded opportunities for social connection. The talk will highlight the formative research to develop Nod, co-development efforts informed by lonely college students and other stakeholders, and share a novel evaluation model that includes the combination of pilot clinical trial and service design research. The discussant will highlight each presentations' contributions to our understanding of loneliness, highlight unique features across the lifespan, and the importance of using innovative strategies to impact loneliness at scale. The symposium will include dedicated time for a question-and-answer session with the panel of presenters.

TEEN LONELINESS AND SOCIAL MEDIA USE: RESULTS FROM A NATIONALLY REPRESENTATIVE SURVEY

Lena Bertozzi, n/a¹, Emma Bruehlman-Senecal, PhD², Vicky Rideout, MA³, Susannah R. Fox, BA⁴, Benjamin F. Miller, PsyD⁵, Jana Haritatos, PhD²

¹Hopelab, BERKELEY, CA; ²Hopelab, San Francisco, CA; ³VJR Consulting, San Francisco, CA; ⁴Internet Geologist LLC, Washington, DC; ⁵Well Being Trust, Oakland, CA

Introduction: Generational increases in loneliness have coincided with the saturation of social media among adolescents and young adults; yet the relationship between social media use and loneliness among young people is poorly understood. We analyzed mixed-methods data from a nationally representative survey of "digital natives" to understand linkages between loneliness and features of social media use.

Methods: From February to March 2018, a nationally-representative sample of adolescents age 14 to 22 (N=1337) completed an online survey. Items included patterns of social media use and loneliness using a short 4-item version of the UCLA loneliness questionnaire. Qualitative data included adolescents' own descriptions of their personal experiences with social media and mental health. Correlational analyses were conducted to explore quantitative relationships, and qualitative data were coded for themes.

Results: Nearly half of respondents (48%) reported sometimes or often feeling like "people were around them but not with them", and 51% said they sometimes or often "feel like no one really knows them". Older adolescents ($r = 0.23, p < .001$), LGBTQ+ youth ($r = 0.25, p < .001$), and youth experiencing greater depressive symptoms ($r = 0.56, p < .001$) had higher loneliness scores. Higher loneliness scores were not associated with more frequent social media use. However, higher loneliness scores were associated with more negative experiences on social media, including receiving negative comments on posts ($r = 0.29, p < .001$), feeling like other people are doing better than you ($r = 0.23, p < .001$), being trolled on social media ($r = 0.23, p < .001$), and deleting something you have previously posted ($r = 0.16, p < .001$). Higher loneliness scores were also associated with using social media as a way of avoiding problems ($r = 0.33, p < .001$) and preferring to communicate over social media rather than in person ($r = 0.21, p < .001$). Even so, adolescents with higher loneliness scores felt social media was more important for feeling less alone ($r = 0.22, p < .001$), and qualitatively described positive emotional experiences during social media use.

Conclusion: Although lonely adolescents are having heightened negative experiences on social media, they are still using it to achieve some social connection. This creates opportunity to reach lonely adolescents where they're engaging and provide them with resources and tools to build stronger connections.

2

8:00 AM-9:15 AM

DEVELOPING AND TESTING THE DESIRABILITY OF A DIGITAL TOOL TO ADDRESS GEN Z LONELINESS

Emma Bruehlman-Senecal, PhD¹, Danielle Ramo, PhD¹, Jana Haritatos, PhD¹¹Hopelab, San Francisco, CA

Introduction: Loneliness is a widespread and significant problem on college campuses. Prolonged loneliness in young adulthood is a risk factor for concurrent and future mental health problems, including anxiety, depression, and suicidality, as well as college dropout, making college a critical time for support. Positive psychology and cognitive behavioral interventions show promise for decreasing loneliness, and have the potential to be widely disseminated through technology. This talk describes the development of the mobile-app *Nod*, designed to address loneliness in the transition to college. It focuses on the theoretical framework guiding *Nod*'s development, and the initial feasibility and desirability testing of *Nod*.

Methods: Guided by Hopelab's 'Innovation Framework', we adopted a two-phase approach towards the development and preliminary testing of *Nod*. In phase 1, the 'Discover' phase, we sought to identify potential psychological and behavioral drivers of loneliness among college students by surveying the empirical literature, and conducting in-person and remote qualitative interviews with college students. In the beginning of stage 2, the 'Build/Test' phase, we assessed the initial desirability and feasibility of *Nod*. We drew upon multiple methods, including participant observation, focus groups, interviews, and surveys, with the aim of tailoring positive psychology and CBT interventions to meet the needs and concerns of college students and administrators.

Results: The 'Discover Phase' yielded the following three evidence-based insights that guided the design of *Nod*: 1) encourage a growth-mindset towards friendship 2) provide scaffolded opportunities for social connection 3) help students process social setbacks with compassion. Early stage co-design sessions and field testing with college students enhanced the desirability of app content, and refined our approach towards in-app gamification. Early testing with college administrators confirmed the feasibility of integrating *Nod* into existing student service systems, and yielded insights regarding reducing the burden to doing so.

Conclusion: Preliminary research demonstrates the initial desirability and feasibility of *Nod*, an evidence-based mobile app designed to decrease loneliness among college students. Further testing, including a randomized controlled pilot test, is planned for Fall 2019 to confirm the initial efficacy of *Nod*.

8:00 AM-9:15 AM

THE SOCIAL BRAIN: EXPLORING NEURAL CORRELATES OF SOCIAL INTEGRATION

Kimberly S. Stevens, Clinical Psychology Doctoral Student¹, Brock Kirwan, PHD², Julianne Holt-Lunstad, PhD²¹UNLV, Henderson, NV; ²Brigham Young University, Provo, UT

Background: Substantial evidence demonstrates that sociality predicts longevity and aspects of physical, mental, and cognitive health. This may be partially explained by social influences on stress and emotional reactions, which affect disease risk over the lifespan. Less is known about the association between quality/quantity of social networks and functional activation in brain regions implicated in plausible health pathways such as regulatory prefrontal areas and downstream paralimbic areas important for stress reactivity. We hypothesized that adults with more diverse social networks would show greater fMRI BOLD activity in regulatory prefrontal areas (particularly the anterior cingulate; ACC) lesser BOLD activity in downstream paralimbic areas important for stress reactivity (particularly the amygdala), and stronger and more inverse functional coupling between prefrontal and paralimbic areas than adults with less diverse social networks. Given much of social contact is shifting to greater "online" than "in-person" contact, we also explored possible equivalencies.

Methods: In a within-subjects design, healthy middle aged (40-65 yr-old) adult men and women (N=42) were recruited from the community. Neuroimaging data were collected via a structural scan, a multi-source interference task, and an emotional regulation task in an MRI scanner. The Social Network Index (SNI) was used to examine network size and diversity, and parallel items were included to differentiate online social contact.

Results: Regression models showed no significant association between SNI Size or Diversity scores and mean activation in ACC, Left Amygdala, or Right Amygdala during tasks of emotional regulation or stress reactivity. Exploratory analyses including online contact as measured by the SNI were also non-significant. Further, in an exploratory whole-brain analysis, there were no clusters which showed differential activation as a function of social network diversity.

Conclusion: We found no evidence that level of sociality as indexed by the SNI significantly influenced functional activation of examined brain regions during stress. More research is needed (including larger sample sizes, more diverse task sets, and non-stress related pathways) in order to better understand brain regions implicated in the health effects of sociality, and any potential moderating effects of non-proximal (online) social contact.

8:00 AM-9:15 AM

THE EFFECTS OF TRAUMA EXPOSURE ON WOMEN'S HEALTH: EXAMINATION OF NOVEL PREDICTORS AND INTERVENTIONS

Natalie R. Stevens, PhD¹, Pamela Geller, PhD², Nancy A. Hamilton, PhD³, Autumn Gallegos, PhD⁴¹Rush University Medical Center, Evanston, IL; ²Drexel University, Philadelphia, PA; ³University of Kansas, Lawrence, KS; ⁴University of Rochester Medical Center, Rochester, NY

Exposure to traumatic stress among women is a significant public health concern, given high rates of child abuse, lifetime sexual violence, and exposure to community violence. Consequences of trauma exposure are often chronic, leading to depression, posttraumatic stress disorder, substance abuse, and suicide, and are associated with poorer physical health including a range of gynecologic, sexual, gastrointestinal, sleep, and pain disorders. Thus, understanding the effects of traumatic stress on women's health is an important component of the national women's health research agenda. The 2018 Report on Research on Women's Health (National Institutes of Health; NIH) reported that women now comprise 50% of all research participants in NIH-funded clinical research, and that 39% of these women represent minority groups, marking a significant increase in the representation of women and minorities in clinical research over the last 25 years. NIH's Office of Research on Women's Health (ORWH) calls for an interdisciplinary research focus on personalized prevention, diagnostics, and therapeutics for women, as well as understanding and eliminating health disparities among populations of women defined by demographic factors. We argue that understanding and ameliorating the effects of trauma exposure on the health of women, particularly women from minority groups, is an important avenue for achieving the national scientific agenda articulated by the ORWH. In this symposium, we will focus on a broad range of issues related to trauma exposure and women's health. Topics include 1) results of an ORWH-funded project investigating the impact of community violence exposure on maternal health and racial disparities, 2) research examining the traumatic effects of perinatal loss in a socio-economically and racially diverse group of women, 3) an investigation of the impact of posttrauma nightmares on sleep and stress among sexual assault survivors, 4) and examining the efficacy of a sleep intervention to enhance recovery from intimate partner violence.

PLACE OF RESIDENCE AND MATERNAL HEALTH DISPARITIES: USING GEOGRAPHIC INFORMATION SYSTEMS (GIS) ANALYSIS TO EXAMINE WHETHER COMMUNITY VIOLENCE EXPOSURE PREDICTS PTSD AND DEPRESSION SYMPTOMS IN URBAN MOTHERS

Natalie R. Stevens, PhD¹, Teresa Lillis, PhD², Linzy Pinkerton, B.A.³¹Rush University Medical Center, Evanston, IL; ²Rush University Medical Center, Chicago, IL; ³Northwestern University Feinberg School of Medicine

Residence in low-resource neighborhoods is associated with higher rates of infant mortality and child abuse/neglect. In urban settings, women of color are more likely to live in low-resource areas, facing greater exposure to violent crime and resultant increased risk of posttraumatic stress disorder (PTSD), compared to residents living in high-resource areas. However, objective data are needed to fully characterize the association between urban violence and health outcomes using objective measures to supplement self-report. In this study we used public records and geographic information system (GIS) analyses to objectively assess violent crime exposure among urban mothers. Participants were drawn from a larger prospective study of PTSD and chronic pain. Female participants (N = 213; age: 18–41 years, M = 30.09, SD = 5.85) with at least one child under 18 years living in the home who completed a baseline assessment of trauma history and PTSD and depression symptoms were included in the analysis. The sample was comprised of mostly low-income (31% living below poverty level) women of color (71% Black/African-American, 24% Hispanic/Latina) with high rates of self-reported trauma history (94% reported at least 1 traumatic event) and exposure to multiple traumas (M = 4.70, SD = 3.16). Addresses and crime coordinates (latitude and longitude) were used for GIS analysis of violent crimes registered in a public database. Non-violent crimes were excluded. Crimes that occurred within a .25 mile radius of the participants' residence within 6 months prior to their baseline assessment were summed to create a single "crime count" variable for each participant. Results identified participants were exposed to an average of 103.96 violent crimes in the past 6 months (SD = 66.11, range 6–329). Crime count was significantly correlated with PTSD symptom severity ($r = .18$, $p < .01$) and depression symptom severity ($r = .22$, $p < .001$), but not self-reported trauma history ($r = -.04$, $p < .05$). Controlling for self-reported trauma history and socio-economic status, crime count significantly predicted both PTSD symptom severity, $F(3, 209) = 12.07$, $p < .05$ and depression symptom severity $F(3, 209) = 7.39$, $p < .001$. Black/African-American mothers were exposed to significantly more violent crimes in the past 6 months (M = 118.61, SD = 65.35) compared to White mothers (M = 67.44, SD = 52.85), $t(211) = -5.44$, $p < .01$, but race did not significantly moderate the relationship between violent crime exposure and PTSD symptom severity, $F(1, 148) = .251$, $p > .05$. Results suggest that exposure to violent crime, based on individualized objective measures, uniquely contributes to maternal PTSD and depression beyond what is captured via self-reported trauma history. Results also suggest that racial disparities in maternal PTSD may, in part, be explained by place of residence and the associated higher exposure to community violence.

8:00 AM-9:15 AM

COPING WITH PREGNANCY LOSS: A TRAUMA FOR WOMEN, A TARGET FOR MEDICAL PROVIDERS

Pamela Geller, PhD¹, Victoria Grunberg, M.S.¹

¹Drexel University, Philadelphia, PA

For the 20% of women in the United States who experience pregnancy loss, the experience can be traumatic. Factors that influence women's trauma experiences remain understudied, especially in minority populations and women with limited access to psychological treatment. The current study gleaned data from a larger investigation examining women's experiences with medical providers when coping with perinatal loss ($N = 825$; Participant age: 18 - 66 years, $M = 31.87$, $SD = 8.69$). To capture a diverse sample that has historically been excluded from pregnancy loss research, data were collected via online survey through social media outlets (e.g., Facebook, Craigslist, YouTube). This innovative method of accessing the target population permitted enrollment of a large proportion of minority women ($N = 391$; 47.40%). Results indicated that 44% ($N = 363$) of women scored in the clinically significant range for PTSD symptoms on the PTSD Checklist (PCL-5; Weathers et al., 2013). Hierarchical regression analysis indicated that when controlling for years since loss and mental health history, women with lower income, less education, and more negative religious coping reported higher levels of PTSD, $F(5, 549) = 41.14$, $p < .001$. When controlling for years since loss, education, income, age, and type of loss, women's report of experiences with medical providers explained a significant proportion of variance in PTSD symptoms, $F(6, 47) = 14.19$, $p < .001$, $R^2 = 13.5\%$. Results identify risk factors for traumatic responses following pregnancy loss; and can inform medical providers of the importance of effective communication and need to support women during this difficult time.

8:00 AM-9:15 AM

THE EFFECTS OF POSTTRAUMA NIGHTMARES ON SLEEP QUALITY AND THE STRESS RESPONSE

Nancy A. Hamilton, PhD¹, Westley Youngren, Master's Thesis², Lauren Boddy, Master's Degree¹, Megan Schulte, University student², Brooke Ostrander, Bachelors of Science², Eliza Hemmer, Bachelors of Science²

¹University of Kansas, Lawrence, KS; ²University of Kansas

Posttrauma nightmares (PNs) about sexual assault interfere with sleep and daytime functioning, even years after the initial trauma and are associated with severe psychological sequelae including suicide and substance abuse. In order to gain a better understanding of mechanisms by which these nightmares affect ongoing health, we examined PNs in college-aged female sexual assault (SA) survivors. Data included sleep diaries (6 days/nights: 146 observations) gathered from a sample of 27 women (age $M=20.5$, $SD=3.08$: 59% White, 22% Hispanic, 11% Asian, 7% African American) who reported PNs related to a SA. Participants in this study were recruited from a larger study and from community mental health care providers. Pre-sleep diaries included reports of daytime perceived stress and the presence or absence of a reminiscent-stimuli (REMSTEM; an event that reminded the individual of the SA). Morning diaries included the Pittsburgh Sleep Quality Inventory (PSQI) and reports about nightmares and other dreams. Compared to Non-Nightmare Nights (NNN), Nights on which PNs occurred (PNO) were associated with a shortened Total Sleep Time (TST; $M=72$ fewer minutes; $p < .01$) and longer Sleep Onset Latency (SOL; $NNN=30.3$ min; $PNO=62.4$ min, $p < .01$). Poor sleep quality was associated with having a PN ($p < .05$), but not a bad dream (BD) that did not produce an awakening ($p > .05$). PNs and BDs had differential effects on stress-reactivity that were not related to TST or SOL. Following a night where a PN occurred and an individual experienced a REMSTEM during the day was associated with higher levels of stress at bedtime ($B=2.65$, $p < .05$). In contrast, following a night with a BD, encountering a REMSTEM was associated with lower levels of stress at bedtime. These data suggested that the toxicity of nightmares might be because of their pervasive effect on daytime and nighttime psychological functioning, affecting sleep itself (TST, SOL), perceived sleep quality, and the perceived ability to respond effectively to a "triggering" stimulus.

8:00 AM-9:15 AM

QUALITY OF LIFE AND SLEEP OUTCOMES AMONG WOMEN SURVIVORS OF INTERPERSONAL VIOLENCE: RESULTS FROM A RANDOMIZED CLINICAL TRIAL OF COGNITIVE-BEHAVIORAL THERAPY FOR INSOMNIA TO INCREASE EFFICACY OF PTSD TREATMENT

Autumn Gallegos, PhD¹, Kathi L. Heffner, PhD¹, Catherine Cerulli, J.D., Ph.D.², Wilfred Pigeon, PhD³

¹University of Rochester Medical Center, Rochester, NY; ²University of Rochester Medical Center; ³Veteran Affairs, Canada, igauga, NY

Exposure to interpersonal violence (IPV)-related traumas (including violence between family members, intimate partners, acquaintances or strangers, including sexual assault) disproportionately affects women and is associated with deleterious mental and medical health comorbidities, including posttraumatic stress disorder (PTSD), major depressive disorder (MDD), insomnia, and diminished quality of life. In the U.S., nearly 1 in 5 women report sexual violence by any perpetrator and 1 in 3 women have experienced sexual violence, physical violence, or psychological aggression by an intimate partner. In a randomized clinical trial of sequentially-delivered insomnia and trauma-focused PTSD treatment (cognitive behavioral therapy for insomnia [CBTi] and cognitive processing therapy [CPT], respectively) for IPV survivors, we found that the addition of insomnia treatment improved insomnia and depression outcomes, but effects on PTSD were modest and non-significant. In this secondary analysis of trial data, we examined whether the addition of insomnia treatment to PTSD intervention affected IPV survivors' quality of life, and the potential role of two important sleep-related contributors to well-being, slow wave sleep (SWS) and rapid eye movement (REM) sleep. In all, 110 participants were randomized (56 to CBTi + CPT; 54 to Control + CPT) and 61 participants were included in the current analysis (37 in CBTi + CPT; 24 in Control + CPT). Assessments, including the WHO Quality of Life (WHOQOL) scale and overnight sleep measures from polysomnography (REM arousals per hour of REM sleep and total SWS minutes), occurred at baseline (T1), after CBTi/Control (T2), and after CPT (T3). General linear models with repeated measures tested time x group interactions from T1-T3 for WHOQOL, REM sleep arousals, and SWS. A significant effect was found on overall quality of life among CBTi + CPT participants, $F(1.70, 100.55) = 4.05$, $p < .05$. There were no significant differences between groups for REM sleep arousals or SWS. Compared to delivering the trauma treatment without addressing insomnia, the use of CBTi in addition to CPT improved quality of life among survivors of violence.

INNOVATIVE INTERVENTIONS TO IMPROVE HEALTH OUTCOMES AMONG SEXUAL AND GENDER MINORITY YOUTH: FROM CONCEPTUALIZING TO TESTING

Sophia Choukas-Bradley, Ph.D.¹, Cesar G. Escobar-Viera, PhD, MD¹, James Egan, PhD, MPH¹, Erin A. Vogel, PhD², Sabrina Ford, PhD³, Sherry Pagoto, PhD⁴

¹University of Pittsburgh, Pittsburgh, PA; ²Stanford University, Stanford, CA; ³Michigan State University, East Lansing, MI; ⁴University of Connecticut, Storrs, CT

Sexual and gender minority (SGM) youth and emerging adults face well-established disparities in a number of mental health and substance use outcomes, many of them related to societal rejection and discrimination. While some digital health and social media health interventions to improve mental health and substance use outcomes exist, very few have been developed with SGM youth in mind. This is a crucial gap because of the unique developmental characteristics and stressors SGM youth face. Interventions that seek to address health disparities among SGM youth should consider these characteristics and stressors. The goal of this symposium is to share the process of conceptualizing, developing, and testing technology-delivered behavioral interventions focused on SGM adolescents and emerging adults. First, Dr. Choukas-Bradley will describe results of two mixed-methods studies focused on mental and behavioral health to provide insights about (a) unique needs of SGM youth with regard to development, identity concerns, and relationships; and (b) optimization of developmentally sensitive social media interventions for this group. Dr. Escobar-Viera will then share the development process and preliminary acceptability results of a social media-delivered intervention to reduce social isolation among rural SGM youth. Next, Dr. Egan will describe feasibility testing results for a web-based game to improve help-seeking behavior and coping among SGM youth. Finally, Dr. Vogel will present 3- and 6-month outcomes of a social media-delivered smoking cessation intervention tailored for SGM emerging adults. Speakers will emphasize the theoretical foundation of the relation between intervention components and expected outcomes. Dr. Sherry Pagoto will integrate the speakers' findings and discuss their implications for the advancement of internet and social media-delivered behavioral interventions and for improving health outcomes among SGM adolescents and emerging adults.

DEVELOPMENTAL AND INTERPERSONAL CONTEXTS OF SEXUAL AND GENDER MINORITY YOUTH: INSIGHTS FOR INTERVENTION DEVELOPMENT

Sophia Choukas-Bradley, Ph.D.¹, Michael P. Marshal, PhD², Brian Thoma, PhD³, Rachel Salk, PhD³, Tina Goldstein, PhD³, Michele D. Levine, PhD³

¹University of Pittsburgh, Pittsburgh, PA; ²University of southern California; ³University of Pittsburgh

Sexual and gender minority youth (SGMY) report disproportionately high rates of mental and behavioral health problems when compared to their cisgender heterosexual peers. While these disparities are well-documented, less is known about the specific developmental and interpersonal contexts that may contribute to elevated mental health concerns among SGMY. Online research and social media-delivered interventions offer a promising avenue to reach SGMY, many of whom may not be able to participate in traditional research studies or interventions.

This presentation offers insights about SGM adolescents' developmental and interpersonal contexts, gleaned from two recent mixed-methods studies of U.S. SGMY. The first study included in-person qualitative interviews with nine GM youth, and an anonymous nationwide online survey with over 1,900 GMY. This study examined a broad range of mental and behavioral health symptoms, as well as social media use, peer and family relationships, and GM-specific identity development. The second study involved in-person qualitative interviews and quantitative surveys with 20 SGMY in treatment for bipolar disorder. Interviews focused on adolescents' experiences at the intersection of SGM identity, mood symptomatology, suicidality, and behavioral health, with an emphasis on relationships with parents, peers, and romantic partners.

Key insights will be discussed regarding the developmental and interpersonal context of SGMY, which can inform intervention development. For example, adolescence is a developmental period during which youth are typically dependent on parents for basic needs, while also heavily influenced by peers and romantic partners. Our data revealed unique stressors in SGMY relationships with parents, peers, and romantic partners. For many adolescents, interactions with peers occur largely online, and for SGMY, social media offers a double-edged sword. Qualitative interviews highlighted that social media can provide an opportunity to connect with and receive support from other SGM peers, paired with risks of peer victimization or negative feedback. Similarly, social media-delivered interventions for SGMY offer both great promise and unique challenges—providing the ability to reach SGMY who may not otherwise be reachable (e.g., those who are rural or not “out” to parents), and to connect SGMY with one another, while also raising ethical and practical challenges. Implications for intervention development will be discussed.

8:00 AM-9:15 AM

A SOCIAL MEDIA INTERVENTION TO REDUCE SOCIAL ISOLATION AMONG RURAL SEXUAL AND GENDER MINORITY YOUTH: STUDY DESIGN AND PRELIMINARY ACCEPTABILITY

Cesar G. Escobar-Viera, PhD, MD¹, Jaime E. Sidani, PhD, MPH, CHES¹, Ariel Shensa, MA¹, Sam Shaaban, MS², Sophia Choukas-Bradley, Ph.D.¹, Bruce Rollman, MD, MPH¹

¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh

Introduction: Sexual and gender minority youth (SGMY) are at higher risk of social isolation and depression than cisgender heterosexual youth. For rural SGMY, this risk is even higher. While family and school connections protect heterosexual youth from depression, these may not be as available for rural SGMY. Indeed, reducing social isolation and increasing access to SGM-specific mental health resources are top needs of rural SGMY. Many of them turn to social media (SM) for resources/support perceived as unavailable in their surroundings. However, SM can also be a conduit for negative experiences, potentially increasing risk of negative outcomes. We seek to reduce rural SGMY social isolation by developing educational modules to help them take advantage of SM positive aspects while reducing risk of negative interactions. Next, we applied principles of human-centered design (HCD) to guide the development of a SM-based intervention to deliver these modules to SGMY.

Methods: Our study comprises a theory-driven, user-informed development, acceptability evaluation, and usability testing of: (1) educational modules and (2) a social media-based delivery tool. For both components, we use an iterative sequence of expert input, development, and participant feedback via 4 rounds of video-recorded online interviews with 40 rural SGMY ages 14–19 recruited from SM. We collect feedback on intervention content and activities as well as design, aesthetics, features, functionality, ease of use, content relevance, and intervention acceptability.

Results: We identified 5 key SM use behaviors (e.g., passive use, negative interactions) consistently associated with social isolation and depression. These behaviors informed the development of 5 SGMY-specific educational modules based on the motivational theory of life-span development and focused on optimizing SM use to reduce social isolation. This presentation will include preliminary results from content and thematic analysis of qualitative data obtained from the video interviews and descriptive statistics for preliminary acceptability.

Conclusions: This is the first study that leveraged HCD to develop and test the acceptability of a SM-delivered intervention focused on reducing social isolation among rural SGMY. While data are still being collected and final results not yet available, we will share insights and lessons learned regarding online recruitment of this population and implementation of HCD techniques for research.

3

8:00 AM-9:15 AM

FEASIBILITY OF A WEB-ACCESSIBLE GAME-BASED INTERVENTION AIMED AT IMPROVING HELP SEEKING AND COPING AMONG SEXUAL AND GENDER MINORITY YOUTH: RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

James Egan, PhD, MPH¹, Matthew DeLucas, BS², Brooke A. Morrill, PhD², Mark S. Friedman, PhD³, Stephanie Corey, M.P.H.³, Emmett Henderson, M.S.³, William Louth-Marquez, MD³, Elizabeth Miller, M.D., Ph.D.⁴, Kimberly Hieftje, Ph.D.⁵, Robert Coulter, Ph.D.³, Dorothy Espelage, Ph.D.⁶, Simon Hunter, Ph.D.⁷, Kaleab Abebe, Ph.D.³

¹University of Pittsburgh, Pittsburgh, PA; ²Schell Games; ³University of Pittsburgh; ⁴Children's hospital of Pittsburgh, Pittsburgh, PA; ⁵Yale University; ⁶University of North Carolina at Chapel Hill; ⁷School of Psychological Sciences and Health, University of Strathclyde, Glasgow, United Kingdom

Introduction: Sexual and gender minority youth (SGMY; e.g., lesbian, gay, bisexual, and transgender youth) experience myriad health disparities compared with their non-transgender heterosexual peers. Despite much research showing these disparities are driven by experiences of bullying and cyberbullying victimization, few interventions have aimed to improve the health of bullied SGMY. One possible way to improve the health of bullied SGMY is via a Web-accessible game intervention. Nevertheless, little research has examined the feasibility of using this kind of intervention with SGMY. We tested the feasibility of a game-based intervention for increasing help-seeking and productive coping skills among SGMY. Primary hypotheses were high levels of implementation fidelity, game demand, and game acceptability.

Methods: We conducted a 2-arm randomized controlled trial (RCT) testing a theory-based, community-informed, Web-accessible computer role playing game intervention. Control condition received a list of resources. Participants completed online surveys at enrollment and 1 and 2-months after intervention delivery. Our primary outcomes were: implementation procedures; game demand; and game acceptability, measured by the valid multidimensional Gaming Experience Questionnaire. We tested hypotheses using a priori benchmarks for feasibility success.

Results: Regarding implementation, 240 SGMY aged 14–18 were randomized into the intervention (n=120) or control (n=120) conditions. All participants completed the baseline survey, 73.3% completed the 1-month follow up, and 64.2% completed the final follow up. Regarding game demand, after enrollment 55.8% of intervention participants successfully downloaded the game, all of whom reported playing it. Of those who played the game, 46.2% reported having a desire to play it again and 50.8% would recommend it to friends. Regarding game acceptability, game-playing participants exceeded hypothesized benchmarks and reported high positive affect (M=2.36; 95% CI=2.13–2.58), low negative affect (M=2.75; 95% CI=2.55–2.95), low tension/annoyance (M=3.19; 95% CI=2.98–3.39), and high competence (M=2.23; 95% CI=2.04–2.43) while playing the game.

Conclusions: We successfully implemented a Web-accessible game RCT with SGMY. Though the demand for the game was lower than anticipated, SGMY found the game to be highly acceptable. A larger scale trial is needed to test whether the game-based intervention can reduce health problems for SGMY.

DIGITAL SMOKING CESSATION INTERVENTIONS FOR SEXUAL AND GENDER MINORITY YOUNG ADULTS: OUTCOMES OF TAILORED AND NON-TAILORED INTERVENTIONS

Erin A. Vogel, PhD¹, Danielle E. Ramo, PhD², Judith J. Prochaska, PhD, MPH¹, Meredith C. Meacham, PhD, MPH², Gary L. Humphreys, PhD²¹Stanford University, Stanford, CA; ²University of California, San Francisco

Introduction: Sexual and gender minority (SGM) individuals have higher smoking and social media use prevalence than their non-SGM peers. We tested 3-month and 6-month versions of the Put It Out Project (POP), a Facebook smoking cessation intervention culturally tailored to SGM young adults.

Methods: Participants were SGM-identified young adult smokers (age 18-25) recruited from Facebook for 3-month (POP-3; N=165) and 6-month (POP-6; N=137) pilot clinical trials. Interventions delivered weekly live counseling sessions and 90 daily Facebook posts to participants in groups individually-tailored to readiness to quit smoking. Analyses compared biochemically verified abstinence, self-reported 7-day point prevalence abstinence, reduction in cigarettes per week by 50+% from baseline, making a quit attempt during treatment, and stage of change between groups at 3-month and 6-month follow-ups. Analysis A compared outcomes between SGM participants who received a 3-month tailored intervention (POP-3), a 3-month non-tailored intervention (NT-SGM), and two historical control conditions. Analysis B examined effects of intervention duration (3 months vs. 6 months) and tailoring (tailored vs. non-tailored) among participants in the POP-3 and POP-6 trials.

Results: Biochemically verified smoking abstinence did not significantly differ between groups, potentially due to challenges with remote biochemical verification (e.g., non-response, nicotine exposure from e-cigarettes). In Analysis A, POP-3 participants were more likely than NT-SGM participants to report abstinence at 3 (23.8% vs. 12.3%; OR=2.50; p=.03) and 6 months (34.5% vs. 12.3%; OR=4.06; p<.001) and reduction in smoking at 3 months (52.4% vs. 39.5%; OR=2.11; p=.03). POP-3 participants were also more likely to report abstinence at 3 months (23.8% vs. 3.3%; OR=6.67, p=.01) and 6 months (34.5% vs. 13.3%; OR=2.78; p=.03) and reduced smoking at 3 months (56% vs. 41.7%; OR=2.70, p=.01) than SGM participants in a historical control condition who received a referral. In Analysis B, tailored interventions resulted in greater likelihood of reported abstinence (Wald chi-square=6.57, p=.010) regardless of duration, and 6-month interventions resulted in greater likelihood of reduced smoking (Wald chi-square=9.49, p=.002).

Conclusions: Findings preliminarily support the effectiveness of a Facebook smoking cessation intervention tailored to SGM young adults. Three months appears sufficient to increase likelihood of abstinence.

HEART DISEASE SELF-CARE

Kenneth E. Freedland, PhD¹, Linda Park, PhD, MS, FNP-BC, FAHA², Judith Skala, PhD, RN³, Barbara Riegel, PhD, RN, FAHA, FAAN⁴, Lora Burke, PhD, MPH, RN, SBM, FAHA, FAAN⁵¹Washington University School of Medicine, Saint Louis, MO; ²University of California, San Francisco, San Francisco, CA; ³Washington University School of Medicine, St. Louis, MO; ⁴University of Pennsylvania, Philadelphia, PA; ⁵University of Pittsburgh, Pittsburgh, PA

Self-care is an umbrella term for a wide range of behaviors that can help to prevent the onset or worsening of chronic diseases or that enable patients to manage their illnesses. Self-care is also relevant to caregivers, many of whom have chronic diseases of their own. Coronary heart disease, heart failure, and other forms of heart disease can impose substantial self-care burdens on patients and caregivers, and a variety of psychosocial, medical, and practical barriers can make it difficult to maintain adequate heart disease self-care. This is a clinically significant problem because inadequate self-care predicts adverse outcomes such as increased risk of rehospitalization in patients with heart disease. Unfortunately, the interventions for heart disease self-care that have been tested so far have met with limited success. Consequently, further research is needed on factors that affect heart disease self-care and on interventions to improve it. This symposium addresses several aspects of heart disease self-care. First, Dr. Linda Park will discuss emerging applications of mobile health (mHealth) strategies to improve self-care in patients with heart disease. Second, Dr. Judith Skala will present the self-care outcomes of a randomized controlled trial of cognitive behavior therapy for major depression in patients with heart failure. Third, Dr. Barbara Riegel will present the design of a recently-funded trial of a self-care intervention for caregivers of patients with heart failure. Finally, Dr. Lora Burke will discuss issues that cut across these three presentations and identify some priorities for heart disease self-care research.

CORRESPONDING AUTHOR: Kenneth E. Freedland, PhD, Washington University School of Medicine, Saint Louis, MO; freedlak@wustl.edu

THE PROMISE OF MOBILE HEALTH TO PROMOTE SELF-CARE OF CORONARY HEART DISEASE

Linda Park, PhD, MS, FNP-BC, FAHA¹¹University of California, San Francisco, San Francisco, CA

Background: Mobile phones are the most commonly used form of technology worldwide and have the potential to promote cardiovascular outcomes. The widespread use of mobile phones has made mobile health (mHealth) a promising solution to advance self-care of coronary heart disease (CHD), which includes supporting health-promoting activities as well as managing illness.

Objective: The aim of this presentation is to outline mHealth strategies that have been applied for self-care of CHD and discuss their efficacy to improve outcomes.

Methods: This is a literature search of clinical trials related to CHD from a comprehensive search of databases from 2000-2019. All articles related to self-care behaviors and CHD were included. The selected studies were critically evaluated to extract and summarize pertinent characteristics and outcomes.

Results: All 18 studies demonstrated text messaging, mobile applications (apps), or a combination of text messaging and mobile apps were effective in improving outcomes. Outcomes of included studies were physical activity, medication adherence, cardiovascular risk profiles (blood pressure, lipids, hemoglobin A1C, smoking cessation body mass index), peak VO₂, quality of life, functional status, and diet. Key factors of success included personalized messages with tailored advice, greater engagement (2-way text messaging, higher frequency of messages), and use of multiple modalities.

Conclusion: Incorporating principles of behavioral activation help promote and sustain healthy lifestyle behaviors in patients with CHD that result in improved clinical outcomes. mHealth strategies have strong potential for improving clinical outcomes; however, long-term efficacy is unknown. Although highly promising, more research is required to determine conclusive results as well as recommendations on clinical implementation.

8:00 AM-9:15 AM

SELF-CARE OUTCOMES OF CBT FOR DEPRESSED PATIENTS WITH HEART FAILURE

Judith Skala, PhD, RN¹¹Washington University School of Medicine, St. Louis, MO**Background:** Depression is a potentially treatable barrier to effective self-care of heart failure.**Objectives:** Our group conducted a randomized controlled trial of a cognitive-behavioral intervention for major depression in 158 outpatients with heart failure. The intervention targeted heart failure self-care deficits in addition to depression. Compared to participants who were randomized to usual care, those in the intervention arm had significantly lower post-treatment scores on the Beck Depression Inventory (BDI-II), but the groups did not differ on the Self-Care of Heart Failure Confidence and Maintenance subscales. Since there was considerable variability in heart failure self-care at baseline, we compared the demographic, medical, and psychosocial characteristics of subgroups classified as exhibiting relatively good vs. relatively poor self-care at baseline.**Methods:** This was a single-blind, randomized controlled trial. Depression at 6 months was the primary outcome; heart failure self-care was a secondary outcome.**Results:** The subgroups did not differ on baseline severity of depression but they did differ on several other characteristics. Self-care confidence improved in participants with poor self-care at baseline but not in those with good self-care at baseline. Self-care maintenance did not improve in either subgroup. We also examined the relationships among changes in self-care from the baseline to the post-treatment evaluation and changes in measures of depression, anxiety, physical and social functioning, and quality of life. Improvement in depression was associated with improvement in self-care confidence ($b=-0.14$, $p=0.0005$) and maintenance behaviors ($b=-0.20$, $p=0.007$).**Conclusions:** These results suggest that although depression does not account for the initial presence of self-care deficits, HF self-care tends to improve in parallel with decreases in depression severity when patients are treated for major depression. However, further research is needed to develop a more efficacious intervention for heart failure self-care deficits in depressed patients.

HEALTH COACHING TO IMPROVE SELF-CARE OF INFORMAL CAREGIVERS OF ADULTS WITH CHRONIC HEART FAILURE (ICARE4ME): STUDY PROTOCOL FOR A RANDOMIZED CONTROLLED TRIAL

Barbara Riegel, PhD, RN, FAHA, FAAN¹¹University of Pennsylvania, Philadelphia, PA**Background:** Persons with chronic heart failure (HF) are living longer. These patients typically live in the community and are cared for at home by informal caregivers. These caregivers are an understudied and stressed group.**Objectives:** The purpose of this two-arm, randomized controlled trial is to test the efficacy of a virtual health coaching intervention on the self-care of HF caregivers. We will (1) compare efficacy of the intervention vs. health information in improving self-care, and (2) estimate the cost and cost-effectiveness of the intervention. An exploratory aim is to examine the effect of caregiver outcomes on HF patient outcomes.**Methods:** A consecutive sample of 250 caregivers of adults with chronic HF is being enrolled from clinic and hospital settings at an institution in the north-eastern US. Both groups receive tablets programmed to provide standardized health information. In addition, the intervention group receives 10 live coaching sessions delivered virtually by health coaches using the tablets. The intervention is evaluated at 6-months, with self-care as the primary outcome. Cost-effectiveness of the intervention is evaluated at 12-months. We are enrolling HF patients (dyads) whenever possible to explore the effect of caregiver outcomes (self-care, stress, coping, health status) on HF patient outcomes (number of hospitalizations and days in the hospital) at 12-months.**Results:** To be determined.**Conclusions:** We expect the proposed study to require 5 years for completion. If shown to be efficacious and cost-effective, our virtual health coaching intervention can easily be scaled to support millions of caregivers worldwide.

8:00 AM-9:15 AM

TO END THE HIV EPIDEMIC, WE MUST CONSIDER INTERSECTIONAL APPROACHES TO HEALTH FOR SEXUAL AND GENDER MINORITIES OF COLOR

Latesha Elopore, MD, MSPH¹, Katherine G. Quinn, PhD², Eric K. Layland, MS³, Oni Blackstock, MD, MHS⁴¹University of Alabama at Birmingham, Birmingham, AL; ²Center for AIDS Intervention Research, Medical College of Wisconsin, Milwaukee, WI; ³Pennsylvania State University, University Park, PA; ⁴New York City Department of Health and Mental Hygiene, New York, NY

Rates of HIV diagnoses stabilized over the last decade, however, some groups continue to experience greater rates of HIV infection and inordinate barriers to care. Despite advances in biomedical intervention to prevent HIV (i.e., pre-exposure prophylaxis, PrEP), HIV infection rates remain disproportionately high among Black and Latinx men who have sex with men (MSM) and transwomen (TW). The national initiative to end the HIV epidemic in the US requires focusing on populations where HIV burden is greatest. We use an intersectional framework to investigate diverse, multi-level determinants of health and HIV prevention among Black and Latinx MSM and TW in HIV high-burden areas.

Abstract 1: For Black MSM in the Deep South, a conservative environment converges with personal challenges to acceptance and expression. In-depth interviews uncovered unique, cultural challenges to identity affirmation, social network value in supporting identity validation, and social network composition complexity. Black women were identified as key players in the social support of Black MSM. Engaging Black MSM in HIV prevention in the Deep South will be improved when these intersecting cultural and social factors are considered.

Abstract 2: An intersectional approach to syndemic theory considers how inequity and oppression experienced by Black gay and bisexual men (GBM) and TW contributes to multiple, converging health burdens. Results demonstrate how intersections of racism, homonegativity, and structural disadvantage among Black GBM and TW influence syndemic conditions including HIV risk. Future application of syndemic theory will be enhanced by considering the impact of intersectional stigma uncovered in this study.

Abstract 3: Inequitable distribution of PrEP services creates structural barriers to HIV prevention among MSM. Geo-spatial mapping of MSM mobile app users revealed inequitable distribution of PrEP services by race/ethnicity, age, and neighborhood. Black, Latino, and Asian MSM were further from PrEP services than White MSM. In neighborhoods with more MSM of color, resources were more limited. These results support the need to consider both individual and structural factors influencing HIV prevention.

The HIV epidemic cannot be ended without centering the experiences of Black and Latinx MSM and TW. Effective intervention is only made possible by acknowledging and addressing intersectional stigma interlocked with structural and social barriers to HIV prevention.

TO ADEQUATELY INCREASE UPTAKE OF PREP AMONG YOUNG BLACK MEN WHO HAVE SEX WITH MEN, MORE EMPHASIS IS NEEDED ON INTERVENTIONS TO INCREASE ACCEPTANCE OF SEXUAL IDENTITY

Latesha Elopore, MD, MSPH¹, Sophia Hussen, MD, MPH², Corilyn Ott, PhD³, Michael Mugavero, MD, MHSc⁴, Janet M. Turan, PhD, MPH⁴¹University of Alabama at Birmingham, Birmingham, AL; ²Emory University; ³University of Alabama at Birmingham; ⁴University of Alabama at Birmingham, Birmingham, AL

Background: The potential to end the HIV epidemic is possible with scientific advances in treatment and prevention of infections among those at highest risk. However in the United States, inequities in infection rates are evident among sexual and racial minority populations, especially Young, Black Men who Have Sex with Men (YBMSM) living in the South. These disparities may be amplified due to disparate utilization of biomedical prevention tools like HIV preexposure prophylaxis (PrEP). Previous in-depth interviews (N = 47) with YBMSM elucidated that intersectional stigma related to race and sexual orientation contextualized in a socially conservative, Southern state was a major barrier to accessing PrEP due to inability to personally accept and freely express sexual identity. As a way forward, we explored potential sources of social support among YBMSM to gain self-acceptance of sexual identity.

Methods: Twenty-five In-depth interviews were conducted with YBMSM using constructs from the Anderson's Behavioral Healthcare Utilization Model (ABM). Inclusion criteria: 1) HIV- negative infection status 2) Cis-gender men with self-reported sex with men (in the past 6 months), 3) African American, 4) English speaking, 5) Age 16-29 years. Coding and analyses were conducted with NVivo software. A preliminary coding scheme was created for first-level analysis based on ABM constructs. Then based on this analysis, more refined second-level coding was conducted.

Results: The median age of participants was 24, with two-thirds reporting having a regular source for healthcare. Common emerging themes were the following: 1) Cultural norms within Southern, Black communities hindered acceptance of sexual identity; 2) Social-support networks facilitated self-validation of sexual identity and; 3) Social support networks were often complex in composition. Within each theme, we discovered several subthemes related to the critical role Black women play in social support networks.

Conclusions: As we move the Ending the HIV Epidemic national public health initiative forward, it is vital to understand the critical steps necessary for largely disenfranchised populations to utilize HIV prevention strategies like PrEP. Results presented have been used to inform quantitative survey development in a mixed methods study to evaluate generalizability among YBMSM in the Deep South. Preliminary results suggests intersectional stigma among YBMSM living in the South must be addressed to reach this national goal.

8:00 AM-9:15 AM

AN INTERSECTIONAL UNDERSTANDING OF SYNDEMICS EXPERIENCED BY YOUNG BLACK GAY AND BISEXUAL MEN

Katherine G. Quinn, PhD¹, Erika Christenson, MPH², Jeffrey A. Kelly, PhD³, Yuri Amirkhanian, PhD³¹Center for AIDS Intervention Research, Medical College of Wisconsin, Milwaukee, WI; ²Medical College of Wisconsin; ³Medical College of Wisconsin, Milwaukee, WI

Background: Syndemic theory has been useful in illuminating the co-existence and reinforcing nature of multiple health and social conditions that contribute to HIV risk. However, one critique of syndemic research has been its tendency to focus on gay and bisexual men (GBM) as a homogeneous population, with little attention to power and oppression along the axes of race, ethnicity, class, or sexual and gender identity. Applying an intersectional framework to syndemics can help demonstrate how social and structural inequities and oppressions facing young Black GBM contribute to and reinforce syndemic health conditions. The current study aimed to characterize and understand syndemics among young Black GBM by incorporating an intersectionality framework.

Methods: In 2018, we conducted 50 in-depth qualitative interviews with a conveniences sample of young Black GBM in Milwaukee, WI and Cleveland, OH. Participants were 18 years of age or older, Black or African American men or trans women, and gay, bisexual, or same-gender-loving. Transcribed interviews were coded using a multi-stage analytic coding strategy in MAXQDA qualitative analysis software. We used thematic content analysis to characterize syndemics and intersectional stigma among this sample and examine how intersectional stigma influences syndemic conditions experienced by Black GBM.

Results: Our results demonstrate how racism, homonegativity, and structural disadvantage contribute to syndemic conditions of childhood trauma, depression, substance use, and HIV risk experienced by Black GBM. Our results highlight the nature of intersectional racism and homonegativity in participants' lives, and the expectations of masculinity and structural disadvantage faced by many Black GBM. We then demonstrate how these experiences of intersectional stigma influences the syndemic conditions of childhood trauma, mental health, substance use, and HIV risk. Excerpts from interviews are used to illustrate these themes and demonstrate the importance of incorporating an intersectional lens to understand syndemics among Black GBM.

Conclusions: This study demonstrates that broader systems of oppression and disadvantage facing young Black GBM contribute to syndemic conditions. Future conceptualizations and measurements of syndemics must capture these experiences to strengthen our understanding of syndemics among young Black GBM.

8:00 AM-9:15 AM

MAPPING INEQUITABLE DISTRIBUTION OF HIV PREVENTION RESOURCES BY RACE/ETHNICITY, NEIGHBORHOOD, AND AGE AMONG MEN WHO HAVE SEX WITH MEN

Eric K. Layland, MS¹, Lik Sam Chan, PhD², Eliza Cassidy, PhD³, Joshua Rosenberger, PhD⁴¹Pennsylvania State University, University Park, PA; ²Chinese University of Hong Kong; ³Queensland University of Technology; ⁴The Pennsylvania State University, University Park, PA

Introduction: Black and Latino men who have sex with men (MSM) disproportionately constitute the majority of new HIV diagnoses. Access to HIV/STI testing and pre-exposure prophylaxis (PrEP) reduces HIV infection risk. However, the location of these resources may not be equally accessible to all MSM, creating subgroups of MSM, often clustered by race/ethnicity, who are at greater risk due in part to limited access to preventative services.

Methods: In November, 2018, profile content and geo-location data were collected from Asian, Black, Latino, and white MSM users of a social and sexual networking mobile application in New York City ($n = 1,692$) and Los Angeles ($n = 1,116$). In each city, user location was mapped and stratified by race/ethnicity then PrEP service locations were subsequently overlaid, and, finally, distances between users and nearest PrEP location were estimated in miles. Regression was used to estimate associations of race/ethnicity, age, and neighborhood with distance to nearest PrEP services.

Results: Overall differences based on race/ethnicity, age, and neighborhood were seen in both cities, with city maps illustrating different proportions of PrEP services and racial/ethnic distribution. In Los Angeles, white MSM were 0.12 to 0.17 miles closer than other MSM to the nearest PrEP services. MSM in south LA, who were predominantly Black, were furthest from PrEP services. In New York, Asian MSM were 0.26 to 0.32 miles further from PrEP services than all other groups, however, within boroughs, Black MSM and Asian MSM were further from PrEP services than white MSM. In both cities, the youngest and oldest men were furthest from PrEP services.

Conclusion: Results of this study highlight potential structural inequities in healthcare access among MSM in Los Angeles and New York. Geo-spatial mapping provides an opportunity to visualize data to understand demographic differences across locations and identify where service needs may be unmet. Future consideration should be given to the characteristics and distribution of MSM when determining where to provide HIV/STI prevention, with a particular focus on race/ethnicity.

Paper Session 1

10:45 AM-11:00 AM

MODELLING MULTIPLE HEALTH BEHAVIOR CHANGE WITH NETWORK ANALYSES: RESULTS FROM A ONE-YEAR TRIAL CONDUCTED AMONG OBESE ADULTS

Guillaume Chevanec, PhD¹¹University of California, San Diego, San Diego, CA

Introduction: health behavior change is a key component of weight management strategies in overweight and obese adults. Improving physical activity, diet, and sleep behaviors reduces weight and improves overall health among adults with obesity. However, it is unclear whether interventions should target these behaviors individually or together in some combinations, and if the latter, which combinations actually promote successful behavior change. The first objective of this study was to examine the between-person patterns of associations between seven self-reported health behaviors measured over one year among overweight and obese adults who participated in a weight loss intervention. The second objective was to assess how these behaviors covary within-individuals across the intervention. Unique to our study, we analyzed behavioral associations using network analyses. Comparing to cluster analyses and mixed-model analyses, this statistical approach offers a unique ability to efficiently visualize, understand and compare the associations and covariations between behaviors.

Method: the present study included data from a 12-month intervention (N = 278). Seven health behaviors (physical activity, sedentary behavior, sleep duration, and consumption of fruits, vegetables, total fat and added sugar) were measured (i.e., via self-reported questionnaires) at baseline, 6 and 12-months. Between- and within-participant network analyses were conducted to examine how these behaviors were associated through the 12-month intervention and covaried across months.

Results: Participants (N = 278, 260, and 253 at baseline, 6-month, and 12-month visits) were 77% male, 41% Hispanic, 44% college graduate or higher, and 22% unemployed. Participants were on average 41.7 (SD = 11.1) years old and had a mean BMI of 32.7 (SD = 3.4) kg/m². At the between-participant level, over the 1-year intervention, associations were found within (i) diet behaviors, (ii) between diet and sedentary behavior and (iii) between sugar and sleep. At the within-participant level (i.e., covariations over months), associations were found (i) between sedentary and diet behaviors, and (ii) within diet behaviors.

Discussion: The findings from our study, and especially those related to the covariations between behaviors suggest that successful weight loss interventions will need, first, to simultaneously target sedentary and diet behaviors, as there are likely to co-vary within-individuals; and, second, address compensatory behaviors (e.g., eating dessert to reward oneself for eating more vegetables) in the diet domain.

11:00 AM-11:15 AM

A LOW-TOUCH ACT-BASED INTERVENTION TO INCREASE MVPA AMONG INACTIVE ADULTS WITH OVERWEIGHT/OBESITY

Jason Lillis, Ph.D.¹, Dale Bond, Ph.D.², Graham Thomas, Ph.D.²¹Brown Medical School, Roseville, CA; ²Brown Medical School, Providence, RI

Despite the importance of adoption of habitual moderate to vigorous-intensity physical activity (MVPA) for health benefits and long-term weight management, current comprehensive lifestyle interventions place little emphasis on theory-based motivational strategies to promote physical activity (PA) behavior change and have only modest impact on MVPA. Research on Self-Determination Theory (SDT) shows that higher autonomous motivation to engage in physical activity relates to higher MVPA levels. Acceptance and Commitment Therapy (ACT), a well validated, newer generation behavioral approach uses values clarification and commitment strategies, along with acceptance-based skills training, to effect health behavior change that is consistent with personally identified values. Thus, ACT serves as a theoretically consistent and potentially powerful intervention framework from which to target values-based autonomous motivation for increasing average weekly MVPA.

In this open trial, 36 insufficiently active adults with overweight/obesity received a 4-hour, ACT-based workshop followed by weekly emails and monthly phone calls for 3 months. Participants received education and training in values clarification and acceptance-based skills to increase values-based autonomous motivation and bouts MVPA. Primary (accelerometer-determined bouts MVPA minutes/week) and secondary (values-consistent action and autonomous motivation) outcomes were assessed at baseline and 3-months. Results demonstrated the intervention was feasible with 76.5% email survey completion, 94.7% phone call completion rate, and 92% retention at 3 months. Participants achieved a near 4-fold increase in daily bouts MVPA from a mean of 34.4 (±46.62) minutes at baseline to a 125.6 (±96.65) at 3 months (p < .001; d = 1.21). Participants also showed significant increases in values-consistent action (p = .044; d = 0.28) and autonomous motivation (p = .006; d = 0.53).

Results: support the feasibility and preliminary efficacy of this relatively low-touch intervention approach, consisting of a single ACT-based group-based workshop, weekly e-mails, and monthly phone calls, for increasing engagement in bouts MVPA among individuals who have overweight/obesity and initially low MVPA. Changes in targeted mechanisms provide additional support for the underlying theory. Additional rigorous testing of this approach in randomized clinical trial is warranted.

USING SOCIAL NETWORKS TO PREDICT TREATMENT OUTCOMES AND ATTENDANCE IN ADULT BEHAVIORAL WEIGHT LOSS INTERVENTIONS

Alena C. Borgatti, B.A.¹, Olivia M. Krantz, Bachelor of Science², Gareth Dutton, PhD¹, Meghan busky, n/a²

¹University of Alabama at Birmingham, Birmingham, AL; ²UAB, Birmingham, AL

Background: Adult behavioral obesity interventions are often delivered in groups, a cost-effective approach that may improve weight loss outcomes. While it has been theorized that support from group members improves treatment outcomes, no studies have evaluated the social relationships formed within these adult groups, or whether such relationships impact treatment outcomes. Similar to recent research in pediatric treatment samples, the current project utilized social network analysis (SNA) to identify structural ties that may improve adherence and weight loss among adults participating in a group-based obesity intervention.

Methods: Participants (N=61, mean weight=103.7kg, 60% African American, 95% female) were enrolled in 4 weight loss groups that met for 1 year, with 24 weekly sessions followed by 12 bi-weekly sessions. Analyses from 6-month networks measured reciprocal ties, a relationship in which two participants list each other as a person they most frequently interact with (interaction ties), go to for advice (advice ties), and like most (popularity ties). Outcomes included attendance at group meetings and weight loss (%) after 1 year. Baseline weight and race were retained as covariates.

Results: Advice tie models significantly predicted attendance ($R^2=0.246$, $F(3, 57)=6.188$, $p<0.01$), with each reciprocated advice tie predicting 2.41 more attended sessions ($B=2.41$, $p=0.003$). Similarly, interaction tie models were significant ($R^2=0.34$, $F(3, 57)=9.89$, $p<0.001$), with attendance increasing by 1.71 sessions per interaction tie ($B=1.71$, $p<0.001$). The popularity tie model had similar results ($R^2=0.39$, $F(3, 57)=12.158$, $p<0.001$), with each popularity tie predicting 2.1 more sessions attended ($B=2.07$, $p<0.001$). In regard to weight loss, popularity tie models were also significant ($R^2=0.192$, $F(3, 47)=3.719$, $p=0.018$), with each popularity tie predicting 1.2% more weight loss ($B=1.23$, $p=0.021$). Similarly, the interaction tie model was significant ($R^2=0.191$, $F(3, 47)=3.699$, $p=0.018$), with each tie resulting in 1.1% more weight loss ($B=1.11$, $p=0.021$) ($p<0.05$). However, advice tie models did not significantly predict weight loss ($R^2=0.142$, $F(3, 57)=2.60$, $p=0.063$).

Discussion: Results indicate that group dynamics and social ties in behavioral weight loss interventions may strongly impact 1-year attendance and treatment outcomes. Future studies are needed to replicate these findings, and to identify strategies that enhance group cohesiveness to potentially improve participant retention and treatment response.

A GENDER-SENSITISED WEIGHT LOSS PROGRAM FOR OVERWEIGHT AND OBESE MEN (AUSSIE-FIT): A PILOT RANDOMISED CONTROLLED TRIAL.

Dominika Kwasnicka, PhD¹, Eleanor Qusted, PhD², Nikos Ntoumanis, Prof², Robert U. Newton, BHMS(Hons), MHMS, PhD³, Daniel Gucciardi, PhD², Cecilie Thøgersen-Ntoumani, Prof², Jenny L. Olson, PhD², Suzanne Robinson, Prof⁴

¹SWPS University of Social Sciences and Humanities, Warszawa, Dolnoslaskie, Poland; ²Curtin University, Perth, Western Australia, Australia; ³Edith Cowan University, MULLALOO, Western Australia, Australia; ⁴Curtin University, Perth, Australia, Perth, Western Australia, Australia

Background: Recent evidence shows that sport settings can act as a powerful 'hook' to engage men in weight loss. The primary objective of this pilot study was to test feasibility of delivering and evaluating preliminary efficacy of Aussie-FIT, a weight loss program delivered in Australian Football League settings for overweight/obese men, in preparation for a future definitive trial.

Methods and Findings: This 6-month pilot trial took place in Perth, Australia. Participants were overweight/obese (BMI >28 kg/m²) middle-aged (35-65 years old) men. The intervention was 12 weekly 90-minute face-to-face sessions, incorporating physical activity, nutrition, and behaviour change information and practical activities delivered at 2 clubs by coaches. Data were collected at baseline and immediately post-intervention. For trial feasibility purposes, 6-month follow-ups were completed. Main outcomes were recruitment and retention rates, and differences in weight loss, self-reported measures (e.g., psychological well-being), device-measured physical activity, waist size, and blood pressure at 3 months. Within 3 days of advertising at each club, 426 men registered interest; 306 (72%) were eligible. Men were selected on first-come-first-served basis ($n=130$; M age=45.78, SD=8.01; M BMI=34.48 kg/m², SD=4.87) and randomised by a blinded researcher. Trial retention was 86% and 63% at 3 and 6 month follow-ups (respectively). At 3 months, mean difference in weight between groups, adjusted for baseline weight and group, was 3.33 kg (95% CI 1.89, 4.77) in favour of the intervention group ($p<0.001$). The intervention group's moderate-to-vigorous physical activity was higher than the control group's by 8.54 mins/day (95% CI 1.37, 15.71, $p=.02$). Meaningful differences were observed in several secondary outcomes favouring the intervention group. No adverse events were reported.

Conclusions: Aussie-FIT was feasible to deliver; participants increased physical activity, decreased weight and reported improvements in other outcomes. In a future trial, retention could be improved by timing assessments away from holiday seasons. Trial registration: Australian New Zealand Clinical Trials Registry: ACTRN12617000515392.

SIMILARITIES AND DIFFERENCES IN HEALTH-RELATED-BEHAVIOR CLUSTERING AMONG OLDER ADULTS IN EASTERN AND WESTERN COUNTRIES

Jing Liao, PhD¹¹Sun Yat-sen University, Guangzhou, Guangdong, China**Aim:** To quantify variations in health-related behaviors (HRB) clustering of older adults in Western and Eastern countries.**Methods:** Using six aging cohorts from the USA, England, Europe, Japan, Korea and China, latent class analysis was applied to access the clustering of smoking, alcohol consumption, physical activity and social activity.**Results:** A total of 104 552 participants (55% women) aged ≥50 years in 2010 were included. Despite a different number of clusters identified, three consistent cluster profiles emerged: “Multiple-HRB” (ex-/never smoking, moderate drinking, frequent physical and social activity); “Inactives” (socially and physically inactive without other risk behaviors); and “(ex-)Smokers with Risk Behaviors”. Sex and cohort variations were shown. For men in Western cohorts, “Multiple-HRB” was the predominant cluster, whereas their Asian counterparts were more likely to be members of the “Smokers with risk behavior” and “Inactives” clusters. Most women, particularly those in Asian cohorts, were never smokers and non-drinkers, and most of them belonged to the socially “Inactives” cluster.**Conclusions:** We provide a person-centered understanding of HRB clustering of older adults over selected countries by sex, informing tailored health promotion for the target population.**CORRESPONDING AUTHOR:** Jing Liao, PhD, Sun Yat-sen University, Guangzhou, Guangdong, China; liaojing5@mail.sysu.edu.cn

AEROBIC EXERCISE TRAINING AND SYSTEMIC INFLAMMATION: RESULTS FROM TWO RANDOMIZED CLINICAL TRIALS

Richard P. Sloan, PhD¹, Peter A. Shapiro, MD², Matthew N. Bartels, MD, MPH³, Vincenzo Lauriola, MS, MS¹, Kathleen McIntyre, MSW², Daichi Shimbo, MD², Martina Pavlicova, n/a⁴, Jennifer Scodes, MS⁵, Tse-Hwei Choo, MPH⁴, C. J. Choi, M.S.⁶, Kevin Tracey, MD⁷, Yaakov Stern, PhD⁴¹Columbia University Irving Medical Center, New York, NY; ²Columbia University Medical Center, New York, NY; ³Albert Einstein College of Medicine/Montefiore Medical Center, Bronx, NY; ⁴Columbia University, New York, NY; ⁵NYSPI, New York, NY; ⁶Research Foundation for Mental Hygiene, New York, NY; ⁷Feinstein Institute for Medical Research, Manhasset, NY**Importance:** The cardioprotective effects of aerobic exercise and the well-established role of inflammation in atherosclerosis suggest that one mechanism by which exercise contributes to cardioprotection is through anti-inflammatory effects. Observational studies consistently support this hypothesis. Intervention studies are less consistent.**Objective:** To determine if aerobic exercise training, compared to control conditions, reduces levels of circulating TNFα, IL-6, and CRP in sedentary adults. We conducted two randomized controlled trials: Trial 1, 2010–2015, 16-week follow-up; Trial 2, 2010–2016, 24-week follow-up. Observers were blind to group assignment.**Setting:** The trials were single site studies, with recruitment from local communities**Participants:** Trial 1: young, healthy but sedentary adults (age 20–45 years, 991 screened, 119 randomized, 98 completed). Trial 2: young and older healthy but sedentary adults (age 20–67 years, 775 screened, 132 randomized, 94 completed).**Interventions:** In Study 1, participants were randomized to a 12-week, 4X/week training program or wait-list control condition. Study 2 participants were randomized to a 24-week, 4X/week training program or a stretching/toning condition. Both exercise groups trained at 55–65%, 65–75%, and at 80% of maximum heart rate based on the study entry cardiopulmonary exercise test in weeks 1–2, 3–4, and the remaining weeks, respectively.**Main Outcomes and Measures:** The primary outcomes were circulating levels of TNFα, IL-6, and CRP.**Results:** Aerobic training but not the control conditions led to significant increases in aerobic capacity (Study 1: 4.13 ml/kg/min, $p < .001$; Study 2: 3.05 ml/kg/min, $p = .007$). Despite these training-induced improvements in aerobic capacity, there were no significant treatment effects on circulating levels of TNFα, IL-6 or CRP at the end of treatment interventions in either study, in both intention-to-treat and per-protocol analyses.**Conclusions:** Aerobic exercise training sufficient to improve cardiorespiratory fitness failed to produce reductions in circulating TNFα, IL-6, or CRP in two separate trials of sedentary but otherwise healthy participants. Although exercise training may promote cardioprotection by anti-inflammatory effects in participants with risk factors for CVD or in patients, these results do not support the hypothesis that this mechanism pertains to exercise training-induced cardioprotection in sedentary but otherwise healthy adults.**CORRESPONDING AUTHOR:** Richard P. Sloan, PhD, Columbia University Irving Medical Center, New York, NY; rps7@columbia.edu

Paper Session 2

POWER LAWS, RESILIENCY, AND RESISTANCE TO PHYSICAL ACTIVITY INTERVENTIONS

Vincent Berardi, PhD¹, Marc A. Adams, PhD, MPH², David Pincus, n/a³, Evan Walker, Masters in Computational and Data science⁴, Michael Todd, PhD², Mindy L. McEntee, PhD², Melbourne Hovell, MA, Ph.D. MPH⁵

¹Chapman University, Long Beach, CA; ²Arizona State University, Phoenix, AZ; ³Chapman University, ALISO VIEJO, CA; ⁴Chapman University, ORANGE, CA; ⁵School of Public Health SDSU, Jamul, CA

Background: Over the past decades, there has been little change in adults meeting moderate-to-vigorous physical activity (MVPA) guidelines. Numerous individual-level MVPA interventions have been performed with varying, but typically modest, success. Recent advances in intervention technology now make it possible to continually assess physical activity for extended periods of time, which enables novel features within MVPA interventions to be examined. One such feature is the robustness of daily MVPA patterns, in terms of resistance to change. Based on the ubiquity of power law distributions in healthy, functioning natural systems, we hypothesized that: a) robustness of daily MVPA patterns could be estimated by how well the distribution of daily MVPA minutes approximates an inverse power law distribution, and b) individuals with more robust patterns would be more resistant to intervention effects, and thus have poorer intervention outcomes.

Methods: Participants (N = 512) were asked to wear an ActiGraph GT9X accelerometer for one year and, depending on their study condition, received financial rewards for either meeting daily MVPA goals or continuing to wear/sync their device. An inverse power law was fit to the distribution of each person's daily MVPA mins over the first 100 intervention days, yielding a fit index that, similar to an r^2 in regression, assessed the strength of the power law characteristic for that person's daily MVPA values. The association between the fit index and intervention performance, as measured by total number of goals met over the remainder of enrollment, was explored via linear regression. A second regression model explored moderation via interaction terms.

Results: Adjusting for mean daily MVPA over the first 100 intervention days, power-law fit index was negatively correlated with the attainment of MVPA goals ($p < 0.001$). An interaction between fit index and mean daily MVPA over the first 100 days was also found ($p = 0.05$), indicating that the negative correlation between fit index and intervention performance was stronger for those with higher mean daily MVPA.

Discussion: Results suggest adherence of daily MVPA patterns to a power law distribution is associated with smaller intervention impact. From a complexity science perspective, power law fits are often associated with healthy stable systems with dynamics resistant to perturbations. Here, the intervention could be viewed as a perturbation that fails to move participants away from a pattern of insufficient activity. The power-law fit index described in this study could serve as a useful diagnostic for assessing the potential effectiveness of an MVPA intervention on a single-case basis.

PHYSICAL ACTIVITY AND MENTAL HEALTH DURING THE TRANSITION FROM ADOLESCENCE TO EMERGING ADULTHOOD: A SYSTEMATIC REVIEW

Matthew Kwan, PhD¹, Alessandra Ceccacci, BHSc², Natalie Paolucci, BHSc³, Amanda L. Rebar, PhD⁴

¹McMaster University, Hamilton, ON, Canada; ²University of Toronto, Hamilton, ON, Canada; ³University of Toronto, Hamilton, ON, Canada; ⁴Central Queensland University, Coee Bay, Queensland, Australia

Background: Late adolescence and emerging adulthood is an important period for onset of mental health problems, and correspondingly, a period of significant declines in physical activity (PA) behaviours. Although it is well recognized that PA has positive benefits on mental health on mental health outcomes, no systematic review or meta-analyses have focused on the relationship between PA and mental health during the broader transition from late adolescence to emerging adulthood. The purpose of this current study was to conduct a systematic review of prospective or longitudinal studies that investigate the associations between PA and the specific outcomes of depressive symptoms, anxiety, perceived stress across this major life transition.

Methods: A total of 3956 studies were initially screened, and were selected if it included: (a) a mean sample age between 15 and 25 years; (b) non-clinical populations; (c) a longitudinal or long-term experimental design; and (d) included either an assessment of PA or a specific PA-based intervention, and at least one outcome measure of depressive symptoms, anxiety, and/or perceived stress.

Results: A total of 19 studies met the eligibility criteria and were included in the current review. The vast majority of the studies identified were intervention trials ($n=16$), while only 3 of the studies used a longitudinal observational design. Among the 12 intervention studies examining the impact of PA on depressive symptoms, 10 (83%) found positive inverse relationships. Results for anxiety and perceived stress were however equivocal, as only 36% (4 of 11) and 57% (4 of 7) of the intervention studies found a significant effect on anxiety and stress, respectively. Only one observational study found a significant association between PA and mental health outcome.

Conclusions: These results reinforce the notion that PA-based programs are important in helping reduce psychological distress during the transition from late adolescence through emerging adulthood. Its impact on anxiety and perceived stress, however, are much less clear. Our results also suggest that there have been few longitudinal observational studies that have examined the relationship between PA and mental health outcomes over time during this critical transition period. More robust longitudinal data examining how the PA is related to mental health outcomes over time is needed, and in particular during the transition from adolescence into emerging adulthood.

RELATIONSHIPS BETWEEN DAILY SYMPTOM RATINGS AND MVPA IN BREAST CANCER PATIENTS UNDERGOING CHEMOTHERAPY: A LONGITUDINAL STUDY

Payton E. Solk, BA¹, Kara L. Gavin, PhD², Whitney A. Welch, PhD¹, Marilyn Lu, BA¹, Jennifer H. La, Bachelor of Science in Health Systems Management¹, Jason Fanning, PhD³, Cesar A. Santa-Maria, MD, MSCI⁴, William Gradishar, MD⁵, Seema A. Khan, MD⁵, Swati Kulkarni, MD¹, Juned Siddique, DrPH¹, Siobhan M. Phillips, PhD, MPH¹

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²University of Wisconsin, Madison, WI; ³Wake forest university, Winston salem, NC; ⁴Johns Hopkins, Baltimore, MD; ⁵Northwestern University, Chicago, IL

Background: Increased moderate to vigorous physical activity (MVPA) during chemotherapy (CT) is beneficial for breast cancer (BC) patients, but treatment-related symptoms may be a barrier to PA participation. Existing data on PA and treatment-related side effects during CT are based on infrequent self-reports. Ecological momentary assessment (EMA) may help us better quantify PA levels and monitor symptom burden during CT for BC because it allows for continuous assessment in real time in the real world. The purpose of this study was to use EMA to examine the relationship between daily PA fluctuations and symptom burden in BC patients during CT.

Methods: Women undergoing CT for BC were instructed to wear an accelerometer 24/7. Text message prompts were sent 4 times/day for 10 consecutive days (3 days pre-, day of, and 6 days post-CT dose) to rate symptoms (i.e. anxiety, depression, fatigue, pain, physical function, cognitive function). This method was repeated at three time points: the beginning, middle and end of CT. Separate mixed models were used to examine the between and within person relationship of average daily symptoms and daily minutes of same day MVPA and next-day MVPA controlling for relevant covariates.

Results: Between subject variation in walking physical function ($\beta=-6.56$, $p=0.04$) and cognitive function ($\beta=6.23$, $p=0.03$) and within person walking physical function ($\beta=-4.89$, $p < 0.001$) and cognitive function ($\beta=3.57$, $p < 0.001$) were associated with same day MVPA. Within person associations for affect ($\beta=1.90$, $p < 0.001$), anxiety ($\beta=-1.41$, $p=0.01$), fatigue ($\beta=-4.93$, $p < 0.001$), pain ($\beta=-1.49$, $p < 0.001$) and everyday activities physical function ($\beta=-4.25$, $p < 0.001$) were significantly associated with same day MVPA. Higher than average symptom ratings on a given day were associated with less MVPA that day. Within person variation in pain ($\beta=0.62$, $p=0.03$) was the only significant symptom associated with next day MVPA. Higher than average pain ratings on a given day were associated with less MVPA the next day.

Conclusions: Daily within and between person variations in symptoms were associated with same day and next day MVPA during CT for BC patients. Tailoring activity interventions to meet the needs of an individual's daily variations in symptoms during CT could enhance MVPA and intervention effectiveness. Future work should explore these relationships further to identify and test effective intervention tailoring strategies.

11:00 AM–11:15 AM

SOCIAL DETERMINANTS OF CANCER CAREGIVERS' HEALTH CHALLENGES: A LONGITUDINAL INVESTIGATION

Youngmee Kim, PhD¹, Hannah-Rose Mitchell, MPH², Amanda Ting, MS¹, Armando J. Mendez, PhD³

¹University of Miami, Coral Gables, FL; ²VA Palo Alto Healthcare System, Los Altos, CA; ³University of Miami, Miami, FL

Cumulative evidence suggests that family caregivers of adult cancer patients are vulnerable to poorer physical health than their non-caregiver counterpart. This study tested the extent to which psychosocial factors would predict poor health manifested in compromised physiological markers and greater development of morbid conditions during the first two years since the relative's cancer diagnosis.

Family caregivers (N=155, 51.1 years old, 72% female, 20% income < \$40,000) of colorectal cancer patients completed questionnaires and provided blood samples around 3 months (T1) and 20 months (T2) after their relative's cancer diagnosis. Age, gender, income, psychosocial factors including caregiving stress (Pearlin Stress Scale), loneliness (UCLA Loneliness Scale), and social support (ISEL), and morbidity (MICCI) were self-reported. Telomere length (TL), a measure of cellular aging, was assayed from the blood samples.

Caregivers had an average 2.7 pre-existing morbid conditions and shorter TL, compared with TL reported in a study with healthy adults, at the start of caregiving. The number of morbidity and TL at T1 were highly correlated with those at T2 ($r > .38$, $p < .02$). General linear modeling predicting morbidity and TL at T2, controlling for those at T1, revealed that poorer social support ($B = -1.56$, $p = .028$) and (marginally) greater loneliness ($B = 1.08$, $p = .097$) at T1 related to increased morbidity at T2, whereas older age ($B = -0.01$, $p = .042$) related to shorter TL at T2. Caregiving stress at T1 and social factors at T2 were not significantly related to development of morbidity and changes in TL at T2.

This study provides the first evidence that older family caregivers and those lacking social resources are vulnerable to pre-mature aging during the first two years of caregiving. Targeting such subgroup of family caregivers at risk and developing interventions to promote the establishment and maintenance of effective social relationships will be critical to attenuate the premature physical health decline among family cancer caregivers, a large under-supported population. A longer follow-up investigation with a larger sample is warranted for elucidating cancer caregiving linking to health challenges.

Paper Session 3

11:15 AM-11:30 AM

AFFECTIVE VARIABILITY AND DEPRESSION IN CANCER CARE-GIVERS: AN ECOLOGICAL MOMENTARY ASSESSMENT FEASIBILITY STUDY

Kelly M. Shaffer, PhD¹, Jillian Glazer, N/A², Tri Le, MD³, Matthew J. Reilly, MD³, Philip Chow, PhD⁴, Lee M. Ritterband, PhD¹

¹University of Virginia School of Medicine, Charlottesville, VA; ²University of Virginia, Charlottesville, VA; ³University of Virginia, Emily Couric Clinical Cancer Center, Charlottesville, VA; ⁴University of Virginia, Christiansburg, VA

Objectives: Approximately 25% of the 3 million cancer caregivers in the US are at risk for developing depression. Prior studies of depressive symptoms in caregivers have limited generalizability and actionability due to reliance on retrospective and/or cross-sectional design. This study undertook one of the first ecological momentary assessment (EMA) studies among active cancer caregivers to examine the feasibility of this approach as well as to better understand caregivers' day-to-day affective experiences and how these relate to their depressive symptoms.

Methods: Caregivers who reported actively supporting a family member or family-like individual receiving cancer care were approached for recruitment at outpatient oncology clinics. Participating caregivers completed a baseline survey, which included the PHQ-8 to measure depressive symptoms. The EMA protocol began the following day and comprised 8 prompts per day for 7 days. EMA prompts included 20 affective items (5 items each for negative deactive [NDA], positive deactive [PDA], negative active [NAA], and positive active affect [PAA]). Caregivers received a feedback survey at the end of the study. Feasibility metrics included enrollment, EMA prompt completion, and feedback survey responses. Affective variability and its relation to caregivers' depressive symptoms was examined using a novel two-stage data analytic approach through the freeware program MIXWILD.

Results: Of 29 caregivers approached, 2 were ineligible, 4 refused, and 23 (79%) enrolled. Participating caregivers completed 70% of EMA prompts on average (Median=78%, range=23%-100%). Of the 18 caregivers that completed feedback surveys, most reported the number of prompts issued per day (n=12, 67%) and the duration to complete each prompt (n=16, 89%) was acceptable. Regarding affective variability, there was significant within-subject variability in each of the four affective domains (ps< .001); there was significant between-subject variability in NDA only (p< .001). Caregivers' higher individual mean levels of NAA and NDA and lower mean levels of PDA related to their higher level of baseline depressive symptoms (ps< .01). For NDA, greater individual variability in NDA also related to a higher level of depressive symptoms (p< .05).

Conclusions: Findings suggest the feasibility of EMA within active cancer caregivers: enrollment for this study exceeded typical recruitment rates for studies of cancer caregivers, the percentage of prompt completion was comparable to other types of EMA studies, and caregivers found overall burden of completing surveys to be acceptable. Findings suggest that level and variability of affect in daily life are associated with depressive symptoms in cancer caregivers, pertinent to the development of event contingent interventions (e.g., just-in-time adaptive interventions) to address depression in this vulnerable population.

THE LONGITUDINAL RELATIONSHIP BETWEEN IMMUNE CELL PROFILES AND FRAILTY IN PATIENTS WITH BREAST CANCER RECEIVING CHEMOTHERAPY

Nikeshia J. Gilmore, PhD¹, Lianlian Lei, MS², Eva Culakova, PhD, MS³, Mostafa Mohamed, MBBS², Allison Magnuson, DO², Ronald Maggiore, MD², Elizabeth Belcher, PhD², Melissa (Kah Poh) Loh, MD², Alison Conlin, MD⁴, Lora Weiselberg, MD⁵, Mary Ontko, RN⁶, Supriya Mohile, MD, MS², Michelle C. Janelins, Ph.D., M.P.H.³

¹University of Rochester, New York, NY; ²University of Rochester, Rochester, NY; ³University of Rochester Medical Center, Rochester, NY; ⁴Providence Health Services, Portland, OR; ⁵Northwell, North New Hyde Park, NY; ⁶DAYTON CLINICAL ONCOLOGY PROGRAM INC, Dayton, OH

Background: Frailty is an important factor for oncologists in determining risk of chemotherapy toxicity. Immune cells involved in inflammatory processes are physiologic features of frailty. Its role and clinical relevance to identify patients at risk of developing frailty with chemotherapy is not fully understood.

Methods: Patients had stage I-III breast cancer (n=583, mean age 53; range 22-81). Measures were completed pre-chemotherapy (T1; ≤ 7 days before first cycle), post-chemotherapy (T2; ≤ 1 month after last cycle), and 6-months post-chemotherapy (T3). Frailty was assessed by a modified Fried score (0-4) using self-reported measures (weakness, exhaustion, physical activity, and walking speed) at T1, T2, and T3. Immune cell counts as well as neutrophil:lymphocyte ratio (NLR) and lymphocyte:monocyte ratio (LMR) were obtained T1 and T2. Separate linear regressions were used to evaluate the associations of T1 cell counts with T1, T2, and T3 frailty and change in cell counts (T2-T1) with T2 frailty and change in frailty [(T2-T1) and (T3-T1)]. We controlled for relevant covariates and T1 frailty.

Results: In this secondary analysis the mean frailty score increased from T1 to T2 (1.3 vs 2.0; p< 0.001) and returned to T1 levels by T3 (1.3 vs 1.3; p=0.8). T1 compared to T2, showed an increase in NLR (3.0 vs 5.0; p< 0.001) and decreased lymphocytes (1.9 vs 1.2; p< 0.01), white blood cells (WBC: 7.4 vs 6.6; p< 0.001), and LMR (5.7 vs 2.8; p=0.04). There was no change in levels of neutrophils. T1 WBC (β=0.04; p< 0.01), neutrophils (β=0.04; p< 0.01), and NLR (β=0.05; p< 0.01) were associated with T1 frailty. From T1 to T2, greater increase in immune cells was associated with frailty (WBC: β=0.2; p< 0.01, neutrophils: β=0.3; p< 0.01, NLR: β=0.03; p< 0.01) and greater changes in frailty (WBC: β=0.2; p< 0.01, neutrophils: β=0.3; p< 0.01, NLR: β=0.03; p< 0.01). These associations remained significant after controlling for the receipt of growth factors with chemotherapy. In all models higher T1 frailty, older age, and being unmarried were predictive of T2 frailty and change in frailty score. There were no associations between T1 and change in (T3-T1) immune counts with T3 frailty or change in (T3-T1) frailty.

Conclusions: In patients with breast cancer undergoing chemotherapy, immune cell counts are associated with frailty. Immune cell counts may help clinicians identify patients at risk of frailty during chemotherapy. Additional research is needed to identify the specific immune subsets associated with frailty in patients with breast cancer receiving chemotherapy.

ADVANCING HEALTH INTERVENTIONS THROUGH ECOLOGICAL BEHAVIORAL OBSERVATION: NEW FRONTIERS FOR INTERVENTION SCIENCE

Deanna M. Kaplan, M.A.¹¹University of Arizona, Providence, RI

Advances in ambulatory assessment technologies facilitated a paradigm shift in behavioral medicine – it is now possible to study health processes and outcomes as they naturally occur during normal daily life. The Electronically Activated Recorder or EAR (Mehl et al., 2001; Mehl, 2017; Kaplan et al., under review) is an ecological behavioral observation method that is increasingly used to answer novel questions about the relationships between everyday behaviors and health. The EAR is a small digital audio recorder worn by participants as they go about their daily lives. It silently and periodically records the sounds of participants' lives that are then quantified through behavioral coding and transcription of speech. In the domain of behavioral medicine, the EAR has been recognized for its utility in psychosomatics (Mehl, Robbins, & Deters, 2012), and has been used, for example, in the study of how couples cope with breast cancer (Robbins, Lopez, Weihs & Mehl, 2014).

Surprisingly, ecological behavioral observation has not yet been applied to behavioral medicine interventions. Given that most behavioral medicine interventions have the explicit goal of creating sustained behavior changes in patients' actual daily lives, methods such as the EAR offer promising new frontiers in the study of health behavior change interventions. This presentation outlines the utility of ecological behavioral observation for: 1) identifying novel daily life intervention targets in populations with chronic diseases, 2) evaluating the efficacy of new intervention approaches on actual behavior change, 3) enabling mechanistic research about the most effective ingredients of interventions with established efficacy, 4) yielding advances in basic science when used in combination with other ambulatory assessment methods (e.g., ecological momentary assessment, ambulatory physiology). This methodologically-focused presentation will draw upon new data from the first application of the EAR method to a clinical intervention study, an RCT of the effects of mindfulness and compassion meditation interventions. Although this was a “nearly null trial” (ClinicalTrials Identifier NCT01643369, manuscript in preparation) in that the interventions tested had minimal effects across all health and psychological outcomes assessed, this first application of the EAR to an intervention study has illustrative implications for how to apply ecological behavioral observation to behavioral medicine intervention science.

11:00 AM–11:15 AM

WHICH METHOD OF ASSESSING DEPRESSION & ANXIETY BEST PREDICTS CESSATION: SCREENING INSTRUMENTS OR SELF-REPORTED CONDITIONS?

Noreen L. Watson, PhD¹, Jaimee L. Heffner, PhD¹, Kristin E. Mull, MS¹, Jennifer McClure, PhD², Jonathan Bricker, PhD³¹Fred Hutchinson Cancer Research Center, Seattle, WA; ²Kaiser Permanente Washington Health Research Institute, Seattle, WA; ³Fred Hutchinson Cancer Research Center/University of Washington, Seattle, WA

Background: Mental health conditions (MHCs; e.g., depression, anxiety) are common among smokers and associated with difficulty quitting smoking. However, it is unknown which method of assessing depression and anxiety best predicts cessation in the context of smoking interventions. Thus, among treatment-seeking smokers, we aimed to assess and compare the predictive utility of two common assessment approaches—screening instruments for depression and anxiety or self-reporting a depression and/or anxiety (D/A) condition. Among those who self-report D/A, we also examined if asking whether they believe the condition(s) will interfere with their ability to quit added predictive utility.

Methods: At baseline, participants (N=2,637) enrolled in a RCT of web-based smoking treatments completed screening instruments for 5 common MHCs (depression, social anxiety, PTSD, generalized anxiety, panic) and a two-part question asking about self-reported D/A and interference beliefs. Outcomes were 12-month self-reported 30-day point prevalence abstinence. Logistic regression models determined the association of each MHC index with cessation; area under the receiver operating characteristic curves (AUCs) were used to compare their ability to predict cessation.

Results: Quit rates ranged from 13% among smokers who self-reported D/A and believed it would interfere quitting to 29% among those who did not screen positive for any MHC assessed. Among those who screened positive for a MHC, quit rates ranged from 23% (panic) to 25% (generalized & social anxiety). Screening positive for depression (OR=0.78; 95% CI: 0.62, 0.98; p=.032), panic disorder (OR=0.73; p=.009), or PTSD (OR=0.78; p=.034) was associated with a significantly lower likelihood of cessation, as was self-reporting D/A (OR=0.61; p<.001) and interference beliefs (OR=0.39; p<.001). No significant differences were found between the AUC values for the screening instruments and single-item self-report question. The highest AUC value was for the two-part self-reported D/A and interference beliefs question (AUC=.578; 95%CI: 0.55, 0.60); it was significantly greater than the AUC for the single-item self-report of D/A (p=.042).

Conclusions: Relative to multi-item screening assessments for common MHCs, both self-reporting a D/A condition and a two-part question assessing self-reported D/A conditions and beliefs about the condition(s) interfering with quitting are at least as useful, and possibly more useful, for identifying those at highest risk for failing to quit. These shorter assessment approaches can yield information to guide treatment-related decisions.

Paper Session 4

11:15 AM-11:30 AM

RELIABILITY AND MODALITY EQUIVALENCY OF ELECTRONICALLY ADMINISTERING THE NEWEST VITAL SIGN TO MEASURE CHILD HEALTH LITERACY

Hannah G. Lane, PhD, MPH¹, Bridget Armstrong, PhD², Erin R. Hager, PhD³, Amy Zemanick, BA³

¹Duke University School of Medicine, Baltimore, MD; ²University of South Carolina, Columbia, SC; ³University of Maryland School of Medicine, Baltimore, MD

Background: The relationship between health literacy and preventative health behaviors is well-established in adults; however it remains understudied in children. This is largely because few age-appropriate measures can be easily administered in non-clinical settings (e.g. schools) that children commonly frequent. This study investigates the reliability and modality equivalency of a low-burden, electronic administration of the Newest Vital Sign (NVS), a validated tool commonly administered to children in clinical settings, compared to the gold standard oral administration.

Methods: 137 students from 13 low-income elementary and middle schools were enrolled as part of a larger randomized trial. Students completed the electronic and oral NVS during school, one week apart, in random order. The instrument contains 5 questions about a nutrition label, which are scored as correct or incorrect. To establish test-retest reliability, Spearman correlations and percent agreement were assessed for both continuous score (0-5) and previously established risk categories (0-1: likely low health literacy, 2-3: possibly limited health literacy, 4+: likely adequate health literacy). Item Response Theory (IRT) was used to calibrate the difficulty of the 5 test items across the electronic and oral NVS versions. Differential item functioning (DIF) tests assessed discrepancies in items' representativeness of the latent construct of health literacy.

Results: The sample was 62.0% female, 53.3% elementary school, and ranged in age from 8-14. Mean scores for oral NVS (1.28, SD=1.38) were significantly higher than electronically administered NVS (0.73, SD=1.19) ($t(136) = -6.27, p < .01$). According to risk categories, the oral and electronic NVS indicated that 63.5% and 81.0% of student were at high risk for likely low health literacy, respectively. Spearman's rho values were adequate and significant ($p < 0.001$) for both the continuous ($r=0.63$) and categorical ($r=0.56$) scoring. Percent agreements were 85.3% and 73.0%, respectively. IRT difficulty parameters were satisfactory, and none of the five items had significant DIF.

Conclusions: Findings indicate good agreement and construct consistency between the electronic and oral NVS, suggesting that the measures are comparable in assessing health literacy; however, scores were consistently higher with the oral administration. The high prevalence of low health literacy in this sample also highlights the need to understand and address health literacy in non-clinical samples. Minimizing administration burden by using the electronic NVS enables health literacy to be assessed among large samples of children, in order to better describe patterns and disparities and to inform non-clinical preventative health interventions grounded in health literacy.

11:30 AM-11:45 AM

ECOLOGICAL MOMENTARY ASSESSMENT VERSUS STANDARD SELF-REPORT MEASURES OF INSOMNIA SYMPTOMS AMONG COLLEGE STUDENTS

Emily P. Midgette, BA¹, Matthew C. Whited, Ph.D, Licensed Psychologist¹, Jordan M. Ellis, MA², Alexander J. Capiaghi, BS¹, Alexander M. Schoemann, PhD¹, Ashley M. Griffith, MA³, Hunter M. Davis, Psychology¹

¹East Carolina University, Greenville, NC; ²East Carolina University, San Antonio, TX; ³East Carolina University, GREENVILLE, NC

Introduction: Sleep disturbances are prevalent and increasing among college students, with as many as 73% reporting at least occasional sleep difficulties and 50% reporting difficulty staying awake throughout the day. Previous findings suggest that a minimum of 7.7% of students suffer from insomnia. Insomnia has a considerable impact on students' ability to succeed in college and is significantly associated with mental health problems including chronic fatigue, depression, increased stress and anxiety, and lower quality of life. As mobile data capture tools are becoming more proliferate in clinical research of college student health, it is important to investigate the performance of patient-reported measures of sleep quality as they relate to real-time measurement of symptoms.

Method: Participants completed the Insomnia Severity Index (ISI) to assess for insomnia symptoms over the past two weeks. Ecological momentary assessment (EMA) was then used to assess perceived sleep quality, daytime sleepiness, and stress as experienced in-the-moment, using a smartphone-based EMA application. Participants ($N = 153$) were asked to respond to questions regarding their subjective sleep quality each morning upon awakening for 7 days. Daytime sleepiness and stress were assessed twice daily (afternoon and evening). This technique allows for assessing sleep quality and daytime dysfunction over one full week to compare baseline insomnia symptoms to day-to-day sleep disturbances. Daily ratings were aggregated across 7 days, and ISI scores were then used to predict the aggregated sleep disturbance scores in linear regression models.

Results: Results found that there was a statistically significant within-subjects association between baseline insomnia symptoms and momentary sleep quality ($B = 0.350, p < 0.001$), duration ($B = -0.108, p < 0.001$), latency ($B = 0.380, p < 0.001$) and perceived difficulty falling asleep ($B = 0.337, p < 0.001$), and restfulness upon awakening ($B = -0.370, p < 0.001$). Within-subjects associations between baseline insomnia symptoms and perceived stress levels ($B = 0.221, p < 0.001$) and sleepiness ($B = 0.282, p < 0.001$) throughout the day were also observed.

Discussion: The results indicate that baseline insomnia symptoms are associated with daily self-reported sleep difficulties. Our findings suggest that momentary measures of sleep difficulties are associated with traditional retrospective self-report measures which supports their validity. However, some variables were associated less strongly, indicating that they provide slightly different information about sleep and sleep quality. Future research should further investigate momentary measures of sleep by comparing them to objective measures of sleep.

10:45 AM–11:00 AM

ARE SALAD BARS ASSOCIATED WITH BETTER NUTRIENT INTAKE DURING LUNCH? A PLATE WASTE ANALYSIS AMONG TITLE I ELEMENTARY SCHOOLS

Elizabeth L. Adams, PhD¹, Laura M. Thornton, N/A², Hollie Raynor, PhD, RD³, Suzanne E. Mazzeo, PhD¹, Melanie K. Bean, PhD¹¹Virginia Commonwealth University, Richmond, VA; ²University of North Carolina at Chapel Hill, RICHMOND, VA; ³University of Tennessee, Knoxville, TN

Background: The Healthy, Hunger-Free Kids Act (HHFKA) implemented changes to the National School Lunch Program (NSLP) in 2012. Salad bars are widely promoted as a strategy for schools to meet these HHFKA guidelines. It is unknown if access to salad bars is associated with better nutrient intake among low-income children at high risk for obesity. We quantified nutrient selection and consumption among children participating in the NSLP in schools with and without salad bars and compared these values to nutrient recommendations.

Methods: Six Virginia Title I elementary schools with 100% free meals were randomly selected. Schools were matched and paired based on minority enrollment and lunchroom environment; half the schools had salad bars, half did not. Students participating in the NSLP were eligible (92.5% participation; 1st–5th graders; 98.6% racial/ethnic minorities). Digital imagery plate waste methods were used to quantify children's lunch selection and consumption on a single school day (N=1,115 trays rated). Nutritional information for reference portions of school lunch items were analyzed using Nutrition Data Systems for Research. Nutrition information was used to quantify children's nutrient intake (e.g., Ca, Na, Fe) and compare this to the 2012 HHFKA and 2009 Institute of Medicine nutrient recommendations. Schools with salad bars vs. control schools were compared based on percent of students meeting nutrient recommendations using multilevel models.

Results: On average, children's lunch selection comprised 552.0±128.3 kcal, of which 315.9±170.3 kcal were consumed. Most students met consumption recommendations for protein (57.1%) and Na (96.7%). Few met recommendations for fiber (7.5%), Fe (12.5%), and Ca (16.3%); had students consumed their full lunch selection, 49–64% would have met recommendations for these nutrients. Recommendations for vitamins A and C were met by 24.2% and 33.7% of students, respectively; 57% and 46% would have met recommendations if they had consumed their full lunch selection. Based on consumption, more children met Fe recommendations in schools with salad bars than in schools without (14.9% vs. 10.4%; p=.01); no differences between salad bar groups were found for total energy, Ca, fiber, and Na (all p's >.05). Significant interactions were found between salad bar group and matched pair in the percentage of children who met recommendations for protein and vitamins A and C.

Conclusion: Percent of students meeting nutrient recommendations for schools with vs. without salad bars was variable and may depend on the types of foods served or school-level factors not assessed. Across all schools, efforts to increase children's consumption of selected foods and beverages should be explored as an avenue for increasing the percentage of children who meet these nutrient recommendations.

HARNESSING SENSOR TECHNOLOGY AND MACHINE LEARNING TO PREDICT DIETARY LAPSES IN A WEIGHT LOSS PROGRAM

Rebecca J. Crochiere, B.A.¹, Evan M. Forman, PhD², Zoe Zhang, PhD², Adrienne Juarascio, Ph.D.²¹WELL Center, Drexel University, Philadelphia, PA; ²Drexel University, Philadelphia, PA

Over 160 million American adults have overweight/obesity, but inability to consistently adhere to a weight loss (WL) diet, i.e., dietary lapse, undermines these individuals' WL efforts. Research has identified specific momentary factors that increase risk of lapse, which can be used to estimate lapse risk and inform interventions that provide support when risk is high (e.g., just-in-time adaptive interventions; JITAIs). These risk factors have typically been measured via ecological momentary assessment (EMA; a data collection method that involves completing multiple brief surveys throughout the day, usually via a smartphone). Yet EMA has several notable shortcomings, including participant burden, self-report bias, poor compliance, and restricted data collection periods (i.e., only collecting data at times when participants complete surveys). Passive sensors, which can automatically, objectively, and continuously measure lapse risk factors, offer discrete advantages over EMA. However, no study has evaluated whether sensor-measured risk factors can predict dietary lapse.

This study investigated whether lapses could be predicted through sensor-measured variables among 24 adults with overweight/obesity enrolled in a 6-week commercial WL program. Participants wore a Fitbit (accelerometer) at all times, completed EMA surveys, and enabled a GPS app that continuously tracked location. Sensor-measured risk factors were physical activity and sleep (measured via accelerometer), geolocation (measured via GPS), and time (measured via clock). EMA was used to measure lapses and categorize GPS coordinates into geolocations. A supervised binary classification model was used to predict lapses based on values of the risk factors at various time granularities (e.g., 5-, 15-, 30-, 60-, and 90-minutes prior to the lapse).

Participants reported low burden of sensors and 98.6% of all possible sensor data was acquired. Further, using only this limited suite of sensors, a machine learning model predicted lapses with 64% sensitivity (true prediction rate of lapse) and 68% specificity (true prediction rate of non-lapse). Findings highlight the promise of sensors as a more acceptable and accurate method by which to measure risk factors, laying the groundwork for sensor-powered JITAIs. Importantly, as sensor technology continues to improve, increasing types of sensors and combinations of sensors will be able to measure additional risk factors and lapses, which will further increase lapse prediction accuracy.

IS THIS PATIENT FOLLOWING THE RECOMMENDED DIET? VALIDITY AND RELIABILITY OF A 3-ITEM DIETARY STAGE OF CHANGE QUESTIONNAIRE

Lindsey D. Pappalardo, BA¹, Andrew Nicholson, MSPH², Binhuan Wang, PhD³, Sangmin Hyoung, EdM⁴, Sundar Natarajan, MD, MSc³

¹Veterans Affairs NY Harbor Healthcare System, Metuchen, NJ; ²VA NY Harbor Healthcare System, New York City, NY; ³NYU School of Medicine, New York, NY; ⁴Veterans Affairs, New York, NY

Background: Hypertension is the most common chronic condition affecting Americans. The Dietary Approaches to Stop Hypertension (DASH) diet can reduce systolic blood pressure (BP) by approximately 8 mmHg, i.e. equivalent to a potent BP-lowering drug. Providers routinely recommend diet modification to patients but assessing diet is difficult, especially in busy clinical settings.

Objective: To assess the validity and reliability of a 3-item dietary stage of change (DSOC) questionnaire used in a successful behavioral intervention trial to control BP.

Methods: The DSOC questionnaire assessed participant readiness to adhere to the DASH diet based on Transtheoretical stages of change. Action and Maintenance stages indicate current adherence. The Willett Food Frequency Questionnaire (FFQ) was used to calculate DASH adherence score. Dietary sodium intake, a critical part of the DASH diet, was assessed using urine sodium/creatinine ratio (UNa/UCr). We evaluated criterion validity by assessing if DSOC is related to DASH scores in total (Kruskal-Wallis test) and by domain (Wilcoxon Mann-Whitney test). Spearman's Correlation (Rho) was used to evaluate the following: Convergent validity by comparing DSOC to UNa/UCr, discriminant validity by comparing DSOC to Psychosocial Support for Exercise Participation, and test-retest reliability by comparing baseline data to 3-month follow-up within the control group.

Results: At baseline (n = 533), more advanced dietary stages of change were associated with higher DASH adherence scores (Kruskal-Wallis $p < 0.0001$). Participants in adherent stages had higher DASH scores in total (Rho 0.34, $p < 0.0001$) and by domain (all $p < 0.05$). Baseline DSOC was associated with UNa/UCr (Rho - 0.11, $p = 0.019$), and not associated with Psychosocial Support for Exercise Participation (Rho 0.05, $p = 0.25$). Finally, baseline DSOC was correlated with 3-month DSOC within the control group (Rho 0.21, $p = 0.0087$).

Conclusions: DSOC is a valid and reliable measure for assessing adherence to the DASH diet. This short survey can swiftly categorize patients into stages, and as adherent or non-adherent, even in busy clinical settings. It is an alternative to more time-consuming dietary assessments. Furthermore, DSOC questions can be easily administered by phone or in person, which can facilitate the implementation of remote dietary interventions.

AUGMENTING SELF-REPORTS WITH WEARABLE VIDEO CAMERA DATA TO IMPROVE DIET-RECALL

Erin R. Bruns, n/a¹, Annie W. Lin, PhD, RD², Rawan Alharbi, n/a², Sougata Sen, PhD³, Josiah Hester, PhD³, Nabil Alshurafa, PhD²

¹Northwestern University, Burr Ridge, IL; ²Northwestern University, Chicago, IL; ³Northwestern University, Evanston, IL

The 24-hour diet recall is commonly used to track dietary intake yet has many limitations, including the reliance on memory and subjective reporting. Understanding which food items are commonly forgotten during a recall can improve the dietitian's ability to trigger a person's memory and thus, the accuracy of the 24-hour diet recall. The purpose of the BeYourself Study was to conduct an in-the-wild experiment to track participants' diet using a fish-eye lens camera strapped around their non-dominant shoulder for 2 weeks and compare against daily 24-hour diet recalls. A registered dietitian conducted 24-hour diet recalls during the study. Fifteen participants (9 obese, 3 overweight and 3 normal BMI) collectively recorded 650 hours of video data and participants completed at least 9 days of recalls. A trained video annotator labeled 514 food items consumed by participants and identified foods that were observed in the video but not the recalls. The missing items were categorized into nine major food groups using the Nutrition Coordinating Center (NCC) Major Food Group Serving Count System by a registered dietitian. There were 87 (17%) food items that were missing from the recalls but were captured by video. On average, a participant missed reporting 5.8 +/- 3.8 items in their recalls over a 2-week period. Grain-based foods were the most commonly forgotten items (21.6%), followed by the following groups: Beverages (17.0%), Dairy and Non-Dairy Alternatives (11.4%), Fruits (9.1%), Meat, Fish, Poultry, Eggs, Nuts, Seeds, and Meat Alternatives (6.8%) and Sweets (6.8%), Miscellaneous (5.7%) and Vegetables (5.7%), and Fats (1.4%). Results from this study suggest that data collection using 24-hr diet recall improves when used with video, and will inform the development of a higher definition camera to capture more precise dietary intake data to aid in diet quality assessments.

COLLEGE PRESCRIPTION OPIOID MISUSE: AN EXPLORATION OF SOCIAL LEARNING, SOCIAL CONTROL, AND STRAIN THEORIES

Julie L. Murray, MS¹, Scott DeBerard, Ph.D.¹, Kala Randazzo, BS¹¹Utah State University, Logan, UT

Prescription opioids, when used as medically intended, can be effective in pain management. However, the consequences and costs of widespread misuse of prescription opioids in the United States are cause for concern. Prescription opioids are related to increased morbidity and mortality. Young adults, between the ages of 18 and 25 have the highest rates of misuse nationally and within this age group, college students may be particularly at risk due to the unique demands and environment of college. Relatively few studies have examined prescription opioid misuse in this population, and even fewer have done so through a theoretical lens. In order to effectively curb the growing misuse of prescription opioids within college populations, we must first have a better understanding of the factors that potentially lead to misuse. The purpose of the present study was to examine whether predictors from social learning, social control, or strain theories could explain prescription opioid misuse within a national sample of undergraduate students from four year universities in the United States and to examine which of the three theories provides the strongest explanation of prescription opioid misuse within this population. A national sample of 616 undergraduates (80% female; 54% non-white) completed a web-based survey designed to assess prescription opioid misuse and identify predictors from social learning, social control, and strain theories. Results showed that 17% of the sample had engaged in lifetime prescription opioid misuse. Logistic regression analyses indicated that variables related to social learning and strain theories, including associating with peers who engage in substance use/misuse, perceived parental attitudes towards prescription misuse, and depression, were significant predictors of prescription opioid misuse, whereas the measures of social control theory were not. An exploratory model combining demographic variables with variables across the three theoretical models was created in order to optimize prediction success. Overall predictive success of the exploratory model was 86.5% with a sensitivity and specificity of 36.2% and 96.9%, respectively. The stunning implications of this degree of prescription opioid misuse among college students and possible ways to mitigate this challenge are discussed.

‘TWO PEOPLE OVERDOSE A DAY HERE’: A QUALITATIVE STUDY EXPLORING SOLUTIONS FOR OPIOID OVERDOSES AT A PUBLIC LIBRARY

Melanie J. Nicholls, LCSW¹, Lianne A. Urada, PhD, LCSW²¹SDSU/UCSD, La Jolla, CA; ²San Diego State University & University of California San Diego, La Jolla, CA

Introduction: In 2018, California experienced 2,311 deaths from opioid overdose, 743 deaths related to fentanyl overdose alone, and these numbers continue to rise nationwide. Southern California is a gateway for fentanyl distribution to the rest of the country. Recently, there has been an increase in substance use and opioid overdoses at public libraries, which are easily accessible public places for those struggling with homelessness. This study aimed to explore the barriers unstably housed people who use substances face in getting help and what innovative solutions the library and its community and research partners might offer.

Methods: From January–June 2019, researchers surveyed 50 library patrons experiencing homelessness and 10 library staff at a large Southern California library. Participants were also either interviewed in-depth (n=31) or participated in a focus group (n=29). Patrons were recruited through fliers via a university-library partnership and consensus organizing

Methods: Sociodemographic data were collected via self-administered surveys. Data were coded and analyzed using a thematic analysis. Coders independently coded text files for data analysis and discussed codes until agreement and inter-coder reliability was reached.

Results: Library patrons were a mean age of 44, (range: 18–75). Approximately half were white (47%) and male (51%). 63% of participants reported housing instability; 22% lived in shelters. About half reported a current or prior substance use history. Participants suggested the library could offer education on the effects and health risks of drugs, fentanyl awareness, and overdose prevention, and connect patrons to treatment resources, e.g., medically assisted treatment (MAT), and Narcan. Findings suggest that barriers to quitting are related to a lack of access to MAT and detox and low knowledge of services for those struggling with opioid addiction.

Conclusion: Public libraries are perceived as one of the few places persons living with homelessness and opioid addiction can safely rest at during the day. Patrons often engage in substance use at the library due to its availability of clean water and bathrooms, leading to an increase in overdoses. Public libraries present an opportunity to provide linkage to care to treatment and education for patrons struggling with substance use.

THE TRUTH ABOUT OPIOIDS: A NATIONAL CAMPAIGN TO PREVENT PRESCRIPTION OPIOID MISUSE IN YOUNG ADULTS

Elizabeth C. Hair, PhD¹, Jessica M. Rath, PhD, MPH, CHES¹, Alexa R. Romberg, PhD¹, Alexis A. Barton, PhD, MS¹, Donna Vallone, PhD, MPH¹

¹Truth Initiative, Washington, DC

Using mass-media to influence health-related behavior can be extremely efficient, given the size of the potential audience and the increasing rates of media usage across multiple devices. The national, anti-tobacco mass-media campaign, *truth*, is uniquely positioned to address the growing opioid crisis using similar strategies to those employed for the national anti-tobacco media campaign since 2000. This study aimed to understand *truth's* role in a mass-media opioid misuse prevention campaign, determine measures, and test ad concepts to change attitudes around risk perceptions and misuse/abuse of opioids.

Campaign development data was collected from over 6,000 young adults ages 15-34. Initial online surveys assessed knowledge of the epidemic and attitudes regarding misuse. Forced exposure studies tested concepts and polished advertisements through focus groups, surveys, and online discussion boards to understand ad effectiveness for message communication and emotional response.

Surveys to evaluate ad effectiveness were disseminated before launch and six months after launch. Questions were asked about participants' attitudes toward those with opioid addiction, importance of the ad message, and likelihood of seeking more information about the opioid epidemic.

Formative research results indicated a clear need for education. Among the youth and young adults interviewed, results found that leftover prescriptions were often sold or given away with no stigma attached. The target audience saw *truth's* brand as a natural fit to take on the issue of the opioid crisis. Ad testing narrowed down concepts and revealed a need for a call to action and message of hopefulness.

The in-field testing revealed that, relative to pre-launch levels, at six months post launch respondents who had seen the ads were 25% more likely to endorse de-stigmatizing statements such as "someone like me could become dependent on prescription opioids" and were 72% less likely to claim that misusing prescription opioids carried no risk of harm. We also saw a 20% increase over baseline in the reported likelihood to "Talk to a friend or loved one about their prescription opioid use."

truth's anti-opioid campaign's long-term goal is to change attitudes around opioid misuse and risk in order to decrease intention to misuse prescription opioids and decrease stigmatizing attitudes toward those suffering from addiction.

SENSE OF PURPOSE IN LIFE AND LOWER LIKELIHOOD OF FUTURE DRUG MISUSE

Eric S. Kim, PhD¹, Carol D. Ryff, PhD², Afton L. Hassett, PsyD³, Chad Brummett, MD³, Vic Strecher, PhD⁴

¹Harvard University, Cambridge, MA; ²University of Wisconsin, Madison, WI;

³Michigan Medicine, Ann Arbor, MI; ⁴University of Michigan School of Public Health, Ann Arbor, MI

Objective: In the United States, 28.6 million people used illicit drugs or misused prescription drugs in the last 30 days. Thus, identifying factors linked with lower likelihood of future drug misuse are important targets for research and practice. Sense of purpose in life has been linked with better behavioral and physical health outcomes. Further, a higher sense of purpose may reduce likelihood of drug misuse because it has been linked with several protective factors including: enhanced ability to handle stress, higher pain tolerance, and lower impulsivity. However, the association between sense of purpose and drug misuse has been understudied. Thus, we tested whether people with a higher sense of purpose at baseline had a lower likelihood of future drug misuse 9-10 years later. We also tested whether people with a stronger sense of purpose were less likely to cope with stress by misusing drugs (a potential underlying mechanism) in a separate cohort.

Methods: This study included 3,535 middle-aged adults from the Midlife in the United States Study (MIDUS) who were not misusing drugs at baseline. Using multiple logistic regression models, we prospectively assessed whether purpose in life was associated with risk of misusing drugs 9-10 years later. This study also included 498 older adults from the Health and Retirement Study (HRS). Using multiple logistic regression models, we cross-sectionally assessed whether purpose in life was associated with risk of coping with stress by misusing drugs.

Results: Among respondents not misusing drugs at baseline in the MIDUS sample, people in the highest quartile of purpose (versus lowest quartile) had 50% lower odds (95% CI:0.31-0.83) of future drug misuse in a demographic-adjusted model. Among HRS respondents, people in the highest purpose quartile (versus lowest quartile) had 76% lower odds (95% CI: 0.10-0.57) of misusing drugs to cope with stress in a demographic-adjusted model. In both sets of analyses (in MIDUS and HRS), associations remained evident after additionally adjusting for psychological distress, baseline health, and health behaviors.

Conclusions: A growing number of studies suggest that a sense of purpose can be increased. With additional research, purpose may emerge as a novel target for drug misuse prevention and intervention efforts.

BODY IMAGE, INTIMATE RELATIONSHIPS, AND SEXUAL HEALTH AMONG GENDER MINORITY YOUTH: A QUALITATIVE STUDY

Allegra R. Gordon, ScD, MPH¹, Rose Eiduson, MPH², Gabriel R. Murchison, MPH³, Madina Agénor, ScD, MPH⁴¹Boston Children's Hospital, Harvard Medical School, Boston, MA; ²Boston Children's Hospital, Jamaica Plain, MA; ³Harvard University, Brighton, MA; ⁴Tufts University, Medford, MA

Background: Gender minority (GM; e.g., transgender, gender non-binary) youth experience substantial sexual health inequities compared to their non-GM peers. These inequities may be driven by exposure to social stressors including stigma and violence, which can negatively impact body image and relationship power, both of which have been linked to adverse sexual health outcomes in non-GM youth. Yet little is known about the role of body image and intimate relationships in reducing or exacerbating sexual health risk factors among GM youth.

Methods: We conducted 30 in-depth interviews with GM young people (18–28 years) in the U.S. Northeast (gender identity: transgender women=8, transgender men=5, non-binary=17; race/ethnicity: White=18; Multiracial=5; Black n=4; Latinx=2; Asian=1). Interviews were transcribed, double-coded, and analyzed using a template-organizing style guided by a gender affirmation framework.

Results: Participants described several ways body image was related to intimate relationships, with implications for sexual health. We identified three themes. (1) Gender dysphoria and experiences with transphobia, racism and fatphobia affected body image and impeded sexual intimacy and perceived sexual decision-making power (i.e., the ability to communicate about sexual desires and/or make decisions about sexual activities) for several participants, and these experiences varied by gender identity. (2) Experiences with sexual violence were common, representing a profound barrier to both positive body image and to sexual health and wellbeing. (3) Multiple forms of resilience enabled participants to cultivate body appreciation and develop a sense of sexual decision-making power—particularly in the context of gender affirming romantic and sexual relationships (e.g., in which partners supported gender identity exploration, used affirming language for body parts and sexual activity, and engaged in dialogue about sexual health decisions such as barrier use for STI prevention).

Implications: In this formative study we identified critical connections between body image, intimate relationships, and sexual health risk factors among diverse GM youth. Sexual health promotion interventions should account for the role of body image and intimate relationships and should build on within-community resilience resources, including the experiences of those in supportive sexual/romantic relationships, in order to better meet the needs of this under-served population.

11:00 AM–11:15 AM

DIFFERENT TYPES OF HIV STIGMA AND MEDICATION ADHERENCE: THE MECHANISTIC ROLES OF ART KNOWLEDGE AND ADHERENCE SELF-EFFICACY

Chengbo Zeng, MPH¹, Xiaoming Li, PhD¹, Shan Qiao, PhD¹, Xueying Yang, PhD¹¹University of South Carolina, Columbia, SC

Background: Previous studies have demonstrated the negative relationship between HIV-related stigma and medication adherence among people living with HIV (PLWH). Yet, little is known about the relationships between different types of stigma (i.e., perceived community stigma, internalized stigma, and enacted stigma) and medication adherence. Additionally, there is few studies investigating the mechanisms through which types of stigma affect medication adherence. Based on the information-motivation behavioral skills (IMB) theory, the current study proposed that different types of stigma could impair medication adherence through their negative influences on ART knowledge and adherence self-efficacy. This study aimed to examine the mechanistic roles of ART knowledge and adherence self-efficacy on the relationships between different types of stigma and medication adherence.

Method: Data were derived from a baseline data of a prospective cohort study. Data collection was conducted from November 2017 to February 2018 in Guangxi, China. Six hospitals/clinics in five cities with the largest number of HIV patients were selected, and 1,198 PLWH were recruited. Participants were assessed on sociodemographic characteristics, medication adherence, different types of stigma (i.e., perceived community stigma, internalized stigma, and enacted stigma), ART knowledge, and adherence self-efficacy. Path analysis was used to examine the indirect paths from different types of stigma to medication adherence through ART knowledge and adherence self-efficacy.

Results: Among the 1,198 PLWH, 64.4% were male, and mean age was 39.4 years. The indirect paths from internalized stigma to medication adherence through ART knowledge (Std.β=-0.013, 95%CI: -0.004~0.000, p=0.049) and adherence self-efficacy (Std.β=-0.033, 95%CI: -0.008~0.003, p< 0.001) were statistically significant. Perceived community stigma could only affect medication adherence through adherence self-efficacy (Std.β=-0.012, 95%CI: -0.003~0.000, p=0.015) but not through ART knowledge (Std.β=-0.001, 95%CI: -0.001~0.000, p=0.526). There were no significant indirect effects from enacted stigma to medication adherence through ART knowledge (Std.β=-0.004, 95%CI: -0.005~0.000, p=0.213) and adherence self-efficacy (Std.β=-0.009, 95%CI: -0.008~0.000, p=0.07).

Conclusion: The mechanistic roles of ART knowledge and adherence self-efficacy are different in the relationships between different types of stigma and medication adherence. To improve medication adherence among PLWH, tailored interventions focusing on different types of stigma are warranted. Health education on increasing ART knowledge and resilience based intervention on improving adherence self-efficacy can also alleviate the negative influences of stigma on medication adherence.

Paper Session 7

11:15 AM-11:30 AM

SEXUAL MINORITY IDENTITY AND DEPRESSION AMONG U.S. YOUNG ADULTS: POTENTIAL MEDIATING ROLE OF NEGATIVE SOCIAL MEDIA EXPERIENCES

Cesar G. Escobar-Viera, PhD, MD¹, Ariel Shensa, MA¹, Michael Marshal, PhD²¹University of Pittsburgh, Pittsburgh, PA; ²University of Southern California, Pittsburgh, PA

Introduction: Sexual minority young adults (SMYA) face higher risk of depression compared to their heterosexual peers. Minority stress theory posits that experiences of rejection and discrimination might influence these outcomes. While social media (SM) is a key source for connecting and finding support among SMYA, it may also be a source of negative (rejection- and discrimination-related) SM experiences among SMYA. No study has explored whether these negative SM experiences influence mental health among SMYA. We sought to fill this gap by assessing a potential indirect path via negative SM experiences in the association between sexual minority identity and depression among a national sample of U.S. young adults.

Methods: Online survey among 2,408 adults ages 18-30. We categorized sexual orientation in lesbian, gay, and bisexual (LGB) and non-LGB. We assessed negative SM experiences with four Likert-scale items covering different types of negative interactions. Answers were averaged to create a continuous scale from 1 'never' through 5 'more often than once a week.' We assessed depression using the Patient Health Questionnaire (PHQ-9), scores 0-27. We used generalized structural equation models and standardized coefficients to assess direct and indirect effects of sexual minority identity on depression via negative SM experiences, controlling for relevant demographic variables. We used Stata 15 for statistical analyses.

Results: We found a statistically significant positive relationship between LGB identity and reporting of higher depressive symptoms (Path C = beta: 0.17; $p < 0.01$; 95% C.I. 0.13 – 0.21). An indirect, statistically significant relation was found between LGB identity and depression (Path C' = beta: 0.13; $p < 0.01$; 95% C.I. 0.09 – 0.17) via negative social media experiences (Path AB = betas: 0.12; $p < 0.01$; 95% C.I. 0.08 – 0.16 and 0.31; $p < 0.01$; 95% C.I. 0.27 – 0.35, respectively). The AB-C' path model explained 19% of variance in depression.

Conclusions: Our findings indicate that reducing negative SM experiences among sexual minority individuals may be a significant intervention to help reducing depressive symptoms among this population. These results suggest it is important to continue studying the unique SM experiences of SMYA. Future research needs to focus on the potential contribution of positive SM interactions to mental health outcomes, as well as change overtime of the potential influence of both positive and negative SM experiences on depression.

CABALLERISMO AND COMMUNICATION AS PREDICTORS OF PARTNER RECRUITMENT AMONG LATINX SEXUAL MINORITY COUPLES

Gabriel Robles, PhD¹, Trey V. Dellucci, MS², Beverlin del Rosario, BS, MA³, Ruben H. Jimenez, n/a⁴, Tyrel J. Starks, PhD⁵¹Hunter College, New York, NY, NY; ²The Graduate Center at CUNY, New York, NY; ³Hunter College/The Graduate Center, CUNY, New York, NY;⁴Hunter College's PRIDE Health Research Consortium, New York, NY; ⁵Hunter College, CUNY, Brooklyn, NY

Background: Latinx sexual minority men (LSMM) have the largest growing incidence rates of HIV diagnoses. Couples-focused research among sexual minorities has received considerable attention, because transmission risk behaviors are higher among main partners. Many dyadic studies utilize a sequential index approach to recruiting couples. One person in the couple (the index case) is recruited into the study. He is then asked to recruit his partner. While this sequential recruitment strategy is promising, some evidence suggests that index recruitment may bias samples to over-represent couples with better dyadic functioning. Given that LSMM have higher incident rates of HIV than other ethnic groups, it is critical to identify factors that would facilitate partner recruitment of LSMM into HIV prevention programs.

Methods: A national sample of 635 Latinx index cases was recruited via social media apps and 95 index partners were able to recruit their partner. Most men identified as gay (88.2%), earned less than \$30k per year (62.6%), had less than a bachelor's degree (61.9%), and were HIV negative/unknown (77.4%). Most index partners identified their main partner's ethnicity as also being Latinx (66.2%) and completed the survey in English (80.3%). Participants provided demographic information and completed the Communication Patterns Questionnaire and the Machismo Scale measuring both *machismo* and *caballerismo* (e.g., chivalry).

Results: Logistic regression analyses were conducted to examine the effect of dyadic communication, *machismo* and *caballerismo*, and demographic factors on the ability to recruit one's partner. The model tested all potential interactions of dyadic communication, *machismo* and *caballerismo* on the ability to recruit one's partner. Non-significant interactions were removed using a reverse hierarchical entry procedure. Analyses adjusted for HIV status, demographics and relationship length. Results indicated that index partners who were high in *caballerismo* and low in *machismo* had greater success in recruiting their partner, while those who were low in both *caballerismo* and *machismo* were the least successful. Second, there was a significant interaction between the constructive communication and *caballerismo*. Those who were high in *caballerismo* and low in constructive communication had the highest probability of successfully recruiting their partner, while positive communication was only a predictor of successful recruitment when *caballerismo* was low.

Conclusion: The findings in the present study have significant theoretical and clinical implications. The findings suggest that although communication is a useful health behavior to examine among couples, these factors would benefit from further consideration of cultural factors relevant to racial minorities, thus, better tailoring campaigns to recruit LSMM and facilitate partner engagement.

Paper Session 8

10:45 AM–11:00 AM

SENSE OF PURPOSE IN LIFE AND HEALTH BEHAVIORS OVER TIME

Eric S. Kim, PhD¹, Koichiro Shiba, N/A², Julia Boehm, PhD³, Laura D. Kubzansky, PhD²¹Harvard University, Cambridge, MA; ²Harvard T.H. Chan School of Public Health, Boston, MA; ³Chapman University, Orange, CA

Objective: A growing body of research has observed that a higher sense of purpose in life is associated with lower risk of chronic conditions and premature mortality, and researchers speculate that health behaviors may partially explain these findings. However, the prospective association between sense of purpose in life and health behaviors is understudied. We tested whether a higher sense of purpose in life at baseline was associated with lower likelihood of engaging in healthy behaviors over time.

Methods: Prospective data were from the Health and Retirement Study, a nationally representative sample of U.S. older adults. Our sample included 13,770 adults assessed up to five times across 8 years.

Results: Among people who met recommended guidelines for a given health behavior at baseline, those in the top versus lowest quartile of purpose in life had a 36% lower likelihood of smoking initiation (95% CI: 0.42–0.99), 24% lower likelihood of becoming physically inactive (95% CI: 0.68–0.85), 34% lower likelihood of developing sleep problems (95% CI: 0.57–0.77), 16% lower likelihood of becoming overweight/obese (95% CI: 0.71–1.00), and there was a null association with likelihood of becoming a binge-drinker (HR=0.93, 95% 95% CI: 0.82–1.06) in sociodemographic-adjusted models. Findings for physical activity and sleep (but not smoking and body weight) remained evident after further adjusting for baseline health status and depression.

Conclusion: Overall, a sense of purpose in life was associated with higher likelihood of maintaining recommended levels of physical activity and sleep quality over 8 years, suggesting that it may be a valuable target for interventions aimed at helping older adults maintain these health behaviors.

Paper Session 8

11:00 AM–11:15 AM

THE ROLE OF SPIRITUALITY IN CONCEPTUALIZATIONS OF HEALTH MAINTENANCE AND AGING AMONG LATIN AMERICAN IMMIGRANTS IN THE BAY AREA

Sophia Weiner-Light, B.A.¹, Sergio Lanata, MD¹, Katherine Rankin, PhD¹, Katherine Possin, PhD¹, Daniel Dohan, PhD¹, Alissa Bernstein, PhD¹¹University of California, San Francisco, San Francisco, CA

Background: As the population ages, there is an increasing focus on addressing the health and wellbeing of older adults. In recent years, academic interest in spirituality and aging has been on the rise, with studies conflicting on the potential health benefits of spirituality and religiosity in older adults. Spirituality may play an especially salient role among immigrants from Latin America, as the emphasis on religion in various Latin American cultures is well-documented and, moreover, organized religion may provide an opportunity for immigrants, regardless of background, to build community. However, few studies identify the role that spirituality may play in the conceptualization of brain aging among immigrants from Latin America. This study aimed to capture the perspectives on aging and the maintenance of brain health of a small, yet diverse cohort of older adults who migrated to the Bay Area from urban and rural regions of Mexico, Nicaragua, El Salvador and Ecuador.

Methods: We conducted ethnographic interviews in Spanish with 15 immigrants over the age of 65. Interview questions addressed perspectives about the brain, aging, dementia, and health-seeking behaviors. Interviews were coded for key themes using Dedoose.

Results: Most participants, who had previously participated in a workshop on brain health, noted the importance of engaging in maintenance strategies to promote brain health, such as physical activity, diet, social activity and sleep. We focus here on the discussion of the role of spirituality and religion as a strategy to promote brain health, which emerged independent of the materials covered in the workshop, in 9 out of the 15 interviews. We identified 5 major themes: (1) *expressing gratitude to God for mental and physical health*, (2) *putting the onus of life and death in God's hands*, (3) *using church as a place to socialize and build community as an approach to leading a healthy lifestyle*, (4) *using prayer as nourishment for the soul and the brain*, and (5) *gaining inner-peace and calmness, and thus maintaining a healthy life, due to a connection with God*.

Conclusions: With the rise of the 65+ population and the expected increase in the incidence of dementia, it is critical to develop successful strategies for promoting brain health. This study illuminates one possible patient-centered approach, pertaining to the incorporation of customized spiritual interventions as a potential mechanism by which to increase the effectiveness of brain health promotion efforts.

Paper Session 8

11:15 AM-11:30 AM

AN E-TRAINING PACKAGE TO ENHANCE CARE OF AGED AND DYING PRISONERS

Valerie H. Myers, PhD¹, Susan J. Loeb, PhD, RN, FGSA, FAAN², Erin Kitt-Lewis, PhD³, Julie L. Murphy, n/a⁴, Rachel Wion, PhD, RN⁵, Tiffany Jerrod, BS, MPH¹

¹Klein Buendel, Inc., Golden, CO; ²The Pennsylvania State University, University Park, PA; ³Penn State, University Park, PA; ⁴King's College, Wilkes Barre, PA; ⁵Pennsylvania State University, University Park, PA

There are more than 2.3 million prisoners in the U.S. Much like demographic trends in the free world, the number of older inmates is growing. Despite advances in the free world, best practices for managing geriatric issues and end-of-life (EOL) care have not been adapted for use in corrections settings. Due to the paramount focus on security, technological advances available in the free world are inaccessible inside prison walls. This project, Enhancing Care for the Aged and Dying in Prisons (ECAD-P), built a full-scale media-rich interactive computer-based learning system for multidisciplinary staff consisting of six modules to address EOL and geriatric care issues in prisons. ECAD-P was iteratively built and tested. Usability testing was conducted in two rounds at two separate prisons located in different states with staff (n=24). The System Usability Scale (SUS), a validated tool for assessing the usability and acceptability of technological products, score was 75.10 (SD=15.45). This score suggests a high level of acceptability and usability since a score of 68 is considered above average. Full scale testing of the ECAD-P learning system occurred at 7 state prisons. A total of 241 participants consented to participate; 173 completed all training modules and post-test (completion rate = 71.78%). Outcomes were (1) knowledge acquisition of the need for and delivery of care for aging and dying inmates (i.e., cognitive measures); and (2) values, motivations, and attitudes for providing care to inmates (i.e., affective measures). A paired-samples t-test was conducted to compare cognitive pre- and post-training measures. Cognitive post-test scores (M=90.74, SD= 8.60) were significantly higher than cognitive pre-test scores (M=81.01, SD=12.53 $t(185) = 11.13, p < .0001$). At post-test, affective measures were statistically higher (M=79.63, SD=18.74; $t(168) = 16.36, p < .0001$) than at pre-test (M=48.20, SD=24.17). ANCOVAs controlling for pre-test values revealed no significant differences at post-test for sex or ethnicity variables (all $p > .05$). The mean SUS score for the large-scale testing (n=171) was 69.34 (SD=16.08). These outcomes reveal that the ECAD-P product is acceptable, feasible, and usable in corrections. Staff improve their knowledge about geriatric and EOL care after receiving the ECAD-P training. Correctional settings across the U.S. face growing demands to better address the health care and management needs of aged, chronically ill, and dying inmates. This e-training holds promise to contribute to better preparation of correctional staff to effectively care for these populations.

CORRESPONDING AUTHOR: Valerie H. Myers, PhD, Klein Buendel, Inc., Golden, CO; vmymers@kleinbuendel.com

Paper Session 8

11:30 AM-11:45 AM

LOSING A LOVED ONE TO CHRONIC ILLNESS IS ASSOCIATED WITH POORER ADJUSTMENT TO GRIEF

Elisabeth McLean, B.A.¹, Jonathan D. Singer, MA², Anthony Papa, PhD³

¹University of Nevada, Reno, Sparks, NV; ²University of Nevada, Reno, Carson City, NV; ³University of Nevada Reno, Reno, NV

Introduction: Numerous studies have identified risk factors for pathological grief disorder (PGD). Studies are equivocal regarding illness as a cause of death as a risk factor for PGD for family members. Identifying if illness moderates the relationship between established modifiable risk factors and PGD may help identify individuals who are at greater risk for PGD.

Methods: First, the study replicated past studies by identifying if caregiving and more contact spent with the person who has died are risk factors for PGD in two unique samples. Second, examines if illness significantly moderates the relationship between the established risk factors (i.e., caregiver; contact) and PGD. Recruitment for both studies was completed through Amazon MTurk. Sample characteristics included: Study 1, N = 301 (175 females), Mage = 37.32 (SD=12.54) and Study 2, N=159 (96 females), Mage = 34.84 (SD=12.44). Results Replicating established findings, there were main effects for increases in caregiving and contact with the person who had passed away predicting significantly increased rates of PGD (p 's < .01). The interaction term between illness and amount of contact ($p < .01$) significantly predicted PG symptomatology in study 1 ($F(3, 297) = 16.72, p < .001$) and study 2 ($p < .05$; $F(3, 145) = 5.63, p < .001$). The interaction term between illness and caregiver or not ($p < .05$) significantly predicted PG symptomatology in study 1 ($F(3, 297) = 8.83, p < .001$) and study 2 ($F(3, 145) = 4.41, p < .001$). Simple slope analysis indicated that for people who had a loved one die of an illness, caregiving was associated with a higher level of grief ($B=2.02, p < .05$). For those whose loved one did not die of illness, caretaking had no effect on intensity of grief ($B=-1.36, p > .05$). Simple slope analysis indicated that for people who had a loved one die of an illness, time spent before their death was associated with a higher level of grief ($B=-3.33, p < .05$). For those whose loved one did not die of illness, time spent before their death had no effect on intensity of grief ($B=0.98, p > .05$). It should be noted that individuals who were caregiving for an individual who did not have an illness reported caring for someone who ended up dying of "old age. Discussion The combined effect of caregiving and losing a loved to a chronic illness confers the greatest risk for poor adjustment to grief. Also, the combined effect of amount of contact prior to their death and losing a loved to a chronic illness resulted in greatest risk for poor adjustment to grief.

Thursday April 2nd, 2020 12:45 PM-1:45 PM

Panel 1

12:45 PM-1:45 PM

THE PROLIFERATION OF DIFFERENT HEALTH BEHAVIOR THEORIES IN BEHAVIORAL MEDICINE IS HINDERING ADVANCES IN RESEARCH AND PRACTICE

Paul Branscum, PhD, RD¹, Ryan E. Rhodes, Ph.D.², Susan Michie, BA, MPhil, DPhil³, Claudio Nigg, PhD⁴, Jane Ogden, PhD⁵, Eric B. Hekler, PhD⁶

¹Miami University, Oxford, OH; ²University of Victoria, Victoria, BC, Canada; ³University College London, London, England, UK; ⁴Karlsruhe Institute of Technology, Karlsruhe, Baden-Württemberg, Germany; ⁵University of Surrey, Guildford, England, UK; ⁶UC San Diego, San Diego, CA

Health behavior theory has become an indispensable tool for research and practice, but recently it has become apparent that there are numerous theories practitioners and researchers can utilize, oftentimes having overlapping perspectives and constructs. For example, in a recent review an expert advisory group searched the literature from 1960 to 2012 and identified 83 theories of behavior change. This points to the need for more uniformity in the field if it is to move forward, as a lot of effort is being exerted studying little known and underutilized theories. Yet, such uniformity could also stifle creativity, as researchers and practitioners may only want to use theories that are well-known. In this session, researchers will debate two different perspectives on the proliferation of different health behavior theories: that advances in behavior change research and practice are hindered by having too many theoretical perspectives to choose from, or having a large number of theoretical perspectives will ultimately help research and practice move forward, as we attempt to uncover vital questions such as “what works”, “when does it work”, and “with whom does it work best”.

PRESIDENTIAL PANEL DISCUSSION: SHARING YOUR FINDINGS: STRATEGIES FOR EFFECTIVE AND ENGAGING SCIENCE COMMUNICATION

Monica Wang, ScD, MS¹, Berly McCoy, PhD², Becky Mackelprang, Ph.D.³, Alexandra Schnoes, PhD⁴, Carly M. Goldstein, PhD⁵

¹Boston University School of Public Health, Newton, MA; ²NPR Scicommers, Coram, MT; ³(Freelance), Berkeley, CA; ⁴iBiology, San Francisco, CA; ⁵The Miriam Hospital/Alpert Medical School of Brown University, Providence, RI

Without science communication, research findings stay in academia. Although training opportunities are growing, it is not yet common practice to teach scientists communication skills concurrently with research training. For those that recognize the importance of science communication, it is often difficult to know where to begin and how to incorporate an added skillset into an already demanding workload. The goal of this panel is to give attendees a practical set of actions they can take to get started in science communication and considerations to keep in mind before they begin engaging in science communication through writing, multimedia, and in person activities. External panelists with expertise in science communication will co-present on the panel. Each will share 1) their journey from science to science communication 2) the current projects they are focusing on and 3) their advice on how to get started communicating science to a particular audience. The panel discussion will include important concepts in communicating science such as understanding an audience, using storytelling as a tool to communicate, and reducing jargon, as well as a myriad of resources available to scientists interested in improving their communication skills.

DHC PRESENTS: DIGITAL HEALTH: THE YEAR IN REVIEW

Emily G. Lattie, PhD¹, Jessica Y. Breland, PhD², Danielle E. Jake-Schoffman, PhD³, Manal Alabduljabbar, PhD Candidate⁴, Charles R. Jonassaint, PhD, MHS⁵, Ellen Beckjord, PhD, MPH⁶, Heather Cole-Lewis, PhD, MPH⁷, Stephen M. Schueller, PhD⁸, Urmimala Sarkar, MD⁹

¹Northwestern University, Chicago, IL; ²VA Palo Alto Health Care System, Menlo Park, CA; ³University of Florida, Gainesville, FL; ⁴Neamah Digital Health, Boston, MA; ⁵University of Pittsburgh, Pittsburgh, PA; ⁶UPMC Health Plan, Pittsburgh, PA; ⁷Johnson and Johnson, Westfield, NJ; ⁸University of California, Irvine, Irvine, CA; ⁹UCSF, San Francisco, CA

Continuing from last year, the Society of Behavioral Medicine's Digital Health Council decided to produce a Digital Health Year in Review. The goal of the Review is to inform SBM and the broader interested public of advances, innovations, and developments in the field of digital health, both within academia and in industry. In this panel, members of the Digital Health Council and the Year in Review Workgroup will describe the methodology used to identify, triage, review, and synthesize information from the peer-reviewed and gray literature to produce the Year in Review. We will present the Review and facilitate a discussion with thought leaders from both within and outside of SBM about the contents of the Review and forecast what may be to come in 2020. Finally, we will describe plans to further disseminate the Review beyond presentation at the Annual Meeting. Panel members will include [blinded for review]

CHALLENGES AND SOLUTIONS OF OPEN SCIENCE RELATED TO OPEN ACCESS PUBLISHING, RESOURCE SHARING, AND CITIZEN SCIENCE

Dominika Kwasnicka, PhD¹, Bradford W. Hesse, PhD², Molly E. Waring, PhD³, Eric B. Hekler, PhD⁴, David E. Conroy, PhD⁵, Sarah Andrus, BA, MBA⁶, Kenneth P. Tercyak, PhD⁷, Abby C. King, PhD⁸

¹SWPS University of Social Sciences and Humanities, Warszawa, Dolnoslaskie, Poland; ²National Cancer Institute, Kailua Kona, HI; ³University of Connecticut, Storrs, CT; ⁴UC San Diego, San Diego, CA; ⁵The Pennsylvania State University, University Park, PA; ⁶Oxford University Press, New York, NY; ⁷Georgetown University / Lombardi Comprehensive Cancer Center, Washington, DC; ⁸Stanford University School of Medicine, Stanford, CA

Background: The “drive for open science” has increased over the past years and has reached heightened visibility with the announcement of large participative program activities such as the National Institutes of Health’s “BRAIN initiative,” the “All of Us” program, and the “Cancer Moonshot.” Legislative efforts have added to the discussion, with public legislation passed to open access to research funded by public funds to the public domain within 12 months after publication. Others see the transition to openness as a necessary growing pain for overcoming the risk of irreproducible results and an inherent publishing bias against findings supporting the null hypothesis. The movement to open science is not without controversy, as opponents and allies exchange deep-felt arguments. For some it is the end of an ordered status quo of discovery, whereas for others it is the promise of accelerated science and advancement. Up to recently, discussions have been confined to the basic and medical sciences; however, there have been some efforts to bring social and behavioral science into the open science arena.

Aims/Methods: As the trend for more and more open science initiatives continues, the Society of Behavioral Medicine (SBM) has convened a Working Group to lead the Society’s exploration of the implications of this movement for its members and others working in behavioral medicine. The aims of this panel discussion are to: (1) Discuss implications of open science for social and behavioral scientists working to improve public health (e.g., what can behavioral scientists learn from the existing experience with open science?; does open science affect collaborative efforts between behavioral scientists and basic science?), (2) Educate SBM members about open science (e.g., are the implications of open science different for established versus early career researchers?), and (3) Outline and discuss proposed recommendations developed by the Working Group that can be adopted by the SBM members.

Key areas: This panel will discuss challenges and potential benefits of open science focusing on three key areas: open access publishing, resource sharing, and citizen science. The panel members will outline and discuss recommendations for the Society and behavioral scientists to address the challenges of open science.

Discussion: We will propose and discuss methods available for increasing transparency and openness. We will debate the incentives and disincentives to increasing transparency and openness and also the social consequences of open science. We will open the discussion to engage the audience in conversation about current practices and suggestions for how to move the field forward adapting best practices for open science, that overcome challenges to open science and leverage these practices to maximize the impact of our science on the nation’s health.

Panel 5

12:45 PM-1:45 PM

ADDRESSING GUN VIOLENCE AT MULTIPLE LEVELS: IN OUR CLINICS, OUR RESEARCH, OUR CLASSROOMS, AND THROUGH OUR POLITICAL PROCESS

Sheela Raja, PhD¹, Pamela Behrman, MS, PhD², Rebecca Cunningham, MD³, Brian (Tate) Guelzow, PhD⁴, Kathryn Maher, Ph.D.⁵, Arlen C. Moller, PhD⁶

¹University of Illinois Chicago, Chicago, IL; ²College of Mt. St. Vincent, New Britain, CT; ³University of Michigan, Ann Arbor, MI; ⁴San Francisco VA Healthcare System, San Francisco, CA; ⁵Virginia, Richmond, VA; ⁶Illinois Institute of Technology, Chicago, IL

Gun violence in the U.S. is a complex and growing public health crisis. The Society of Behavioral Medicine (SBM) is comprised of a variety of behavioral scientists and clinicians, uniquely conducting research and practice at the intersection of trauma and health, often on the “front lines.” Gun violence has adverse influences on both physical and mental health and as SBM members, we are uniquely trained to examine this interaction. This panel discussion will focus on some of the ways that SBM’s cross-disciplinary members are contributing to finding and leading evidence-based solutions. We hope this open discussion will inspire more SBM members to use their expertise toward addressing this challenging public health crisis in all its forms. Specifically, panel members will describe their ongoing work to reduce gun violence in a variety of settings including medical and clinical settings, research, higher education, our communities, and through policy advocacy. One theme involves recognizing the impact of trauma, and its far-reaching impact on health. How can SBM members raise awareness to increase trauma informed care, particularly to other health care providers and behavioral scientists? A second theme involves raising awareness of research and behavioral interventions around gun violence (e.g., safely locking firearms at home, or when appropriate, outside the home, to reduce risk of suicide and unintentional injury). Panel members will also discuss unique challenges related to political partisanship, and invite audience participation. In sum, the goal of this panel is to echo past-President Sherry Pagato’s message from last year, that: “*In an era where fake news and misinformation are spreading like wildfire, it is more imperative than ever that we communicate our science and public health messaging loudly and clearly.*” We hope this panel discussion will further lead the narrative on gun violence by stimulating, leveraging, and disseminating evidence-based behavioral science.

Panel 6

12:45 PM-1:45 PM

COMPATIBILITIES BETWEEN THE MULTIPHASE OPTIMIZATION STRATEGY AND IMPLEMENTATION SCIENCE: AN OPEN DISCUSSION

Heather Wasser, PhD, MPH¹, Kate Guastaferrro, PhD, MPH², Paul Estabrooks, PhD³, Gary Bennett, PhD⁴, Marya Gwadz, PhD, MA⁵

¹University of North Carolina at Chapel Hill, Carrboro, NC; ²Pennsylvania State University, University Park, PA; ³University of Nebraska Medical Center, Omaha, NE; ⁴Duke University, Durham, NC; ⁵New York University, New York, NY

This panel discussion seeks to identify ways in which the Multiphase Optimization Strategy (MOST) can be utilized to promote the goals of Implementation Science, which is the study of methods to promote the adoption, adaptation, and integration of evidence-based practices (EBP), interventions and policies into routine health care and public health settings. More specifically, Implementation Research involves examining mechanisms of EBP dissemination and quality implementation, testing strategies to address mechanisms, and studying the potential for EBP adaptation, systemic integration, scale-up/out, and sustainability. Key is a focus on clinical and community systems that require implementation facilitation across multiple levels (e.g., administrative decision making, those responsible for EBP implementation). While it seems that MOST, a systematic framework by which to improve multicomponent behavioral treatment packages, could be useful in Implementation Research, we currently find no examples of MOST being used in the field of Implementation Science. Conversely, researchers who are using MOST are largely doing so to elucidate the most effective package of components on a given behavioral or biological outcome, but rarely incorporate the outcomes considered by implementation researchers. This is despite optimization being defined as “the process of identifying an intervention that provides the best expected outcome obtainable within key constraints imposed by the need for efficiency, economy, and/or scalability.” To best facilitate a discussion around the intersection of the MOST framework and Implementation Science, we will begin with brief overviews of MOST and Implementation Research, including our panel members’ initial thoughts on their compatibilities. This will be followed by two examples of current research projects utilizing the MOST framework and open discussion around ways in which such projects might incorporate Implementation Research methods, as well as a broader discussion of how the MOST framework might be applied within the field of Implementation Science. This panel discussion may be most useful and of interest to those already familiar with the MOST framework or Implementation Science. Audience participation in the discussion will be highly encouraged.

Panel 7

12:45 PM-1:45 PM

ENGAGING UNDERSERVED OR VULNERABLE POPULATIONS IN RESEARCH: MOVING BEYOND THE NIH INCLUSION ENROLLMENT REPORT

Shelby Langer, PhD¹, Felipe G. Castro, PhD, MSW¹, Rebecca E. Lee, PhD¹, Linda K. Larkey, PhD¹, Elizabeth Reifsnider, PhD, RN, WHNP-BC, PHCNS-BC, FAANP, FAAN¹, Shawn Youngstedt, PhD², Kelly Davis, Ph.D.¹, Rodney P. Joseph, PhD¹, Gabriel Shaibi, PhD³

¹Arizona State University, Phoenix, AZ; ²ASU, Phoenix, AZ; ³Center for Health Promotion and Disease Prevention, Phoenix, AZ

Background: The Belmont Report (1979) outlined basic ethical principles for conducting biomedical and behavioral research involving human participants. The Code of Federal Regulations (45 CFR 46) further specifies requirements to ensure protections for vulnerable populations. We propose a panel discussion that describes strategies to adhere to and advance important considerations when working with vulnerable populations. These include minority women and children, undocumented immigrants, veterans with mental health conditions, trauma survivors, and patients near end-of-life. These populations are at greater risk for adverse health outcomes and are less likely to have access to personalized health care.

Panel composition: Investigators from a Research 1 university will discuss challenges faced and lessons learned in the process of recruiting, engaging, and retaining research participants from a variety of underserved or vulnerable populations: Latinx children, adolescents, and families with obesity; Latinx adults with varying levels of acculturation; African American women at risk for cardiometabolic diseases; severely depressed and/or suicidal Veterans; women with histories of trauma and interpersonal violence; and patients with life-limiting illness and their caregiving partners. Participants in studies conducted by these investigators have been recruited to descriptive, observational, experimental or interventional studies through various networks including clinics and health-care organizations, community centers and schools, and social media and other online outlets. We will share typical recruitment and retention rates and culturally appropriate actions to promote engagement. Other topics to be covered include challenges faced such as fear and mistrust (e.g., among Latinx families, regardless of their immigrant status or documentation); avoiding perception of coercion; data security; the importance of investigator cultural competence; the need to develop and foster a sense of trust coupled with bidirectional communications with stakeholders and citizen scientists; the need to design interventions that address a community-defined need; and ethical issues in providing practical assistance and appropriate compensation to facilitate participation. These topics will be discussed in light of changing demographics and healthcare landscapes, and the need to balance scientific advancement and community/clinic engagement.

Panel 8

12:45 PM-1:45 PM

USING PUBLIC HEALTH MESSAGING AND COMMUNICATION CAMPAIGNS FOR MEANINGFUL BEHAVIOR CHANGE

Alan R. Teo, M.D., M.S.¹, Miriam H. Eisenberg Colman, Ph.D.², Aisha Langford, PhD³, Ronne Ostby, MA²¹VA Portland Health Care System, Portland, OR; ²Fors Marsh Group, Arlington, VA; ³NYU School of Medicine, New York, NY

Communication campaigns are planned efforts featuring an organized set of messages, strategies, and tactics tied to one or more objectives intended to generate specific outcomes or effects in large audiences, within a specific period of time. Long used as an intervention to promote public health and behavior change, communication campaigns have the potential to influence not only knowledge and attitudes, but also trigger individual actions. At the same time, communication campaigns have been often critiqued for being too broad with vague goals and not showing return on investment.

In this Panel Discussion, we will present a structured, sequential overview to the use of public messaging and communication campaigns for health behavior change. The first presenter will describe best practices for designing and developing effective health communication campaigns. This discussion will include strategies for understanding the consumer/patient mindset and using that information to refine the campaign messages. Using hypertension as an example, the second presenter will address the process of translating messages for a public (lay) audience and when tailoring vs. targeting may be appropriate. Plain language principles and strategies for evaluating health communication efforts will also be discussed. The third presenter will provide an in-depth examination of communication campaigns related to suicide prevention, drawing from recent and ongoing communication campaigns targeting service members and military veterans. Particular attention will be drawn to empirical studies of communication campaigns providing evidence for (and against) behavior change, such as help-seeking behavior. The panel chair will probe panelists with questions about challenges they have faced, lessons they have learned, and advice they have for SBM members interested in developing effective health communication campaigns and translating their research skills to inform communication campaigns.

Panel 9

12:45 PM-1:45 PM

IMPACTFUL HEALTH AND AGING POLICY: PRACTICAL APPROACHES FOR BEHAVIORAL MEDICINE RESEARCHERS

Lauren R. Bangerter, PhD¹, Renae L. Smith-Ray, PhD, MA², Akilah Dulin, PhD³, Joanna Buscemi, PhD⁴¹Mayo Clinic, Minneapolis, MN; ²Walgreen Co, Deerfield, IL; ³Brown University, Providence, RI; ⁴DePaul University, Chicago, IL

With an aging population that is now living longer than ever before, one of the greatest challenges for the U.S. is ensuring that health policies provide the best possible health outcomes and quality of life for aging adults and their families. Evidence-based state and federal policies in health and aging can have a substantial positive impact on older adults' health outcomes, however, many behavioral medicine researchers do not receive policy-based training and may not know how to become involved in health policy. The objective of this panel is to stimulate behavioral researchers' interests in contributing their scientific expertise in behavioral medicine to the health policy process. The panel will highlight federal policies that address aging, with emphasis on some of the most recent policies, including the reauthorization of the Older American's Act, the RAISE Family Caregiver Act, and the Supporting Grandparents Raising Grandchildren Act. The dialog will center on the conception, development, and implementation of these broad federal policies. Using diabetes-related policy as an example, the panel will discuss how differing health policies by state have been associated with varied health outcomes of older adults. Practical approaches to influencing policy will also be discussed, including the importance of policy briefs and op-eds. The panel will also feature discussion about how SBM is involved in the health policy brief process. Panel attendees will participate in an interactive session where they will work collaboratively to draft a policy brief in their respective research areas. The panel session will be an opportunity for behavioral medicine researchers to gain insight into the policy process, and learn about practical steps to ensure that scientific knowledge is translated to impactful health policy that promotes health across the lifespan.

Panel 10

12:45 PM-1:45 PM

THE OBESITY MEDICAL EDUCATION COLLABORATIVE: DISSEMINATION, IMPLEMENTATION, AND THE ROLE OF BEHAVIORAL MEDICINE

Catherine L. Davis, PhD, FTOS, FABMR, FSBM¹, Robert F. Kushner, MD², Taraneh Soleymani, MD FTOS³, Joshua D. Brown, PhD, FTOS⁴, Sherri Sheinfeld Gorin, PhD⁵, Judith K. Ockene, MA, MEd, PhD⁶¹Georgia Prevention Institute, Medical College of Georgia, Augusta University, Augusta, GA; ²Feinberg School of Medicine, Northwestern University, Chicago, IL; ³Summit Medical Group, Morristown, NJ; ⁴Wake Forest Baptist Health, Winston-Salem, NC; ⁵University of Michigan, NYPAC, Ann Arbor, MI; ⁶University of Massachusetts Medical School, Worcester, MA

The Obesity Medical Education Collaborative (OMEC; 63 members from 15 national professional organizations, including SBM) developed obesity-related competencies and benchmarks for medical education (undergraduate (MD), residency, fellowship, and continuing education for MDs, PAs and NPs) using the six core competencies of the Accreditation Council for Graduate Medical Education. After undergoing an external review by 19 organizations, including the Association of American Medical Colleges, the competencies and associated benchmarks were published in June 2019 (<https://onlinelibrary.wiley.com/doi/10.1002/oby.22471>) and endorsed by 20 national professional organizations including SBM. The competencies draw on behavioral medicine expertise and are intended to be used by medical, nursing, and physician assistant educators.

During this panel discussion, participants will learn about the obesity medicine competencies and benchmarks from those who crafted them. We will focus on the potential contributions of behavioral medicine on implementing the OMEC standards in medical education. With obesity and diabetes as exemplary conditions, we will discuss evidence-based interventions in counseling, weight loss, and physical activity (e.g., DPP and Look AHEAD trials) that align with the benchmarks. The panel will be led by authors of the standards. Chairs, SBM members who worked on these standards, will engage the panelists and attendees in a moderated discussion.

Sponsored by the Scientific & Professional Liaison Council and the Diabetes, Evidence-Based Behavioral Medicine, Obesity & Eating Disorders, and Physical Activity Special Interest Groups.

Panel 11

12:45 PM-1:45 PM

IN PURSUIT OF CANCER HEALTH EQUITY

Marian L. Fitzgibbon, PhD¹, Christina Ciecierski, PhD², Laura L. Hayman, PhD, MSN, FAAN, FAHA, FPCNA³, Isabel C. Scarinci, PhD, MPH⁴, Karriem S. Watson, DHS, MPH, MS⁵, Betina Yanez, PhD⁶

¹University of Illinois at Chicago, Chicago, IL; ²Northeastern Illinois University, Chicago, IL; ³UMass Boston, 100 Morrissey Blvd. Boston, MA 02125-3393, Boston, MA; ⁴University of Alabama at Birmingham, Birmingham, AL; ⁵University of Illinois Cancer Center at UIC, Chicago, IL; ⁶Northwestern University, Chicago, IL

This panel discussion is based on the premise that today's healthcare challenges are ideally addressed through community-academic partnerships. To meet the aims of this year's conference, this panel discussion uses the U54 Comprehensive Partnerships to Advance Cancer Health Equity (CPACHE) Program as a framework to provide a forum for discussion from individuals at institutions funded under this NCI mechanism. The overarching expectation of CPACHE is to advance the national cancer research agenda through the development of partnerships between institutions that serve underserved cancer health disparity populations and NCI-designated cancer centers. The partnerships are expected to develop a multidisciplinary, multi-institutional approach to improve institutional capacity that increases cancer research at the minority serving institutions. They are also expected to increase research, training and community engagement opportunities for minority students and investigators. Additionally, there is an expectation that the designated cancer centers will enhance their research portfolio in cancer disparities research, increase the number of underserved populations on clinical trials, and that there will be meaningful inroads to engage and benefit their surrounding underserved communities. There is a growing body of evidence showing the benefits of diversity to increase innovation, communication, and broaden the health disparities research agenda. The panelists are each involved in a U54 partnership, representing institutions with substantially different cultures and contrasting institutional demands. The institutions include a public teaching institution, urban public research-intensive institutions, and comprehensive cancer centers. Therefore, each panelist has a unique perspective on both strengths and challenges their institution brings to the partnership and how they have addressed these in their respective U54. Each panelist will discuss faculty and community stakeholder engagement as well as their paths in identifying collective aims, inter-institutional research projects and training programs. A central theme will be how these objectives were developed and addressed through the lens of their respective institutional culture and mission. A primary goal is to engage the audience to advance a dialogue to help move the field forward regarding what elements can foster the success of these mutually beneficial, collaborative partnerships.

ALIGNING REAL-WORLD EVIDENCE COLLECTION WITH THE NIMH RESEARCH DOMAIN CRITERIA (RDOC) FOR ASSESSING MENTAL HEALTH DISORDERS

Uma Vaidyanathan, PhD¹, Abhishek Pratap, MS², Emily G. Lattie, PhD³, Isaac Galatzerlevy, PhD⁴

¹National Institute of Mental Health (NIMH), Bethesda, MD; ²Sage Bionetworks / University of Washington, Seattle, WA; ³Northwestern University, Chicago, IL; ⁴AiCure, Brooklyn, NY

Smartphones offer a powerful way for scientists to gather large scale real-world evidence (e.g., life space, social interaction, self-assessments) frequently and have changed the landscape of behavioral medicine research. Several large scale studies have shown the feasibility of enrolling thousands of participants remotely and gathering high-frequency behavioral data using active and passive remote assessments. There is tremendous potential in using these large datasets to answer key questions on behavioral and mental processes. However, much remains to be understood about how best to synthesize and utilize high-frequency real-world data in relation to mental health and illness. One way to do so would be to use the National Institute of Mental Health's (NIMH) Research Domain Criteria (RDoC) framework. RDoC is a dynamic evidence-based framework that links quantifiable dimensional constructs of human behaviors to measurable units of analysis (or methodologies) such as genes, molecules, circuits, physiology, behaviors, and self-reported data. The constructs were defined on the basis of extant evidence for (1) a particular behavioral or cognitive function (e.g., fear or working memory), (2) a neural circuit or system that implements the function, and (3) their association with mental disorders.

In this panel, we discuss the challenges and opportunities of using remote digital technology for assessing and quantifying human behavior specifically as it relates to the RDoC constructs. We will start with a brief introduction to the RDoC research framework, followed by a discussion of key initial considerations emerging from some of the recent large-scale fully remote clinical studies in mental health. Discussions will include but not be limited to the need for engaging participants remotely, developing best practices for user-centered design research to elicit valid and reliable data for mental health, and enabling the exchange of real-world datasets to enable large scale computational phenotyping. We will then open the floor to discussion on ways to advance the study of digital mental health on both the conceptual (e.g., designing reliable and valid studies with adequate sample sizes) and implementation (e.g., establishing open-source tech platforms and data sharing standards) fronts.

12:45 PM-1:45 PM

PRACTICAL AND ETHICAL CONSIDERATIONS FOR CONDUCTING ONLINE RESEARCH AMONG SEXUAL AND GENDER MINORITY YOUTH

Kimberly M. Nelson, PhD, MPH¹, Sophia Choukas-Bradley, Ph.D.², Allegra R. Gordon, ScD, MPH³, Kathryn Macapagal, PhD⁴

¹Boston University School of Public Health, Boston, MA; ²University of Pittsburgh, Pittsburgh, PA; ³Boston Children's Hospital, Harvard Medical School, Boston, MA; ⁴Northwestern University, Chicago, IL

Sexual and gender minority (SGM) adolescents and young adults experience substantial mental and physical health disparities. As SGM youth are often considered “hidden” or “difficult-to-reach,” many researchers seeking to address SGM health disparities use online methods to recruit, assess, understand, and intervene with these youth. Although online methods can be effective, they also have drawbacks and unique ethical considerations. This is particularly true for research that is asking about or intervening on more sensitive topics (e.g., sexual health, suicidality, substance use, eating disorders, traumatic experiences) or recruiting participants who are below the age of majority and not “out” about their SGM status to their guardians.

The proposed panel will include four researchers who utilize a diverse array of online methods (e.g., online focus groups, surveys, social media, interactive intervention websites/apps) to assess and address SGM health disparities among youth. Panelists will provide an overview of online methods for recruitment, data collection, intervention development/implementation, and community engagement with SGM youth. Within each of these topics panelists will present the benefits/challenges of selected methods and ethical considerations specific to working with SGM youth. Following that overview, there will be a discussion of how to address the rapidly evolving technology and consumer preference landscape when designing and conducting online research with SGM youth. The panel will conclude with time for audience questions and discussion. The overall goal of the panel is to introduce the SBM audience to the unique benefits, challenges, and ethical issues of conducting online research with SGM youth and highlight the importance of addressing these factors throughout the research process.

PRACTICAL GUIDELINES ON TREATING CHRONIC PAIN AND CO-OCCURRING SUBSTANCE USE DISORDERS FOR ALL CLINICIANS

Payal Mapara, PsyD¹, Sarah A. Palyo, PhD², Stephanie L. Cardoos, PhD³

¹San Francisco VAMC, San Francisco, CA; ²San Francisco VA Healthcare System, San Francisco, CA; ³San Francisco VA Medical Center, San Francisco, CA

Historically, pain management services and substance use disorder services have been siloed. Furthermore, the intersection of chronic pain and substance use disorders has not been well understood by treatment providers, resulting in patients who struggle with both conditions having limited treatment options. Rates of co-occurring chronic pain and substance use disorders continue to rise especially in light of the current opioid epidemic. Identifying substance use as an exclusion criteria for chronic pain treatment not only limits access to care, but may serve to further worsen both conditions as substances are often used as a means of pain and stress management in chronic pain populations. At the San Francisco VA Medical Center, we have developed treatment strategies to integrate substance use disorder treatment in every level of care across our stepped care model for pain, to integrate treatment for pain into substance use disorder programs, and to treat both within primary care medicine. We will discuss the rationale for such an integration, the barriers to integration, and case examples that illustrate need for integration. We will present on current research on the psychological treatment of chronic pain and substance use disorders, present interdisciplinary models of care developed at the SFVA for integrated treatment at the primary and tertiary level of care, and share lessons learned from our experiences including practical tips on suicide risk assessment and Narcan education and distribution. Lastly, we will provide learners with evidence based behavioral pain management skills that can be utilized within any clinical setting and implemented by any health-care provider.

MONITOR → INNOVATE: MULTI-LEVEL ADAPTIVE IMPLEMENTATION APPROACH TO INCREASE IRON FOLIC ACID SUPPLEMENT DEMAND IN RURAL INDIA

Ichhya Pant, MPH, DrPH(C)¹, Lipika Patro, BA², Erica Sedlander, MPH, DrPH(C)³, Rajiv N. Rimal, PhD⁴

¹GWU School of Public Health, Arlington, VA; ²IPE Global, Washington DC, DC; ³GWU School of Public Health, Washington DC, DC; ⁴Johns Hopkins University, Baltimore, MD

Background: Operational and methodological constraints as well as meaningful stakeholder participation in the monitoring and implementation process is challenging. Donors, evaluators, participants, and implementers alike seek timely, rigorous, inclusive, and nimble monitoring systems to inform and innovate implementation delivery. With the proliferation of the digital age, Information and Communication Technologies (ICTs) have the potential to improve monitoring and implementation processes especially when combined with data triangulation and adaptive implementation management.

Objectives: The goal of the Reduction in Anemia through Normative Innovations (RANI) project is to increase iron folic acid (IFA) supplement use and reduce anemia among women of reproductive age in Angul, Odisha. Our innovative process evaluation and adaptive implementation approach aims to leverage ICTs and developmental evaluation methods to monitor and improve the delivery of several social behavior change communication strategies.

Methods: We will use a multi-level mixed-methods approach grounded in developmental and participatory evaluation philosophies. We will use surveys and structured observation to monitor fidelity to implementation and receptivity to implementation activities among study participants. Quantitative data will evaluate implementation dose, coverage, exposure, and reach of intervention activities, and qualitative data will delve more deeply into reasons for high or low functioning. IFA supply and demand will also be monitored for potential disruption. Data will be collected from 130 intervention villages in real-time. We will use live dashboards thematic analysis to analyze our data.

Monitoring data will also be triangulated with survey data at regular intervals. Sense-making activities will engender a shared-understanding of ground realities for geographically dispersed and culturally diverse stakeholders to systematically identify implementation feedback loops and facilitate timely course corrections. Specifically, we will identify opportunities to implement feedback loops for ongoing supportive supervision for our community facilitators promoting joint problem-solving, and communication. Monthly media and hemoglobin level demonstration strategies will be informed by participant engagement and receptivity. Disruption in the supply and demand of IFA supplements will activate contingency plans to mobilize local stakeholders and advocate for timely resolutions. Unintended effects will be monitored based on ongoing feedback from our community facilitators.

Conclusions: Documenting our processes will inform the future scale up of RANI or projects with similar objectives embracing a technology-enabled adaptive monitoring and implementation approach in low or high resource settings.

Symposium 18

2:00 PM-3:15 PM

TWEET, RETWEET, AND LIKE IT: THE SPREAD OF HEALTH MISINFORMATION IN ONLINE COMMUNITIES

Sherry Pagoto, PhD¹, Molly E. Waring, PhD¹, Kelsey M. Arroyo, B.S.², Jaime E. Sidani, PhD, MPH, CHES³, Wen-ying Sylvia Chou, PhD, MPH⁴

¹University of Connecticut, Storrs, CT; ²University of Connecticut, Vernon, CT; ³University of Pittsburgh, Pittsburgh, PA; ⁴National Cancer Institute, Bethesda, MD

The 2020 SBM Annual Meeting theme, *Finding Innovative Solutions to Tomorrow's Health Challenges*, tackles grand challenges confronting public health today. Viral health misinformation is arguably one such grand challenge. The new media environment has Americans making billions of posts on social media every day. Online communities coalesce around shared interests, hobbies, and even health conditions. According to transportation theory, information shared by peers in online communities is highly influential to community members who have common characteristics and experiences. This is good or bad news depending on the veracity of the information shared. The purpose of this symposium is to discuss how health misinformation is shared in online communities on Twitter and Facebook. Three communities will be featured: e-cig enthusiasts on Twitter, adults in Facebook weight loss groups, and mothers in a Facebook group on parenting healthy teens. Each presenter will characterize the prevalence and type of health misinformation shared in their respective online community, the form misinformation takes, and who is posting it. The first presenter will characterize 10.5 million tweets about e-cigs, including the proportion coming from commercial versus non-commercial accounts, the proportion containing health misinformation, and patterns of spread. Findings will be instrumental in informing the design of public health counter-messaging campaigns. The second presenter examined the extent to which participants (N=175) in a professionally-moderated Facebook-delivered weight loss intervention shared links to health misinformation. Across 8,438 posts, only 0.2% contained links to health misinformation. Blogs, social media feeds, and magazines were the most common sources of health misinformation. Findings suggest that participants in private online communities that are moderated by a health professional may be protective against health misinformation. However, the type of professionally-moderated online community may matter. The third presenter also studied a professionally-moderated Facebook intervention but this time targeting moms interested in learning how to keep their teens healthy. Topics included nutrition, HPV vaccine, substance abuse, tanning, mental health, and smoking. Higher rates of health misinformation sharing were observed, with 18% of 175 participant posts containing health misinformation. This collection of studies reveals that the nature, form, and source of health misinformation shared in online communities varies widely depending on health topic and community characteristics. The discussant will compare and contrast these findings in context with relevant research emerging from NCI's portfolio and describe the research agenda needed to advance our knowledge on how to counteract health misinformation in the new media environment.

HEALTH MISINFORMATION SHARED BY PARTICIPANTS IN PROFESSIONALLY MODERATED WEIGHT LOSS GROUPS ON FACEBOOK

Sherry Pagoto, PhD¹, Molly E. Waring, PhD¹, Kelsey M. Arroyo, B.S.², Jared Goetz, BA³, Matthew W. Schroeder, B.S., B.A.¹, Laurie C. Groshon, B.A.¹, Ran xu, PhD⁴

¹University of Connecticut, Storrs, CT; ²University of Connecticut, Vernon, CT; ³University of Connecticut, Dudley, MA; ⁴University Of Connecticut

While health misinformation has spread widely on social media, little is known about the degree to which it infiltrates private professionally-led online health communities. Because weight loss is a topic for which misinformation is common, the purpose of the present study was to examine the extent to which participants of professionally-moderated weight loss groups on Facebook shared links to health misinformation.

Design and Methods: Data were participant posts and comments from 3 studies of Facebook-delivered weight loss interventions (combined N=175 in 6 groups). Study feeds were based on the Diabetes Prevention Program and the moderators were professional weight loss counselors. Interventions were 8-16 weeks in length and involved twice daily posts that were intended to help participants execute behavioral weight loss strategies. Weight loss counselors replied to health misinformation with evidence-based feedback. Experts reviewed posts and comments that contained external links and coded the type of content being shared, whether health misinformation was present in the linked article, and the types of websites that reported health information and health misinformation specifically.

Results: Participants made a total of 8,438 posts and comments. Only 2% (n=189) of participant posts and comments contained links to external content. Of 189 links shared, 31% were recipes, 27% were health articles, 21% were resources (e.g., community events, workout videos), 6% were weight loss stories, and the remainder were humor (4%), motivational meme (3%), other (4%), or unknown/dead link (4%). A third (32%) of links contained health information. The types of websites of links containing health information were blogs/social media (23%), news outlets (23%), medicine/science websites (22%), magazine (13%), commercial product (5%), mobile app or podcast (5%), government agencies (5%), and recipe websites (3%). Health misinformation was present in 28% of links containing health information or 8% of all external links shared, which represented 0.2% of all participant posts/comments. The types of websites of links containing misinformation were 29% blogs/social media feeds, 24% magazines, 18% news, 18% science/medicine, 6% recipe websites, and 6% mobile app/podcasts.

Conclusion: A very small proportion of participant engagement included external links and a small proportion of those contained health misinformation, representing 0.2% of all participant posts and comments. Participants shared health information they found largely on blogs, in the news, or on public-facing medical/science websites. Although health misinformation is widely available on the internet, very little was shared in three professionally moderated weight loss groups. The presence of health professionals providing evidence-based health information may deter participants from sharing misinformation.

2

2:00 PM-3:15 PM

FREQUENCY AND TYPE OF HEALTH MISINFORMATION IN PARTICIPANT COMMENTS IN A FACEBOOK-DELIVERED CANCER RISK REDUCTION INTERVENTION

Kelsey M. Arroyo, B.S.¹, Jared Goetz, BA², Molly E. Waring, PhD³, Julia Berteletti, MSW⁴, David B. Buller, PhD⁴, Barbara Walkosz, PhD⁴, Katie Baker, PhD⁵, Joel J. Hillhouse, PhD⁵, Kim Henry, PhD⁶, Jerod Stapleton, PhD⁷, Sherry Pagoto, PhD³

¹University of Connecticut, Vernon, CT; ²University of Connecticut, Dudley, MA; ³University of Connecticut, Storrs, CT; ⁴Klein Buendel, Inc., Golden, CO; ⁵East Tennessee State University, Johnson City, TN; ⁶Colorado State University; ⁷Rutgers Cancer Institute of New Jersey, New Brunswick, NJ

Social media users often use online platforms to seek health information and while they find that information to be helpful, concerns still remain about the quality of such information. Social media is increasingly being used to deliver group-based health behavior interventions and health education campaigns, but little is known about the extent to which participants share health misinformation in these media. Monitoring health misinformation provides an opportunity for counter messaging but it may also compromise outcomes. The aim of this study was to examine the degree to which participants share health misinformation in a Facebook-delivered health education intervention for moms of teenage daughters and to describe the types of health misinformation shared. We examined comments to 42 randomly selected intervention posts on health topics such as lifestyle behaviors (n=9), indoor tanning (n=8), substance use (n=8), vaccines (n=6), mental health (n=5), parenting (n=4) and smoking (n=2) from May 2018 (first half of intervention) and January 2019 (second half of intervention). Posts had a total of 175 comments. We categorized comments as sharing an opinion, a personal experience, an intention, or information. Comments were then analyzed to examine whether misinformation was conveyed. Misinformation was defined as a fact, belief, opinion, or action that is not supported by scientific evidence. Participants (N=971) were 43 (SD=7) years old on average, and 84% were non-Hispanic white. The majority (77.1%) of participant comments shared a personal experience, 27.4% shared an opinion, 12.0% stated an intention, and 7.4% shared information. A total of 18.3% (n=32) of comments included misinformation. Misinformation was conveyed most often in comments classified as sharing an experience (56.25%), followed by opinions (25.0%), intentions (6.25%), information (6.25%) and comments reporting both an experience and intention (6.25%). This work reveals that health misinformation is shared in groups moderated by health professionals and is also conveyed when participants are sharing their intentions, opinions, and experiences. That these groups are moderated by health professionals presents a unique opportunity to combat misinformation. Further research is needed to examine how community members react to the sharing of misinformation in social media delivered interventions.

3

2:00 PM-3:15 PM

IDENTIFYING CONTEXTS AND DISSEMINATION PATTERNS OF ELECTRONIC NICOTINE DELIVERY SYSTEM (ENDS) MISINFORMATION ON SOCIAL MEDIA

Jaime E. Sidani, PhD, MPH, CHES¹, Jason Colditz, MEd¹, Ariel Shensa, MA¹, Eleanna Melcher, BA, BPhil¹, Sanya Taneja, BTech², Beth L. Hoffman, MPH¹, Esa Davis, MD, MPH, FAAFP², A. Everette James, JD¹, Brian A. Primack, MD, PhD³, Kar-Hai Chu, PhD¹

¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh; ³University of Arkansas, Fayetteville, AR

Background: Traditional surveillance methods have identified common misconceptions about electronic nicotine delivery systems (ENDS; e.g., e-cigarettes, vaping) and nicotine. For example, 63% of youth who use JUUL do not know that it always contains nicotine, and some youth believe that nicotine is harmless. Social media platforms present the opportunity to conduct real-time surveillance with rich qualitative information to further understand these misconceptions. Despite a substantial amount of ENDS-related content on social media containing health misinformation, there is a dearth of research about the spread of this misinformation. Therefore, this project seeks to examine the context of ENDS-related misinformation as well as how it spreads through Twitter networks.

Methods: We collected 10.5 million tweets matching ENDS-related keywords from April 2018 through March 2019. We then filtered these tweets using nicotine-related keywords (n = 148,799) and further selected a random 2% subsample (n = 2,975) of tweets for human coding. A codebook was developed to indicate relevance to ENDS and presence of misinformation within specific domains. Inter-rater reliability will be assessed for independent double-coding and disagreements will be adjudicated. We will operationalize the spread of each tweet by assessing the number of retweets (i.e., rebroadcasting others' tweets).

Results: Preliminary findings from codebook development indicated that 95% of tweets were relevant to ENDS, 10% were related to ENDS product marketing, and 13% presented statements about ENDS-related nicotine or addiction. Of the tweets that presented such statements, 72% presented misinformation in one of four, non-exclusive domains (claims that nicotine is entirely safe and/or has substantial health benefits; misrepresentation of available research evidence; overgeneralization of subjective/anecdotal experiences; exaggeration of public health messages). An in-depth qualitative analysis of these domains, as well as determination of additional domains, will continue to be conducted. Additionally, we will use social network analysis to operationalize dissemination of these messages across Twitter user networks.

Conclusions: These results will help to inform public health advocates and practitioners on strategies to conduct surveillance, understand the context in which ENDS-related nicotine misinformation is being spread, and how to evaluate and counter the impact of these messages.

Symposium 19

2:00 PM-3:15 PM

HEALTH INFORMATION TECHNOLOGY INTERVENTIONS FOR PATIENT ENGAGEMENT IN SYMPTOM MANAGEMENT

Betina Yanez, PhD¹, Joan M. Griffin, PhD², John Devin Peipert, PhD³, Aricca D. Van Citters, MS⁴¹Northwestern University, Chicago, IL; ²Mayo Clinic, Rochester, MN; ³Northwestern University Feinberg School of Medicine, Chicago, IL; ⁴Geisel School of Medicine at Dartmouth, HANOVER, NH

Patients undergoing treatment for chronic diseases may experience severe symptoms. Assessing patient-reported outcomes (PROs) can provide valuable information on severe or life-threatening symptoms that may lead to deleterious clinical outcomes. Therefore, prompt recognition, discussion, and management of PROs can prevent severe adverse events, improve clinical outcomes, and improve health-related quality of life. Health information technology (HIT) platforms can facilitate the rapid assessment of PROs and patient-facing symptom management information. This symposium will present several studies that use electronic health records to link the assessment of PROs with patient-facing symptom management. The four projects in this symposium have a common goal of accelerating the adoption of HITs to collect and analyze PROs, provide guideline-concordant symptom management information to patients, and enhance patient-provider communication. The first two speakers will focus on projects that are part of the National Cancer Institute initiative for Improving the Management of Symptoms Across Cancer Treatment (IMPACT) and the third and fourth speakers will focus on studies using principles of health co-production to design and implement HIT platforms across two major healthcare settings. More specifically, the first speaker will present on the development of an innovative HIT platform that provides tailored feedback on PROs and symptom management for patients diagnosed with cancer. The second speaker will present on the development of a randomized pragmatic clinical trial that capitalizes on patient engagement to evaluate a guideline-informed, HIT-facilitated cancer symptom control care model. The third speaker will present on the process of using a health co-production approach to build and implement a patient- and clinician-facing dashboard to enhance shared treatment decision-making among patients with cancer and chronic kidney disease. The fourth speaker will present on the development of a HIT dashboard that leverages data infrastructure to enhance communication and outcomes among people living with a chronic illness, their caregivers, and their clinicians. Lessons learned from the development of these studies and initial study findings will have implications for approaches to patient engagement in trial design, symptom management in clinical care, and may inform the development of additional scalable and sustainable symptom management programs.

2:00 PM-3:15 PM

PATIENT ENGAGEMENT IN THE DEVELOPMENT OF AN INNOVATIVE HEALTH INFORMATION TECHNOLOGY MANAGEMENT PROGRAM

Betina Yanez, PhD¹, Emily G. Lattie, PhD¹, Michael Bass, Ph.D.¹, Justin Smith, Ph.D.¹, Denise Scholtens, Ph.D.², Frank Penedo, PhD³, David Cella, PhD¹, Sofia Garcia, PhD¹¹Northwestern University, Chicago, IL; ²Northwestern University; ³Sylvester Comprehensive Cancer Center, Miami, FL

Background: Unmanaged symptoms can lead to worsening health-related quality of life (HRQOL) and clinical outcomes among patients diagnosed with cancer. Integrating patient-reported outcomes (PROs) into clinic settings can improve patient symptom monitoring and enhance opportunities for symptom management. The goal of this study is to evaluate a novel health information technology (HIT)-based program that links PROs with tailored, evidence-based symptom management information for patients diagnosed with cancer.

Methods: We are evaluating the effectiveness and implementation of *My Care Corner*, an HIT-linked program designed for ambulatory oncology patients. The goal of *My Care Corner* is to provide feedback on PROs, enhance symptom management and HRQOL, and improve care delivery. *My Care Corner* was developed with the input of key stakeholders through a process of usability testing to ensure integration of user-centered features that will increase uptake and adherence to the program. *My Care Corner* is programmed to provide patients with updated, tailored feedback and symptom management based on their recently completed electronic health record-based PRO assessments. *My Care Corner* also features a symptom library with information on evidence-based management tools for common cancer-related symptoms, a well-being resource library with information on diet and nutrition assistance, stress management strategies, and community-based resources. All content in this program is presented in an interactive format with audio and visual enhancements and is available in English and Spanish to appeal to a broader range of patients.

Discussion: We will discuss challenges to implementation of the program as well as strategies for successful patient-engagement within the program development and throughout the trial implementation. We will also discuss implications of this program for clinical care.

2

2:00 PM-3:15 PM

PATIENT ENGAGEMENT IN A STEPPED-WEDGE PRAGMATIC CLINICAL TRIAL TO IMPROVE MANAGEMENT OF COMMON SYMPTOMS ASSOCIATED WITH CANCER

Joan M. Griffin, PhD¹, Aaron Leppin, MD, MSc², Jennifer Ridgeway, PhD¹, Lila J. Ruten, PhD¹, Andrea Cheville, MD, MSCE², Kathryn Ruddy, MD, MPH³, Colleen Young, BA²

¹Mayo Clinic, Rochester, MN; ²Mayo Clinic; ³Mayo Clinic, Rochester, MN, Canada

The prevalence of inadequate symptom control among cancer patients is high despite availability of definitive clinical care guidelines. We are conducting a Hybrid II stepped-wedge cluster randomized pragmatic clinical trial to evaluate a guideline-informed, patient-centered care model. Medical oncology teams at Mayo Clinic-Rochester and Mayo Clinic Health System sites in the Midwest that care for patients with a range of cancers are being randomized to implement the “Enhanced, EHR-facilitated Cancer Symptom Control (E2C2)” study intervention. The intervention includes patients self-reporting sleep disturbance, pain, anxiety, depression, fatigue symptoms and/or limitations in physical function using 11-point numeric rating scales. Based on symptom scores, low-touch automated and high-touch manual clinical responses are generated using discrete EHR-embedded algorithms. Patients reporting moderate symptoms/limitations receive low-touch, automated self-management resources and patients reporting severe symptoms and/or functional limitations receive nurse-managed collaborative care. To assure the intervention addresses patient needs and to support adoption of self-management resources, cancer patients are engaged in the trial two ways: as patient advisors and study participants. Eight volunteer patient advisors have met either online, in person (5 times), or via private discussion board (15 conversation threads) to assist in the planning activities for the trial. Their efforts have led to these results 1) developing and testing usability of self-management materials and study website; 2) developing/acting in patient introductory video; 3) providing guidance on how clinicians should use patient information to support self-management; 4) developing an online peer support network available to study participants to help them manage symptoms, improve quality of life, and provide researchers insight to participant self-management. The trial will also employ mixed methods to identify disparities in the adoption and implementation of the E2C2 intervention among elderly and rural-dwelling cancer patients. Qualitative interviews will be conducted with a purposeful sample of rural/urban and elderly/non-elderly patients from each study site (stratified on response/non-response to electronic symptom reporting). Participants will be queried about their experience with the intervention, in order to improve its implementation and reduce disparities in care. The E2C2 intervention offers a patient-centric, pragmatic, scalable approach to deliver guideline-based symptom and function management for cancer patients. Patient engagement in the refinement of study-specific materials and processes, peer support network development and in the implementation strategies will support efforts to meet patients’ specific needs and improve health equity.

2:00 PM-3:15 PM

IMPLEMENTING THE HEALTH COPRODUCTION MODEL TO IMPROVE SHARED DECISION-MAKING AMONG CANCER AND KIDNEY DISEASE PATIENTS

John Devin Peipert, PhD¹, Betina Yanez, PhD², Sofia Garcia, PhD², Jeffrey Linder, MD, MPH³, Sheetal Kircher, MD⁴, Nisha Mohindra, MD⁴, Vikram Aggarwal, MD⁵, Victoria Morken, MPH⁶, Ronald T. Ackermann, MD MPH⁷, Cindy Barnard, PhD, MBA, MSJS⁸, David Cella, PhD²

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Northwestern University, Chicago, IL; ³Department of Medicine, Division of General Internal Medicine and Geriatrics, Northwestern University Feinberg School of Medicine; ⁴Department of Medicine, Division of Hematology and Oncology, Northwestern University Feinberg School of Medicine; ⁵Department of Medicine, Division of Nephrology and Hypertension, Northwestern University Feinberg School of Medicine; ⁶Department of Medical Social Sciences, Northwestern University Feinberg School of Medicine; ⁷Northwestern Medicine, Chicago, IL; ⁸Northwestern Memorial HealthCare

As new approaches to patient-centered healthcare emerge, there is an urgent need to test and implement promising care models that incorporate patient-reported outcomes (PROs) and increase opportunities for shared decision-making. Specifically, greater focus is needed on approaches to foster collaboration between patients and clinicians to generate treatment decisions that are timely, effective, and consistent with patients’ goals. Such approaches should leverage the advantages of health information technology (HIT) to extend opportunities for PRO assessments, source PRO data to clinicians through medical record platforms already in use clinically, and integrate these data with other information from the medical record to generate a more complete picture of the patient’s health, which can then be used to determine when new treatments are needed and which treatments are most appropriate to both patients and clinicians. Here, we describe the rationale, approach, and progress to date of a new, innovative project based on the health coproduction model that brings-together advancements in shared treatment decision-making, PRO science, and HIT to develop and test the effectiveness of the Northwestern Medicine Symptom Management Shared Decision-Making (NM-SMSDM) dashboards with advanced oncology and chronic kidney disease patients. The NM-SMSDM is being designed using a healthcare coproduction approach that involves sustained input from patients, clinicians, and other key stakeholders. Accessible to patients and clinicians, NM-SMSDM dashboards will track patients’ goals for care, lab values, PROs [symptoms and health-related quality of life (HRQOL)] assessed through a novel HIT platform, and treatment instructions to provide a common touchstone for how and when to start or change treatments that both patients and clinicians value. The presentation will focus on: 1) the theoretical basis for health coproduction dashboards; 2) the qualitative approach and results for dashboard co-design involving patients, caregivers, physicians, frontline-clinicians, and health informaticists; 3) our plans and protocol for a single-arm trial to test the impact of the NM-SMSDM on symptom control and HRQOL, increased shared decision-making, improved patient engagement, and increased satisfaction with care. We will conclude with actionable recommendations for implementation of the NM-SMSDM, and how we plan to implement in the NM-SMSDM routine care at Northwestern Medicine.

4

2:00 PM-3:15 PM

A VISUAL DASHBOARD TO GUIDE COPRODUCTION OF CARE FOR PEOPLE LIVING WITH SERIOUS ILLNESS

Aricca D. Van Citters, MS¹, Inas Khayal, PhD², Megan Holthoff, MSHS², Shoshana Hort, MD², Catherine Saunders, MPH², Stephanie Tomlin, MPA, MS², Meredith MacMartin, MD, MPH², James Bowling, MPH², Amber Barnato, MD, MPH², Kathryn Kirkland, MD², Eugene Nelson, DSc, MPH²

¹Geisel School of Medicine at Dartmouth, HANOVER, NH; ²Geisel School of Medicine at Dartmouth

Background: Healthcare system complexity interferes with effective communication and goal-aligned services for people living with serious illness and their caregivers. The aim of this project is to codesign a dashboard that leverages data infrastructure and health information technology (HIT) to enhance communication among people living with a serious illness, their caregivers, and their clinicians and to enable healthcare services to meet their unique needs, goals, preferences, and values.

Methods: We engaged key stakeholders – patients (n=2), caregivers (n=3), clinicians (n=9), and researchers (n=3) – in the codesign and rapid prototyping of an electronic pre-visit survey (PVS) and a point-of-care dashboard. The team used user-centered and engineering design methods to identify user needs and context, to design prototypes, and to assess the ability of HIT solutions to enable prototypes. We worked with our health system's electronic medical record (EMR) development team to design and evaluate prototypes within the outpatient setting of a rural academic medical center.

Results: The dashboard is a visual display that combines patient- and clinician-generated information in one view that is accessible to both patients and care team members. The dashboard is populated in advance of the visit by patients and caregivers completing a PVS that helps set the agenda for the visit. Dashboard functions include (1) facilitating communication within each visit to focus on what matters most; and (2) improving the quality and efficiency of care by capturing, sharing, and displaying data collected before and during a clinic visit. The pre-visit survey includes questions with free-text response options, and validated patient-reported outcome measures. The dashboard design was optimized to support the development of a coproduced care plan built around the patient's most pressing concerns, goals, and barriers in achieving goals. It was designed and prototyped to be integrated with the EMR.

Discussion: The codesign process accounted for factors that affect patient engagement and integrated those into the functionality and form of the pre-visit survey and dashboard. Prototypes are being evaluated for their ability to support end users in achieving higher value healthcare by improving communication and coordination of care, and focusing on what matters most to patients.

Symposium 20

2:00 PM-3:15 PM

DEPRESSION AND SUPPORTIVE ONCOLOGY CARE: WHEN GREATER NEED TRANSLATES TO GREATER RELUCTANCE

James Gerhart, PhD¹, Michael Hoerger, PhD, MSCR², Chandysten Nightingale, PhD, MPH³, Laurie E. McLouth, PhD⁴, Rina S. Fox, PhD, MPH⁵, Sarah Thilges, PhD⁶

¹Central Michigan University, Mt. Pleasant, MI; ²Tulane University, New Orleans, LA; ³Wake Forest School of Medicine, Winston-Salem, NC; ⁴University of Kentucky College of Medicine, Lexington, KY; ⁵Northwestern University Feinberg School of Medicine, Chicago, IL; ⁶Loyola University Medical Center, Maywood, IL

Recognizing a heightened risk of distress among patients with cancer, accrediting bodies now mandate that patients with cancer are screened for psychosocial distress, and provided supportive care when indicated. This symposium presents the results of a program evaluation of a large distress screening program and explores barriers to uptake of psychosocial and supportive care in cancer. Mediation models are presented and suggest that the nature of psychological distress itself and its linkages to avoidant emotion regulation strategies may deter patients from seeking supportive care. The symposium concludes with a discussion of the feasibility of including caregivers to enhance engagement in supportive care when intervening with patients alone may not be feasible.

The first presentation reviews referral patterns to psychosocial oncology and supportive care in an academic cancer center. Of 3,370 patients approached for screening, 325 declined (9.6%). Completed PHQ-4s were obtained from 2,506 patients (74.4% of original sample). Of these, 470 met screening criteria for significant distress (18.8% of those screened/13.9% of sample), and 165 (33.4% of those with distress) were referred to psychosocial oncology. Of the total sample, 4.9% received referral to psychosocial oncology. This rate of referral approximates estimates of yearly psychotherapy uptake in the general population.

The second presentation provides insight into plausible barriers to care with an emphasis on the intersectionality of stigma, shame and avoidant coping. Data are presented from an international survey of 598 patients with a history of cancer. Patients with higher levels of depression reported greater inhibition of emotional expression that in turn predicted more reticence to seek supportive care. One interpretation is that at increasing levels of distress patients are less willing to report distress (e.g., decline screening), and/or seek supportive services (e.g., denied referral).

The third presentation explores an alternative avenue for intervening with the caregiving system. This approach involves a web-based intervention that's being delivered to caregivers during their time in clinic to identify their unmet needs and connect them with supportive care resources in the hospital, community, and nation-wide. Feasibility data and preliminary outcomes from 16 patient-caregiver dyads will be discussed.

The program ends with a discussion of emerging alternative avenues for addressing supportive care needs, particularly when patients are not amenable to traditional forms of psychotherapy.

2:00 PM-3:15 PM

PSYCHOSOCIAL DISTRESS SCREENING AND RATES OF REFERRAL IN AN ACADEMIC CANCER CENTER

James Gerhart, PhD¹, Aidnag Diaz, MD², Teresa Lillis, PhD³, Sean O'Mahony, MB, BCH, BAO³, Christine Weldon, MBA⁴

¹Central Michigan University, Mt. Pleasant, MI; ²The University of Arizona Cancer Center at Dignity Health St. Joseph's Hospital and Medical Center.; ³Rush University Medical Center, Chicago, IL; ⁴Center for Business Models in Healthcare

Depression and other forms of psychosocial distress are related to poorer health outcomes for patients with cancer. These poorer outcomes include greater risk of mortality. Accrediting bodies mandate that all patients are screened for psychosocial distress, and provided with referrals and other resources when indicated. Despite guidelines for screening and referral, a number of patients with cancer and elevated levels of distress may be reticent to utilize supportive care services. This study investigated patterns of referral to psychosocial oncology in the context of a comprehensive supportive oncology screening program at an academic cancer center. Patients visiting comprehensive cancer clinics and the chemotherapy infusion center were asked to complete a supportive oncology screening tool based on the Patient Health Questionnaire – 4 Item (PHQ-4), the National Comprehensive Cancer Network Distress Thermometer, and the Patient Reported Outcomes Measurement Information System. In total, 3,370 patients were approached for screening. Although the vast majority agreed to screening, a notable portion declined to participate in screening ($n = 325$, 9.6%). Completed PHQ-4 scores were obtained from 2,506 patients (74.4% of original sample). Of these, 470 met screening criteria for significant distress (18.8% of those screened/13.9% of sample), and 165 (33.4% of those with distress) were referred to psychosocial oncology. Of the total sample of patients who were approached for screening, 4.9% received referral to psychosocial oncology. The rate of referral is comparable to rates of yearly mental health service utilization of U.S. adults more generally. It is also notable that most patients reporting significant distress did not receive referral to psychosocial oncology. Future efforts to evaluate the impact of distress screening programs should systematically track and examine reasons patients and their clinicians decline to initiate referral to psychosocial oncology.

FEAR OF EXPRESSING EMOTIONS MEDIATES THE ASSOCIATION OF DEPRESSION AND LOWER PREFERENCES FOR PALLIATIVE CARE

Michael Hoerger, PhD, MSCR¹

¹Tulane University, New Orleans, LA

Many patients with cancer who stand to benefit from palliative care are reluctant to consider and utilize services. One possibility is that patients experiencing acute distress may be reluctant to consider palliative care because they fear the consequences of accepting their vulnerable emotions, and expressing them to others. These fears could deter patients from considering and utilizing palliative care services if they fear negative consequences of expressing their emotions to others including supportive care professionals. The current study investigated the associations of depression, fear of emotional expression, and attitudes toward palliative care in a large sample of adult patients with diverse cancer diagnoses ($N = 598$). It was hypothesized that the association between depression and less favorable attitudes toward palliative care would be mediated by fear of emotional expression. Depressive symptoms were strongly associated with higher levels of emotional inhibition ($r = .60$, $p < .001$), and less favorable attitudes toward palliative care ($r = -.20$, $p < .001$). Emotional inhibition was also associated with less favorable attitudes toward palliative care ($r = -.20$, $p < .001$). Mediation modeling revealed a significant direct effect of depression on lower preferences for palliative care services ($B = -1.31$ SE = .56 95% CI = -2.42 to -.20). A significant indirect effect through higher levels of fear of emotional expression was also obtained ($B = -.85$ SE = .34, 95% CI = -1.54 to -.19). These findings provide insight into the possibility that patient with cancer who also experience depressive symptoms may be reluctant to consider supportive care services. This reluctance may be explained in part by difficulty expressing negative emotions. Patients more comfortable expressing their emotional experiences may be more inclined to utilize supportive care. Further study of emotion regulation and expression in cancer settings could inform efforts to enhance patient engagement in supportive care services.

2:00 PM-3:15 PM

DESIGN AND EARLY UPTAKE OF THE CAREGIVER ONCOLOGY NEEDS EVALUATION TOOL (CONNECT-L) FOR LUNG CANCER CAREGIVERS

Chandlyen Nightingale, PhD, MPH¹, David Miller, MD², Laurie E. McLouth, PhD³, Katherine Sterba, PhD, MPH⁴, Beverly Levine, PhD⁵, Alex Dest, MPH², Paul Yelton, MS⁶, Eric Kirkendall, MD, MBI⁷, Jimmy Ruiz, MD², Kathryn Weaver, PhD, MPH¹

¹Wake Forest School of Medicine, Winston-Salem, NC; ²Wake Forest School of Medicine; ³University of Kentucky College of Medicine, Lexington, KY; ⁴Medical University of South Carolina, Charleston, SC; ⁵Wake Forest School of Medicine, Winston-Salem, NC; ⁶The Wake Forest Center for Healthcare Innovation; ⁷Wake Forest School of Medicine; The Wake Forest Center for Healthcare Innovation

Background: For cancer patient populations with high distress and low supportive care utilization, intervening with informal (unpaid) caregivers may be a promising strategy to reduce patient distress, support patient care, and improve caregiver wellbeing. Yet the US healthcare system fails to systematically assess and address caregiver needs. To address this gap, we developed a technology-based intervention for routine cancer care to empower and educate caregivers about the benefits of engaging in supportive care services, identify unmet needs, and recommend tailored resources. We are testing the feasibility of this intervention initially in lung cancer (LC) patient-caregiver dyads.

Methods: Our interdisciplinary team reviewed common unmet supportive care needs in LC caregivers and compiled a database of local and national resources. An advisory panel comprised of a thoracic oncologist, nurse navigator, and psycho-oncology professionals reviewed the needs assessment and resource database. Through an iterative process engaging the advisory panel, informaticists, and videographers, we developed CONNECT-L, a website with an educational video, needs assessment, and algorithms to support tailored resource recommendations and optional automated referrals to services. We are conducting a pilot randomized controlled trial of 40 LC caregiver-patient dyads assigned to CONNECT-L or a minimally enhanced usual care control group. Dyads complete assessments pre-randomization (T0), 1-month post- (T1), and 3-months post-CONNECT-L (T2).

Results: CONNECT-L includes a 1.5 minute video, 17-item needs assessment, and database of 100 resources. To date, 16 patient-caregiver dyads have been recruited (accrual=8/month; participation=64%). Caregivers are on average 62 (SD=5.7) years of age, majority female (68.8%), Caucasian (87.5%), and a spouse/partner to the patient (75%). The majority of patients have stage IV (62.5%) cancer and are receiving chemotherapy (with or without immunotherapy) (75%). Seven caregivers have received CONNECT-L, taking on average 11 minutes to complete (range=8-18). All caregivers endorse at least one need; cancer education is the most common need (71%; $n=5$).

Conclusions: Preliminary findings suggest LC caregivers desire connection to supportive resources and support the potential of technology-based interventions in clinic to reach caregivers. Future analyses will describe adherence to referrals, study retention, and overall acceptability of CONNECT-L.

2:00 PM-3:15 PM

INNOVATIVE METHODS FOR STUDYING AND ADDRESSING ENGAGEMENT IN JUST-IN-TIME ADAPTIVE INTERVENTIONS FOR HEALTH BEHAVIOUR CHANGE

Olga Perski, BSc, MSc, PhD¹, Guillaume Cheavance, PhD², Emily Hébert, DrPH³, Stephanie P. Goldstein, PhD⁴, Eric B. Hekler, PhD⁵¹University College London, London, England, UK; ²University of California, San Diego, San Diego, CA; ³Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK; ⁴Alpert Brown Medical School/The Miriam Hospital Weight Control and Diabetes Center, Providence, RI; ⁵UC San Diego, San Diego, CA

The goal of just-in-time adaptive interventions (JITAI) for health behaviour change is to provide the right type of support to users, at the right time. For example, smokers attempting to quit may benefit from receiving an intervention at a moment when they are at high risk of lapse. Engagement is logically necessary for health behaviour change interventions to be effective; however, engagement with digital interventions tends to be low. As JITAI are highly personalised and adaptive, they may offer a promising solution to the observed 'engagement crisis'. Nevertheless, JITAI have their own engagement challenges. For a JITAI to successfully deliver support at the right time, users are not only expected to engage with momentary interventions but are also required to engage with frequent (e.g. daily, hourly) real-time assessments of psychological, physiological and contextual factors. Low engagement with such real-time measurements can drastically reduce the JITAI's ability to detect future moments of vulnerability and limit researchers' and practitioners' ability to estimate intervention effects.

This symposium will bring together an international team of speakers with expertise in the design and evaluation of JITAI for smoking cessation, alcohol reduction, weight loss and physical activity. First, we will outline different engagement challenges pertaining to digital interventions in general, and JITAI in particular. We will then provide four examples of innovative methods for studying engagement in JITAI. The first talk (Dr. Olga Perski) will highlight ways in which JITAI may offer a promising solution to the 'engagement crisis', drawing on data from a series of N-of-1 studies with users of an alcohol reduction app. The second talk (Dr. Guillaume Cheavance) will outline a computational model of habituation (i.e., an objective decline in behavioural response to the intervention over repeated exposure) in JITAI. The third talk (Dr. Stephanie Goldstein) will discuss the associations between engagement patterns and the proximal and distal outcomes of a JITAI for eating behaviour. The fourth talk (Dr. Emily Hébert) will discuss the use of machine learning to identify patterns of response fatigue in a JITAI for smoking cessation. In the final part of the session, Prof. Eric Hekler will discuss the implications of these innovative methods for building potent JITAI, and how they can help answer broader scientific questions such as why engagement matters.

CORRESPONDING AUTHOR: Olga Perski, BSc, MSc, PhD, University College London, London, England, UK; olga.perski@ucl.ac.uk

CAN JUST-IN-TIME ADAPTIVE INTERVENTIONS OFFER A PROMISING SOLUTION TO THE 'ENGAGEMENT CRISIS' IN DIGITAL BEHAVIOUR CHANGE INTERVENTIONS?

Olga Perski, BSc, MSc, PhD¹, Eric B. Hekler, PhD², Felix Naughton, PhD³, Jamie Brown, PhD⁴¹University College London, London, England, UK; ²UC San Diego, San Diego, CA; ³University of East Anglia, Norwich, England, UK; ⁴University College London

Background: The frequency and intensity of engagement with digital behaviour change interventions (DBCIs) are likely to influence their effectiveness. However, engagement with DBCIs tends to be suboptimal: in trials of web-based health interventions, on average, only 50% of participants engage as intended by the intervention developers. This observed 'engagement crisis' is problematic as engagement is positively associated with successful behaviour change. Emerging evidence from studies harnessing ecological momentary assessments (EMAs) of users' behaviours and cognitions in real-time highlights that engagement is dynamic (i.e. it fluctuates over time) and manifests idiosyncratically. Just-in-time adaptive interventions (JITAI) harness self-reported and automatically detected data on psychological, physiological and contextual variables with a view to providing the right type and intensity of support to individuals, at the right moment in time. As such, JITAI are by design highly tailored to users' unique and evolving needs.

Objective & Methods: This presentation will draw on findings from a series of qualitative and quantitative studies involving apps for alcohol reduction and smoking cessation to i) illustrate the 'engagement crisis' in DBCIs and ii) discuss why, how and for whom JITAI may offer a promising solution.

Results: Findings from think aloud, interview and focus group studies involving different DBCIs suggest that many of our current DBCIs are not sufficiently tailored to users' unique situations. Evidence from a series of N-of-1 studies harnessing twice-daily EMAs with users of an alcohol reduction app indicates that within-person variability in the state of engagement can be predicted by daily fluctuations in users' motivation to change and perceived usefulness of the app. On the basis of these findings, a potential JITAI could, for example, push a funny/stern/empathetic message at a moment in time when a user's perceived usefulness of the app is low.

Conclusion: Taken together, these findings highlight the potential of JITAI to promote the intensity and frequency of engagement with DBCIs. Hence, not only does future work involving the development and evaluation of JITAI have the potential to advance behaviour change science and practice, but it also has the potential to advance the science of engagement with DBCIs.

2:00 PM-3:15 PM

HOW TO PREVENT INTERVENTION HABITUATION IN DIGITAL HEALTH BEHAVIOR CHANGE INTERVENTIONS? A COMPUTATIONAL FRAMEWORK FOR JUST-IN-TIME ADAPTIVE INTERVENTIONS

Guillaume Chevance, PhD¹, Golaszewski Natalie, PhD², Predrag Klasnja, PhD³, Daniel E. Rivera, PhD⁴, Olga Perski, BSc, MSc, PhD⁵, Eric B. Hekler, PhD⁶

¹University of California, San Diego, San Diego, CA; ²UCSD; ³University of Michigan, Ann Arbor, MI; ⁴Arizona State University, Tempe, AZ; ⁵University College London, London, England, UK; ⁶UC San Diego, San Diego, CA

Introduction: Digital behavior change interventions (DBCIs) use alerts such as push notifications to promote users' daily engagement with health behaviors. Estimates indicate that individuals receive 60 to 100 notifications per day and tend to ignore them over time, thus challenging their utility for engendering behavior change. A common pattern of results observed in the literature is that digital interventions result in short-term behavioral improvements, which are not sustained. This phenomenon matches on to the classic psychological concept of habituation, i.e., an objective decline in behavioral response to a repeated delivery of a stimulus (in this case, an intervention). One way of addressing this engagement issue is to foster the development of just-in-time adaptive interventions (JITAs), defined as interventions aiming to provide the right type of support at the right moment in time. JITAs could mitigate this habituation issue by dynamically adapting the amount and type of support to individuals' evolving needs. However, there has yet to be a conceptual framework to help researchers understand and anticipate the habituation issue within DBCIs, specifically JITAs.

Purpose: The purpose of this presentation will be to: (1) report on computerized simulations grounded in basic models of habituation at various timescales (i.e., daily, weekly, monthly), with empirical data from an existing DBCI promoting walking as validation; and (2) report simulation results from a computational model intended to guide decision-making within a JITAI, explicitly meant to counteract habituation.

Method: For the first objective, concrete hypotheses about the habituation phenomenon are translated into a system of mathematical equations and then simulated and refined using MATLAB. To address the second objective, a computational model manipulating various scenarios (i.e., quantity and type of intervention) is used to simulate habituation, to help guide future JITAI decision-making.

Expected results: These analyses will help visualize and improve our understanding of the habituation phenomenon within DBCIs and JITAs. The computational model will also enable more robust dynamic theory-generation to help guide future JITAI development.

Discussion: Habituation to notifications is a common issue in DBCIs. A conceptual framework is necessary to understand this engagement issue and, ultimately, build effective JITAs able to counteract or limit habituation.

2:00 PM-3:15 PM

IDENTIFYING RESPONSE FATIGUE AND NON-COMPLIANCE IN JUST-IN-TIME ADAPTIVE INTERVENTIONS: A MACHINE LEARNING APPROACH

Emily Hébert, DrPH¹, Ashley Mathews, MS², Daryl Geller, BS², Akshay Gaur, MS², Summer Frank-Pearce, PhD, MPH³, Michael S. Businelle, PhD⁴, Darla E. Kendzor, PhD⁴

¹Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK; ²University of Oklahoma Health Sciences Center; ³Oklahoma Tobacco Research Center/University of Oklahoma Health Sciences Center, Oklahoma City, OK; ⁴University of Oklahoma Health Sciences Center, Oklahoma City, OK

Significance: Ecological momentary assessment (EMA) allows for a more granular understanding of the relationship between affect, socioenvironmental context, and smoking lapse. EMA involves frequent measurements in an individual's natural environment, reducing recall bias that is characteristic of self-report instruments. Yet, there is no gold standard method of validating EMA reports of momentary smoking. Lack of adherence to self-initiated event reporting and participant response fatigue (i.e., when the quality of the data provided begins to deteriorate in association with participant burden) can lead to misclassification of smoking lapse or abstinence. The purpose of this study is to use machine learning methods to identify response fatigue and predict non-compliance with EMA protocols.

Methods: Participants were adults from a clinic-based smoking cessation program. Participants were loaned smartphones and prompted to complete 5 EMAs each day from 1 week pre-quit to 4 weeks post-quit, and to self-initiate an EMA whenever they lapsed. EMAs evaluated mood, smoking urge, environmental context, and smoking lapses. Meta data from EMA reports (e.g., participant time in study, average time to complete each question, grade reading level, etc.) were used as potential indicators of participant engagement and response fatigue. Gradient boosted decision trees with k-fold cross validation were used to predict EMA completion and response time.

Results: A total of 29,618 scheduled EMAs and 8,582 participant-initiated EMAs were included for analysis. Participants completed 81.3% of all prompted EMAs. Predictive features included question type, number of times a question has been seen, order of questions, and participants' median response time. Final models, including practical suggestions for identifying response fatigue will be discussed.

Conclusion: Accurate identification of momentary smoking episodes and their context is crucial for the development of effective just-in-time adaptive interventions for smoking cessation. The methods discussed herein may be effective in identifying patterns of non-compliance and fatigue that can be used to refine future EMA study protocols.

EXAMINING PATTERNS OF ENGAGEMENT WITH A SMARTPHONE-BASED JUST-IN-TIME ADAPTIVE INTERVENTION FOR DIETARY LAPSES: IMPLICATIONS FOR PROXIMAL AND DISTAL OUTCOMES

Stephanie P. Goldstein, PhD¹, Graham Thomas, Ph.D.², Leslie Brick, PhD³, Evan M. Forman, PhD⁴

¹Alpert Brown Medical School/The Miriam Hospital Weight Control and Diabetes Center, Providence, RI; ²Brown Medical School, Providence, RI; ³Quantitative Sciences Program, Alpert Brown Medical School; ⁴Drexel University, Philadelphia, PA

Background: Deviations from the prescribed diet (i.e., dietary lapses) in behavioral obesity treatment are frequent and associated with poor weight loss outcomes. Given that lapses are triggered by momentary changes in psychological, physiological, and environmental factors, they may benefit from an intervention that promotes self-assessment of triggers and delivers preventative intervention directly in moments of need (e.g., just-in-time adaptive intervention [JITAI]). As such, we developed a smartphone-based JITAI that utilizes ecological momentary assessment (EMA; repeated sampling using electronic surveys) to facilitate self-reporting of lapse triggers, predicts lapses using machine learning, and delivers alerts to lapse risk with brief tailored intervention to prevent lapses. Given the established importance of user engagement with mobile health interventions, the aim of this secondary analysis is to evaluate the association between weekly engagement with the two main JITAI components (i.e., EMA and opening risk alerts), and the hypothesized proximal (i.e., lapses) and distal (i.e., percent weight loss) outcomes.

Methods: Participants (N=121) with overweight/obesity (MBMI =34.51; 84.3% female; 69.4% White) used our JITAI along with a digital weight loss program for 10 weeks. Engagement with JITAI components (i.e., EMA, proportion of opened risk alerts) was recorded automatically, participants self-reported dietary lapses via EMA, and weighed weekly using Bluetooth scales.

Results: Generalized linear mixed models revealed that higher weekly engagement with EMA ($B=.47, p=.001$) and proportion of opened risk alerts ($B=.44, p=.02$) were associated with greater weekly percent weight losses. Higher weekly engagement with EMA ($B=6.03, p<.001$), but not proportion of opened risk alerts ($B=.35, p=.63$), was associated with more self-reported dietary lapses.

Discussion: Findings highlight the importance of JITAI engagement in evaluating proximal and distal outcomes. While causality is unclear, JITAI component engagement was associated with better weekly percent weight loss. This pattern of results was not found for dietary lapses, possibly because participants who were more engaged with the JITAI were also more adherent to reporting lapses. Future studies should untangle the direction of these associations and investigate other potential explanatory variables (e.g., motivation) that may govern both intervention engagement and adherence to weight control strategies.

USING DIGITAL HEALTH INTERVENTIONS TO PROMOTE HEALTHY HABIT FORMATION

Tammy Stump, Ph.D.¹, Ashley B. West, MS², PETER Pirolli, Ph.D., FNAI³, David E. Conroy, PhD⁴, Bonnie Spring, PhD⁵, Angela F. Pfammatter, PhD⁶, Samuel L. Battalio, n/a¹, Nabil Alshurafa, PhD¹, Donald Hedeker, Ph.D.⁷, Necole Streeper, MD⁸, Edison Thomaz, ECE⁹

¹Northwestern University, Chicago, IL; ²The Pennsylvania State University, State College, PA; ³Institute for Human and Machine Cognition, San Francisco, CA; ⁴The Pennsylvania State University, University Park, PA; ⁵Northwestern University Feinberg School of Medicine, CHICAGO, IL; ⁶Northwestern University Feinberg School of Medicine, Chicago, IL; ⁷University of Chicago, Chicago, IL; ⁸Penn State Health, Hershey, PA; ⁹UT Austin, Austin, TX

Digital health technologies provide new opportunities to help users form healthy habits and to better understand the complex dynamics of habit formation. Habit theories posit that repetition of behavior in consistent contexts is key to attaining a new habit. However, traditional health interventions rely on retrospective reports of behavior and, therefore, do not provide the fine-grained information needed to assess and intervene on this habit formation process. In contrast, due to the nearly ubiquitous nature of digital technologies in daily life, digital health interventions can make use of detailed information about users' contexts (e.g., location, physical state) and past behavior in determining when and how to intervene. This information also holds promise for yielding new insights on how habits are formed and maintained over time.

In this symposium, three talks will provide examples of how digital health technologies can be implemented to promote habit formation and provide insight on the habit formation process. First, a novel intervention designed to increase fluid consumption habits among kidney stone patients will be presented. This intervention utilized a connected water bottle, smartwatch, and smartphone application to provide context-sensitive hydration reminders, producing increases in habit strength for hydration (as measured by perceived automaticity) that persisted at a 3-month follow-up. The second presentation will focus on computational models designed to assess the dynamics of habit formation during a technology-assisted diet and physical activity intervention which used behavior change techniques designed to produced habit formation (e.g., implementation intentions). These computational models assessed habit formation using a dual-systems approach in which behavior is first guided by controlled goal-striving processes but, with repeated practice, later becomes automatic. Ways in which these models can help to refine theories of habit formation, self-efficacy, and intended effort will be discussed. The third presentation will review evidence that behavior consistency serves an important marker of habit formation. This talk will review evidence on how consistency in context, timing, and levels of behavior predict health behavior changes that persist over time. The presenter will also discuss how digital health tools can be used to assess these forms of consistency to improve the efficiency and efficacy of digital health interventions. The discussant will provide an integrative overview of the opportunities and challenges of using digital health technologies to promote habit formation.

BEHAVIORAL CONSISTENCY AS A MARKER OF HABIT FORMATION WITHIN DIGITAL HEALTH INTERVENTIONS

Tammy Stump, Ph.D.¹, Bonnie Spring, PhD², Donald Hedeker, Ph.D.³, Angela F. Pfammatter, PhD⁴, Nabil Alshurafa, PhD¹, Samuel L. Battalio, n/a¹

¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, CHICAGO, IL; ³University of Chicago, Chicago, IL; ⁴Northwestern University Feinberg School of Medicine, Chicago, IL

The goal of many health interventions is to produce healthy habits that persist over time. Traditionally, intervention success is determined by whether, on average, an individual has met a criterion level of behavioral improvement. An assessment of intervention outcomes in this manner is agnostic to whether the behavior change represents the formation of a new habit that is likely to persist over time. Evaluation of habit formation during interventions could provide new insights on which interventions are most likely to produce changes that maintain over time and could even guide decisions about intervention tailoring during adaptive interventions. While some studies have applied measures of the perceived automaticity of behaviors to assess habit formation over time, we posit that this measurement method is problematic because: 1) self-reports of automaticity rely on a degree of introspection that is likely unrealistic, and 2) the behaviors of interest in health interventions tend to be composed of multiple sub-behaviors, which vary in terms of the degree of automaticity that can be expected to be achieved or is desirable.

New opportunities to assess habit formation during behavior interventions have emerged from the use of technology-assisted interventions. Because these interventions often provide a rich assessment of behavior through repeated self-monitoring and passive assessments, these studies hold promise for determining the behavioral patterns that indicate when a new healthy or unhealthy habit has emerged. Specifically, the intensive longitudinal data yielded by digital health tools permits evaluation of the consistency of behavior in terms of context, timing, and amount of the behavior. Drawing on habit theories, in this presentation, we review the evidence for consistency in these three domains being important predictors of behavior. This review will feature past empirical studies, such as those using frequency-in-context measures of habit formation and ecological momentary assessment methods, including our own past research indicating that a successful intervention led to an increase in behavioral consistency uniquely for targeted behaviors. Potential methods for assessing consistency of context, timing, and amount of behavior using digital health tools will be discussed along with the potential applications of these measures to improve the efficiency and efficacy of digital health interventions.

2:00 PM-3:15 PM

SIPIT: A DIGITAL HEALTH JUST-IN-TIME INTERVENTION TO INCREASE FLUID CONSUMPTION HABITS AMONG PATIENTS WITH KIDNEY STONES

Ashley B. West, MS¹, Nicole Streeper, MD², Edison Thomaz, ECE³, David E. Conroy, PhD⁴

¹The Pennsylvania State University, State College, PA; ²Penn State Health, Hershey, PA; ³UT Austin, Austin, TX; ⁴The Pennsylvania State University, University Park, PA

Background: Guidelines recommend that patients with kidney stones consume enough fluids to produce at least 2.5L/day of urine to prevent a recurrence of a stone, yet less than 50% of patients adhere to this guideline. Not being thirsty and forgetting to drink are barriers to adherence so we developed the sip^{IT} intervention to support habit formation for fluid intake. The sip^{IT} intervention combines semi-automated tracking of fluid intake with context-sensitive behavior change techniques to strengthen habits for fluid consumption. Reminder notifications were delivered after every half hour when patients did not achieve prespecified fluid intake goals. This study used a single-group pre-post design to evaluate changes in habit strength (behavioral automaticity) and perceived barriers to adherence.

Methods: Patients with a history of kidney stones and iPhones ($N=31$, $M_{age}=40.0$) were provided with a connected water bottle, smartwatch and the sip^{IT} mobile app for their smartwatch and iPhone, and were encouraged to drink at least 4oz every 30 minutes. Patients completed the behavioral automaticity scale from the Self-Report Habit Index and reported barriers using a checklist at baseline, one and three months.

Results: Completion rate was high for the intervention (84%, $N=26$). Habit strength for fluid consumption increased ($F[2,24] = 7.80$, $p = .003$, $d = 0.69$), with significant change occurring between baseline and one month ($p = .006$) that was maintained at three months. Forgetting to drink and lack of thirst were less common barriers to fluid consumption. Most patients (85%) perceived sip^{IT} helped them achieve their fluid consumption goals.

Conclusions: Habit strength for fluid consumption increased while using the sip^{IT} tools and patients accepted the intervention. Digital health interventions that include semi-automated tracking and context-sensitive behavior change techniques are feasible. Randomized controlled trials are needed to determine the efficacy of this intervention for improving clinical outcomes.

COMPUTATIONAL COGNITIVE MODELS OF HABIT ACQUISITION IN DIGITAL HEALTH

PETER Pirolli, Ph.D., FNAI¹¹Institute for Human and Machine Cognition, San Francisco, CA

Our research on the Fittle+ mobile health systems use *scaffolding interventions* to provide support for the acquisition and maintenance of healthy habits. The Fittle+ systems have core multi-week programs to improve eating and physical activity with individualized daily goals. Computational models have been developed using the ACT-R theory of cognition and fit to data collected on the dynamics of behavior change and habit formation in two Fittle+ experiments that were shown to successfully change behavior. The first model was fit to individual-level data from $n=65$ adults in a 28-day experiment showing significant improvements in daily goal achievement when goals are algorithmically personalized. The second model was fit to individual-level data from $n=64$ adults in a 28-day experiment demonstrating significant effects of implementation intentions and the moderating effects of reminders. The models refine current psychological theories of *self-efficacy*, *intended effort*, *implementation intentions*, and *habit formation*.

The theory and models assume that habits are gradually learned through the association of specific behaviors to triggering cues in the environment. There are dual systems involved in habit acquisition and strengthening. First, a deliberative or controlled goal-striving process motivates and guides seminal attempts at behavior in the relevant contexts. Second, habit learning and strengthening processes form new habits through repeated practice, and habitual behaviors eventually are executed without effortful, controlled, goal striving. Habit formation typically depends on a long period of goal-mediated, consciously controlled, exploration, repetition, and practice of behavior. Well-practiced habits occur automatically without mediating goals, motivation, or deliberative thought.

Fine-grained predictive models will need to be developed to better predict and control dynamic digital health interventions. Progress in predictive modeling will lead to the development of user modeling approaches for precision behavioral medicine. This also opens up a path for scientific psychology that extends laboratory-developed theories and models out into real-world in vivo experiments.

Symposium 23

2:00 PM-3:15 PM

HOW BEHAVIORAL SCIENCE CAN PLAY A ROLE IN THE INTER-CONNECTION BETWEEN DIET AND CLIMATE CHANGE

Brie Turner-McGrievy, PhD, MS, RD¹, Christopher Gardner, PhD², Jillian Ryan, B Psych (Hons), PhD³, Melanie Hingle, PhD, MPH, RDN⁴, Helen Harwatt, PhD⁵

¹University of South Carolina, Columbia, SC; ²Stanford University, PALO ALTO, CA; ³Commonwealth Scientific and Industrial Research Organisation, Adelaide, South Australia, Australia; ⁴University of Arizona, Tucson, AZ; ⁵Harvard Law School, Hull, England, UK

The recent report on climate change and land commissioned by the United Nations and developed by the Intergovernmental Panel on Climate Change (IPCC) called for substantial changes in global land use, agriculture, and human diets. Climate change is one of the most pressing public health issues that we will face. The IPCC report stressed that significant changes in consumer behavior will be required to prevent future worsening of the climate. Changes recommended by the report include strategies such as wasting less food and persuading more people to shift their diets away from meat and to encourage “(t)he consumption of healthy and sustainable diets, such as those based on coarse grains, pulses and vegetables, and nuts and seeds.” This dietary shift “presents major opportunities for reducing greenhouse gas emissions” but will require significant shifts in current dietary behaviors. Behavioral scientists are well-positioned to develop effective and evidence-based strategies to promote dietary shifts that can help prevent further climate change. This symposium, comprised of US-based and international scientists, will present an overview of how dietary choices impact climate change and discuss effective behavioral interventions that have successfully helped individuals to transition to more plant-focused diets. The symposium will discuss the challenges in changing dietary behaviors, including addressing cultural traditions, taste preferences, cost, and regional cuisines. The session will conclude with a discussion around strategies that behavioral scientists can use to promote adoption of diets lower in greenhouse gas emissions. In addition, the panel will discuss current policy and research gaps in this area and strategies for filling those gaps going forward.

THE NUTRITIOUS EATING WITH SOUL STUDY: BEHAVIORAL STRATEGIES FOR FACILITATING ADOPTION OF PLANT-BASED DIETS

Brie Turner-McGrievy, PhD, MS, RD¹, Marian Botchway, PhD², Mary Wilson, MPH², Marty Davey, MS, RD², Anthony Crimarco, PhD¹, Sara Wilcox, PhD¹, Edward Frongillo, PhD², Angela Murphy, PhD²

¹University of South Carolina, Columbia, SC; ²University of South Carolina

Background: The recent EAT-Lancet report on Food, Planet, and Health emphasized a switch from animal-based to plant-based diets (PBD), benefiting both planetary and human health. There are barriers that make shifting to a more environmentally friendly diet difficult. The Nutritious Eating with Soul (NEW Soul) study aims to help participants adopt PBD as part of a 24-month randomized behavioral nutrition intervention for African American (AA) adults.

Objective: To provide an overview of the behavioral strategies used to facilitate adoption of PBD and present qualitative feedback on factors that promoted adoption of PBD from participants' perspectives.

Methods: Participants were randomized to follow 1 of 2 healthy, plant-focused versions of a soul food diet (vegan or omnivorous) and attended group meetings/cooking classes. For the qualitative study, men and women from the first cohort were eligible to participate. The Unified Model of Vegetarian Identity (UMVI) was used as the conceptual model for the qualitative study and helped inform question development.

Results: AA adults (n=158, 20% male, mean age of 48.2±10.6 y, mean BMI of 36.9±7.0 kg/m²) enrolled in NEW Soul. Strategies used in NEW Soul to facilitate adoption of PBD included 1) collaborating with AA soul food community chefs/restaurant owners to provide cultural adaptations of PBD that are palatable and familiar and provide hands-on cooking demonstrations; 2) bringing in AA experts in health, emotional eating, and religion to address dietary-related issues that are specific to the AA community; 3) partnering with local non-profit FoodShare, which provides affordable access to fresh fruits and vegetables; 4) hiring AA community members to serve as facilitators that lead group discussions with participants around diet challenges they face; 5) providing numerous sources of information and support, including face-to-face meetings, private Facebook groups, and podcasts. In our qualitative study, themes that emerged related to facilitators of dietary change included awareness of diet choices, being in control, family support, and influencing others to be healthier.

Conclusions: The NEW Soul study uses numerous strategies, including partnering with local soul food restaurants and chefs, to deliver an intervention that helps to address barriers to adopting PBD related to culture, cost, cooking skills, and taste.

2:00 PM-3:15 PM

STEALTH NUTRITION – PROTEIN AT THE INTERSECTION OF SOCIAL JUSTICE AND HEALTH ISSUES AMONG COLLEGE STUDENTS

Christopher Gardner, PhD¹

¹Stanford University, PALO ALTO, CA

Many college age young adults are currently interested in social justice issues, and some of this involves being at an age of ongoing identity formation. Protein lies at the intersection of environmental sustainability, animal rights and welfare, and dietary health, and thus involves social justice issues that are accessible topics of interest to anyone that eats—including students who frequently eat in college dining halls.

We recently published a review of dietary protein that covers requirements, recommendations, plant vs. animal protein, current intake, and the impact of protein sources on greenhouse gasses (GHG) emissions, water use, and human health. The review proposes decreases in overall protein intake and a shift to greater proportion of plant to animal protein, and models the beneficial impacts on GHG, water, and health. This background and these connections have been used in a *Food and Society* class at Stanford University that resulted in a publication about reported changes in student eating behaviors.

Student eating behaviors can be studied in campus dining halls. This requires collaboration between researchers, dining hall operators, chefs, and more. This novel type of collaboration has been emerging in colleges and universities around the country. Led by founders from Stanford University and the Culinary Institute of America, there are now more than 60 universities in the US that have joined the Menus of Change University Research Collaborative (MC-URC) (<https://moccollaborative.org>). Pilot protocols are typically developed at a single university, and then an invitation is opened to the other member universities to help in replicating the research protocols. The MC-URC organization is now 5 years old, and publications from this research are beginning to appear in peer reviewed journals.

One of the major themes of MC-URC is the Protein Flip. The “flip” refers to putting more plant food and less meat at the center of the plate – vegetables, nuts, beans and grains at the center of the plate as the main item, with meats in smaller portions, and as condiments or side dishes. These could be vegetarian or vegan, but they could also just be less meat, better quality meat. What has been very rewarding is working with chefs and keeping a focus on great taste and appearance so that we keep, or put back, the essential ideas of joy and pleasure in eating food.

It is also rewarding and inspiring to work with engaged Gen Z'ers who are passionate about social justice issues, and have many meals ahead of them. Changing social norms for these college aged students has the tremendous potential of influencing their families, friends and colleagues, hopefully leading to a Tipping Point that will align future global eating behaviors with the vision of a Great Food Transformation and a Planetary Health Diet as proposed in the 2019 EAT-Lancet report.

3

2:00 PM-3:15 PM

TESTING THE RELATIVE EFFECTIVENESS OF HEALTH, PRICE, SUSTAINABILITY, AND ANIMAL WELFARE MESSAGES IN PERSUADING MEAL CHOICE: A DISCRETE CHOICE EXPERIMENT.

Jillian Ryan, B Psych (Hons), PhD¹¹Commonwealth Scientific and Industrial Research Organisation, Adelaide, South Australia, Australia

Although the impact of food intake on individuals' physical health is well-understood, recent reports have also recognised the overconsumption of calories, packaged foods, and animal-source products as key drivers of climate change and the biodiversity crisis. The convergence of diet as a causal factor for multiple wicked problems offers novel opportunities to harness consumers' internal motivations to nudge towards more ideal food choices. The current study aimed to gain a greater understanding of the relative effects of different meal attributes on meal choice, with a focus on the influence of emerging values relating to climate change and animal welfare. Australian adults (N=2,040) participated in a discrete choice experiment that was embedded in a self-administered online survey. Respondents made nine selections between two hypothetical meals, each of which varied on four attributes: healthiness, price, carbon emissions (as marker of environmental sustainability), and animal welfare, each with three levels (best, moderate, worst). Binary logistic regression was performed to ascertain the effects of the four attributes on meal choice. The model was statistically significant, $\chi^2(8) = 442.094$, $p < .0001$, explained 41.0% (Nagelkerke R²) of the variance in meal choice, and correctly classified 64.3% of cases. All four attributes were significant ($< .001$), positive predictors of meal choice, meaning that higher values of each attribute were associated with increased likelihood of meal choice. Across the sample, meal healthiness had the strongest and carbon emissions the weakest influence on meal choice, regardless of participant age, sex, or socio-economic status. Specifically, results showed improvements in meal selection odds of 3.1 for every one-unit increase in meal healthiness, followed by animal welfare (OR 2.5), cost (OR 1.8), and carbon emissions (OR 1.7). Subgroup analyses showed that the comparative influence of the attributes differed depending on participant socio-demographic characteristics. Notably, marked differences were observed between males and females on impact of animal welfare (females OR 3.1, OR males 1.9) and differences in the influence of price based on income (low-income OR 2.0, high-income OR 1.6). Taken together, results suggest messages emphasising the health and animal welfare characteristics of meals may be the most persuasive for consumers. On the other hand, carbon emissions had the least influence on meal choice, which may reflect the prevalent climate change scepticism attitude or the distal nature of climate change consequences. Understanding the changing values and motivations behind consumers' food choices is something that can be achieved through choice experiments and is essential to maximising the impact of public education campaigns targeting human health and environmental sustainability.

2:00 PM-3:15 PM

EATING OUR WAY TO A SAFE PLANET: ADDRESSING THE ENVIRONMENTAL BURDENS OF FOOD SYSTEMS

Helen Harwatt, PhD¹¹Harvard Law School, Hull, England, UK

The Scientists' second warning to humanity provides a stark picture of the burgeoning environmental problems upon us, and the urgency required in providing solutions. The goal of this presentation is to provide an overview to behavioural scientists about the role of food systems. Our food choices make a major contribution to creating environmental burdens, and reconfiguring them to align with planetary restoration is essential. Agriculture is the major driver of transgressing beyond a safe operating space for land use change, biosphere integrity (wildlife loss), and biogeochemical flows (the nitrogen and phosphorus cycles); and is a significant contributor to surpassing a perceived safe level of anthropogenic greenhouse gas emissions contributing to climate change. I present the main ways that food systems have contributed to the unsafe state of four Planetary Boundaries: climate change, land use change, wildlife loss, and the nitrogen and phosphorus cycles (nutrient pollution). I identify solutions for reducing the burden of the food system on the four Planetary Boundaries, and how our food choices can also play a crucial role in restoring healthy ecosystems and meeting the goals of the Paris Agreement climate change treaty. I close with a proposal for a three step strategy for feeding a growing population while minimising pressure on the four Planetary Boundaries, which could be adopted by individual consumers, institutions, businesses and policy makers.

NOVEL BRAIN HEALTH INTERVENTIONS FOR OLDER ADULTS

Ana-Maria Vranceanu, PhD¹, Ryan Mace, MS², Jonathan Greenberg, PhD¹, Katherine Hall, PhD³, Kathi L. Heffner, PhD⁴, Jonathan W. King, PhD⁵

¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Durham VA Health Care System, Durham, NC; ⁴University of Rochester Medical Center, Rochester, NY; ⁵National Institute on Aging / NIH, Bethesda, MD

Within the last century, we have witnessed a dramatic increase in the proportion of older adults. As people are expected to live longer, brain health – maintaining brain structure and function over the lifespan – has become a national priority. While the leading predictors of brain disease, age and genetics, are not yet modifiable, mounting evidence suggests that behavioral interventions can modify lifestyle risk factors. In line with SBM's 2020 annual meeting theme: "Finding Innovative Solutions for Tomorrow's Challenges", this symposium brings together novel interventions aimed at preserving and optimizing brain health and performance with advancing age, which we organized according to the National Institute of Aging stage model. First, *Ryan Mace* will discuss the development of "Active Brains", the first group mind-body physical activity program aimed at improving emotional, physical and cognitive function in older adults with chronic pain and cognitive impairment. "Active Brains" was developed through a mixed methods approach that integrated quantitative and qualitative data from 26 older adults. *Jonathan Greenberg* will present proof of concept trial data from adults (N = 20) enrolled in "My Healthy Brain," a group program aimed to preserve brain health and prevent cognitive decline through evidence-based lifestyle changes. *Katherine Hall* will report findings from a pilot RCT (N = 54) that tested a supervised exercise program for older veterans with PTSD (M age = 67.7; 83% African American) to reduce unhealthy lifestyle behaviors and cognitive impairment. *Kathi Heffner* will share results from an RCT (N = 110) in dementia caregivers that support the use of cognitive training (specifically targeting visual-based speed of processing) to enhance older adults' stress adaptation capacity and healthy aging. *Jonathan King* will place these development studies within the larger context of evidence-based behavioral medicine interventions for cognitive aging, and discuss future directions in brain health research.

CORRESPONDING AUTHOR: Ana-Maria Vranceanu, PhD, Massachusetts General Hospital/Harvard Medical School, Boston, MA; AVRANCEANU@mg.h.harvard.edu

THE ACTIVE BRAINS PROGRAM: ADDRESSING CHRONIC PAIN AND MEMORY PROBLEMS IN OLDER ADULTS

Ryan Mace, MS¹, Melissa V. Gates, BA², Breanna Bullard, BA³, Ethan G. Lester, PhD¹, Ilyssa Silverman, Undergraduate³, Ana-Maria Vranceanu, PhD⁴

¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, South Boston, MA; ³Integrated Brain Health Clinical and Research Program; ⁴Massachusetts General Hospital/Harvard Medical School, Boston, MA

Chronic pain and memory problems often cooccur in older adults, and the prevalence of both are expected to increase alongside longer life expectancy. Chronic pain uniquely contributes to memory problems and their cooccurrence can decrease psychosocial functioning through the use of ineffective coping strategies (e.g., pain catastrophizing and avoidance). In the absence of available non-pharmacological treatments, there is an unexplored opportunity to teach sustained, pain management habits before cognitive decline with aging. This presentation will introduce *Active Brains* as the first group mind-body physical activity program aimed at improving emotional, physical, and cognitive function in older adults with chronic pain and memory problems. *Active Brains* was developed through a mixed methods approach that integrated quantitative and qualitative data from older adults (N = 26) with chronic pain and memory problems who participated in semi-structured focus groups. Thematic analyses revealed four main themes to tailor *Active Brains* to patient needs: (1) specific challenges of living with chronic pain and memory problems, (2) perspectives on increasing physical activity using a Fitbit, (3) thoughts on *Active Brains* skills (e.g., mindfulness, pain reappraisals, behavioral reinforcement), and (4) anticipated barriers to program adherence. Correlational analyses of self-report measures indicate that pain (numerical rating scale), physical functioning (PROMIS), cognitive complaints (eCOG), and emotional well-being (PROMIS, UCLA Loneliness) are interrelated and associated with disability (r range with the WHODAS = 0.63 to 0.83). In contrast, higher self-efficacy in managing pain (PSEQ) was significantly ($p < 0.001$) associated with decreased disability ($r = -0.90$), sleep disturbance (PSQI, $r = -0.75$), depression ($r = -0.70$), anxiety ($r = -0.67$), cognitive complaints ($r = -0.57$), and loneliness ($r = -0.52$). Complementary mixed-methods results suggest that an integrative approach, such as *Active Brains*, is needed to address chronic pain and memory problems. Older participants were interested in combining mind-body skills with mild physical activity (via Fitbit) to improve psychosocial functioning and provided critical feedback to inform treatment adaptations. Future trials are warranted to determining the feasibility, acceptability and efficacy of *Active Brains* in this population for improving physical, cognitive, and emotional functioning.

2:00 PM-3:15 PM

THE ‘MY HEALTHY BRAIN’ PROGRAM: PROMOTING BRAIN HEALTH THROUGH LIFESTYLE CHANGES

Jonathan Greenberg, PhD¹, Ryan Mace, MS², Ethan G. Lester, PhD², Ana-Maria Vranceanu, PhD¹¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA

Over the last decade there has been a proliferation of research that provided a paradigm shift in our understanding of brain health and performance across the lifespan. Specifically, we now know that lifestyle factors and cognitive reserves are protective against cognitive decline as we age. However, individuals interested in preserving brain health and preventing cognitive decline face numerous barriers to adopting healthier lifestyles and building cognitive reserves, such as lack of scientifically based educational information, challenges with setting goals and sustaining motivation, and mental health concerns (e.g., depression, loneliness, anxiety). As such, we need to develop brain health interventions aimed at bypassing these barriers and improving both lifestyle factors and cognitive reserve. In response to this need, we developed *My Healthy Brain*, an 8-week group program to promote a healthy lifestyle (e.g., diet, exercise, alcohol, sleep, social support) and build cognitive reserves (e.g., learn memory compensatory strategies). Here we report on a proof of concept, open trial of this novel program, to determine the feasibility, acceptability, and effect sizes of improvement after group participation in adults with self-reported concerns about cognitive decline. Twenty-four adults participated in 4 groups. Eighteen participants provided post-test (75%). Eighty-seven % of participants were “mostly” or “very” satisfied with the program. Rates of heavy/hazardous drinking reduced from 44% at baseline to 29% at post-program. The percentage of participants who meet the World Health Organization (WHO) recommendations for physical activity (600 weekly metabolic-equivalent minutes) increased from 58% to 81%. Participants improved eating, self-efficacy, distress, anxiety and overall satisfaction with life (ES=.45-.59). Results support a randomized controlled trial of this program, as well as longitudinal assessments on objective and subjective cognitive functioning over time.

3

2:00 PM-3:15 PM

EXPLORING THE EFFECTS OF SUPERVISED EXERCISE ON COGNITIVE FUNCTION AND SLEEP IN OLDER VETERANS WITH PTSD: A PILOT RANDOMIZED CONTROLLED TRIAL

Katherine Hall, PhD¹, Christi Ulmer, PhD², Miriam Morey, PhD², Jean Beckham, PhD³¹Durham VA Health Care System, Durham, NC; ²Durham VA Healthcare System, Durham, NC; ³Durham VA Healthcare System

Posttraumatic stress disorder (PTSD) is prevalent among older veterans and associated with poor lifestyle behaviors (e.g., physical inactivity, sleep disturbance) and impaired cognitive function. Previous studies have reported benefits of exercise on cognition in older adults, but this has never been tested in the context of PTSD. Fifty-four older Veterans with PTSD (N=54; M age=67.6; male = 94%) were randomized in a 2:1 ratio to either a 12 week Warrior Wellness exercise program (WW; N=36) or wait-list usual care (W-L; N=18). WW participants engaged in supervised exercise sessions 3 days per week. Memory complaints were assessed using the Frequency of Forgetting (FOF) Scale derived from the Memory Functioning Questionnaire. Sleep was assessed with the PSQI and PSQI-PTSD Addendum questionnaires. In this pilot study underpowered for efficacy, we examined effect sizes for evidence of a “signal” for exercise on memory relative to usual care. Factors associated with 12-week changes in FOF were also examined using bivariate correlation analyses. Forty-eight participants completed assessments at baseline and 12 weeks. At baseline, mild-to-moderate memory complaints were reported by 84% of the sample (FOF score < 6), and 16.7% reported major memory problems. Comparison across conditions revealed a small, negative effect (MD=-0.25, Cohen's d=-0.41 [95% CI -0.64,0.15]) for exercise on self-reported memory problems compared to W-L. Participants in WW showed a small decrease of -0.10 on the FOF (indicative of more memory complaints) across 12 weeks, compared to W-L which demonstrated a small increase of 0.15. Between-group effects for sleep parameters ranged from small to moderate, favoring exercise. In the total sample, improvements in memory complaints over 12 weeks were significantly associated with reduced PTSD symptom severity ($r=-0.34$, $p<0.05$) and improvements in sleep ($r=-0.35$, $p<0.05$). Contrary to our hypothesis, 12 weeks of supervised exercise did not confer any benefits to self-rated memory in older veterans with PTSD. Improvements in sleep with exercise were associated with reduced memory complaints over 12 weeks, suggesting a possible mediation pathway. Future exercise studies of longer duration with more sensitive measures of cognitive function appear warranted in this population with substantial memory and sleep deficits.

4

2:00 PM-3:15 PM

COMPUTERIZED COGNITIVE TRAINING FOR CAREGIVERS OF A LOVED ONE WITH DEMENTIA: TARGETING FLUID COGNITIVE ABILITIES TO ENHANCE STRESS ADAPTATION AND HEALTHY AGING

Kathi L. Heffner, PhD¹¹University of Rochester Medical Center, Rochester, NY

The chronic emotional stress of caregiving for a loved one with Alzheimer's disease or related dementia (ADRD) accelerates aging-related declines in cognitive and immune function. Premised on evidence for neurobiological integration of cognition, emotion, and physiological stress regulation, we are currently conducting a National Institute on Aging-funded randomized controlled trial (RCT) to determine whether visual speed of processing and attention (VSOP/A) training will strengthen caregivers' capacity for stress adaptation, and, ultimately, slow immune aging. Discussed here is preliminary work that supported the trial, as well as an ancillary analysis of trial data, that together provide support for our premise that targeting fluid cognitive abilities holds potential as a means to enhance stress adaptation. In an observational laboratory study, we found that among community-dwelling adults over 50 years of age, ($N=110$; $M(SD)$ age = 60.5(8.4), worse cognitive performance (e.g., processing speed, attention, working memory) was associated with markers of poorer stress regulation, including maladaptive heart rate variability and negative affect response to acute stressors, and higher circulating levels of plasma interleukin-6, a marker of inflammation. To subsequently test a causal role for fluid cognitive ability in stress adaptation, stressed ADRD caregivers are currently being randomized to an 8-week VSOP/A training or video education control intervention. Cognitive function, emotion regulation, heart rate variability, and immune measures are assessed at baseline (T1) and then immediately (T2), 6 months (T3), and 12 months following the intervention period. Using ancillary data from $n=104$ caregivers 50-85 years of age ($M(SD)$ age = 68.8(7.8)) who have completed assessments through 6 months, we find evidence from linear mixed modeling that VSOP/A training enhances performance on a demanding working memory task (group \times time: $F(2, 75)=4.3$, $p=.02$; VSOP/A: T1 mean(SE)=32.4(.86); T2 mean(SE)=34.6(.88); T3 mean(SE)=35.6(1.01); Control: T1 mean(SE)=32.7(.90); T2 mean(SE)=34.1(.94), T3 mean(SE)=32.5(.99)) suggesting better cognitive performance during an acute psychophysiological stressor. Together, this evidence suggests that targeting fluid cognitive abilities via computerized cognitive training, a self-administered, home-based intervention, may benefit stress adaptation, including cognitive resilience to stressors, in caregivers of a loved one with dementia.

Symposium 25

2:00 PM-3:15 PM

ENGAGEMENT OF LATINOS IN BEHAVIORAL INTERVENTION TRIALS: EVIDENCE FROM THE FIELD, LESSONS LEARNED, AND BEST PRACTICES

Lisa Goldman Rosas, PhD, MPH¹, Dara Sorkin, PhD², Larkin Strong, PhD, MPH³, Patricia Rodriguez Espinosa, Ph.D., M.P.H.⁴, Elva M. Arredondo, Ph.D.⁵¹Stanford University, Palo Alto, CA; ²University of California, Irvine, Irvine, CA; ³University of Texas MD Anderson Cancer Center, Houston, TX; ⁴Stanford School of Medicine, Palo Alto, CA; ⁵San Diego State University, San Diego, CA

Latinos are the largest racial/ethnic minority group in the US and they are disproportionately represented among those with chronic disease such as diabetes and cardiovascular disease. Latinos accounted for approximately half of the US population growth over the last two decades and are expected to reach over 100 million by 2050. The Latino population is also aging more quickly than any other racial/ethnic group in the US. A high prevalence of obesity and other risk factors such as physical inactivity among Latinos underscore the urgent need to develop innovative, efficacious, and scalable chronic disease prevention interventions for this population. Despite this need, Latinos are underrepresented in behavioral lifestyle intervention trials. NIH data show that fewer than 8% of enrollees in clinical trials are Latino. In trials that focus on Latinos, study recruitment, engagement in the intervention, and retention remain challenges. In this symposium we will present evidence from 5 behavioral lifestyle intervention trials to provide lessons learned and best practices for recruiting, engaging, and retaining Latino participants in behavioral lifestyle intervention trials:

1. Lisa Goldman Rosas (chair) will present evidence to inform best practices for engaging Latino men based on the HOMBRE study, a comparative effectiveness trial of two approaches to weight management among Latino men ($n=424$) in primary care.
2. Dara Sorkin (Co-presenter) will discuss challenges and solutions to engaging Latina women in a weight loss intervention from the Unidas por la Vida study that recruited mothers with type 2 diabetes and their overweight/obese adult daughters ($n=721$).
3. Larkin Strong (Co-presenter) will present data on recruitment strategies from the Tu Salud, ¡Si Cuenta! trial that is recruiting adult Latino family dyads ($n=458$) to test the effectiveness of a family-based physical activity and nutrition intervention.
4. Patricia Rodriguez Espinosa (Co-presenter) will present data from two physical activity intervention trials with Latinos, COMPASS2 ($n=245$) and On The Move ($n=350$) that used targeted bilingual mailings for recruitment.

Overall, we will provide evidence from engaging approximately 2,200 participants to equip attendees with lessons learned and best practices for engaging Latinos in chronic disease prevention trials. Elva Arredondo, and expert in Latino chronic disease prevention, will serve as a discussant for the symposium.

2:00 PM-3:15 PM

THE HOMBRE TRIAL: ENGAGING LATINO MEN IN A BEHAVIORAL LIFESTYLE INTERVENTION FOR WEIGHT MANAGEMENT

Lisa Goldman Rosas, PhD, MPH¹, Nan Lv, PhD², Steven Hooker, PhD³, Elizabeth M. Venditti, PhD⁴, Megan A. Lewis, PhD⁵, Lan Xiao, PhD¹, Kristen Azar, RN, MSN/MPH⁶, PATRICIA ZAVELLA, n/a⁷, Jun Ma, MD, PHD²

¹Stanford University, Palo Alto, CA; ²University of Illinois at Chicago, Chicago, IL; ³San Diego State University, El Cajon, CA; ⁴University of Pittsburgh School of Medicine, Pittsburgh, PA; ⁵RTI International, Seattle, WA; ⁶Sutter Health, Palo Alto, CA; ⁷University of California, Santa Cruz, Santa Cruz, CA

Background: Approximately 40% of Latino men are obese, however, they are drastically underrepresented in trials testing behavioral interventions for obesity. Understanding Latino men's preferences for behavioral interventions is critical for engaging this underrepresented group.

Methods: We examined preferences for engaging in a behavioral intervention for weight loss among 202 Latino men who were randomized to receive the HOMBRE intervention in a comparative effectiveness trial based in primary care. The HOMBRE intervention included a coach-facilitated choice among three options: in-person coach facilitated group, online coach facilitated group via video conferencing, and self-directed using online videos. All three options provided the same evidence-based behavioral lifestyle intervention that included 12 weekly sessions and 9 monthly phone calls. We examined demographic, technology access/use, psychosocial, and clinical factors associated with men's intervention preferences. We also examined men's engagement in the in-person and online group sessions.

Results: Participants were middle aged (avg 47.3 yr + SD 11.8), educated (77% attended some college), employed full or part time (86%), and had access to a computer (90%) and smartphone (97%). Intervention preferences were: 40% in-person groups, 38% self-directed online videos, and 22% online groups. The majority preferred to engage in the intervention in English (71%) vs Spanish (29%). Those who chose in-person groups were more likely ($p < 0.05$) to have lower education, be retired or unemployed, speak Spanish only, be less acculturated, and not have access to a computer or tablet compared to those who chose the two technology-mediated options. There was no significant difference ($p > 0.05$) in choice according to clinical factors such as body mass index, blood pressure, depression symptoms, or psychosocial factors such as overall and obesity-specific quality of life. There was no significant difference ($p > 0.05$) in class attendance between the in-person and online groups. Overall in both groups 86% attended >25%, 82% attended >50%, and 58% attended >75% of the classes.

Conclusion: Demographic and computer access differences were significantly associated with preferences for engaging in a behavioral intervention among Latino men. Providing options that accommodate the diversity of Latino men's preferences is important for increasing engagement in behavioral interventions.

2:00 PM-3:15 PM

INSIGHTS FROM THE UNIDAS POR LA VIDA RESEARCH STUDY ABOUT ENGAGING LOW-INCOME WOMEN IN A DYADIC BEHAVIORAL WEIGHT LOSS INTERVENTION

Dara Sorkin, PhD¹, Laura Prieto, BA², Ariana Martinez, M.S.², Anne Escaron, Ph.D.², Joceline Porron, B.A.², Daniela Macias, B.A.¹, Maribel Cervantes-Ortega, M.S.³, Jessica Solares, MPH², Karen Rook, PhD¹

¹University of California, Irvine, Irvine, CA; ²AltaMed; ³University of California, Irvine

Background: Longitudinal community-based prevention programs have been shown to positively impact weight loss and improve diabetes control in participants with type 2 diabetes. Although these programs have proven to decrease participants' average baseline weight by 4%, recruitment and retention of low-income minority groups remain challenging. Engagement strategies are critical factors in recruiting and maintaining participation in year-long health intervention programs. We present strategies developed during the recruitment and retention phases of an NIH-funded diabetes behavioral intervention program targeting low-income Latina women recruited from federally qualified health centers (FQHCs).

Methods: Prospective participants, mothers with type 2 diabetes and their overweight/obese adult daughters (N=721), were identified from seven sites across two FQHCs. Latinas were invited to participate in the dyadic weight loss intervention via clinic appointments, telephone calls, and mailed letters. Participant contact notes and data were examined to identify obstacles to engagement, and tailored messages were developed to promote participation in the research study and in group classes and follow-up assessments at 6 and 12 months.

Findings: Common barriers to participation in the research study included lack of time, transportation difficulties, family and work obligations. Common barriers to participation in group classes included participants' work hours, family obligations, financial struggles, secondary issues including, physical and mental health stressors, health literacy, and transportation. To overcome some of these common engagement and participation barriers we prioritized building credibility, being flexible with our scheduling, addressing hesitation, personalizing their experience throughout all study communications with participants, and increasing incentives and assisting with transportation, where feasible.

Conclusions: By adopting this approach, we achieved recruitment goals. Nonetheless, participation in group classes remained lower than desired. Recruiting and retaining research participants from under-resourced communities requires the commitment of additional resources (e.g. financial, personnel) to promote and support participation across all phases of the program.

2:00 PM-3:15 PM

RECRUITMENT OF LATINOS FOR A DYADIC FAMILY LIFESTYLE INTERVENTION STUDY: EXPERIENCES FROM THE TU SALUD, ¡SI CUENTA! TRIAL

Larkin Strong, PhD, MPH¹, MinJae Lee, PhD², Shaili Bhavsar, BS³, Tianlin Xu, MPH⁴, Jemima John, PhD⁵, Lorna McNeill, PhD, MPH⁶, Margaret Goetz, MD⁷, Susan Schembre, PhD, RD⁸, Deanna Hoelscher, PhD, RDN⁹, Belinda Reininger, DrPH¹⁰

¹University of Texas MD Anderson Cancer Center, Houston, TX; ²McGovern Medical School, UTHealth, Houston, TX; ³UTHealth School of Public Health; ⁴University of Texas Health Science Center at Houston, Houston, TX; ⁵MD Anderson Cancer Center, Houston, TX; ⁶MD Anderson Cancer Center, Pearland, TX; ⁷ProSalud; ⁸University of Arizona College of Medicine, Tucson, AZ; ⁹UT Health School of Public Health, Austin, TX; ¹⁰UT Health School of Public Health, Harlingen, TX

Background: Researchers have increasingly advocated for lifestyle interventions with Latinos to incorporate an explicit focus on the family, yet few studies engage multiple family members, and the feasibility of recruiting Latino family members into a clinical trial is unclear. Tu Salud, ¡Si Cuenta!/Your Health Matters is an ongoing RCT testing the effectiveness of a 6-month family-based physical activity and nutrition intervention for adult Latino family members, compared to a contact control. This presentation will describe experiences recruiting predominantly low-income and Spanish-speaking adult Latino family dyads into a behavioral intervention study and will examine demographic and study-related characteristics associated with enrollment outcomes.

Methods: Prospective participants (e.g., aged 18-70 years, not meeting physical activity or fruit and vegetable recommendations) are recruited from community sites (e.g., community centers, community events, churches, schools) in three predominantly Latino communities in Houston, TX by bicultural research staff and community health workers. Chi-square tests were performed to evaluate associations of dyad and individual factors with enrollment outcomes in screened and eligible dyads.

Results: To date, 930 individuals have been screened for eligibility, and 542 individuals were eligible to enroll as 271 dyads (39% spouses, 36% parent/child, 11% siblings, 14% other relationships). Of these eligible dyads, 52% completed a baseline assessment, 23% cancelled or did not show up for their baseline assessment, and 25% could not be reached after initial recruitment. These enrollment outcomes were not significantly associated with dyad relationship or individual age or gender but were significantly associated with recruitment source ($p=0.001$). For example, among eligible dyads recruited from community events, 63% enrolled in the study compared to 46% from community centers. Enrollment outcomes were also associated with neighborhood of residence ($p=0.02$): study enrollment ranged from 43% of eligible dyads in one neighborhood to 69% in another.

Conclusions: Recruiting family dyads for a lifestyle intervention added extra steps to the process, and success varied by neighborhood and approach. Identification of factors associated with enrollment outcomes is critical for the refinement of recruitment approaches to more effectively engage underserved populations in culturally appropriate chronic disease prevention research.

USING TARGETED MAILINGS TO RECRUIT LATINO AND OTHER UNDERSERVED ADULT POPULATIONS FOR BEHAVIORAL HEALTH INTERVENTION TRIALS

Patricia Rodriguez Espinosa, Ph.D., M.P.H.¹, Ines Campero, BA², Michele Escobar, Social Science Research Coordinator¹, Abby C. King, PhD³

¹Stanford School of Medicine, Palo Alto, CA; ²Stanford University School of Medicine, Palo Alto, CA; ³Stanford University School of Medicine, Stanford, CA

Latinos, the largest racial/ethnic minority group in the US, are disproportionately affected by chronic conditions (e.g., diabetes, cancer) compared to non-Latino Whites. Nonetheless, this population continues to be underrepresented in randomized controlled trials (RCTs). We describe the use of targeted mass mailings as a strategy for recruiting Latinos and other groups into behavioral RCTs. Issues in using targeted mass mailings include obtaining targeted mailing lists adapted for the population of interest, representativeness of samples obtained, and tracking of response rates. We describe how this strategy was used in two successfully completed RCTs for increasing physical activity among older Latinos -- the COMPASS2 trial (N=245) and the On The Move Trial (N=350). Both NIH-funded trials were conducted in the San Francisco Bay Area. As part of recruitment activities, potentially eligible community residents received targeted bilingual mass mailing materials. We will present data on the proportion of participants enrolled in each trial in response to this, vs. other, recruitment approaches (e.g., community outreach, referrals) and their percent participation during the intervention compared to the other strategies used. We also present insights from an ongoing RCT, Steps for Change (n=250). In this trial, ethnically diverse, low-income residents were randomly mailed two different types of recruitment letters -- a more standard letter describing the study, or an adapted, more personal letter that highlighted potential benefits of study participation for others and the community. We hypothesized that residents, given values of personalism and collectivism, would be more likely to respond to the latter version. Preliminary analysis indicates a modest, non-significant preference towards the adapted letter - 157 letter responses vs. 136 for the more standard letter (X2 [2, n = 328] = 3.38, $p=.18$). Full results will be presented. We will also address benefits of using targeted mass mailings (e.g., ability to reliably project response rates over time), and challenges, including costs and staff time needed for screening and tracking. As the US continues to become increasingly diverse, optimizing research recruitment methods for racial/ethnic populations is a key priority in order to accelerate health equity-related science.

Symposium 26

2:00 PM-3:15 PM

NEW EVIDENCE FOR PSYCHOLOGICAL AND OTHER NON-PHARMACOLOGIC APPROACHES FOR MANAGING CHRONIC PAIN

Christine M. Rini, PhD¹, Susmita Kashikar-Zuck, PhD², Lynn DeBar, PhD MPH³, Francis J. Keefe, Ph.D.⁴¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Cincinnati Children's Hospital Medical Center, Cincinnati, OH; ³Kaiser Permanente Washington Health Research Institute, Seattle, WA; ⁴Duke University, Durham, NC

The individual and public health impact of chronic pain is clear and pressing. People who live with chronic pain are at elevated risk for depression and have impaired functioning in their daily life, including in valued roles involving family, social, and work activities. Many use medications to help manage their pain, but these treatments often cause undesirable symptoms and toxicities. Non-pharmacologic therapies such as exercise and psychological pain interventions (e.g., those applying principles of cognitive behavioral therapy, or CBT) can help people manage chronic pain and do not cause unwanted side effects, making them an important component of multidisciplinary pain care. In fact, they are a recommended part of various pain treatment guidelines despite being underused in clinical pain care. The studies described in this symposium extend evidence on these therapies in ways that can optimize their efficacy and advance their use in clinical care. The first speaker will evaluate current research on psychological and exercise-based treatments for pediatric chronic pain; describe a novel intervention approach that combines these therapies to optimize their efficacy in children with juvenile fibromyalgia syndrome; and describe how to design studies to improve understanding of brain mechanisms underlying pain in pediatric populations. The second speaker will describe the findings and lessons learned from a recently completed large scale pragmatic trial that embedded a multidisciplinary team within primary care clinics in several areas of the country to deliver a combined CBT and yoga-based movement program to patients with chronic pain on long term opioid therapy. This speaker will also describe intervention elements that have been adapted for sustained use in these settings. The third speaker will describe a study that showed changes in people's selection of adaptive and maladaptive pain coping responses after completing pain coping skills training, which her team delivered to people with osteoarthritis in a self-directed, web-based program. The study used a novel research method to elicit pain coping strategies participants would use in situations likely to increase their pain, comparing responses in the intervention group to those in a control group to yield evidence for mechanisms underlying benefits of pain coping skills training. The Discussant, an internationally-recognized expert in non-pharmacologic pain management, will synthesize evidence from the talks and highlight and future directions in this line of research.

2:00 PM-3:15 PM

WEB-BASED PAIN COPING SKILLS TRAINING CHANGES COPING STRATEGIES PEOPLE WOULD USE IN HYPOTHETICAL SITUATIONS LIKELY TO INCREASE PAIN

Christine M. Rini, PhD¹, Ariana Katz, MPH², Ada Nwagugbo, MPH³, Laura S. Porter, PhD⁴, Tamara Somers, PhD⁵, Francis J. Keefe, Ph.D.⁶¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²RTI International; ³US Government Accountability Office; ⁴Duke University Medical Center, Durham, NC; ⁵Duke University School of Medicine, Durham, NC; ⁶Duke University, Durham, NC

Background: Pain coping skills training (PCST) helps people manage persistent pain with evidence-based cognitive and behavioral skills such as relaxation, distraction, activity pacing, and positive coping thoughts. Evidence shows that PCST can reduce pain and related impairment. The assumption is that it does so by changing the coping strategies people identify as potential responses to life situations that may increase their pain, including more adaptive strategies such as relaxation and activity pacing and fewer maladaptive strategies such as avoiding valued activities and overuse of pain medication. We tested this assumption in people with osteoarthritis (OA) who completed a self-directed, web-based PCST program previously found to be efficacious in this population. At baseline and post-intervention they completed a novel research task that elicited the types of pain coping strategies they would use in situations likely to exacerbate pain. We examined changes in adaptive and maladaptive pain coping strategies identified by the web-based PCST group compared to changes in strategies identified by a control group.

Methods: 107 people with hip or knee OA and associated pain enrolled in a 2-arm randomized trial in which they completed either a highly interactive, 8-session, self-directed web-based PCST program or study assessments with no PCST (control condition). In baseline and post-intervention assessments, we presented participants with four vignettes describing hypothetical situations likely to increase OA pain. After each vignette, they had 2 minutes to describe how they would prevent or manage OA pain in that situation. Trained staff coded their audio-recorded responses to count discrete mentions of specific adaptive and maladaptive pain coping strategies. Participants also reported their perceived risk for increased pain in each situation and their self-efficacy for controlling and avoiding pain in the described situation and future situations.

Results: Compared to the control group, the web-based PCST group became less likely to identify maladaptive behavioral pain coping strategies ($p = .002$) and more likely to identify at least one cognitive pain coping strategy ($p = .01$) at post-intervention. They also demonstrated greater reductions in perceived risk for pain ($p = .03$) and greater improvements in self-efficacy ($ps < .001$).

Conclusions: Findings demonstrate possible cognitive and behavioral mechanisms through which people with OA may benefit from completing web-based PCST.

2:00 PM-3:15 PM

INTEGRATING PSYCHOLOGICAL AND EXERCISE-BASED THERAPIES IN NOVEL WAYS FOR THE TREATMENT OF CHRONIC MUSCULOSKELETAL PAIN IN PEDIATRIC POPULATIONS

Susmita Kashikar-Zuck, PhD¹¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Safe and effective non-pharmacologic treatments that have strong and sustained effects are urgently needed for the proper management of chronic widespread musculoskeletal pain in children and adolescents. The objectives of this presentation are to 1) critically evaluate current research on psychological and exercise-based treatments for pediatric chronic pain, 2) highlight a novel combined intervention approach that has the potential for greater pain reduction and functional restoration than prior treatments using new research in juvenile fibromyalgia syndrome (JFM) as a model, and 3) describe how such treatment studies can serve as a vehicle for enhancing our understanding of the mechanisms of chronic musculoskeletal pain in pediatric populations. The speaker will discuss how a novel approach to exercise – neuromuscular training, derived from injury prevention research and focusing on improving body biomechanics and movement competence can be used in combination with coping skills training to reduce pain and disability in JFM. The group-based Fibromyalgia Integrative Training for Teens (FIT Teens) program potentially has stronger effects on pain and disability in JFM than previously studied non-pharmacologic treatments. Early results show strong improvements in self-reported pain and disability after treatment. Moreover, objectively measured improvements are seen in physical ability using technologically advanced methods including 3-dimensional motion capture of movement biomechanics. A large multi-site RCT of the FIT Teens program is ongoing. The potential for incorporation of technological advancements such as motion capture and virtual reality into behavioral treatments for chronic musculoskeletal pain will be discussed. Finally, treatment studies of this type can be used to probe the underlying brain mechanisms of chronic pain and its treatment and point the way for exciting new research directions in pain management.

3

2:00 PM-3:15 PM

CHANGING CLINICIAN AND PATIENT BEHAVIOR AS A MEANS OF PROMOTING EVIDENCE BASED BEHAVIORAL MANAGEMENT STRATEGIES FOR CHRONIC PAIN MANAGEMENT IN PRIMARY CARE SETTINGS.

Lynn DeBar, PhD MPH¹¹Kaiser Permanente Washington Health Research Institute, Seattle, WA

This talk will discuss behavioral, psychological, and healthcare system factors that affect the readiness of clinicians and patients with chronic pain to communicate about and work in partnership to optimize patients' motivation and follow through in adopting nonpharmacotherapeutic strategies for chronic pain management. The speaker will utilize examples from her and her close collaborators' recent and current NIH- and PCORI-funded studies (both pragmatic trials and multi-method evaluations of US policy initiatives) promoting and evaluating patients' uptake of evidence-based behavioral interventions and complementary and integrative health approaches to manage chronic pain within a variety of busy everyday primary care settings. Further, the speaker will summarize primary outcome findings and lessons learned from a recently completed large scale cluster randomized pragmatic clinical trial of an interdisciplinary behavioral intervention embedded in primary care for chronic pain management. The trial included 850 patients with chronic pain on long term opioid treatment from across three regions of the country (Pacific Northwest, Georgia, Hawaii). Patients in the intervention arm sustained larger reductions in pain impact over follow-up, .47 greater reduction at 3 months, .49 at 12 months. Significant differences between study arms over time for opioid use were not observed. Overall, the findings suggest that a primary care-based behavioral intervention to develop self-management skills helped patients receiving long term opioid treatment for diverse chronic pain conditions. The intervention produced modest but significant and sustained reductions in pain impact, pain-related disability, and benzodiazepine. Effects were achieved in routine primary care using frontline clinicians.

Symposium 27

2:00 PM-3:15 PM

PROGRESS IN BEHAVIORAL ONTOLOGIES AND IMPLICATIONS FOR BEHAVIORAL MEDICINE

William T. Riley, Ph.D.¹, Alexander J. Rothman, Ph.D.², Christine M. Hunter, PhD³, DAWN A. MORALES, Ph.D.⁴, Susan Michie, BA,MPhil, DPhil⁵, Pól G. Mac Aonghusa, PhD⁶¹National Institutes of Health, Bethesda, MD; ²University of Minnesota, Minneapolis, MN; ³Office of Behavioral and Social Sciences Research, National Institutes of Health, Bethesda, MD; ⁴National Institute of Mental Health, Bethesda, MD; ⁵University College London, London, England, UK; ⁶IBM, Carbury, Kildare, Ireland

Behavioral medicine lags behind biomedicine in the development and implementation of controlled vocabularies, taxonomies, and ontologies. These taxonomic structures facilitate research and practice communications, elucidate relations among constructs, encourage data sharing and integration, and provide the basis for a more cumulative science. This symposium will describe various approaches for developing behavioral ontologies and progress in the development of these ontologies. Following a brief introduction to the topic, Drs. Hunter and Morales will describe the range of initial efforts by the National Institutes of Health (NIH) to encourage the development of behavioral ontologies and link these ontologies to existing biomedical taxonomic structures. Dr. Michie will highlight her extensive research program on behavior change taxonomies and recent advances in linking behavior change components to theoretical mechanisms of action. Dr. Pól Mac Aonghusa will describe the synergies between ontologies and artificial intelligence in predicting, explaining and recommending behavioral interventions. The discussant, Alex Rothman, will discuss potential implications of behavioral ontologies efforts on behavioral medicine research and practice.

2:00 PM-3:15 PM

PROGRESS ON BEHAVIORAL ONTOLOGIES AT THE NIH

Christine M. Hunter, PhD¹¹Office of Behavioral and Social Sciences Research, National Institutes of Health, Bethesda, MD

The complexity of describing and measuring dynamic human behaviors and social interactions has resulted in a proliferation of terms, constructs, measures and theories in the behavioral and social sciences. For example, it is not uncommon to find the same terms used for different constructs or different terms used for identical or similar constructs. This complexity, combined with the rapidly increasing volume of available data, presents challenges for categorizing, reporting, integrating, and understanding the inter-relationships among variables of interest. This presentation will highlight the efforts of the NIH's Behavioral Ontology Development Working Group to address some of these challenges and advance ontology creation and use across scientific multiple domains. We will describe different approaches to ontology development and our progress in several research domains; including data on the application of natural language processing to capture existing relationships between constructs and measures in PubMed in the domains of self-regulation and resilience. We will also describe our approach to enhance behavioral and social science categorization in Medical Subject Headings (MeSH); the hierarchically-organized terminology for indexing and cataloging articles in PubMed. Finally, we will describe some NIH efforts to build partnerships between behavioral and social science subject matter experts and knowledge representation scientists to accelerate evidence synthesis and support the de-fragmentation of science.

2:00 PM-3:15 PM

THE BEHAVIOUR CHANGE INTERVENTION ONTOLOGY: VISION AND DEVELOPMENT

Susan Michie, BA, MPhil, DPhil¹¹University College London, London, England, UK

Evidence about behavioural interventions is currently produced on a vast but fragmented scale and more rapidly than humans can synthesise and access. This presentation will explain the usefulness of ontologies in organising large volumes of complex knowledge about behavioural interventions to synthesise evidence at scale about what works and how to generate new hypotheses about behaviour change. It will present the Behaviour Change Intervention Ontology developed by a large team of behavioural scientists in collaboration with computer scientists and system architects as part of the Human Behaviour-Change Project (HBCP; www.humanbehaviourchange.org). The HBCP is building a prototype of an artificial intelligence system to scan the world literature evaluating behavioural interventions to extract key information and use this to answer queries and generate new insights about behaviour change.

Development of the Behaviour Change Intervention Ontology is by five iterative stages [<https://osf.io/86m75/>]: 1. Identification of key entities and preliminary definitions by searching for relevant terms from existing ontologies and typologies that can be appropriately reused 2. Refinement of the Ontology (through annotating published intervention evaluation reports), 3. international stakeholder review and feedback on comprehensiveness and clarity, 4. Inter-rater reliability testing of assignment of text to ontology categories, and 5. Finalising and specifying relationships within the Ontology. The BCIO comprises a BCI Plan, a BCI Scenario and a BCI Comparison (the evaluation methodology). The upper-level of the BCI Scenario currently has 11 inter-linked entities: Intervention Content (Behaviour Change Techniques and Dose), Delivery (Mode, Source, Schedule), Reach and Engagement, Mechanisms of Action, Context (Setting and Population) and Outcome Behaviour. Each entity has its own ontology and once finalized will be posted on [<https://github.com/HumanBehaviourChangeProject>, <https://www.humanbehaviourchange.org/>].

2:00 PM-3:15 PM

ONTOLOGIES MEET ARTIFICIAL INTELLIGENCE

Pól G. Mac Aonghusa, PhD¹¹IBM, Carbury, Kildare, Ireland

As applications of artificial intelligence (AI) technology becomes increasingly ubiquitous in our personal and professional lives, it is easy to forget how complex and opaque the underlying technologies and processes are. In the behaviour change domain, where recommendations from algorithms have real-life consequences for practitioners and patients, the need for transparency and trust in AI systems is particularly apparent. Ontologies are helpful as an organising framework to represent subtle, and sometimes non-obvious, statistical patterns and relationships encountered in AI systems in ways that a human can interpret. This presentation will discuss the successes, challenges and potential opportunities of using ontologies to build interpretable AI systems using the Human Behaviour Change Project (HBCP) as a relevant example. This presentation will also touch on larger questions of trust, transparency, fairness and bias that will become increasingly topical as a topic for interdisciplinary research.

Symposium 28

2:00 PM-3:15 PM

DEFINING THE “IT” IN DISSEMINATION – CONCEPTUALIZATIONS AND STRATEGIES FOR GLOBAL EFFORTS

Edwin B. Fisher, PhD¹, Kate Lorig, DrPH², Redford B. Williams, M.D.³, Joost Dekker, PhD⁴, Patrick Y. Tang, MPH⁵

¹Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC; ²Self-Management Resource Center, Mountain View, CA; ³Duke University School of Medicine, Durham, NC; ⁴Amsterdam University Medical Centers, Amsterdam, Noord-Holland, Netherlands; ⁵Peers for Progress, DURHAM, NC

Fidelity and standardization challenge dissemination. To say that a program was successfully transferred from site A to site B, we must first be able to define and measure it. Criteria for standardization and fidelity are seldom written and often based on judgment. Additionally, choices of methods to convey programs through materials, training, program models, certification, licensing, contracts, etc. are not self-evident. This symposium explores these issues through three programs developed in the US that have achieved implementation and effectiveness in other countries. Kate Lorig and her colleagues developed the *Chronic Disease Self Management Program* with great concern for program fidelity amidst the varied definitions and methods addressing self management. Commitment is to effectiveness not depending on setting. Process measures characterize and monitor fidelity. Training is highly regulated through requirements that those implementing the program complete rigorously defined training from individuals certified as master trainers. These requirements are supported by licenses that specify the acceptable use of the protocols and materials the program includes. Virginia and Redford Williams developed *Williams LifeSkills* based on extensive research of their own and others implicating the roles of stress and anger in disease. The program includes 10 modules and protocols for teaching them, with subsequent quality controls. Facilitator trainees initially engage as workshop participants who practice with personal examples, then take turns as facilitators with coaching. During and after this second phase everyone considers suggestions for modification of any aspects of the protocol that retain fidelity but increase cultural sensitivity. Edwin Fisher and colleagues guided *Peers for Progress* to promote peer support as a general approach in prevention and care. Defining peer support are five key functions, e.g., being there, assistance in daily management. The program then encourages varied approaches to addressing these functions, such as with individuals or groups, face-to-face or through varied media including digital apps that may share functions with support from another human. Rather than promoting a specific intervention protocol, the program serves as a clearinghouse for varied intervention materials and resources. Discussion will include the importance of guiding choices among these and other strategies by the objectives and nature of the programs to be disseminated.

CORRESPONDING AUTHOR: Edwin B. Fisher, PhD, Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC; edfisher@unc.edu

1 2:00 PM-3:15 PM 3 2:00 PM-3:15 PM

GLOBAL PROMOTION OF PEER SUPPORT: STANDARDIZATION BY FUNCTION, NOT CONTENT

Edwin B. Fisher, PhD¹, Patrick Y. Tang, MPH²

¹Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC; ²Peers for Progress, DURHAM, NC

Recognizing the utility of peer support leads quickly to recognizing its variety. *Promotores*, lay health advisors, peer support specialists, community health workers, and Village Health Volunteers in Thailand provide it, to name a few. They work in health care or social services but also in self-governing mutual support. It happens face-to-face, individually or in groups, by telephone or text, and more recently online. It addresses disease knowledge, information about treatments, problem solving, emotional encouragement, individual and community capacity, or help in finding clinical or other services. Further, when *Peers for Progress* began in 2007 to promote peer support in health care and prevention, there were already many, many peer support programs around the world. An international consultation through the WHO advised recognizing that peer support be tailored to local circumstances, needs, and populations, but to focus global promotion on the key functions of peer support. These emerged as 1) assistance in daily management; 2) emotional and social support; 3) linkage to clinical care and community resources; 4) ongoing availability of support in recognition that the chronic diseases and many other problems for which peer support is helpful are lifelong; and 5) being there from consideration of peer support in dealing with social isolation and loneliness. Development focuses then on how the 5 key functions may be implemented in the context and for the purposes of a particular program. Measuring success of such a general approach is a challenge, but 14 projects funded in 9 countries on 6 continents were able to use the key functions across variation in culture, audience, health systems, and settings and achieved a range of benefits. As a scorecard, the key functions have been useful in understanding some apparent failures. More recently, they have supported thinking of how peer support provided by live peer supporters and that provided by versatile apps may be complementary in combining “high tech and soft touch.” In Shanghai, the key functions have guided applications across primary care and community settings, gaining recognition of peer support as a strategy for achieving the Shanghai Ministry of Health’s 2030 objective of chronic disease self management. *Peers for Progress* sought to promote the general approach of peer support. For this, the emphasis on key functions has served it well.

2 2:00 PM-3:15 PM

MOVING PEER LED SELF-MANAGEMENT PROGRAMS FROM RE-SEARCH TO PRACTICE

Kate Lorig, DrPH¹

¹Self-Management Resource Center, Mountain View, CA

The ideal of most developers of interventions is to have these interventions widely used. In this presentation I will discuss how peer led self-management intervention have moved from ROI to world wide use. Several factors made this possible 1) the original intervention design, including designing for multi-cultural use 2) the choice of outcome measures and how research was presented 3) links with national and international organizations wishing to use the programs 3) training packages that do not depend on the developer, 4) strong fidelity standards, 5) continual updating and 6) a business model allowing for sustainability. All of these will be discussed as well as the pros, cons, and rational for each.

THE WILLIAMS LIFESKILLS PROGRAM – A MEANS OF DELIVERING COGNITIVE BEHAVIORAL STRESS MANAGEMENT AND INTERPERSONAL SKILLS TRAINING IN DIVERSE CULTURES AROUND THE WORLD

Redford B. Williams, M.D.¹, Virginia Williams, PhD in European Intellectual History²

¹Duke University School of Medicine, Durham, NC; ²Williams LifeSkills, Inc.

The Williams LifeSkills (WLS) provides training in 10 skills that enable one to be aware of and evaluate negative thoughts and feelings in distressing situations. One learns to decide between deflection of those thought and feelings or acting to try to change the situation in positive ways. To improve relationships with self and others, focus is on effective speaking, listening, empathy and increasing positives in encounters with self and others. Controlled clinical trials in the U.S. have shown WLS training to decrease psychosocial risk factors and blood pressure in caregivers, medical students, high school students and hypertensive employees. WLS has been adapted for use in Singapore, Hungary, China, Brazil and Colombia. During facilitator training, adaptations were made to retain fidelity and maximize appropriateness of each skill for that country’s culture. The leaders of the teams trained to deliver the WLS program have evaluated the impact of the WLS program on psychosocial factors in their countries. A randomized controlled trial of coronary bypass patients in Singapore found improvements in depression, anger, anxiety, satisfaction with social support and life and SBP and HR, both at rest and during anger recall in those randomized to WLS training. An observational trial of WLS in distressed working persons in Hungary found significant improvements in anxiety, depression, somatic symptoms, coping skills, well-being, life meaning and life satisfaction. Controlled trials of WLS in China found significant improvements in social support, anxiety, depression and self-esteem in medical students, in verbal aggression, auto-aggression and physical aggression scores in young violent offenders, and in behavior problems in left-behind children. Preliminary observational trials of WLS in Brazil and Colombia have shown improvements in psychosocial risk factors. Papers reporting these findings have been published in peer-reviewed journals. This evidence regarding delivery of WLS training in Singapore, Hungary, China, Brazil and Colombia indicates that it is possible to deliver and document effectiveness of a standardized program providing training in cognitive behavioral stress management and interpersonal relationship skills in diverse cultures around the world.

Symposium 30

2:00 PM-3:15 PM

FUTURE DIRECTIONS OF BEHAVIORAL MEDICINE: PERSPECTIVES FROM THE NEXT GENERATION

Claudio Nigg, PhD¹, Sasha A. Fleary, PhD², Kellie A. Walters, PhD³, Christine Chard, PhD⁴, Xiaomeng (Mona) Xu, PhD⁵¹Karlsruhe Institute of Technology, Karlsruhe, Baden-Württemberg, Germany; ²Tufts University, Medford, MA; ³California State University, Long Beach, Long Beach, CA; ⁴Colorado State University, FORT COLLINS, CO; ⁵Idaho State University, Pocatello, ID

Behavioral medicine/health is able to explain about 30% of behavior across various topic areas (physical activity, healthy eating, etc.). Innovative ideas are needed to improve on this and to reach vulnerable populations who are at highest risk for chronic diseases. Senior Scientists contribute to the field in having their established research programs, however new and innovative ideas are needed. This symposium will highlight innovative ideas from selected up-and-coming researchers.

Dr. Fleary's research utilizes health literacy to empower underserved children and families to advocate for their personal health and factors affecting health in their community. By collaborating with and designing programs for public libraries, Dr. Fleary is simultaneously promoting the public library as a health space, addressing common barriers to accessing interventions in underserved communities, and centering health literacy as an essential literacy. Dr. Walters' and Dr. Chard's research primarily focuses on developing, implementing, and evaluating Smart Fit Girls (SFG), a non-profit program aimed at promoting positive self-esteem, body image, and physical activity enjoyment in adolescent girls. Recently Dr. Walters and Dr. Chard have engaged in youth participatory approaches to design, implement and evaluate a culturally responsive version of SFG among girls of color. This research is novel as it takes a health positive (e.g., focusing on body positivity and utility rather than weight loss) and youth centric approach to improving adolescent girls' health. Dr. Xu will highlight the importance of interdisciplinary research by discussing the self-expansion model (which originated in the close relationships field within social psychology) and how it has informed our understanding of behavioral health. This will include a review of research demonstrating the positive impact of self-expanding experiences (characterized by novelty, excitement, challenge and/or interest) on smoking cessation, cigarette cue-reactivity, weight control, and physical activity. Dr. Nigg will integrate these research programs in the larger context of health psychology/behavioral medicine and the promise they bring to our field.

2:00 PM-3:15 PM

READING, WRITING, HEALTH LITERACY: LIBRARIES AS HEALTH SPACES

Sasha A. Fleary, PhD¹¹Tufts University, Medford, MA

According to a 2016 Pew survey, 53% of Americans 16 years and older had some interaction with public libraries in the last year. The public library is viewed as a safe gathering space that promotes community, a source of trusted information, and a place to help individuals find health information and job opportunities. Further, Latinos, women, and individuals with low incomes were more likely to report that if their neighborhood libraries were to close it would have a major impact on their families. Children and families who are low income and/or otherwise underserved are at increased risk for poor preventive health, low health literacy, and health disparities. Given that the library is an important gathering space for these children and families and already viewed as a source of trusted information and health information, the library is an ideal space for promoting preventive health and teaching health literacy skills. Preventive health practitioners and programmers should work with libraries to reimagine the library's physical space and purpose in the community as it relates to health. This talk will provide an overview of how US public libraries are currently used as "health spaces" and factors impacting their use as such using quantitative and qualitative data from a representative sample of US libraries. Future directions for collaborating with libraries to design and disseminate suitable health literacy and preventive health behavior interventions will be discussed.

2

2:00 PM-3:15 PM

ADDRESSING THE HEALTH OF ADOLESCENT GIRLS USING A NOVEL GIRLS EMPOWERMENT PROGRAM

Kellie A. Walters, PhD¹, Chrissy Chard, PhD²¹California State University, Long Beach, Long Beach, CA; ²Colorado State University

In addition to the physical benefits, individuals who are highly physically active are more likely to have a greater self-esteem, better body image, and increased physical activity self-efficacy. Compared to adolescent boys, girls are more likely to be sedentary and suffer from psychosocial distress, such as anxiety and depression. Current recommendations suggest that adolescents participate in 60 minutes of moderate intensity physical activity per day yet there is a clear ethnic disparity in the prevalence of youth meeting these guidelines with only 17.1% of black girls (compared to 27.6% of white girls, 39.9% of black boys, and 42.6% of white boys).

Much of the research the authors have conducted has been on the development and efficacy of an empowerment program for middle school girls: Smart Fit Girls (SFG). This program is unique because rather than focusing on weight loss, SFG focuses on creating a positive health environment where all girls, no matter their size, shape, color, race, or ability, learn to appreciate their bodies for what they can do (body utility) rather than what they look like (aesthetics). Based in self-determination theory, SFG aims to foster autonomy, competence and relatedness among participants. SFG promotes both the physical and mental health of adolescent girls – a novel approach to health promotion in youth. Preliminary data demonstrate the powerful effect of this program, including improved self-esteem, body image and physical activity enjoyment. Unique aspects of their research include evaluating the program in a variety of settings (after-school, in-school, and a 1 week camp) and the use of youth participatory action research practices in culturally adapting the Smart Fit Girls curriculum. Cultural adaptation of programming is critical. While various programs have been developed to improve the health of adolescent girls, the limited research conducted has been done primarily in white adolescent girls, leaving a clear racial gap in our scientific knowledge base. Therefore, our recent work has explored the unique experiences of Black and African-American girls in regards to their perceptions of self-esteem, body image and physical activity, which has demonstrated a clear need for programming to promote mental health among this population.

3 2:00 PM-3:15 PM 1 2:00 PM-3:15 PM

SELF-EXPANSION AND BEHAVIORAL HEALTH

Xiaomeng (Mona) Xu, PhD¹

¹Idaho State University, Pocatello, ID

The self-expansion model (Aron & Aron, 1986) states that people are motivated to engage in experiences that grow the self-concept by increasing perspectives, identities, resources, and efficacy. These experiences tend to be characterized by novelty, challenge, interest, and or/excitement. Initially, research in this area focused on self-expansion within the context of close relationships, elucidating the processes of relationship initiation and maintenance. Recently, research has shown that self-expansion also occurs at the individual level (e.g., outside of close relationships in the context of the workplace, hobbies, and other activities) and is important in a number of domains including behavioral health. Several studies have examined self-expansion and health, focusing on behaviors such as smoking, weight control, and physical activity. This talk will provide a brief overview of the self-expansion model, show the development of this line of research from close relationships to individual processes, and then highlight some of the recent behavioral health studies. First, research on self-expansion and nicotine smoking will be covered. This will include a community study of former and current smokers showing that self-expansion is positively associated with both smoking cessation (among those who successfully quit) and duration of quit attempts (among those who ultimately returned to smoking). Next, functional magnetic resonance imaging (fMRI) neuroimaging studies of self-expansion among smokers will be reviewed. These studies show that self-expansion (in the context of close relationships and utilizing exciting/challenging vs. control video games) attenuates cigarette-cue reactivity in the brains of overnight abstinent smokers. Next, self-expansion studies of behavioral weight loss and physical activity will be reviewed. These studies include daily diary and randomized controlled trial methodology. Results of this longitudinal research indicate that self-expansion is associated with greater self-reported and Fitbit-measured physical activity. Additionally, self-expansion is associated with greater percentage weight loss and likelihood of achieving clinically-significant weight loss outcomes among those in overweight and obese BMI categories. Finally, implications and future directions of self-expansion and behavioral health will be discussed.

Symposium 31 2:00 PM-3:15 PM

PRENATAL LIFESTYLE INTERVENTIONS AND IMPACT OF OBESITY: THE PAST, THE PRESENT AND THE FUTURE

Rebecca Krukowski, PhD¹, Michelle Cardel, PhD, MS, RD², Suzanne Phelan, PhD³, Leanne Redman, PhD, FTOS⁴

¹University of Tennessee Health Science Center, College of Medicine, Memphis, TN; ²University of Florida, Gainesville, FL; ³Cal Poly, San Luis Obispo, CA; ⁴Pennington Biomedical Research Center, Baton Rouge, LA

This symposium will focus on translational research related to eating behavior, body weight, gestational weight gain, and obesity-related disease outcomes among women of childbearing age and their infants/children. First, Dr. Michelle Cardel will discuss behavioral, environmental, and psychosocial factors influencing adverse eating behavior and risk for obesity and obesity-related diseases among women of childbearing age. Next, Dr. Suzanne Phelan will summarize the effectiveness of prenatal interventions in reducing excess gestational weight gain and preventing postpartum weight retention. She will end by reviewing effects of prenatal interventions on pregnancy complications and childhood obesity and the potential need to intervene during preconception period. Dr. Leanne Redman will end the session discussing new observational data and how this may shape future controlled clinical interventions and implementation trials. Dr. Rebecca Krukowski will be the chair/discussant of the session and will provide a short summary integrating the presentations, make research and treatment recommendations, and lead the question and answer session.

CORRESPONDING AUTHOR: Rebecca Krukowski, PhD, University of Tennessee Health Science Center, College of Medicine, Memphis, TN; rkrukows@uthsc.edu

PSYCHOSOCIAL DETERMINANTS OF EATING BEHAVIOR IN WOMEN OF CHILDBEARING AGE

Michelle Cardel, PhD, MS, RD¹

¹University of Florida, Gainesville, FL

Dr. Cardel will present on the psychosocial determinants that influence eating behavior and the development of obesity among women of childbearing age. The presentation will include a look at under-represented racial/ethnic minority groups and the relationships and potential causal mechanisms driving the relationships between poverty, low social status, stress, and food insecurity on adverse eating behavior and obesity among women. Specifically, she will discuss her research demonstrating that experimentally manipulated low social status is associated with increased caloric intake and 24-energy balance among childbearing women. Additionally, she provides data indicating that food insecurity results in excess caloric intake, which can impact weight-related outcomes over the long term.

2 2:00 PM-3:15 PM

EFFICACY OF PRENATAL LIFESTYLE INTERVENTIONS FOR IMPROVING MATERNAL AND CHILD HEALTH OUTCOMES.

Suzanne Phelan, PhD¹

¹Cal Poly, San Luis Obispo, CA

Dr. Phelan will present the IOM weight gain guidelines for pregnant women and summarize the various lifestyle intervention trials targeting gestational weight gain and maternal and child health outcomes. The objective of this talk will be to demonstrate the effectiveness of prenatal lifestyle interventions for reducing excess gestational weight gain and postpartum weight retention. Dr. Phelan will end with review of the effects of prenatal interventions on pregnancy complications and child obesity and discuss a potential need for preconception intervention.

3 2:00 PM-3:15 PM

LIFESTYLE INTERVENTIONS TO ADDRESS GESTATIONAL WEIGHT AND MATERNAL HEALTH

Leanne Redman, PhD, FTOS¹

¹Pennington Biomedical Research Center, Baton Rouge, LA

Dr. Redman will conclude the session with a talk that discusses the current hypotheses as to why prenatal lifestyle interventions in pregnant women with obesity delivered improvement in gestational weight gain, weight retention, lower C-section rate, among other outcomes. Central to this talk will be a discussion of new observational data related to fertility post bariatric surgery, and how this might shape future controlled interventions and implementation trials.

Symposium 32

2:00 PM-3:15 PM

1

2:00 PM-3:15 PM

DEVELOPING AND TAILORING HIV PREVENTION INTERVENTIONS WITH AND FOR ADOLESCENT AND EMERGING ADULT SEXUAL MINORITY MALES

Kristi Gamarel, PhD¹, Tyrel J. Starks, PhD², Lisa Hightow-Weidman, MD³, Rob Stephenson, PhD¹, Kimberly M. Nelson, PhD, MPH⁴¹University of Michigan, Ann Arbor, MI; ²Hunter College, CUNY, Brooklyn, NY; ³University of North Carolina, Pittsboro, NC; ⁴Boston University School of Public Health, Boston, MA

In the United States, adolescent and emerging adult sexual minority males are disproportionately impacted by the HIV epidemic. Researchers and clinicians have increasingly recognized the importance of developing and tailoring HIV prevention interventions among these priority populations. This symposium therefore brings together interdisciplinary and cutting-edge research that aims to understand how to develop and tailor HIV prevention interventions for these key populations. These projects also seek to identify ways interventions can be readily scaled up into health care services. The presentations included in this symposium consider different intervention modalities (i.e., online vs. in-person) and formats (dyadic vs. individual). They describe developmentally-appropriate content and tailoring; consider the impact of unique forms of conflict and intimate partner violence for intervention research and program planning; and draw on intervention studies at different phases of implementation. The first talk presents preliminary findings from two different ongoing relationship-focused HIV prevention studies which have developed adjunct relationship skill building components to Couples HIV Testing and Counseling (CHTC)—delivered online and in person—to adolescent sexual minority males. The second talk describes the development of an online sexual health promotion intervention that provides adolescents with media literacy tools. The third talk examines manifestations of conflict in counseling sessions with young same-sex male couples focused on HIV prevention and substance use and identifies effective provider strategies for responding to conflict. The final talk presents findings on the unique forms and consequences of intimate partner violence among young sexual minority men in the context of HIV prevention intervention design. The discussion will be led by Dr. Lisa Hightow-Weidman who is a world-renowned researcher with substantial expertise in HIV prevention interventions for adolescents and young adults and will focus on future directions for research, practice, and policy efforts related to reducing inequities in HIV among sexual minority male adolescents and young adults.

CORRESPONDING AUTHOR: Kristi Gamarel, PhD, University of Michigan, Ann Arbor, MI; kgamarel@umich.edu

THE IMPORTANCE OF “OPTIONS” IN RELATIONSHIP-FOCUSED HIV PREVENTION EFFORTS: TWO INTERVENTIONS WITH ADOLESCENT SEXUAL MINORITY MALES

Kristi Gamarel, PhD¹, Tyrel J. Starks, PhD², Sarah Feldstein Ewing, PhD³, Sonia Lee, PhD⁴, Travis Lovejoy, PhD⁵, Lynae Darbes, PhD⁶, Lisa Hightow-Weidman, MD⁷, Sylvie Naar, n/a⁸, Patrick Sullivan, PhD, DVM⁹, Rob Stephenson, PhD¹¹University of Michigan, Ann Arbor, MI; ²Hunter College, CUNY, Brooklyn, NY; ³Oregon Health and Science University, Portland, OR; ⁴NICHHD, Bethesda, MD; ⁵Oregon Health & Science University, Portland, OR; ⁶University of Michigan; ⁷University of North Carolina, Pittsboro, NC; ⁸Florida State University, Tallahassee, FL; ⁹Emory University, Atlanta, GA

Background: Young gay, bisexual, and other men who have sex with men (YGBMSM) continue to be disproportionately affected by HIV. Although a substantial number of new HIV infections occur in the context of romantic partnerships, there have been limited biomedical and behavioral intervention efforts designed to address the relational context of HIV prevention with and for YGBMSM in romantic relationships.

Methods: As part of the Adolescent Medicine Trials Network for HIV/AIDS Interventions (ATN), two projects seek to develop and test relationship-focused HIV prevention interventions for YGBMSM and their partners. *We Prevent* is an online intervention delivered via telemedicine nationally whereas, *We Test* is delivered in person in New York City and Detroit. To date, both studies have completed two of the three phases of these implementation science programs (e.g., qualitative interviews and one-arm first-phase studies to inform and refine the intervention content and format for the Phase 3 RCT).

Results: In both studies, YGBMSM ages 15 to 19 completed interviews and a one-arm of each intervention. Phase 1 *We Prevent* themes that led to intervention content included: (1) negotiating sexual consent and boundaries; (2) stigma surrounding sexuality and relationships; (3) monogamy as implied and never explicitly discussed; (4) communication around relationships and HIV prevention. Phase 1 *We Test* formative findings included barriers to Couples HIV Testing and Counseling (CHTC) and relationship dynamics that led to the development of a communication skills video and a brief Motivational Interviewing (MI) focused on Assisting with Identification and Development (MI-AID) in-person. For Phase 2, 6 dyads completed the *We Prevent* one-arm pilot and 12 YGBMSM completed the *We Test* one-arm. Across the studies, participants discussed the importance of communication yet many had difficulty communicating with their partners to complete the sessions. Findings highlighted the need for a menu of delivery options (i.e., individual and dyadic) to accommodate YGBMSM's readiness to engage their partners.

Conclusions: Both studies highlight the value of integrating relationship skills and HIV testing, as well as the provision of options for individual- and dyadic-level participation in order to accommodate the needs and preferences of YGBMSM. The next steps of these projects will be discussed on how to provide YGBMSM with the skills and tools they desire to address HIV prevention in their relationships.

2

2:00 PM-3:15 PM

MOTIVATIONAL INTERVIEWING WITH MALE COUPLES TO REDUCE SUBSTANCE USE AND HIV RISK: MANIFESTATIONS OF PARTNER DISCORD AND STRATEGIES FOR FACILITATING DYADIC FUNCTIONING

Tyrel J. Starks, PhD¹, Gabriel Robles, PhD², Kendell M. Doyle, BA³, Mark Pawson, PhD⁴, Paula Bertone, MA⁵, Brett M. Millar, PhD⁶, Karen S. Ingersoll, PhD⁷

¹Hunter College, CUNY, Brooklyn, NY; ²Hunter College, New York, NY, NY; ³The Graduate Center, City University of New York, Brooklyn, NY; ⁴Purdue University; ⁵New York State Psychiatric Institute; ⁶Hunter College, New York, NY; ⁷University of Virginia, CROZET, VA

Background: While the efficacy of Motivational Interviewing (MI) to reduce substance use is well-established, its use with couples has had mixed results. The development of such interventions is relevant for same-sex male couples, as rates of substance use in this population are high and use is associated with aspects of sexual relationship functioning. One challenge noted in previous research on MI with couples is how to respond when partners disagree with one another or argue against change. Guided by Couples Interdependence Theory (CIT), our group conceptualized conflicts within session as failures in the accommodation process. We utilized qualitative analysis to examine manifestations of conflict in session and identify effective provider strategies for responding to conflict.

Methods: The sample included 14 cis-male couples where at least 1 partner was aged 18-29; reported substance use; and was HIV-negative. All couples completed 3 MI sessions lasting 60-75 minutes each. Sessions were transcribed and coded for analysis using Dedoose.

Results: Observed conflicts included: conflating thoughts and feelings (expressing thoughts or assumptions as though they were emotions, which often were perceived as blaming and elicited defensiveness), vague or indirect communication (language or signals that were easily misunderstood), and inaccurate assumptions (incorrect inferences about a partner's thoughts or behavior). Effective provider responses included: correcting assumptions (catalyzing disclosure between partners to clarify their attitudes and behavior for one another), shifting focus (to thinking about a preferred past or an ideal future scenario), relationship repair (making amends and moving forward together), "common ground" reflections (which describe shared values and perspectives), and relationship affirmations (which capture relationship strengths and resources).

Conclusions: Observed conflicts aligned with conceptualizations of destructive resolutions to the accommodation process. Elements of both Exit-type resolutions (e.g., blaming or defensiveness), and Neglect-type resolutions (e.g., conflict avoidance or withdrawal) were present. Effective provider responses facilitated dyadic functioning and catalyzed constructive accommodation. Many of these provider responses build upon existing MI skills such as reflections and affirmations; however, they require providers cultivate the ability to direct utterances towards partners individually and the couple as a whole. Use of these provider skills also requires knowledge of dyadic functioning in order to accurately identify and reflect relationship strengths and successful accommodation.

2:00 PM-3:15 PM

UNDERSTANDING INTIMATE PARTNER VIOLENCE AMONG YOUNG MALE COUPLES IN THE UNITED STATES: IMPLICATIONS FOR HIV PREVENTION INTERVENTION PLANNING

Rob Stephenson, PhD¹, Oksana Kutsa, BS², Matthew Rosso, MPH², Catherine Washington, BS², Lynae Darbes, PhD², Lisa Hightow-Weidman, MD³, Ramona Rai, MPH⁴, Kristina Felder Claude, MPH⁵, Patrick Sullivan, PhD, DVM⁶, Kristi Gamarel, PhD¹

¹University of Michigan, Ann Arbor, MI; ²University of Michigan; ³University of North Carolina, Pittsboro, NC; ⁴Emory University; ⁵University of North Carolina; ⁶Emory University, Atlanta, GA

Background: Intimate partner violence (IPV) is a prevalent and pressing public health concern that affects people of all gender and sexual identities. Though studies have identified that same-sex male couples may experience IPV at rates as high as or higher than heterosexual couples, the body of literature addressing IPV among adolescent and young adult sexual minority men is nascent. Young sexual minority men face unique stressors in their relationships as they struggle with identity development, disclosure and familial support, and communication in their relationships. This qualitative study explored perceptions of relationship tensions and support among a sample of YGBMSM to guide HIV prevention intervention efforts.

Methods: As part of a larger HIV prevention study for young male couples ("We Prevent"), qualitative interviews were conducted with 30 young men who reported they were in a relationship with another male. In-depth interviews (IDI) were conducted online via video-chat with participants from 17 states in the U.S. Participants were recruited via social media platforms. Interviews focused on communication, relationship strengths and challenges, as well as potential ideas for intervention content that could support the HIV prevention needs of YGBMSM in romantic relationships. Audio data were recorded, transcribed and de-identified. Thematic analyses were used to understand the forms and precipitants of IPV.

Results: Participants' age ranged from 15 to 19 (M=17.8, SD = 1.1) and 48% identified as a person of color. Most identified as gay (83%) or bisexual (13%), and over half of the sample (55%) had been with their partner for less than 6 months. Participants most commonly reported emotional IPV and monitoring and controlling behavior from their intimate male partners, which took the form of judgement, belittling sexual or emotional needs, and power imbalances. While no participants reported physical IPV, several participants reported being pressured to have sex or participate in certain sexual acts. Most participants reported feeling that they lacked the skills to communicate with their partners around sex, boundaries, and consent.

Conclusions: Findings support the importance of attending to IPV in HIV prevention approaches for YGBMSM. Future research and interventions approaches will be discussed on how to address IPV in different HIV prevention intervention modalities.

THE YOUNG MEN & MEDIA PROJECT: DEVELOPING A COMMUNITY-INFORMED, ONLINE HIV PREVENTION INTERVENTION FOR 14-17 YEAR OLD SEXUAL MINORITY MALES

Kimberly M. Nelson, PhD, MPH¹, Nicholas Perry, PhD², Michael P. Carey, PhD³

¹Boston University School of Public Health, Boston, MA; ²Brown University, Warren Alpert Medical School, Providence, RI; ³The Miriam Hospital and Brown Univ, Providence, RI

Background: Adolescent sexual minority males (ASMM) are disproportionately affected by HIV and other sexually transmitted infections (STIs) in the United States (US). Despite increased HIV/STI risk, there is a lack of formal sexual health education resources to prepare ASMM for engaging in healthy sexual activity. Lacking such guidance, ASMM often turn to the Internet, including pornography, to get information about male-male sexual relationships. Although the Internet can be a convenient and affirming source of sexual health information, it can also be unreliable, often providing misinformation or misleading characterizations of male-male sexual relations. The primary goal of the Young Men & Media project is to develop a community-informed, online sexual health program that promotes the critical examination of online media by ASMM in order to promote healthy sexual development and to decrease their sexual risk-taking.

Methods: Two sources of information were used to develop and create the content and form of the intervention website: (1) a cross-sectional online survey of ASMM from across the US ($N = 207$, 14-17 years old) and (2) a Youth Advisory Board ($N = 4-5$, 16-18 years old). Website programming followed an iterative process from initial development/design to alpha/beta testing in collaboration with the Youth Advisory Board and the website developer.

Results: Four main topics areas were identified by youth as important foci for the intervention: (1) male anatomy, including information about how anal sex can be pleasurable and about anal health; (2) HIV/STI prevention information (e.g., transmission risks, accessing testing, condom use); (3) general sexual health information (e.g., types of male-male sex, consent, dating safety, partner communication); and (4) porn literacy (e.g., differences between porn and reality, what's behind the scenes on a pornography set, normalization of porn use among male youth). Youth felt that intervention content should be interactive (e.g., games, videos, animations) and the website should have an interface that would be familiar to ASMM (e.g., similar to Netflix). Youth preferred a website with a responsive design (i.e., will work on a mobile device, tablet, or computer) as opposed to a downloadable phone application.

Conclusions: Sexual health interventions that address the sexual health needs of ASMM are needed to decrease the HIV/STI disparities occurring among these youth. A community-informed, iterative approach to online intervention development with ASMM is likely to result in an intervention that meets the needs and wants of ASMM and, ultimately, may prove to be feasible, acceptable, and effective at preparing them for healthy sexual activity.

FROM STIGMA TO PSYCHOLOGICAL AND BEHAVIORAL HEALTH AMONG POPULATIONS IMPACTED BY HIV

Valerie A. Earnshaw, PhD¹, Jessica L. Maksut, PhD², Eric K. Layland, MS³

¹University of Delaware, Newark, DE; ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ³Pennsylvania State University, University Park, PA

For people living with HIV (PLWH) and individuals vulnerable to HIV infection (transwomen; men who have sex with men, MSM), stigma is a major driver of behavioral and psychological health risks. Stigma arises from conflict between the norms of dominant, majority groups and members of disadvantaged groups. Both internalized and enacted stigma contribute to elevated psychological stress and dysregulated behavioral responses among PLWH, transwomen, and MSM. Identifying pathways from stigma to psychological and behavioral health in populations impacted by HIV can help illuminate mechanisms driving disparities and opportunities for intervention.

Substance use can impact HIV treatment, and PLWH use substances at greater rates than people not living with HIV. In the first study, results provide evidence that associations between HIV stigma and substance use are partially mediated by depression among PLWH. Both internalized and enacted HIV stigma were associated with depression, and depression was associated with self-reported number of substances used, substance use severity, and testing positive on a drug test. Interventions on substance use among PLWH must consider links among HIV stigma, mental health, and substance use.

For transwomen, discrimination drives elevated rates of mental health issues and creates barriers to affirming healthcare. In the second study, gender identity and sexual behavior stigmas were associated with severe psychological distress. Experiencing gender identity stigma was also associated with higher prevalence of past year suicide ideation and attempts. Structural and interpersonal interventions to reduce experiences of stigma are critical to preventing psychological distress and suicidality among transwomen.

For young MSM of Color, race-based objectification and rejection by sexual and romantic partners contribute to distress and poor coping. In the final study, trait level mindfulness moderated associations of sexual racism with prevalence of depression, suicide ideation with a plan, and non-suicidal self-injury. For MSM of Color who reported greater trait mindfulness, the association between sexual racism and mental health was weaker. Mindfulness is a promising tool for interventions seeking to modify the effects of stigma experienced by young MSM of Color.

Among populations impacted by HIV, experiences of stigma continue to drive disparities in psychological and behavioral health. The studies in this symposium identify potential points of intervention, including depression, gender identity and sexual behavior stigma, and mindfulness, that may be instrumental in improving the health and quality of life for groups often pushed to the margins. By centering these groups and individuals in health care and interventions, psychological and behavioral health disparities can be narrowed and individual disease burdens reduced.

HIV STIGMA AND SUBSTANCE USE PROBLEMS AMONG PEOPLE LIVING WITH HIV: DO DEPRESSIVE SYMPTOMS MEDIATE?

Valerie A. Earnshaw, PhD¹

¹University of Delaware, Newark, DE

In the United States, people living with HIV (PLWH) are affected by substance use problems at higher rates than people not living with HIV. In addition to harming overall mental and physical health, substance use problems undermine HIV treatment and secondary prevention efforts. Research identifying risk factors for substance use problems among PLWH is needed to strengthen HIV treatment and prevention efforts. We examined whether internalized and enacted HIV stigma are associated with three indicators of substance use problems among people living with HIV (PLWH), including numbers of: (1) substances used, (2) substances used at moderate to high risk, and (3) times substances were used before sex, via the mediator of depressive symptoms. Participants included 358 PLWH aged 18-35 from Georgia. At baseline, participants completed measures of internalized and enacted stigma, depressive symptoms, and substance use severity. Substance use was additionally tested via urinalysis. Following baseline, participants reported their use of substances before sex for 28 days via daily text messaging. Data were analyzed using path analysis in R. On average, participants tested positive for 1.24 (range: 0-6) substances used, reported moderate to high risk on 2.01 (range: 0-8) substances, and reported using substances 1.57 (range: 0-20) times before sex over 28 days. Internalized and enacted stigma were associated with greater depressive symptoms, and depressive symptoms were associated with all three indicators of substance use problems. Moreover, the indirect effects between internalized and enacted stigma with indicators of substance use problems were significant, suggesting that depressive symptoms partially mediated associations between stigma and substance use problems. Discussion will identify intervention strategies to address stigma among PLWH to reduce depressive symptoms and substance use problems, ultimately supporting support HIV treatment and prevention efforts.

2

2:00 PM-3:15 PM

GENDER IDENTITY AND SEXUAL BEHAVIOR STIGMAS, PSYCHOLOGICAL DISTRESS, AND SUICIDALITY IN AN ONLINE SAMPLE OF TRANSGENDER WOMEN IN THE UNITED STATES

Jessica L. Maksut, PhD¹, Stefan Baral, MD, MPH², Travis Sanchez, DVM, MPH³, Maria zlotorzynska, PhD, MPH³, Carrie Lyons, MPH², Ayden Sheim, PhD⁴, John Mark Wiginton, MPH¹

¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²Johns Hopkins Bloomberg School of Public Health; ³Emory Rollins School of Public Health; ⁴Drexel University Dornsife School Of Public Health

Introduction: Studies have consistently documented a high prevalence of adverse mental health outcomes among transgender women in the United States and across the world. Trans-related discrimination limits access to resources in several critical domains (e.g., health care) and serves as a determinant of adverse physical, sexual, and mental health outcomes. Limited scholarship examines how other forms of stigma – including perceived and anticipated stigmas – and stigma due to other socially marginalized attributes or behaviors – including sexuality or sexual behaviors – are associated with adverse mental health outcomes among transgender women. In the present study, we explored associations between perceived, anticipated, and enacted gender identity and sexual behavior stigmas with severe psychological distress, suicidal ideation, and suicide attempts among $N=381$ transgender women.

Methods: Chi square tests were used to compare the prevalence of severe psychological distress, suicidal ideation and suicide attempts across demographic groups, and modified Poisson regression models with log links and robust variance estimators were used to assess unadjusted and adjusted associations between gender identity and sexual behavior stigmas with severe psychological distress, suicidal ideation, and suicide attempts. Covariates included in adjusted models were demographic characteristics that were significantly ($p < 0.05$) associated with the abovementioned three outcomes of interest.

Results: 198 participants (52%) had severe psychological distress, as defined as a K6 score ≥ 13 . In addition, 226 (59.3%) participants reported suicidal ideation in the past year, and 50 (13.12%) reported one or more suicide attempts in the last year.

Overall, participants were young with about half ($n=194$, 50.9%) aged 15-24 years. Most participants were white, non-Hispanic (276, 72.4%) and 44.4% ($n=169$) identified as bisexual or pansexual. Approximately one third ($n=132$, 34.6%) of the sample made less than \$20,000 annually, and nearly 40% ($n=150$) reported attending some college or having an associate's degree.

Treated as scales, gender identity stigma (aPR 1.07, 95% CI: 1.03, 1.11) and sexual behavior stigma (aPR 1.03, 95% CI: 1.01, 1.07) were significantly, positively associated with severe psychological distress. In addition, gender identity stigma was significantly, positively associated with suicidal ideation (aPR 1.09, 95% CI: 1.06, 1.12) and suicide attempts (aPR 1.13, 95% CI: 1.03, 1.26) in the past year.

Conclusion: Gender identity and sexual behavior stigmas are significantly, positively associated with adverse mental health outcomes among transgender women in the United States. Stigma reduction interventions may have the potential to contribute to reductions in adverse mental health outcomes, including severe psychological distress and suicidality among transgender women.

2:00 PM-3:15 PM

SEXUAL RACISM HURTS, BUT MINDFULNESS CAN HELP: MINDFULNESS MODERATES DISCRIMINATION'S EFFECT ON MENTAL HEALTH FOR BLACK AND LATINO MEN WHO HAVE SEX WITH MEN

Eric K. Layland, MS¹, Marco Hidalgo, PhD², Katrina Kubicek, PhD³, Michele Kipke, PhD⁴¹Pennsylvania State University, University Park, PA; ²University of Southern California; ³Southern California Clinical and Translational Science Institute; ⁴Children's Hospital Los Angeles

Background: Sexual minority men of color not only experience stigma targeting their sexual orientation and their race/ethnicity, but also unique stigma that specifically targets the intersection of these identities. Sexual racism is the rejection or objectification of sexual minority men of color by potential romantic and sexual partners. Like other stigma, sexual racism is associated with elevated incidence of adverse mental health consequences. Mindfulness moderates the effects of stress among African Americans but is predominantly unexplored among young men who have sex with men (YMSM). We examined the potential moderating role of trait mindfulness on the association between perceived sexual racism and psychological symptoms among diverse YMSM.

Methods: A community sample of 448 Black, Latino, and Black/Latino YMSM (mean age=22.3 years) reported past week psychological symptoms (somatization, depression, anxiety), past year suicide ideation, ideation with a plan, and attempts, and past three months non-suicidal self-injury (NSSI). Participants also reported frequency of sexual racism and trait mindfulness. We used logistic regression to examine the association between sexual racism and odds of psychological symptoms, suicidality, and NSSI. We then investigated mindfulness as a moderator of this association.

Results: Latino YMSM experienced sexual racism less often than Black and Black/Latino YMSM. Sexual racism was associated with higher odds of psychological symptoms (OR: 1.76-1.91), suicidal ideation with a plan in the past year (OR: 1.92), and NSSI (OR: 1.77). Main effects suggested the protective potential of mindfulness, however, mindfulness only moderated the effects of sexual racism on suicidal ideation with a plan (OR: 1.77) and NSSI (OR: 1.89), with marginal buffering effects on depression (OR: 1.34).

Conclusions: By framing this study at the intersection of sexual orientation and race/ethnicity stigma, we identify a unique social determinant of health among Black and Latino YMSM. Findings add to limited research on sexual racism underscore the potential utility in exploring its impact on mental health among Black and Latino YMSM. We offer promising evidence of the potential benefit of mindfulness as a buffer against the effects of sexual racism on depression, suicide ideation with a plan, and NSSI. Future interventions among Black and Latino YMSM may be improved by considering the unique impact of sexual racism and by integrating mindfulness components.

Symposium 34

2:00 PM-3:15 PM

ADAPTING AN EVIDENCE-BASED RESILIENCY-INTERVENTION TO THE NEEDS OF DIVERSE PATIENT POPULATIONS

Elyse R. Park, Ph.D., MPH¹, Daniel L. Hall, Ph.D.², Giselle K. Perez, PhD², Brittain Mahaffey, Ph.D.³, William N. Elwood, Ph.D.⁴¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital/Harvard Medical School, Boston, MA; ³Stony Brook University School of Medicine, Stony Brook, NY; ⁴National Institutes of Health, BETHESDA, MD

Based on decades of clinical work and evaluation research, we created an evidence-based mind-body group intervention for resiliency. Conceptualizing resiliency as an individual's ability to adaptively cope with chronic, ongoing stress, our research mission is to increase resiliency among coping with chronic illness and disorders. Pairing physiological science, meditation science, theoretical models of CBT, and positive psychology, we developed an 8-session multicomponent group intervention: the Relaxation Response Resilience Program (3RP). Core intervention constructs, and corresponding core measures, were established. The treatment model has been shown to be efficacious for patients with varied chronic health conditions. We are broadening the reach of this intervention to vulnerable populations, including pregnant women experiencing elevated prenatal maternal stress, subgroups of cancer survivors, and parents of children with developmental disabilities. To target the illness experience vulnerabilities of these populations, we conducted evidence-based pilot trials to adapt the 3RP. Specifically, we conducted mixed methods studies to adapt the 1) context, 2) content, 3) delivery, and 4) assessment of the resiliency intervention.

Dr. Perez will discuss results from a mixed methods pilot one arm trial, which integrated oncology clinician and patient feedback to adapt and deliver, via telehealth, the 3RP for lymphoma patients transitioning off active treatment.

Dr. Mahaffey will discuss data from a mixed methods study aimed at assessing barriers to engaging with mental healthcare during pregnancy. She will also detail how these data are being used to adapt both the content and delivery of 3RP for this population.

Dr. Hall will discuss a proof-of-concept, mixed methods feasibility trial of the 3RP adapted to address fear of cancer recurrence among cancer survivors. He will describe adaptations to the intervention content and procedures, synthesize qualitative feedback from trial participants, and highlight trends in key patient-reported outcomes.

Dr. Park will present results from a pilot national trial of parents of children with developmental disabilities (i.e., ADHD, autism, dyslexia). This is an exploratory study in which she partnered with national organizations to elicit input from advocates, professionals, and parents to adapt and deliver the 3RP virtually to target caregiver and family stress.

2:00 PM-3:15 PM

ADAPTING A MIND-BODY RESILIENCY TREATMENT TO PARENTS WITH CHILDREN WITH LEARNING AND ATTENTIONAL DISABILITIES

Elyse R. Park, Ph.D., MPH¹, Emma Chad-Friedman, B.A.², Jacqueline Proszynski, B.A.³, Giselle K. Perez, PhD⁴, Christina Luberto, Ph.D.⁵, Rachel Millstein, Ph.D.⁶

¹Massachusetts General Hospital, Boston, MA; ²University of Maryland; ³Benson-Henry Institute for Mind Body Medicine, Brooklyn, NY; ⁴Massachusetts General Hospital/Harvard Medical School, Boston, MA; ⁵MGH Psychiatry, Jamaica Plain, MA; ⁶MGH Psychiatry, Boston, MA

Background: One in five children have a learning or attentional disability (LAD). Parents of children with LAD are vulnerable to high levels of distress. We conducted a mixed methods study to 1) identify sources and impacts of parental stress and resources available and 2) adapt and assess the efficacy of virtual delivery of a mind-body resiliency group program, the Relaxation Response Resiliency Program (3RP), for parents of children with LAD.

Methods: We conducted a 2-phase exploratory mixed methods study, including qualitative interviews and a randomized waitlist control pilot. In Phase 1, qualitative interviews were conducted with 5 clinicians, 2 groups with advocacy organizations, and 4 parent groups (N=25). Content analyses were conducted using NVivo 11 (reliability of kappa = 0.93). In Phase 2, 53 parents nationally were randomized, and surveys were administered at baseline (T1 intervention group; T1 and T2 3 months apart for control group) and post-treatment. Efficacy outcomes included distress (analog scale; primary), resiliency (CES), stress coping (MOCS-A), mood (PHQ-4), and social support (MOS-SSS).

Results: Qualitative interview findings confirmed high levels of parental stress and lack of psychosocial programs. Primary sources of stress were advocating for their child's needs and communication. Identified intervention targets were 1) emotional and physical exhaustion, 2) strained relationships, and 3) social isolation. 3RP treatment adaptations were made to the structure (creating a group intake) and intervention content (targeting? social support needs based on child's developmental stages; highlighting acceptance to normalize loneliness and child's challenges; focusing on positive reappraisal of child; enhancing communication. Interactive session exercise examples were modified to reflect shared stressors, such as LAD children being excluded socially. Fifty-six parents (mean age=46.8; sd=5.7; 89% female, 88% percent white, non-Hispanic) participated in the pilot trial. T1-T2 comparisons found that intervention vs control participants showed significant improvements in distress [VAS], $\Delta M = -1.95$; $d=.83$, resilience, $\Delta M = 6.38$; $d=.83$, stress coping $\Delta M = 8.69$; $d=1.39$; mood, $\Delta M = -1.79$; $d=.71$; and social support, $\Delta M = 5.47$; $d=.71$.

Conclusions: Parents caring for children with LAD experience high levels of stress, particularly affecting relationships and communication; however, parents report few support strategies. Our adapted intervention showed promising efficacy in delivering a virtually-delivered resiliency treatment that improved parents' overall levels of distress, stress coping, and resiliency, and support.

2:00 PM-3:15 PM

A MULTIMODAL, MIND-BODY INTERVENTION FOR FEAR OF RECURRENCE AMONG CANCER SURVIVORS: ADAPTATION, FEASIBILITY, AND PATTERNS OF CHANGE

Daniel L. Hall, Ph.D.¹, Elyse R. Park, Ph.D., MPH², Gloria Yeh, MD, MPH³

¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Harvard Medical School

Background: Our recent meta-analysis suggests that a cohesive intervention integrating multiple mind-body techniques may be helpful for reducing fear of recurrence (FOR) in cancer. Thus, this study aimed to (1) adapt an evidence-based, multimodal, mind-body intervention (Relaxation Response Resiliency Program; 3RP) to target FOR and (2) test its preliminary feasibility and acceptability, (2) explore patterns of pre-post intervention change among key FOR and coping variables.

Methods: We convened three panels of experts (the parent 3RP, cancer survivorship, and clinical oncology) to provide tiered feedback to guide adaptations. The intervention comprised eight 90-minute group sessions and included skills in the relaxation response, cognitive restructuring, health behavior change, and positive psychology. Early stage survivors 3-30 months post primary treatment were recruited an academic hospital in Boston. Feasibility was assessed by recruitment/enrollment rate, session attendance, and adherence to follow-up assessments. Acceptability was assessed by Likert scales (enjoyableness, convenience, helpfulness, and relevance). Validated self-report measures assessed FOR and resiliency-related outcomes at baseline, post-intervention, 1- and 3-months post-intervention. Cohen's d scores were computed from baseline to post-intervention, and repeated-measures ANOVAs assessed longitudinal patterns across all four timepoints.

Results: Of 68 cancer survivors screened, 40 were eligible. Enrolled participants (N=23, response rate 58%) included survivors of seven common cancer types (time since treatment $M=12$ months). Attendance was high ($M=6.1$ sessions) and 93% completed all follow-up surveys. Participants reported robust increases in independent relaxation practice. Most sessions (87%) had "High" or "Very High" acceptability. Exit interviews revealed cognitive, behavioral, emotional, and existential benefits. Medium to large, significant improvements were observed in key FOR and resiliency self-report measures from baseline through 3-month follow-up.

Conclusions: The adapted 3RP intervention was acceptable, feasible, and associated with favorable improvements in FOR and resiliency. Testing in a randomized trial is warranted.

3

2:00 PM-3:15 PM

HOW CAN WE HELP THE LYMPHOMA SURVIVOR MANAGE THE CHALLENGES OF EARLY POSTTREATMENT SURVIVORSHIP?: THE ART OF BALANCING PROGRAM ADAPTATION WHILE MAINTAINING PROGRAM INTEGRITY

Giselle K. Perez, PhD¹, Kit Quain, B.S.², Emily A. Walsh, B.A.³, Jeremy S. Abramson, MD, MMSc.¹, Elyse R. Park, Ph.D., MPH⁴

¹Massachusetts General Hospital/Harvard Medical School, Boston, MA; ²Sidney Kimmel Medical College, Thomas Jefferson University; ³University of Miami, Miami, FL; ⁴Massachusetts General Hospital, Boston, MA

Background: Although treatment advances have led to improved survival, compared to other survivors, lymphoma patients experience significant physical and emotional challenges posttreatment. This trade-off between survival and quality of life leaves lymphoma survivors feeling unprepared and distressed as they strive to adjust to a new “normal.” Despite these concerns, there are no known interventions that help lymphoma survivors adjust to the posttreatment re-entry period. This presentation will describe our process of adapting an evidence-based mind-body resiliency program (Relaxation Response Resiliency Program; 3RP) for lymphoma survivors transitioning into posttreatment survivorship.

Methods: We used a 3-phase, mixed methods, single-arm pilot feasibility trial to test a virtual, 8-week mind-body group program for lymphoma survivors (0-2yrs posttreatment). In-depth individual interviews with 11 survivors and clinical group interviews with the lymphoma treatment team generated information about program content, outcomes of interest, and in-session activity adaptations to target the 3RP for lymphoma. 30 patients enrolled in the single-arm pilot; emotional distress, fatigue, and coping outcomes were completed at baseline, post-3RP, and 1-month follow-up. A random subset of patients completed exit interviews about their experience.

Results: We adapted each of the 3RP's core coping skills (relaxation response [RR] elicitation, stress awareness, and adaptive strategies) based on identified patient needs and challenges with a focus on maintaining the integrity of the core program. The 3RP-lymphoma emphasized the practice of concrete RR skills that facilitated the *breaking away* from ruminative thoughts and that replaced negative body associations through warming sensations. Stress awareness highlighted worry thoughts and fatigue as a stress trigger and signal, and strategies helped survivors *return to normalcy* by re-introducing activities through pacing. Adaptive strategies focused on generating perspectives of empowerment, self/other empathy, and self-compassion to manage fears of uncertainty and regain social connection. Improvements in anxiety, tolerance of uncertainty, and coping were noted post-treatment.

Conclusion: This study is among the first to address a critical time of transition for this survivor population. Findings underscore our ability to effectively adapt a mind-body resiliency program tailored to the needs of early posttreatment lymphoma survivors.

2:00 PM-3:15 PM

ADAPTING A MULTIMODAL MIND-BODY RESILIENCY PROGRAM FOR PRENATAL MATERNAL STRESS

Brittain Mahaffey, Ph.D.¹, Elyse R. Park, Ph.D., MPH², Adam Gonzalez, Ph.D.¹, Marci Lobel, PhD³

¹Stony Brook University School of Medicine, Stony Brook, NY; ²Massachusetts General Hospital, Boston, MA; ³Stony Brook University, Stony Brook, NY

Background: Prenatal Maternal Stress (PNMS) is defined as the combination of stressful life-events, elevated general stress, pregnancy-specific stress, and symptoms of depression and anxiety. It is a risk factor for preterm delivery and low birthweight, as well as postpartum maternal mental health problems. Despite this, PNMS often remains untreated due to stigma and logistical barriers accessing care. There is evidence that cognitive behavior therapy (CBT) and mind-body therapies are feasible, and low-risk treatments for perinatal mental health conditions. Much of the work in this area, however, has focused on intervening after pregnancy, or single modality programs (e.g., yoga) that demonstrate only short-term benefits and do not address the complex psychosocial factors underlying PNMS. In this talk, we will describe using a mixed methods approach to identify treatment needs of a sample of women with elevated PNMS and explain how this data is being used to create a tailored, web-based mind-body intervention.

Methods: A three-phase mixed methods design was used to adapt the Relaxation Response Resiliency (3RP) group treatment for this population. This included conducting focus groups, obtaining survey data, and soliciting expert feedback. A sample of pregnant and postpartum (< 6 months) women were recruited from local obstetrical clinics and online parenting groups. Twenty-six women reporting elevated PNMS during their most recent pregnancy (n = 16 pregnant, n = 10 postpartum) were enrolled in one of six focus groups. Interviews were coded by two independent raters using the sort and sift, think and shift approach. This data was combined with survey data to develop the SMART-Pregnancy manual and protocol.

Results: Focus groups were conducted from 02/2019-08/2019. Participants were primarily Caucasian (50%), Latina (27%), or Black (12%). Approximately half (46%) were nulliparous, with a mean age of 31.23 years. Identified themes related to pregnancy-specific stress included: health concerns, discrimination, trouble with interpersonal communication, and challenges accessing resources. Reported barriers to treatment engagement included: logistical barriers (e.g., lack of transportation), lack of knowledge about mental health, and feeling physically ill. Treatment preferences included: a desire for a group format and for additional postpartum support.

Conclusions: The results of this study are consistent with the literature suggesting the importance of social support during pregnancy and the need for continued postpartum support. They also underscore the need for flexible and innovative treatment approaches. As such, example modifications include: adding training on interpersonal communication, adding 2 postpartum group check-ins, and making supplemental, self-guided materials available online. Additional program and protocol modifications will be discussed.

Paper Session 9

3:30 PM-3:45 PM

PHYSICAL ACTIVITY MONITOR WEAR-TIME AMONG LOW-INCOME MINORITY WOMEN IN A RANDOMIZED CLINICAL TRIAL

Sharmilee Nyenhuis, MD¹, Guilherme M. Balbim, MS², Devin Dixit, n/a¹, Spyros Kitsiou, PhD², Lisa K. Sharp, PhD²

¹University of Illinois at Chicago, CHICAGO, IL; ²University of Illinois at Chicago, Chicago, IL

Background: Fitbit activity trackers are often considered to be user-friendly, reliable, and feasible in a variety of research studies. Adherence to Fitbit activity trackers has been variable but has not been extensively studied in low-income, minority populations. We aimed to examine adherence to the Fitbit Charge HR in participants of a multi-component physical activity (PA) intervention designed for low-income African American (AA) women with asthma.

Methods: AA women, age 18-70 with uncontrolled asthma were recruited from an urban minority-serving academic health system to participate in a 24-week PA intervention. Women were randomized to the control (CG) or intervention (IG) group. The CG received quarterly asthma newsletters, a Fitbit Charge HR, and attended one educational session on exercising safely with asthma and Fitbit setup/operation. The IG received a multi-component PA education session, a Fitbit Charge HR, individualized step goals, motivational and Fitbit-related text messages, and monthly in-person group meetings. Adherence was defined as daily Fitbit wear time calculated by subtracting the total number of “non-wear time” from the total number of minutes per day, with non-wear time defined as any interval with at least 60 consecutive seconds of non-recorded heart rate data from the Fitbit device. A secure web-based research platform (iCardia) was used to obtain all Fitbit data in real-time (wear time, physical activity, sedentary time) and send text-messages to participants. Fitbit lapses were defined as no wear time for ³4 consecutive weeks. Mann Whitney test was used to assess differences in median daily wear time between groups at $p < 0.05$ significance level.

Results: Fifty-three women enrolled in the study (NCG = 28; NIG = 25). Fitbit wear time was 601 minutes/day (Q1-Q3 = 490-720 min/day) in CG versus 1000 minutes/day (Q1-Q3 = 918-1040 min/day; $p < 0.001$) in IG. Lapses in Fitbit use over 24-weeks occurred in 71% (n=20) of CG vs. 24% (n=6) of IG.

Conclusion: CG participants' adherence to Fitbit use was lower than IG participants. Providing a Fitbit and instructions for use is not enough to ensure Fitbit adherence in minority populations. Additional components such as text message reminders to sync, charge and wear the Fitbit, monthly group sessions and individualized step goals may be needed to enhance the adherence to Fitbit, especially in low-income, minority populations.

3:45 PM-4:00 PM

DEVELOPMENT OF THE FIT2THRIVE PHYSICAL ACTIVITY PROMOTION SMARTPHONE APP WITH A NATIONWIDE SAMPLE OF BREAST CANCER SURVIVORS

Jennifer H. La, Bachelor of Science in Health Systems Management¹, Whitney A. Welch, PhD¹, Kara L. Gavin, PhD², Payton E. Solk, BA¹, Marilyn Lu, BA¹, Frank Penedo, PhD³, Bonnie Spring, PhD⁴, Ronald T. Ackermann, MD MPH⁵, Juned Siddique, DrPH¹, Kerry S. Courneya, PhD⁶, Siobhan M. Phillips, PhD, MPH¹

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²University of Wisconsin, Madison, WI; ³Sylvester Comprehensive Cancer Center, Miami, FL; ⁴Northwestern University Feinberg School of Medicine, CHICAGO, IL; ⁵Northwestern Medicine, Chicago, IL; ⁶University of Alberta, Edmonton, AB, Canada

Purpose: Increased moderate and vigorous physical activity (MVPA) is associated with better health outcomes in breast cancer survivors (BCS). Yet, the majority of BCS are insufficiently active. Mobile health MVPA promotion interventions using smartphone applications (apps) may be a scalable strategy to increase MVPA among BCS, but few evidence-based apps exist. The purpose of this study is to describe the development of the Fit2Thrive app, a MVPA promotion app for BCS.

Methods: A user-centered, iterative design process was conducted over 18 months. Preferred app features were identified from a nationwide sample of stage I-III BCS (n=96, $M_{age}=55.8$) via an online survey and semi-structured interviews. Based on results, an app prototype was developed. A randomly selected subsample of BCS (n=22) interacted with the app for ≥ 3 days and completed the Post-Study System Usability Questionnaire at the end of the test period to rate usability characteristics (functionality, aesthetics and engagement). Additionally, a random subsample of BCS (n=15) indicated whether they liked, disliked, or felt neutral toward potential app notification messages. Data were analyzed using descriptive statistics.

Results: Fit2Thrive app prototypes were rated highly for efficiency ($M=6.1$, $SD=1.3$), comfort of use ($M=5.4$, $SD=0.66$), organization of information ($M=5.2$, $SD=1.3$), pleasantness of interface interaction ($M=5.3$, $SD=1.4$), overall satisfaction with ease of use ($M=5.2$, $SD=0.9$), and moderately for ease of learning the app ($M=4.9$, $SD=1.3$), finding information ($M=3.8$, $SD=1.4$), and clarity of information ($M=3.7$, $SD=1.2$). The majority of BCS (60%) indicated the app worked overall/had negligible problems, was easy to learn/immediately intuitive to use (62%), had pleasant/beautiful visual appeal (70%), moderate/highly relevant information quality (89%), and okay or better information quantity (88%). A more moderate proportion indicated content was designed for the target audience with minor/no issues (57.8%) and navigation was understandable (57.1%); 82% rated app engagement as mostly boring/only briefly entertaining. Almost half (47.6%) indicated they would use the app >50 times in next 12 months. BCS indicated positive response for 80% of self-monitoring, 100% of MVPA entry reminder, 78% of motivational, and 85% of goal attainment app notification messages.

Conclusions: BCS rated Fit2Thrive app functionality, aesthetics, and message content moderately to positively but noted engagement needed improvement. These formative data were used to inform the final version of the Fit2Thrive app to be tested in a factorial trial using the Multiphase Optimization Strategy framework.

PILOT STUDY EXAMINING THE EFFICACY OF HOME-BASED HIGH INTENSITY INTERVAL TRAINING (HIIT) ON PHYSICAL ACTIVITY ADHERENCE

Beth A. Lewis, PhD¹, Katie J. Schuver, Kinesiology, PhD¹, Shira Dunsiger, PhD²
¹University of Minnesota, Minneapolis, MN; ²Brown University, Portsmouth, RI

Only 19% of women and 26% of men meet the USDHHS physical activity (PA) recommendations despite the numerous health benefits associated with PA. A majority of adults report lack of time as a barrier to physical activity adherence. High intensity interval training (HIIT), which consists of short bursts of high-intensity PA followed by recovery or light PA, potentially addresses this time barrier since it takes less time than traditional moderate intensity activity. Additionally, preliminary research indicates that HIIT may be more enjoyable than continuous moderate activity. The purpose of this pilot study was to examine the feasibility and preliminary efficacy of a home-based HIIT intervention on PA adherence among low active adults. Affective response to exercise was also examined. Participants (n=47) were randomly assigned to a home-based HIIT intervention or wait-list control lasting 12 weeks. Participants in the HIIT intervention received eight telephone calls designed to increase PA adherence by utilizing strategies based on Self-Determination Theory. Participants were instructed to complete three HIIT sessions and one moderate intensity session per week to compare the affective responses to HIIT vs. moderate intensity activity. Participants received access to a website that included the home-based session instructions and videos demonstrating proper form. Both aerobic and resistance training exercises were prescribed. The wait-list condition received the intervention upon completion of the 12 weeks. Participants in the HIIT intervention increased their vigorous intensity PA from 3.9 minutes per week at baseline to 40.0 minutes at six weeks and 61.8 minutes at 12 weeks, which met the study's vigorous intensity goal of 60 minutes of HIIT per week. The control increased their vigorous activity from 14.2 minutes at baseline to 16.3 minutes at six weeks and 34.6 at 12 weeks. There were significant differences at six weeks, $f(1,44)=5.15$, $p < .05$ but not 12 weeks. Based on a within subjects analysis of the feeling scale among the participants in the HIIT intervention, participants rated the HIIT sessions as more enjoyable than the moderate intensity sessions, $f(1,21)=3.27$, $p=.085$. The retention rate was 100% for both groups at 6 and 12 weeks. This study provides evidence for feasibility and possible efficacy of a home-based HIIT intervention; however, additional studies are needed with larger samples sizes to confirm efficacy of home-based HIIT interventions.

WALKIT ARIZONA: IMPACT OF MHEALTH INTERVENTIONS ON WALKING FOR LEISURE VERSUS TRANSPORTATION

Mindy L. McEntee, PhD¹, Emily Foreman, BS Exercise and Wellness (Health Promotion)², Alison Cantley, BS¹, Christine Phillips, PhD³, Michael Todd, PhD¹, Siddhartha S. Angadi, PhD, FACSM⁴, Vincent Berardi, PhD⁵, Melbourne Hovell, MA, Ph.D. MPH⁶, Marc A. Adams, PhD, MPH¹

¹Arizona State University, Phoenix, AZ; ²Arizona State University, Maricopa, AZ; ³Atria Senior Living, Louisville, KY; ⁴Arizona State University - Downtown Phoenix Campus, Phoenix, AZ; ⁵Chapman University, Long Beach, CA; ⁶School of Public Health SDSU, Jamul, CA

Background: WalkIT Arizona is a 2x2 factorial trial testing goal type and reward timing to enhance adoption and maintenance of accelerometer-measured walking and moderate-to-vigorous physical activity (MVPA) among insufficiently active adults. Self-reported PA augmented objective data and can detect domain-specific changes in activities, such as walking for leisure or transportation.

Purpose: To examine effects of goal setting (static vs. adaptive) and financial reinforcement timing (delayed vs. immediate) on self-reported walking midway through a 12-month intervention.

Methods: Healthy, insufficiently active adults (N=512, 65% female, ages 18-60) were enrolled in the mHealth intervention and completed the International Physical Activity Questionnaire (IPAQ) long form at baseline (BL) and six months. Static goals prescribed 30 MVPA min/day; adaptive goals adjusted up, down, or stayed the same daily. Delayed incentives escalated in value and were delivered every 60 days; immediate incentives awarded points for meeting daily PA goals, which were redeemed for e-gift cards. Intervention effects were estimated using negative binomial hurdle models, each comprised of two submodels: any walking (vs. none), estimated with logistic regression, and non-zero values, estimated with a negative binomial regression. Intervention effects on walking for transportation and leisure at six months, adjusting for BL activity, were examined separately.

Results: Overall, participants reported increased walking at six months for both transportation (+38.7 min/wk, $Z = -7.32$, $p < .001$) and leisure (+47.0 min/wk, $Z = -7.93$, $p < .001$). For transportation, there were no significant effects of goal type or reward timing for either the hurdle (any vs. zero) or count model. Among participants who reported transportation walking at six months, mean time was 102.2 min/wk. Goal type and reward timing had significant and independent effects on leisure walking. Negative binomial regression estimates showed the adaptive goal group reported 20.6% fewer min/wk compared to the static goal group ($p=.02$), and the immediate reward group reported 34.4% more min/wk compared to the delayed reward group ($p < .01$). Among those reporting any leisure walking at six months, mean time was 109.8 min/wk.

Conclusion: Reported walking time increased for both transportation and leisure at six months, although effects of goal type and reward timing were significant only for leisure walking.

4:30 PM-4:45 PM

MAPTREK RESIDENTIAL: A MULTILEVEL MHEALTH INTERVENTION FOR INCREASING PHYSICAL ACTIVITY AMONG OLDER ADULTS

Katie Hosteng, MS¹, Lucas Carr, Ph.D.²¹University of Iowa, IOWA CITY, IA; ²University of Iowa, Iowa City, IA

Background: Older adults (>65 years) are the largest growing population in the U.S., projected to reach 78.0 million by 2035. The number of older adults living in long-term care facilities (e.g., retirement communities, nursing homes) will likely double from 13 million in 2000, to 27 million by 2050. Older adults have the highest prevalence of physical inactivity placing them at increased risk for a number of chronic diseases and mortality. Past interventions have been primarily focused on the individual level. Multilevel interventions are more effective but few examples exist.

Objective: To determine the efficacy and acceptability of a multilevel mHealth intervention (MapTrek Residential) for increasing physical activity of older adults living in a retirement community.

Methods: We recruited 54 retirement community-dwelling older adults (81.2 years, 77.8% Female, 98.1% White) and 14 staff members (45.1 years, 92.9% Female, 100% White) to participate in an 8-week intervention. MapTrek Residential is a multilevel mobile health platform that engages users to participate in a series of team based virtual walking challenges. Participant's physical activity is monitored daily with a Fitbit Zip which automatically syncs with public monitors located within the retirement community. The monitors display team results and daily educational/motivational messages. Psychosocial outcomes (self-efficacy for exercise, social support, outcome expectations, social isolation) were measured at pre- and post-intervention. Descriptive statistics and linear mixed models were used to determine the intervention effects.

Results: Participant adherence was high with participants wearing the Fitbit 93.4% of all intervention days. Participants walked an average of 5005 steps/day at baseline (95% CI, 4189-5821) which increased significantly to 6111 steps/day by Week 8 (95% CI, 5265-6956). No significant changes were observed for outcome expectations, social support, or social isolation. Self-efficacy for exercise significantly declined from baseline to post-intervention ($p = 0.01$).

Conclusions: These findings suggest the multilevel mHealth physical activity intervention was effective for increasing physical activity (+22.1%) among a sample of older adults over eight weeks. Further research is needed to refine and test the intervention among older adults residing in retirement communities that lack access to physical activity resources.

Paper Session 10

3:30 PM-3:45 PM

THE ACCEPTABILITY AND EFFICACY OF SHARING DIGITAL SELF-MONITORING DATA WITH WEIGHT LOSS COACHES TO ENHANCE ADHERENCE

Meghan L. Butryn, PhD¹, Kathryn Godfrey, PhD¹, Mary K. Martinelli, MA¹, Fengqing Zhang, PhD¹, Evan M. Forman, PhD¹¹Drexel University, Philadelphia, PA

Introduction: Maintaining motivation for long-term weight loss is challenging. A strong sense of supportive accountability may help promote adherence to weight control behaviors. This study tested the acceptability and preliminary efficacy of enhancing supportive accountability by giving weight loss coaches access to participant data collected by digital self-monitoring (SM) devices.

Methods: In Phase I, participants ($n = 77$) received group-based treatment to induce weight loss (months 1-3), then were randomized to a Phase II condition for weight loss maintenance (months 4-12). In Phase II, all participants received weekly text messages and monthly phone calls from their Phase I coach (no in-person contact), and were told to use a wireless body weight scale, digital food log, and activity sensor daily. In LM+SHARE, coaches regularly viewed the weight, eating, and moderate-to-vigorous physical activity (MVPA) data from these devices and gave data-driven feedback in their text messages and phone calls. In the LM condition, coaches had no access to SM data. Outcomes included change from 3-12 months in weight (measured in the research clinic,) MVPA (using research-grade accelerometers) and SM engagement (objectively assessed with device data). Imputation was used for missing weight and MVPA data.

Results: Acceptability and feasibility of LM+SHARE was high, as demonstrated by high satisfaction with treatment (M item rating = 5.5 out of 7), high rates of completion of phone calls (89.7%) and text messages (93.9%), and 12-month retention (97.4%). During Phase II, participants in LM+SHARE, compared to LM, engaged in more frequent SM of weight (58% vs. 43% of days, $p = 0.02$) and SM of eating (67% vs. 41% of days, $p < .001$). SM of PA was high in both conditions and did not differ (80% vs. 79% of days, $p = 0.85$). The decline in MVPA during Phase II was less in LM+SHARE vs. LM, at a marginally significant level ($p = 0.05$); at 12 months, PA was 108.1 min/week in LM+SHARE vs. 84.6 min/week in LM. Weight change during Phase II did not significantly differ by condition ($p = 0.23$); at 12 months, weight loss was 7.1% in LM+SHARE vs. 6.1% in LM.

Conclusion: The results suggest that when coaches monitor and react to digital SM data during remote weight loss maintenance treatment, it increases the likelihood of participants engaging in SM of weight and eating and facilitates maintenance of MVPA. With longer use and additional intervention enhancement, there is the potential for this to improve outcomes.

Paper Session 10

3:45 PM-4:00 PM

PRIMARY OUTCOMES OF THE EXPERIENCE SUCCESS TRIAL: VIRTUAL REALITY SKILLS TRAINING TO ENHANCE AN ONLINE WEIGHT LOSS PROGRAM

Graham Thomas, Ph.D.¹, Carly M. Goldstein, PhD², Dale Bond, Ph.D.¹, Peter W. Tuerk, PhD³¹Brown Medical School, Providence, RI; ²The Miriam Hospital/Alpert Medical School of Brown University, Providence, RI; ³University of Virginia, Charlottesville, VA

Online delivery of behavioral obesity treatment improves access to care while alleviating other important barriers such as cost and the need for frequent clinic visits. However, online programs lack opportunities for experiential learning and molding of behavioral weight management skills common to in-person treatment, which may be important for driving positive treatment outcomes. Web-based virtual reality (VR) holds potential for filling this gap while preserving scalability and cost. Thus, this study tested whether addition of an interactive VR component to the widely available Weight Watchers commercial online platform improved short-term weight loss.

Participants (N=146; 83.7% women, mean±SD BMI 33.1±4.9 kg/m-squared) were randomized to 6-months of no-cost access to the Weight Watchers online platform alone (WWO), or WWO enhanced with the Experience Success (ES) program. The ES program provided four 15-minute Web-based VR training sessions designed to improve behavioral weight loss skills applicable to the home environment, the workplace, physical activity, and social situations (i.e., a party at a friend's house). The scenarios were released at 2-week intervals and included dozens of choice points that guided how the scenarios played out. Objective weight was measured at baseline, 3 and 6-months. Primary outcomes analysis focused on weight loss employed the intent-to-treat principle and linear mixed effects models with maximum likelihood estimation. The Weight Control Strategies Scale (WCSS; range 0-120) was used to measure the frequency with which study completers used 30 empirically validated weight management skills in the previous 4 weeks.

Retention was 70% at 3-months and 62% at 6-months. Mean±SE weight loss did not differ between WWO and WWO+ES at 3-months (2.1±0.7 kg vs. 3.8±0.7 kg, respectively; p=.086) but WWO+ES had greater weight loss at 6-months (2.3±0.7 kg vs. 4.4±0.7kg, respectively; p=.042). WWO and WWO+ES did not differ on mean±SD WCSS at 3-months (64.5±17.3 vs. 68.0±17.5, respectively; p=.336) or 6-months (58.9±18.5 vs. 61.6±16.7, respectively; p=.686).

WWO+ES achieved nearly double the weight loss compared to WWO alone at 6-months. These results demonstrate the potential of Web-based VR skills training to enhance outcomes of commercial online weight management programs that are widely accessible, often at low cost. Lack of difference between these groups on use of weight control strategies warrants additional testing of mechanisms.

WHAT LEVEL OF PERSONALIZATION MATTERS IN DIGITAL WEIGHT LOSS TREATMENT FOR YOUNG ADULTS?

Melissa A. Napolitano, PhD¹, Meghan Mavredes, MPH¹, Jessica A. Whiteley, PhD², Ashley H. Tjaden, MPH³, Samuel J. Simmens, Ph.D.⁴, Loretta DiPietro, PhD, MPH¹, Laura L. Hayman, PhD, MSN, FAAN,FAHA,FPCNA⁵, Jamie M. Faro, PhD⁶, Ginger Winston, MD, MPH⁷¹The George Washington University, Washington, DC; ²UMass Boston, Boston, MA; ³The George Washington University, Rockville, MD; ⁴George Washington University, Washington, DC; ⁵UMass Boston, 100 Morrissey Blvd. Boston, MA 02125-3393, Boston, MA; ⁶University of Massachusetts Medical School, Worcester, MA; ⁷George Washington University, Medical Faculty Associates, Washington, DC

Introduction: Young adults with overweight and obesity are a population in need of innovative delivery channels for intervention. Little is known about the level of personalization necessary for successful weight outcomes.

Methods: Young adults with overweight/obesity (n=459; 78.6% female, mean±SD: age 23.3 ± 4.4 years, weight: 86.6 ± 15.6 kg, body mass index [BMI] 31.2 ± 4.4 kg/m²) recruited from two sites, were randomly assigned to receive one of three digitally delivered 18-month interventions. Two were based on the Diabetes Prevention Program and focused on weight loss with either personalized (Tailored; n=150) or generic (Targeted; n=152) messages and feedback while the third (Contact Control; n=157) provided general healthy body content (e.g., body image, hydration). Objectively measured weight outcomes were assessed at 6, 12, and 18 months. Analysis of covariance tested weight differences adjusting for study site, sex, age, baseline weight, and height.

Results: Six month follow-up weights were available for 77.1% (n=354) of randomized participants. For each group, weight changes from baseline were Tailored: -1.0 ± 4.1kg; Targeted: -0.5 ± 4.3kg, and Control: -0.3 ± 4.7kg, p=0.5 and percent weight changes were Tailored: -1.2 ± 4.6%; Targeted: -0.6 ± 5.2%, and Control: -0.1 ± 4.7 %, p=0.19. There was no overall effect of study group on 6 month weight losses (p=0.50); however, the pre-planned baseline weight x study group interaction test was statistically significant (p < 0.001). Plots and the Johnson-Neyman technique indicated a significantly greater weight loss in the Tailored and Targeted groups compared to the Control group for participants with a lower baseline weight. For example, among the lowest tertile for baseline weight (n=152), the Tailored group lost 2.1kg [-3.3, -0.6] more than the Control group and the Targeted lost 1.9kg [-3.5, -0.7] more than the Control group after adjustment for covariates.

Conclusion: Digital interventions hold promise for delivering weight loss treatments to young adults, particularly for those who begin treatment at a lower body weight. More intensive interventions (e.g., in-person, telephone, or combination) may be needed for young adults who already have obesity. Future research and practice implications will be discussed including recommendations of providing a stepped care approach to meet the needs of those with range of initial body weights.

4:15 PM-4:30 PM

BOT VS HUMAN: COMPARING ENGAGEMENT WITH AUTOMATED VS. HUMAN-GENERATED TWEETS FROM WEIGHT MANAGEMENT APPS

Jared M. Goetz, BA¹, Greg J. Champion, M.A.², Aviana O. Rosen, n/a³, Kelsey M. Arroyo, B.S.⁴, Molly E. Waring, PhD⁵, Sherry Pagoto, PhD⁵¹University of Connecticut, Dudley, MA; ²University of Rhode Island, West Hartford, CT; ³University of Connecticut, West Hartford, CT; ⁴University of Connecticut, Vernon, CT; ⁵University of Connecticut, Storrs, CT

Health apps often include social features to help users garner social support from other users in their online social networks. Two popular weight loss apps, MyFitnessPal and Lose It, include an automated feature that allows users to tweet progress updates (e.g., weigh-ins) to their followers. The tweets include the app's hashtag which allow users to connect and engage with each other on Twitter. We examined the proportion of tweets using the hashtags #myfitnesspal and #loseit that are automated versus organic (i.e., written by the user), and compared them on engagement. From July 9-16, 2019, we used NCapture to collect English-language tweets that included the hashtags #myfitnesspal or #loseit. Tweets were characterized as either automated or organic and then categorized by type (e.g., weigh-in, exercise report). Organic tweets included only the subset of non-automated tweets likely made by actual app users and not those from accounts that were advertising, using #loseit unrelated to the app or weight, or health influencers, professionals, or organizations not sharing their personal experience using the app. Engagement (likes, comments, retweets) from all organic tweets by app users (n=254) and an equal number of randomly-selected automated tweets (n=254) was recorded and compared using chi-square tests. A total of 18,472 #myfitnesspal and 7,101 #loseit tweets were collected over the 7-day sampling period. The vast majority of tweets (98%) were automated (#myfitnesspal: 99%; #loseit: 96%). Organic tweets were more likely to receive any engagement than automated tweets (39.4% vs 4.4%; $p < 0.001$). No automated tweets received retweets; 0.4% had 1 reply, 3.2% had 1 like, and 0.8% had 2-5 likes. Engagement with organic tweets was also low: replies (1 reply: 5.2%; 2-5 replies: 4.0%, >5 replies 1.2%), likes (1 like: 22.1%; 2-5 likes: 11.7%, >5 likes: 3.2%) and retweets (1 retweet: 5.2%; 2-5 retweets: 0.4%). The majority of tweets with app hashtags were automated and these received negligible engagement. Organic tweets also received very low engagement. That a search of these hashtags produces mostly automated tweets with no engagement could explain the lack of organic interactions. Automated posts to social media platforms may not be effective at soliciting social support or connecting users. Health apps might be improved by designing more effective means for users to elicit social support and engage their social connections in their behavior change efforts.

Paper Session 10

4:30 PM-4:45 PM

DO DIFFERENT REFERRAL METHODS INFLUENCE THE REACH, RETENTION, AND EFFECTIVENESS OF A DIGITALLY-DELIVERED WEIGHT LOSS PROGRAM?

Gwendolyn C. Porter, MS¹, Paul Estabrooks, PhD¹¹University of Nebraska Medical Center, Omaha, NE

The purpose of this study was to examine the utility of different physician referral and engagement strategies for improving reach (i.e., number, proportion, and representativeness of participants), initial retention, and effectiveness of an evidence-based, digitally-delivered, 12-month weight loss program in a rural region. Five primary care physicians were randomly assigned to a sequence of 4 referral strategies: point of care (POC) referral with active telephone follow-up (ATF); POC referral, no ATF; population health registry-derived letter referral with ATF; and letter referral, no ATF. All patients who received a referral and expressed interest (either through ATF or directly contacting the research team) completed a telephone screening and, if eligible, attended a brief enrollment appointment with a member of the research team. All participants received a Bluetooth-enabled home scale. A total of 573 of a potential 991 referrals were made over 16 weeks and 98 patients, representative of the region, enrolled in the program (60% female; 94% Caucasian; 94% Non-Hispanic). Letter referrals reached a significantly higher proportion of patients than POC (100% vs 17%) and yielded more participants (12% vs 8%, $p < .05$). Patients receiving ATF were significantly more likely to be screened (47% vs 7%; $p < .05$) and enrolled (15% vs 7%, $p < .05$) when compared to those without ATF. Finally, when considering total number enrolled, POC with ATF (n=27), letter with ATF (n=30), and letter with no ATF (n=27) were comparable while POC with no ATF accrued the fewest participants (n=14). Over the first 16 weeks, 77 participants (79%) recorded an initial weight and 54 (55%) completed at least one additional weigh-in. On average, participants lost a significant amount of weight (3.8 ± 7.8 lbs; $p < .01$) and approximately 13% had lost $\geq 5\%$ of their initial body weight. Retention and weight change did not differ significantly by referral strategy. Population health management approaches provide a much higher proportion of patients an opportunity to engage in an evidence-based weight loss program and will not result in higher attrition or attenuate weight loss relative to POC strategies. Unexpectedly, from an overall yield perspective, ATF may be less necessary following a population health referral method—but doubled the number of participants accrued through point of care referrals. Future cost assessment across referral strategies relative to accrual rates is planned.

DETERMINING THE TIMING AND FREQUENCY OF FINANCIAL TOXICITY ASSESSMENTS IN ONCOLOGY PATIENTS

Bridgette Thom, PhD¹, Brooke Barrow, BA², Catherine Benedict, PhD³, Deborah Korenstein, MD¹, Christina Tran, BS¹, Victoria S. Blinder, MD, MSc¹

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Warren Alpert Medical School at Brown University, Providence, RI; ³Stanford University School of Medicine, Palo Alto, CA

Background: Rising costs and shifts in payment structures have drawn attention to the financial impact of cancer, giving yield to studies of financial toxicity (FT), the economic distress associated with care. There is emerging literature measuring FT, but there is, to our knowledge, no research describing the timing and frequency of FT assessment within the treatment trajectory. Understanding when patients and caregivers are most likely to be impacted by FT is essential for developing a methodology to study FT and determining the optimal timing of interventions.

Objective: To determine the timing and frequency of FT assessment in primary research studies.

Methods: We conducted a systematic literature search of quantitative studies of FT in cancer patients and their caregivers, following PRISMA guidelines. We included US and non-US studies published after 2009 and excluded articles that only measured out-of-pocket costs (without assessing their context or impact) or societal economic burden. We used descriptive statistics and bivariate testing to characterize current FT research.

Results: After screening 209 articles, we included 82 full-text articles: 67% (n=55) employed a cross-sectional assessment of FT; 33% (n=27) were longitudinal. 52% (n=43) of studies took place outside of the US, but study type did not vary by location ($p=.20$). Of cross-sectional studies, 56% (n=30) included at least one reference to assessment timing (mean/median time since treatment or diagnosis). Of longitudinal studies, the median number of assessments was 3 (range: 2-8). Median time of last assessment was 12.0 months (range: 1-60) from baseline. Of studies that included patients (n=60), 26% were of patients on active treatment, 27% in long-term follow-up, and 23% of both; 24% did not define a treatment phase. Covariates included measurements of employment status (72% of articles), socioeconomic status (65%), income (48%), work hours (37%), quality of life (33%), and sick leave/time (27%).

Conclusions: Over one-third of the studies in this review did not include information about the timing of FT assessment, many omitted important covariates, and most longitudinal studies followed patients for no longer than one year. As cancer treatment is associated with long-term and late effects that impact patients' and caregivers' ability to work, it is vital to promote longitudinal FT research that reports important details and follows patients well into the survivorship period.

COMORBIDITIES, QUALITY OF LIFE AND HEALTH BEHAVIORS AMONG CANCER SURVIVORS: FINDINGS FROM MEPS

Peiran Guo, MS¹, Xianming Tan, PhD², Ting Guan, MS³, Lixin Song, PhD, RN, FAAN²

¹UNC-CH, Chapel hill, NC; ²UNC-CH, Chapel Hill, NC; ³University of North Carolina at Chapel Hill, Chapel hill, NC

This study aimed to examine the effect of comorbidities on quality of life (QOL) and the mediation effects of health behaviors on the relationships between comorbidities and QOL among cancer survivors. Longitudinal data were from the 2011 to 2015 Medical Expenditure Panel Survey (N=793 adult cancer survivors who reported to have been diagnosed with at least one of the most common types of cancers in the US). Using the Structural Equation Modeling with weights that combines Confirmatory Factor Analysis (CFA) and multiple regression, we examined the latent structure of comorbidities measured by 11 observed illnesses and detected the potential direct effects of comorbidities on QOL and indirect effects of comorbidities on QOL through health behaviors (mediation). We evaluated the goodness of fit based on recommended statistics: CFI 0.95; TLI 0.95; and RMSEA (<0.10). Health behaviors focused on smoking, physical activity, and BMI (a proxy for healthy diet). QOL was measured using the SF-12 V2 that consists of the Mental Component Summary (MCS) and Physical Component Summary (PCS) to represent mental and physical well-being. The CFA revealed moderate to high (standardized) factor loadings for angina (0.827), coronary heart disease (0.821), hypertension (0.813), diabetes (0.649), high cholesterol (0.645), heart attack (0.630), stroke (0.548) and other heart disease (0.538) (all $p < .001$). CFA results indicated optimal model fit. The significant results of structural model included 1 direct effect of comorbidities on PCS (2.124; $p < .001$); 2 indirect effect of comorbidities on PCS through BMI (-0.76; $p < .001$); 3 indirect effect of comorbidities on PCS through physical activity (-0.67; $p = .012$); 4 indirect effect of comorbidities on MCS through physical activity (-0.39; $p < .001$); 5 total effect of comorbidities on PCS and MCS (-3.425; $p < .001$) (-0.39; $p < .001$), respectively; and 6 negative relationships between smoking and PCS (-2.486, $p < .001$) and MCS (-1.136, $p = .023$). The negative effects of comorbidities on PCS can be mitigated by enhancing physical activities and reducing BMI. Physical activity also mitigates the negative impact of comorbidities on MCS. Smoking cessation improves PCS and MCS but does not influence the effects of comorbidities on PCS or MCS. We used individual weights and information of strata and cluster to estimate covariance matrix in the complex survey design, and thus, improved the generalizability of our results.

Figure 1. Comorbidities, Quality of Life and Health Behaviors

Note:
Cancer included: breast, prostate, lung, colon, bladder, uterine corpus, melanoma, non-Hodgkin Lymphoma, thyroid, and kidney and renal pelvis
Illnesses included coronary heart disease, stroke, high cholesterol, angina, heart attack, diabetes, other heart disease, hypertension, chronic bronchitis, joint pain and arthritis

CARE FOR CAREGIVERS: AN EVIDENCE-BASED PSYCHOSOCIAL INTERVENTION TRIAL FOR CAREGIVERS OF STEM CELL TRANSPLANT RECIPIENTS

Jamie M. Jacobs, PhD¹, Ashley M. Nelson, PhD², Lara Traeger, PhD³, Lauren Waldman, BS⁴, Showly Nicholson, BS⁵, Annemarie D. Jagielo, BA², Jennifer D'Alotto, M.Ed., MSW², Joseph A. Greer, PhD², Jennifer S. Temel, MD⁴, Areej El-Jawahri, MD¹

¹Massachusetts General Hospital Cancer Center, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Massachusetts General Hospital/Harvard Medical School, Boston, MA; ⁴MGH, Boston, MA; ⁵Harvard Medical School, Boston, MA

Background: Informal family and friend caregivers of patients undergoing hematopoietic stem cell transplantation (HCT) experience substantial caregiving burden and psychological distress across the HCT continuum. We sought to assess the feasibility of a brief, tailored, multimodal psychosocial intervention (BMT-CARE) compared to standard care for caregivers of HCT recipients. In addition, we aimed to examine preliminary group differences in caregivers' quality of life (QOL), burden, mood, self-efficacy, and coping.

Methods: From 12/2017 to 4/2019, caregivers of HCT recipients at an academic medical center were enrolled and randomly assigned to receive either the BMT-CARE intervention or usual care, stratified by transplant type. Usual care included meeting with social work prior to HCT. BMT-CARE was usual care plus a six-session coping skills intervention that integrated medical information with cognitive-behavioral strategies specific to the HCT trajectory. Each caregiver met with a trained study therapist in person, by telephone, or by videoconference for four weekly and two semi-monthly sessions beginning prior to HCT and continuing after discharge. Feasibility metrics included a) accrual [$\geq 60\%$ of eligible caregivers] and b) attendance [$\geq 60\%$ of caregivers attend $\geq 50\%$ of sessions]. Caregivers completed study questionnaires including the CareGiver Oncology QOL, Hospital Anxiety and Depression Scale, Caregiver Reaction Assessment, Cancer Self-Efficacy Scale-Transplant, and Measures of Current Status at enrollment, 30 days post-, and 60 days post-HCT. Mixed linear effects models with Maximum Likelihood, adjusting for baseline values, were used to longitudinally assess group differences in caregiver outcomes.

Results: One hundred caregivers were enrolled and 92 were randomized to BMT-CARE (n=45) or usual care (n=47). Caregivers were a median age of 61 (range 22-93) and most were married to the patient (75/92, 81.5%). Feasibility was demonstrated with 73% of eligible caregivers enrolled (100/138) and 80% (36/45) attending $\geq 50\%$ (3/6) of sessions. Caregivers randomized to BMT-CARE reported improvements in QOL ($\beta=6.11$, $p < .001$, 95% CI [3.50, 8.71]) and decreased caregiving burden ($\beta=-6.02$, $p < .001$, 95% CI [-8.49, -3.55]) compared to those receiving usual care. In addition, those in BMT-CARE experienced reduced symptoms of anxiety ($\beta=-2.18$, $p < .001$, 95% CI [-3.07, -1.28]) and depression ($\beta=-1.23$, $p < .001$, 95% CI [-1.92, -0.54]) compared to the control group. Finally, compared to usual care, caregivers in BMT-CARE reported improvements in self-efficacy ($\beta=7.22$, $p=.003$, 95% CI [2.41, 12.03]) and coping skills ($\beta=4.83$, $p < .001$, 95% CI [3.04, 6.94]).

Conclusions: A brief psychosocial intervention tailored for caregivers of HCT recipients is feasible and may improve QOL, mood, coping, and self-efficacy while reducing caregiving burden during acute HCT recovery.

POST-TRAUMATIC STRESS SYMPTOMS IN HEMATOPOIETIC STEM CELL TRANSPLANT (HCT) RECIPIENTS

Alyssa L. Fenech, BA¹, Olivia Van Benschoten, n/a², Joseph A. Greer, PhD¹, Jennifer S. Temel, MD³, Areej El-Jawahri, MD⁴

¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³MGH, Boston, MA; ⁴Massachusetts General Hospital Cancer Center, Boston, MA

Background: HCT is an intensive and potentially curative therapy for patients with hematologic malignancies. Patients admitted for HCT experience a prolonged, isolating hospitalization and endure substantial physical and psychological symptoms. However, there is a paucity of research on the impact of HCT on long-term post-traumatic stress (PTSD) symptoms in transplant survivors. Furthermore, predictors of PTSD in this population have not been explored.

Methods: This secondary analysis included longitudinal data from 250 patients who underwent autologous and allogeneic HCT at Massachusetts General Hospital between 7/2013-1/2016. We used the Post-Traumatic Stress Checklist (PTSD-CL) to assess for PTSD symptoms at six months post-HCT. We used the Functional Assessment of Cancer Therapy – Bone Marrow Transplant, and the Hospital Anxiety and Depression Scale to assess quality of life (QOL) and depression and anxiety symptoms at the time of admission for HCT, at week-2 during HCT hospitalization, and at six months post-HCT. We used multivariate regression models to assess factors associated with PTSD symptoms. Given collinearity between QOL, depression, and anxiety symptoms, we modeled these separately.

Results: The mean age for study participants was 56.3 years (SD = 13.3). The majority were White (88.0%, 220/250), and female (51.2% 128/250). The rate of clinically significant PTSD symptoms at six months post-HCT was 18.9% (39/206). Participants with clinically significant PTSD symptoms experienced hypervigilance (92.3%), avoidance (92.3%), and intrusion (76.9%) symptoms. Among patients without clinically significant PTSD symptoms, 24.5% had clinically significant hypervigilance symptoms and 13.7% had clinically significant avoidance symptoms. Lower QOL at time of HCT admission ($B = -0.04$, $P = 0.004$), and being single ($B = -3.35$, $P = 0.027$) were associated with higher PTSD symptoms at six months post-HCT. Higher anxiety at time of HCT admission ($B = 1.34$, $P < 0.001$), change in anxiety during HCT hospitalization ($B = 0.59$, $P = 0.006$), and being single ($B = -3.50$, $P = 0.017$) were associated with higher PTSD symptoms at six months. In a separate model incorporating depression, younger age ($B = -0.13$, $P = 0.017$), being single ($B = -3.58$, $P = 0.018$), and higher baseline depression symptoms were also associated with higher PTSD symptoms at six months ($B = 0.97$, $P < 0.001$).

Conclusions: Approximately one fifth of patients undergoing HCT experience clinically significant PTSD symptoms at six months post-transplant. The prevalence of hypervigilance and avoidance symptoms are notable even among patients who do not have clinically significant PTSD symptoms. Patients' baseline QOL and psychological symptoms emerge as important predictors of their risk for PTSD at six months post-HCT. Interventions to prevent and treat PTSD symptoms in HCT recipients are clearly warranted.

INFLAMMATORY AND CLINICAL RISK FACTORS FOR CHEMOTHERAPY-INDUCED PERIPHERAL NEUROPATHY (CIPN)

Ian Kleckner, PhD, MPH¹, Todd Jusko, PhD¹, Eva Culakova, PhD, MS¹, Amber S. Kleckner, PhD², Matthew Asare, PhD, MPH, MBA³, Julia E. Inglis, Ph.D., R.D.¹, Melissa (Kah Poh) Loh, MD², Luke J. Peppone, Ph.D., M.P.H.⁴, Jessica Miller, BS⁵, Marianne Melnik, MD⁶, Samer Kasbari, MD, MS⁷, Deborah Ossip, PhD¹, Karen M. Mustian, PhD, MPH¹

¹University of Rochester Medical Center, Rochester, NY; ²University of Rochester, Rochester, NY; ³Baylor University, Waco, TX; ⁴University of Rochester Medical Center, Rochester, NY; ⁵Metro Minnesota Community Oncology Research Program, St Louis Park, MN; ⁶Cancer Research Consortium of West Michigan NCORP, Grand Rapids, MI; ⁷Southeast Clinical Oncology Research Consortium (SCOR), Winston Salem, NC

Background: Chemotherapy-induced peripheral neuropathy (CIPN) is a common dose-limiting side effect of taxane and platinum chemotherapy. The sensory symptoms of CIPN include numbness, tingling, and cold sensitivity. The etiology of CIPN is not well understood, making it difficult to predict which patients will experience symptoms. Although inflammation has been suggested to play a role in CIPN in rodent models, evidence is limited in humans. Our goal was to identify the strongest predictors of CIPN utilizing patient-specific measures assessed before taxane or platinum chemotherapy, including serum measures of inflammation.

Methods: Fifty-five sedentary women with breast cancer (mean age 57 years) receiving taxane or platinum chemotherapy rated the severity of (1) numbness and tingling, and (2) hot/coldness in hands/feet on 0-10 scales before and after their first 6 weeks of chemotherapy. To identify predictors of CIPN, all possible linear regression models without interaction terms were fit to predict CIPN symptom severity at 6 weeks. Independent variables included those related to inflammation (serum IL-1 β , IL-6, IL-8, IL-10, IFN- γ , sTNFR1), clinical factors (cancer stage, baseline neuropathy, fatigue, anxiety, depression, using medications for diabetes [yes/no]), behavior (daily pedometer steps), and demographics (age at consent, race) measured before chemotherapy. The model with the lowest AIC goodness of fit was deemed the final model for identifying the strongest predictors of CIPN.

Results: The four strongest pre-chemotherapy predictors of numbness and tingling after 6 weeks of taxane chemotherapy included baseline neuropathy (explaining 28% of variance), stage I cancer vs. stage II-IV (17%), worse patient-reported fatigue/anxiety/depression (15%), and higher serum levels of the pro-inflammatory cytokine IFN- γ (12%). The four strongest predictors of hot/coldness in hands/feet included worse fatigue/anxiety/depression (26%), higher serum IFN- γ (18%), baseline neuropathy (14%), and platinum vs. taxane or platinum+taxane chemotherapy (11%).

Conclusions: The strongest pre-chemotherapy predictors of both numbness and tingling and hot/coldness in hands/feet included baseline neuropathy, worse fatigue/anxiety/depression, and pro-inflammatory IFN- γ . Clinicians should consider assessing these factors before initiating chemotherapy to inform the patient's risk for CIPN. These findings also suggest that inflammation may underlie the etiology of CIPN in humans.

Creating more physical activity-supportive built environments is recommended by the World Health Organization for controlling non-communicable diseases. The IPEN (International Physical Activity and Environment Network) Adult Study was undertaken to provide international evidence on associations of built environments with physical activity and weight status in 12 countries on five continents (n >14,000). This presentation includes re-analyzed data from eight primary papers to identify patterns of findings across studies. Neighborhood environment attributes, whether measured objectively or by self-report, were strongly related to all physical activity outcomes (accelerometer-assessed total physical activity, reported walking for transport and leisure) and meaningfully related to overweight/obesity. The differences in total physical activity minutes/week across the least and most activity-supportive neighborhoods were 35 minutes/week with environments measured by GIS and a similar 41 minutes/week by self-report measures. Relative effect sizes across the least and most activity-supportive neighborhoods accounted for up to a 13.3% difference in prevalence of overweight/obesity. Multi-variable indexes of built environment variables were more consistently related to all outcomes than single-environment variables. Designing activity-supportive built environments should be a higher international health priority. Results provide evidence in support of global initiatives to increase physical activity and control non-communicable diseases while achieving sustainable development goals.

PICTURE THE STEPS: COMBINING SELF-REGULATION AND MENTAL IMAGERY TO INCREASE EXERCISE BEHAVIOR OVER 90 DAYS

Erika A. Waters, PhD, MPH¹, Nicole Ackermann, MPH², Julia Maki, PhD³, Linda Cameron, Ph.D.⁴, Chelsey R. Carter, MA⁵, Ying Liu, MD, PhD², Deborah J. Bowen, Professor⁶, Graham A. Colditz, n/a⁷, Hank Dart, MS²

¹Washington University in St Louis, St Louis, MO; ²Washington University School of Medicine, St. Louis, MO; ³Washington University in St. Louis, St Louis, MO; ⁴University of California, Merced, Merced, CA; ⁵Washington University in St. Louis, St. Louis, MO; ⁶University of Washington, Seattle, WA; ⁷Washington UNiversity School of Medicine, St Louis, MO

Purpose: The gap between health behavior intentions and actions is a key barrier to reducing chronic disease morbidity and mortality. We test whether a self-regulation intervention that incorporates mental imagery, administered after provision of personalized disease risk information, increases exercise over 90 days.

Methods: 500 community-dwelling adults aged 30-64, with < 150 minutes of exercise in the last week, and with < =1 (men) or 2 (women) comorbidities were randomized to one of six experimental conditions in a 3 (risk display format: text vs. table vs. risk ladder) x 2 (mental imagery topic: exercise vs. sleep hygiene [active control]) factorial design. Participants saw personalized risk and risk reduction estimates for up to 2 cancers and 3 chronic diseases in one of the 3 display formats. Participants completed a survey assessing cognitive and affective reactions to the risk information (results reported elsewhere). Then, they listened to an audiorecording that used mental imagery to guide them in developing goals related to exercising or sleep hygiene behaviors and in making plans for achieving those goals. Participants received text message reminders to complete the mental imagery for 3 weeks post-intervention, 4 weekly text message surveys, and a mailed survey 90 days post-baseline. Data were analyzed using ANCOVA. The primary outcome was a difference score in exercise minutes/week from baseline to 90-day followup. The predictor was mental imagery topic, and covariates were: risk display format, sex, race/ethnicity, age, education, health literacy, season, perceived intervention acceptability, and baseline minutes of exercise. After listwise deletion of missing data points and accounting for participants lost to follow-up (n=56), 420 participants were included in the analysis.

Results: The exercise imagery condition increased exercise over 90 days by 19.5 more minutes per week (95%CI: 2.0, 37.1) than the sleep condition (p=.03). This effect varied by risk display format (i.e., the interaction term between risk display format and mental imagery topic yielded p< .05). Post-hoc analyses that probed the interaction revealed that, for participants who saw a risk ladder, the exercise condition increased exercise by 92.2 minutes/week (95%CI: 67.4, 117.1), significantly more (p=0.006) than the increase of 37.5 minutes/week (95%CI: 11.1, 63.8) for the sleep condition. This effect was not observed in for the text or table risk display format conditions.

Conclusions: Self-regulation interventions that include mental imagery can increase exercise behavior over time, but the magnitude of the effect may vary based on what other intervention components individuals receive.

A DYNAMICAL SYSTEMS MODEL OF THE IMMEDIATE EFFECTS OF MONETARY REINFORCEMENT ON PHYSICAL ACTIVITY

Vincent Berardi, PhD¹, Marc A. Adams, PhD, MPH², Mindy L. McEntee, PhD², Melbourne Hovell, MA, Ph.D. MPH³, Michael Todd, PhD²

¹Chapman University, Long Beach, CA; ²Arizona State University, Phoenix, AZ; ³School of Public Health SDSU, Jamul, CA

Title: A Dynamical Systems Model of the Immediate Effects of Monetary Reinforcement on Physical Activity

Background: Contingency management interventions have demonstrated that financial rewards can increase and maintain moderate-to-vigorous physical activity (MVPA). Because these studies typically rely on self-reported measures of MVPA and/or non-immediate, infrequent presentation of MVPA-contingent rewards, the dynamic, immediate effect of monetary reinforcement on MVPA in real world settings has not been examined.

Methods: Participants (N=236) were asked to wear an ActiGraph GT9X wrist-worn accelerometer daily during awake hours for a year and to sync (i.e., upload) data from their accelerometer each day to our data servers. For each day, participants were presented with an MVPA goal and, after syncing, were informed of whether the goal was met. Financial reinforcement was provided for achieving daily goals with reward magnitude and frequency governed by a sequence of reinforcement schedules that participants progressed through. An automated cloud-based system was designed for this study and online 24 hours/day, 365 days per year to receive and process accelerometer data, determine goal achievement, calculate financial rewards, transmit text message feedback to participants, and send e-gift cards, when appropriate. For each participant, a person-specific, lag-linear dynamical systems model was built that allowed the magnitude and duration of the monetary reinforcement's effect on MVPA to be examined. Results were considered in aggregate to gain a general understanding of how financial rewards affected behavior in this trial.

Results: For 70 participants (30%), receiving a financial reward had a significant effect on MVPA within 3 days. For 18 (26%) of these participants, reinforcement had an effect after 1 day had elapsed, while for 26 (37%) and 25 (36%), reinforcement had an effect after two or three days, respectively. The direction of one-day effects vs. two/three-day effects on MVPA min/day were qualitatively different, with the 25th/75th percentile of regression coefficients of significant one-day effects ranging from 12.3 to 19.6 while 2-day and 3-day effect quartiles ranged from -16.1 to 17.0 and -8.9 to 18.1, respectively. These results suggest that 1-day effects of reinforcement were generally associated with increases in MVPA; 2-day and 3-day effects, however, were significant more frequently, but associated with both increases and decreases in MVPA.

Discussion: In the short term, when monetary rewards had an effect, it tended to increase MVPA. Longer-term effects though could either promote or inhibit MVPA, with the latter potentially due to the effects of activity or the use of non-activity as a reward. Understanding these phenomena will help improve the design of MVPA-promoting interventions.

TESTING A BRIEF INTERVENTION TARGETING REMEMBERED AFFECT AND SELF-EVALUATIONS IN EXERCISE: AN EXPERIMENTAL MEDICINE APPROACH

Austin S. Baldwin, PhD¹, Bree Geary, MPH¹¹Southern Methodist University, Dallas, TX

Objective: How pleasantly an exercise bout is remembered and positive self-evaluations post-exercise are prospectively associated with physical activity (Kangas et al., 2015; Kwan et al., 2017). Thus, post-exercise remembered affect (RA) and self-evaluations (SE) are promising intervention targets to increase physical activity. Actively reflecting on the positive aspects of an exercise bout could be an effective approach to target post-exercise RA and SE (see Peters et al., 2010). We tested a brief guided reflection intervention delivered at the end of an exercise bout on RA and SE. We also examined the effects of post-exercise RA and SE on physical activity during the subsequent week.

Methods: Participants (N = 84) were healthy young adults (66% female, 71% Caucasian, mean age = 20.0 years, mean BMI = 22.9) who completed a 15-minute, vigorous intensity treadmill bout. During the 3-minute cool down, participants were randomized to: 1) a brief audio recording to guide active reflection on positive aspects of the exercise bout, or 2) no audio recording. The recording included guided reflections on benefits of exercise, accomplishment on completing it, and mindful awareness. RA, assessed on a scale from +100 (*very pleasant*) to -100 (*very unpleasant*), and SE, assessed on a scale from 1 (*very bad about myself*) to 7 (*very good about myself*), were both measured 15 minutes post-exercise. Participants received a hip-worn accelerometer to wear for the next 7 days to assess moderate-to-vigorous physical activity (MVPA). Analyses were guided by an experimental medicine approach (Riddle et al., 2015) in which we tested (a) the intervention effect on RA and SE (using linear regression), and (b) the effect of RA and SE on MVPA minutes (using gamma regressions, controlling for baseline MVPA and intervention condition).

Results: The brief guided reflection intervention did not have a significant effect on post-exercise RA ($t = 0.45$, $p = 0.67$) or SE ($t = 1.64$, $p = 0.11$). However, post-exercise RA (Wald chi-square = 6.20, $p = .013$) and SE (Wald chi-square = 4.15, $p = .042$) both significantly predicted MVPA minutes during the subsequent week.

Conclusions: The intervention was not effective in changing post-exercise RA and SE. Given that both targets predicted MVPA minutes, findings suggest they are viable intervention targets to increase physical activity but a different intervention strategy is needed to change them. Alternative approaches will be discussed.

Paper Session 12

4:30 PM-4:45 PM

CHANGES IN DELAY DISCOUNTING RATE FOLLOWING THE WALKIT ARIZONA INTERVENTION

Mindy L. McEntee, PhD¹, Christine Phillips, PhD², Vincent Berardi, PhD³, Michael Todd, PhD¹, Melbourne Hovell, MA, Ph.D. MPH¹, Marc A. Adams, PhD, MPH¹¹Arizona State University, Phoenix, AZ; ²Atria Senior Living, Louisville, KY; ³Chapman University, Long Beach, CA; ⁴School of Public Health SDSU, Jamul, CA

Background: Delay discounting (DD) refers to the tendency to devalue distant consequences in favor of those that are more proximal: individuals with higher discounting rates are more likely to select smaller, immediate rewards over larger, delayed rewards. Evidence suggests DD is predictive of unhealthy behaviors, but research on change in DD rates over time is limited, particularly as an unintended consequence of interventions to enhance health-promoting behavior like physical activity. The current study examined changes in DD across participants' enrollment in WalkIT Arizona, a 12-month, 2x2 factorial trial testing mHealth interventions to increase physical activity among healthy, insufficiently active adults.

Methods: DD rate scores were obtained for 423 adults (64.5% female, ages 18-60, median education = college graduate, median income = \$40,000-59,000) who completed the 27-item Monetary Choice Questionnaire (MCQ) at baseline (BL) and after completing the 12-month intervention. Overall delay discount rate (k value) was calculated at each time point by computing the geometric mean of small, medium, and large magnitude MCQ trials. A natural log transformation was applied to address skewness. Changes in DD (ln geomean k) were evaluated using ANOVAs with time (within-person) and intervention condition (between-person) factors, adjusting for potential confounders (age, sex, education, household income).

Results: Across conditions, DD significantly increased from BL to 12 months, $t(422) = -5.20$, $p < .001$. A significant Time x Reward Schedule interaction was found ($F = 10.45$, $p = .001$), such that participants receiving immediate financial incentives showed a greater increase in DD relative to delayed rewards at 12 months. Participants receiving static goals displayed larger DD rates at both time points compared to those with adaptive goals, but neither this main effect nor the Time x Goal Type interaction was significant.

Conclusion: Overall delay discounting rate increased with completion of a 12-month intervention utilizing financial incentives to increase physical activity; this increase was greatest among participants receiving immediate financial incentives. Further analysis should examine the stability of this change and effects on maintaining physical activity in the absence of financial rewards.

Paper Session 13

3:30 PM-3:45 PM

“MINDFUL MOMS”- A MINDFUL PHYSICAL ACTIVITY INTERVENTION FOR PERINATAL DEPRESSION

Patricia A. Kinser, PhD, WHNP-BC, RN¹, Leroy Thacker, PhD², Sara Moyer, n/a², Ananda Amstadter, PhD², Suzanne E. Mazzeo, PhD²

¹Virginia Commonwealth University School of Nursing, Richmond, VA; ²Virginia Commonwealth University, Richmond, VA

Objective: Nearly 20% of women experience clinically significant depressive symptoms during pregnancy, yet many pregnant women are concerned about stigma, adverse effects, and/or costs of “usual care” for depressive symptoms (e.g., antidepressants, psychotherapy). To address the need for an accessible, non-pharmacologic, complementary approach for these women, we seek to evaluate the effects of a 12-week group-based mindful physical activity program (“Mindful Moms”), which involves group prenatal yoga, home-based physical activity, and aspects of motivational interviewing.

Methods: In this NIH/NICHD-funded mixed-methods pilot trial, we examined preliminary effects of the “Mindful Moms” intervention on maternal depressive symptoms, perceived stress, and anxiety from baseline to end of intervention in pregnant women with high depressive symptom severity at baseline ($n=41$). Qualitative data were collected through semi-structured interviews with participants in order to inform and explain the quantitative findings.

Results: Overall, there was a significant effect of time on depression ($F_{3,86} = 35.04$, $p < 0.0001$), stress ($F_{3,84} = 17.30$, $p < 0.0001$), and on anxiety ($F_{3,81} = 11.05$, $p < 0.0001$). Analysis of qualitative data is on-going using phenomenology as a method of inquiry and will be complete in time for SBM 2020; preliminary analysis suggests that the intervention provided a sense of empowerment for participants which enabled them to engage in self-management of their depressive symptoms.

Conclusions: Findings from this study address the urgent need for adjunctive treatments for depressive symptoms in pregnancy, particularly those that target self-management of current symptoms and prevention of recurrent symptoms.

Paper Session 13

3:45 PM-4:00 PM

THE MINDFULNESS-PSYCHOLOGICAL SYMPTOMS LINK VIA SPIRITUAL WELL-BEING IN ADVANCED LUNG CANCER PATIENTS AND SPOUSAL CAREGIVERS

Dalnim Cho, PhD¹, Seokhun Kim, PhD², Sania Durrani, MPH³, Kathrin Milbury, PhD³

¹UT Texas MD Anderson Cancer Center, Houston, TX; ²UT School of Public Health, Houston, TX; ³The University of Texas MD Anderson Cancer Center, Houston, TX

Objectives: Given the incurable nature of the disease, metastatic lung cancer (LC) patients and their spousal caregivers are at high risk of psycho-spiritual symptom burden and overall quality of life (QoL) deficits. It has been recognized that mindfulness enhances QoL through spiritual well-being. Based on interdependence theory, which has been translated into couples coping with cancer, we hypothesized that caregivers’ mindfulness would be associated with patients’ lower psychological symptoms via their own and patients’ spiritual well-being, and vice versa.

Methods: In this cross-sectional study, we examined the actor-partner interdependent model of mediation (APIMeM) with 78 couples, who were stage IV LC patients and their spousal caregivers. A total of 4 APIMeM analyses were conducted: 1 predictor (mindfulness) \times 2 mediators (meaning/peace, faith) \times 2 outcomes (depressive symptoms, cancer distress). We conducted structural equation modeling with 1,000 bootstrapped resamples controlling for covariates (gender, age, relationship length). Missing data was treated with full information maximum likelihood method.

Results: Direct effects were found: 1) from caregivers’ mindfulness to patients’ meaning/peace (*partner effect*: 2.43, $p < .05$); 2) from patients’ meaning/peace to their own depressive symptoms (*actor effect*: -.86, $p < .001$) and cancer distress (*actor effect*: -1.25, $p < .05$); and 3) from caregivers’ meaning/peace to their own depressive symptoms (*actor effect*: -.73, $p < .001$) and cancer distress (*actor effect*: -.86, $p < .05$). Indirect effects of meaning/peace were also found: 1) from caregivers’ mindfulness to their own depressive symptoms (*actor effect*: -2.53, $p < .01$) and cancer distress (*actor effect*: -2.53, $p < .01$) via their own meaning/peace and 2) from caregivers’ mindfulness to patients’ depressive symptoms via patients’ meaning/peace (*partner effect*: -2.08, $p < .05$). However, indirect effects of faith were not found.

Discussions: This is the first study that examined spiritual well-being as a mediator in the link between mindfulness and psychological symptoms in cancer patients and spousal caregivers. Results highlight the interdependence of mindfulness, meaning/peace and psychological symptoms between patients and caregivers. Mindfulness-based interventions for palliative cancer care need to focus on meaning/peace of both patients and caregivers to reduce their psychological symptoms and eventually enhance their QoL. Future studies should assess other aspects of mindfulness, spirituality, and QoL at more than one time point in the dyads.

Paper Session 13

4:00 PM-4:15 PM

FEASIBILITY, ACCEPTABILITY, AND USABILITY OF A MINDFULNESS SMARTPHONE APPLICATION

Ashley Lewson, BS¹, Ekin Secinti, M.S.², Catherine E. Mosher, Ph.D.³, Patrick V. Stutz, B.A.⁴, Shelley A. Johns, PsyD⁵¹Indiana University - Purdue University Indianapolis, Indianapolis, IN; ²Indiana University Purdue University Indianapolis, Indianapolis, IN; ³Indiana University-Purdue University Indianapolis, Indianapolis, IN; ⁴Indiana University School of Medicine, Indianapolis, IN

Growing evidence supports the efficacy of mindfulness-based interventions for improving psychological well-being. However, mindfulness researchers report difficulty objectively measuring home practice adherence. To address this limitation, we developed a novel application (app) that is readily available to researchers, provides reliable tracking of participants' home practice adherence, and offers customizable audio-based practice recordings. The current study assessed the feasibility, acceptability, and usability of the smartphone app.

Participants ($N=19$) were recruited from one of three community-based mindfulness programs to field test the app. A brief, nondirective task-based assessment (TBA) with a research assistant served as a one-on-one app orientation. Participants then completed the validated 10-item System Usability Scale (SUS) and were asked to use the app as their sole method of home mindfulness practice. After field testing and finishing their mindfulness course, participants again completed the SUS and a satisfaction survey. Qualitative data were collected during the TBA and satisfaction survey.

Participants were mostly female (84%) and White (74%) with an average age of 43 years ($SD = 16$). Regarding feasibility, 90% of testers used the app at home at least once ($M_{\text{use/week}}=3.4$, $SD=2.6$), and 100% completed all outcome measures. The app was acceptable with the 9 satisfaction items averaging 3.9 on a 5-point scale ($SD=0.9$). SUS results ($M_{\text{post-TBA}}=91$, $M_{\text{post-field testing}}=84$) suggest the app was highly usable and easy to learn, with scores corresponding to system usability at the 95th percentile or higher. Only one participant reported an issue in field testing, which was resolved with technical support.

Analysis of qualitative feedback revealed the app was generally well-received. Unprompted, the majority of testers noted the ease of use and simple interface. During the TBA, testers found several problems (e.g., difficulty downloading the app on cellular data) and provided suggestions for improvement, such as adding customizable practice reminders or a goal-setting feature.

All predetermined feasibility, acceptability, and usability goals were exceeded, suggesting the app is user-friendly and ready for use in future mindfulness clinical trials. This app may provide researchers with a reliable way of measuring home practice adherence and calculating dosage effects of mindfulness home practice on study outcomes.

PRELIMINARY VALIDATION OF THE COGNITIVE AFFECTIVE MINDFULNESS SCALE-REVISED (CAMS-R) IN CANCER POPULATIONS

Kelly Chinh, M.S.¹, Ekin Secinti, M.S.², Shelley A. Johns, PsyD³, Patrick V. Stutz, B.A.³, Patrick O. Monahan, PhD⁴, Catherine E. Mosher, Ph.D.⁵¹Indiana University - Purdue University Indianapolis, Indianapolis, IN; ²Indiana University Purdue University Indianapolis, Indianapolis, IN; ³Indiana University School of Medicine, Indianapolis, IN; ⁴Indiana University, Indianapolis, IN; ⁵Indiana University-Purdue University Indianapolis, Indianapolis, IN

Growing evidence supports the use of mindfulness-based interventions with cancer populations. However, few self-report measures of mindfulness, a key potential mechanism of these interventions, have been validated in cancer populations. To reduce patient burden, a short yet comprehensive measure of mindfulness is needed. Thus, the aim of this study was to examine the factor structure, internal consistency, and construct validity of the Cognitive Affective Mindfulness Scale-Revised (CAMS-R) in cancer patients.

Patients with breast, gastrointestinal, lung, or prostate cancer were recruited from academic and public clinics in Indianapolis, IN to participate in a cross-sectional survey. Participants were primarily White (80%) with an average age of 63 years ($SD=11$), and half were women (51%). Group 1 ($n=196$) consisted of stage I-II survivors ≥ 6 months post-curative treatment while Group 2 ($n=194$) consisted of patients with stage IV disease on active or supportive treatment. Patients completed the 10-item CAMS-R and other psychological measures. We modified CAMS-R instructions to focus on the past two weeks. Confirmatory factor analysis (CFA) was used to examine the dimensionality of the measure for each group. Internal consistency of the CAMS-R was calculated, and construct validity was assessed through correlations with theoretically-related variables.

CFA showed that the original CAMS-R 4-factor, second order structure had adequate fit for both samples (Group 1: $\chi^2=115.65$, $p<.001$, $RMSEA=.12$, $CFI=.91$, $SRMR=.05$; Group 2: $\chi^2=107.69$, $p<.001$, $RMSEA=.11$, $CFI=.92$, $SRMR=.05$). Factors included attention, present focus, awareness, and acceptance, along with an overarching mindfulness construct. Internal consistency in each group was excellent (Groups 1 and 2: $\alpha=.90$). In both groups, the CAMS-R showed significant positive associations with commonly used mindfulness and self-compassion questionnaires (Group 1: $rs=.60-.68$; Group 2: $rs=.62-.64$). In addition, the CAMS-R showed significant negative associations with anxiety, depressive symptoms, rumination, psychological inflexibility, and avoidant coping (Group 1: $rs=-.37--.57$; Group 2: $rs=-.34--.58$).

Findings provide preliminary support for the use of the modified CAMS-R with cancer patients. Future research should assess the CAMS-R's sensitivity to change in an interventional context.

PARTNERSHIP TO ADAPT A TELEPHONE-BASED MINDFULNESS PROGRAM FOR DIVERSE PRIMARY CARE LATINA PATIENTS

Jolaade Kalinowski, Ed.D.¹, Tanya Spruill, PhD¹, Matthew Allison, MD, MPH², Adriana M. Bearse, MS³, Mallory Rutigliano, MPA¹, Leydi K. Payano, BS⁴, Laura A. Diaz, MPH⁵, Linda C. Gallo, PhD⁶, Gregory A. Talavera, MD, MPH⁶, Sheila F. Castaneda, PhD⁷

¹NYU School of Medicine, New York, NY; ²University of California San Diego, San Diego, CA; ³San Ysidro Health, Chula Vista, CA; ⁴NYU Langone Health, ny, NY; ⁵NYU Langone, New York, NY; ⁶San Diego State University, Chula Vista, CA; ⁷SDSU, San Diego, CA

Background: Hypertension is a well-known risk factor for cardiovascular disease (CVD). Targeting prehypertension can prevent or delay progression to hypertension and thereby reduce CVD risk. Mindfulness-based interventions have been shown to improve psychological functioning and reduce blood pressure, however, applications to low-income, Spanish-speaking Latino adults is unknown. The aim of this study was to translate and culturally adapt a telephone-delivered version of mindfulness-based cognitive therapy through formative research with diverse Latina populations in San Diego, CA and New York, New York.

Methods: We conducted focus groups with Spanish-speaking Latina patients at a large Federally-Qualified Health Center (FQHC) in the US-Mexico border region of San Diego, CA (SD) and a large public hospital in New York City (NYC). Topics included experiences of stress, coping strategies, perceived need for stress management and interest in mindfulness programs. Feedback was also collected on the proposed recruitment and intervention materials.

Results: The sample consisted of 64 middle-aged Latina women (mean age = 54 [SD] and 59 [NYC]), the majority of whom who were born outside the US (SD=85%, NYC=73%). Key sources of stress included illness, time, finances, work (NYC), and traffic (SD). The majority of participants at both sites reported being moderately or extremely interested in learning skills to help deal with stressful situations (SD=91%, NYC=73%). Women in NYC were more likely than those in SD to consider participating in a phone-based stress management program with other Latina women (87% and 35%, respectively). Almost all reported access to a mobile phone. Perceived barriers to participating in the program included uncertainty about program benefits, access and lack of time. Program materials and study protocols were modified based on participant feedback, e.g., simple language, study branding, emphasis of clinic partners' involvement to mitigate issues around trust.

Conclusion: Differences observed in the SD and NYC samples informed modifications to the respective study protocols and recruitment materials for pilot clinical trials being conducted at each site. If found to be effective, this innovative, scalable mindfulness intervention may be a promising strategy to prevent hypertension and CVD among diverse women. Patient-, provider- and healthcare system-related implementation issues and lessons learned will be discussed.

NEGATIVE AFFECT MEDIATES THE RELATIONSHIP BETWEEN DISPOSITIONAL MINDFULNESS AND DIETARY INTAKE AMONG HEALTHY MIDLIFE ADULTS.

Shannon D. Donofry, PhD¹, Kirk I. Erickson, PhD², Peter J. Gianaros, PhD², Matthew F. Muldoon, MD, MPH³, Stephen B. Manuck, PhD²

¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA; ³University Pittsburgh School of Medicine, Pittsburgh, PA

Background: Emerging evidence suggests that mindfulness, a practice of non-judgmental awareness of present experience, may reduce eating psychopathology and emotion-driven eating. However, few studies have explored the relationship between mindfulness and normative dietary patterns or sought to identify factors that mediate the effect of mindfulness on diet.

Methods: Community-dwelling midlife participants (N=406; Mage=43.19, SD=7.26; MBMI=27.08, SD=5.28; 52% female) reported dispositional mindfulness using the Mindful Attention Awareness Scale, and positive affect (PA) and negative affect (NA) using the Positive and Negative Affect Schedule. Dietary intake was assessed using the Block Food Frequency Questionnaire. Direct and mediating effects of dispositional mindfulness, PA, and NA on intake of calories and macronutrients were analyzed using the PROCESS macro with bias-corrected bootstrapped confidence intervals (BootCI). Age, sex, education and weight were entered as covariates in all models.

Results: Higher dispositional mindfulness was associated with lower intake of calories ($\beta=-0.143$, $p<0.01$) protein ($\beta=-0.110$, $p=0.02$), carbohydrates ($\beta=-0.112$, $p=0.02$), and total fat ($\beta=-0.153$, $p<0.01$), but not cholesterol ($\beta=-0.076$, $p=0.12$) or sugar ($\beta=-0.073$, $p=0.13$). NA significantly mediated the relationship between dispositional mindfulness and intake of calories ($\beta=-0.077$, BootCI=-0.149, -0.013), protein ($\beta=-0.076$, BootCI=-0.152, -0.007), carbohydrates ($\beta=-0.068$, BootCI=-0.139, -0.007), and fat ($\beta=-0.074$, BootCI=-0.146, -0.011) such that higher mindfulness was associated with lower intake through lower NA. PA was significantly positively correlated with dispositional mindfulness but did not mediate any relationship between mindfulness and dietary intake.

Conclusions: Among healthy community adults, higher dispositional mindfulness was associated with lower NA, which in turn was related to lower intake of protein, carbohydrates, and fat. Although higher dispositional mindfulness was correlated with higher PA, PA was not associated with dietary intake, indicating that the affective pathway linking mindfulness to diet may be specific to NA. These cross-sectional findings suggest that mindfulness may influence normative dietary patterns, in part, by reducing negative affect.

PAIN OVEREATING: FURTHER INVESTIGATION OF THE YALE EMOTIONAL OVEREATING QUESTIONNAIRE IN WEIGHT LOSS SEEKING PATIENTS

Robin M. Masheb, PhD¹, Alison G. Marsh, B.A.², Amanda M. Kutz, n/a³, Megan Douglas, Ph.D.⁴, Mary A. Driscoll, PhD⁵¹Yale School of Medicine/VA CT Healthcare System, North Haven, CT; ²VA Connecticut Healthcare System, Wakefield, MA; ³Salt Lake City VA Healthcare System, Salt Lake City, UT; ⁴Baylor Scott & White Institute for Research, Dallas, TX; ⁵VA Connecticut Healthcare System, Newtown, CT**Objectives:** Providers and patients frequently report pain as a barrier to weight loss. However, the relationship between pain and eating behavior is not well understood. Given the high independent rates of overweight and chronic pain in the Veteran population, the current study investigates overeating in response to physical pain (Pain Overeating) in a sample of weight-loss seeking Veterans.**Methods:** Veterans (N = 126; 89.7% male; 75% white) with overweight/obesity (BMI = 38.0), who attended orientation sessions for weight management treatment at VA Connecticut Healthcare System, were consecutively evaluated. Participants completed the Yale Emotional Overeating Questionnaire (YEOQ), a measure used to assess the frequency of overeating in response to a range of emotions that was adapted to include a Pain Overeating item (i.e., on how many days out of the past 28 days have you eaten an unusually large amount of food, given the circumstances, in response to feelings of physical pain). They also completed, a validated measure of pain. Pain Overeating, and its associations with Body Mass Index (BMI), short-term pain intensity and interference, and validated measures and screeners for eating pathology and mental health were examined.**Results:** Short-term, clinically meaningful pain was common in over 50% of this sample. The YEOQ was internally consistent ($\alpha = .95$), and the new pain item was significantly and moderately correlated with all other YEOQ items (range .37 to .78). Fifty-one participants (42.5%) engaged in at least one overeating episode in the past month in response to physical pain, and 17 (14.2%) engaged in this behavior daily. Pain Overeating was significantly related to short-term pain intensity and interference scores ($r = .60, p < .01$). Pain Overeating accounted for unique and statistically significant variance in predicting BMI ($\beta = .23, p = .04$), eating disorder pathology ($\beta = .23, p = .04$) and depression ($\beta = .26, p = .01$), but not PTSD.**Conclusions:** Pain Overeating is common in a large subset of Veterans seeking weight loss treatment, and is associated with high short-term pain intensity and interference rating scores. When present eating in response to physical pain may also have serious implications for weight, pathological eating behavior and mental health. Findings suggest eating behavior in relation to pain be addressed in Veteran weight loss efforts.

Paper Session 14

4:00 PM-4:15 PM

EXAMINATION OF THE BIOSOCIAL MODEL AS A THEORY OF EMOTIONAL EATING

Abby Braden, PhD¹, LaNaya Anderson, MA¹, Rachel Redondo, BA¹, Tanya S. Watford, M.S.², Elizabeth Emley, MA¹, Emily L. Ferrell, n/a¹¹Bowling Green State University, Bowling Green, OH; ²Bowling Green State University, Boise, ID**Background:** Behavioral interventions using adapted versions of Dialectical Behavioral Therapy (DBT) have been used to target emotional eating (EE). DBT is based on the Biosocial Model which claims that emotional sensitivity and childhood invalidation combine to influence the development of psychological and behavioral problems. According to this theory, emotional sensitivity and invalidation interfere with the development of adaptive emotion regulation, leading to unhealthy emotion regulation strategies. Adapted DBT programs that target EE assume that emotional sensitivity, childhood invalidation, and emotion dysregulation are mechanisms of EE. However, no studies have directly examined whether the Biosocial Model is supported as a possible explanation for EE. The current study aimed to examine whether emotion regulation difficulties mediated relationships between biosocial variables (i.e., emotional sensitivity and childhood invalidation) and EE.**Methods:** Adults (n = 256; age = 36.52 ± 11.02 ; 50% female) were recruited using Amazon Mechanical Turk. Body mass index (BMI) was calculated from self-reported height and weight. EE was assessed with the depression subscale of the Emotional Eating Scale (EES). The Difficulties in Emotion Regulation Scale (DERS), the Invalidating Childhood Environment Scale (ICES; mother and father subscales), and the Perth Emotional Reactivity Scale (PERS) were also administered. Three separate mediation analyses were performed using Preacher and Hayes' (2017) SPSS macro for bootstrapping methods.**Results:** Results revealed that the relationship between ICES-mother and EES was mediated by DERS (indirect effect = 0.42, $SE = 0.07$, 95% CI = 0.30, 0.57). Results also showed that the relationship between ICES-father and EES was mediated by DERS (indirect effect = 0.37, $SE = 0.07$, 95% CI = 0.25, 0.51). Finally, the relationship between PERS and EES was mediated by DERS (indirect effect = 0.02, $SE = 0.01$, 95% CI = 0.01, 0.03). When gender and BMI were entered as covariates, results were unchanged.**Conclusions:** The current study is limited by a cross-sectional design, but it is a first step toward showing that relationships between biosocial variables (i.e., emotional reactivity and perceived invalidation from mother and father) and EE may be explained by poor emotion regulation. Consequently, targeting emotion regulation in treatment may improve EE outcomes.

4:15 PM-4:30 PM

ASSOCIATIONS BETWEEN A WEIGHT LOSS ATTEMPT, FOOD PLANNING BEHAVIORS, AND THE HOME FOOD ENVIRONMENT

Madeline Johnson, M.S.¹, Kristin Schneider, Ph.D.², Bradley Appelhans, PhD³¹Rosalind Franklin University of Medicine and Science, Great Lakes, IL;²Rosalind Franklin University of Medicine & Science, North Chicago, IL; ³Rush University Medical Center, Chicago, IL

Approximately 50% of U.S. adults report a weight loss attempt in the past year. Those making a weight loss attempt may engage in more food planning behaviors to create a healthier home food environment (HFE) and facilitate weight loss. We hypothesized that those who report a weight loss attempt would endorse more frequent meal planning and grocery list use, resulting in fewer obesogenic foods and more fruits and vegetables (FV) in the home. This was a secondary data analysis. Over 14 days, researchers entered 196 participants' homes four times, collecting data on demographics, the HFE, and food planning behaviors (age M=44.38 yrs.; 83.7% female; 82.15% not Latino). Four separate regressions with mediation were used to analyze whether food planning behaviors explained the relationship between a weight loss attempt and the HFE. A reported weight loss attempt in the past year was the independent variable (Yes=1; No=2); percent of obesogenic foods and FV in the home were the two dependent variables; frequency of meal planning and grocery list use were the two mediators. Meal planning did not explain the relationship between a weight loss attempt and obesogenic foods, ($b=0.000$, 95% CI [-0.001, 0.002]) or FV in the home ($b=0.000$, 95% CI [-0.001, 0.002]). Grocery list use did not explain the relationship between a weight loss attempt and obesogenic foods ($b=0.000$, 95% CI [-0.002, 0.002]) or FV in the home ($b=0.000$, 95% CI [-0.001, 0.002]). Since a BMI of 28.0 reflects a threshold for when an individual may attempt to lose weight, post-hoc mediation analyses only included participants with BMIs >28.0 ($N=112$). Making a weight loss attempt was associated with fewer obesogenic foods ($t=3.24$; $p=.002$) and more FV ($t=-2.25$; $p=.026$) in the home, but mediation analyses, evaluating food planning behaviors, were non-significant ($ps>.05$). Food planning behaviors may be used for reasons aside from losing weight, such as time management and organization. The historical nature of the weight loss question and not knowing the success of the weight loss attempts were limitations. Results indicated that foods in the HFE may be different in the context of a weight loss attempt, in individuals with BMIs >28.0. Since the HFE accounts for a majority of calories consumed, future studies should evaluate planning strategies, such as meal preparation, that could influence the HFE to help develop effective weight loss strategies.

LONGITUDINAL FAST FOOD CONSUMPTION TRAJECTORIES AND RELATED PHYSICAL AND MENTAL HEALTH OUTCOMES

Lindsay M. Stager, B.A.¹, Aaron D. Fobian, PhD¹¹The University of Alabama at Birmingham, Birmingham, AL

Obesity represents a leading U.S. public health issue. While past research has uncovered many factors related to adolescent eating behaviors, there is a lack of longitudinal research regarding health outcomes of fast food consumption across the transition into adulthood. This gap is critical, as fast food consumption relates to multiple negative health outcomes including obesity.

The present study used data from The National Longitudinal Study of Adolescent to Adult Health, focusing on 9,421 participants who reported on fast food consumption in waves II-IV (49.5% male; 53.4% white, 21.6% Black, and 16.9% Hispanic). A group based modeling technique (PROC TRAJ) was used to determine fast food consumption trajectory groups across these waves. Groups were then used as predictors of wave IV inflammation (measured using CRP) and depression (measured using the CESD) in two separate ANCOVAs.

Four fast food consumption trajectory groups emerged. Group 1, "low", had the overall lowest consumption. Group 2, "spike", had high consumption at wave III, followed by reduced consumption at wave IV. Group 3, "raised", increased consumption across waves, ending with the second highest consumption at wave IV. Group 4, "max" followed a similar trajectory as group 3, but ended with markedly higher consumption at wave IV.

Trajectories were significantly related to outcomes of CRP and depression. Group 4 had significantly higher CRP as compared to individuals in groups 1 (adj. Mdif= 2.02, SE=.89; $t(128) = 2.25$, $p=.03$), 2 (adj. Mdif= 2.23, SE=.90; $t(128) = 2.48$, $p=.01$), and 3 (adj. Mdif= 2.23, SE=.91; $t(128) = 2.45$, $p=.02$). Group 1 also had significantly higher levels of CRP than individuals in group 2 (adj. Mdif= 0.21, SE=.10; $t(128) = 2.18$, $p=.03$).

Group 4 had significantly elevated depressive symptomology as compared to groups 1 (adj. Mdif= 0.26, SE=.07; $t(128) = 3.98$, $p=.00$) and 2 (adj. Mdif= 0.23, SE=.08; $t(128) = 3.01$, $p=.00$). Group 3 also had significantly higher levels of depressive symptomology than groups 1 (adj. Mdif= 0.14, SE=.03; $t(128) = 4.49$, $p<.0001$) and 2 (adj. Mdif= 0.11, SE=.04; $t(128) = 2.39$, $p=.02$).

Overall, this study highlights the impact of fast food consumption in specific areas of physical and mental health across the transition from adolescence to adulthood. Given the observed relationships, fast food companies may be encouraged to improve the nutritional quality of their food products, and policy change regarding fast food's labeling may be warranted.

3:30 PM-3:45 PM

REAL-TIME CONTINUOUS GLUCOSE MONITORING AS A BEHAVIOR CHANGE TOOL IN TYPE 2 DIABETES SELF-MANAGEMENT: A SYSTEMATIC REVIEW

Solangia Engler, MS¹, Sherecce Fields, PhD²¹Texas A&M University, COLLEGE STATION, TX; ²Texas A&M University, College Station, TX

Background: Real-time continuous glucose monitoring (RT-CGM) allows for the continuous measurement of interstitial glucose levels and the evaluation of detailed blood glucose profiles in patients with type-2 diabetes (T2D). Recent studies note that RT-CGM can be a valuable motivational tool to change patients' lifestyle and to improve their quality of life. Thus, this review seeks to synthesize the existing literature for reported effectiveness of behavioral interventions that incorporate RT-CGM as a behavior-change tool when compared to standard clinical care in patients with T2D.

Methods: A search was conducted in MEDLINE, Embase, CINAHL, PsycINFO, ClinicalTrials.gov and Cochrane for studies published between January 2000 and August 2019 that incorporate the use of RT-CGM into behavioral interventions for T2D self-management. Articles were included if they: 1) evaluated an unblinded RT-CGM as an behavior-change tool for T2D, and 2) used a randomized control trial design. Two coders independently reviewed abstracts and extracted data, and discrepancies were resolved through discussion.

Results: Initially, 2562 were screened for eligibility. After removing studies not including the use of RT-CGM as a self-management tool nor as a component of a behavioral intervention (n = 368), not using a randomized control trial design (n = 998), and not evaluating patients with T2D (n = 1186), a total of 13 met the inclusion criteria. The intervention protocols of included studies varied by type of guidance patients received while wearing the RT-CGM device. Eight studies provided patient's with a general overview of RT-CGM use prior to the start of the intervention, 4 studies provided moderate instruction and lifestyle education periodically throughout the intervention, and 1 study provided detailed guidance, individualized education, and behavioral counseling throughout the intervention. Patient clinical and behavioral outcomes are also reported. Significant improvements in measured outcomes were observed more often following short-term compared to long-term intervention periods (e.g., 8 weeks vs. 24 weeks).

Conclusion: This review provides evidence to suggest that RT-CGM can be a valuable behavior-change tool for successfully reaching short-term health goals, particularly when coupled with individualized T2D education. This review could guide future research and development of technology-assisted interventions that address patient self-management of T2D.

3:45 PM-4:00 PM

BEHAVIOURAL AND PSYCHOSOCIAL CHARACTERISTICS AMONG ADULTS AT DIFFERENT STAGES OF TYPE 2 DIABETES DIAGNOSIS.

Jillian Ryan, B Psych (Hons), PhD¹, Ian Zajac, PhD¹, Sinead Golly, PhD¹, Bonnie Wiggins, B Psych (Hons), Masters of Marketing¹, David Cox, PhD¹¹Commonwealth Scientific and Industrial Research Organisation, Adelaide, South Australia, Australia

Landmark prevention trials have shown that the onset of Type 2 diabetes can be prevented in at-risk individuals through interventions that address the disease's lifestyle-related determinants. Yet prevalence has tripled in the past three decades and continues to rise, suggesting that community uptake of programs and advice has been limited outside of controlled trials. A possible explanation is that current interventions fail to address the complex range of psychosocial challenges that serve as barriers to adoption of the necessary lifestyle changes in diverse populations. To explore this hypothesis, the current study takes a data-driven approach to identifying key behavioural and psychosocial intervention objectives that may be overlooked in current offerings. Adults (N = 3206) at different stages of diabetes diagnosis (no diagnosis, at-risk, and with type 2 diabetes) completed a comprehensive battery of self-report assessments spanning behavioural (e.g. physical activity, diet, and smoking status), psychosocial (consideration of future consequences, health literacy, and psychological distress) and demographic factors (sex, age, and financial security). The extent to which outcome variables predicted membership to healthy, at-risk, or T2 diabetes subgroups was examined using multinomial logistic regression. The model was statistically significant, $p < .0001$ and explained 27.0% (Nagelkerke R²) of the variance in diabetes status. Of outcomes assessed being male, financially insecure, physically inactive, and favouring immediate over future consequences were the strongest predictors of being at-risk or with Type 2 diabetes. Lower health literacy and financial security were unique characteristics of membership to the Type 2 diabetes diagnosis subgroup, suggesting that these may be an important factor mediating the progression to diabetes. In this paper, differences in behavioural, psychosocial, and demographic profiles between subgroups with different diabetes diagnoses are interrogated, with insights framed to guide the development of effective programs in the future. Such data-driven approaches can inform the development of human-centred prevention programs to more effectively address stubborn public health problems.

PEER COACH DELIVERED STORYTELLING PROGRAM IMPROVED DIABETES MEDICATION ADHERENCE: A CLUSTER RANDOMIZED TRIAL

Susan Andreae, PhD MPH¹, Lynn J. Andreae, MPH², Monika M. Safford, MD³¹University of Wisconsin-Madison, Madison, WI; ²University of Alabama at Birmingham, Birmingham, AL; ³Weill Cornell Medicine, New York, NY

Background: Because good adherence to medications is linked to better patient outcomes in diabetes, there have been numerous interventions to improve medication adherence. However, suboptimal adherence persists, and the modest effects seen in prior programs necessitate continued research into intervention strategies. Storytelling and peer support are promising approaches for improving diabetes self-care. The purpose of this study was to evaluate the effectiveness of an intervention that combined storytelling and peer support to improve medication adherence and health outcomes in individuals with diabetes.

Methods: Living Well with Diabetes was a cluster randomized controlled trial in Alabama adults living with diabetes. Intervention participants received a six-month, peer-delivered telephone program that consisted of education and behavioral strategies to improve medication adherence and other self-care activities. Educational videos integrated personal stories of community members accepting their illness and overcoming barriers to medication-taking, and peer coaches reinforced these messages during telephone sessions. Control participants received a self-paced general health advice program. Outcomes were changes in medication adherence and physiologic measures (hemoglobin A1c, systolic blood pressure, low-density lipoprotein cholesterol, body mass index). Explanatory outcomes were medication beliefs and medication use self-efficacy.

Results: Of the 403 participants with follow-up data, 78% were female, 91% were African American, 56.4% had high school education or less, and 70% had an annual income of < \$20,000. At follow-up, compared to controls, intervention participants had greater improvement in medication adherence ($\beta = -0.25$ [-0.35, -0.15]). Physiologic measures did not change significantly in either group. Intervention participants had significant improvements in beliefs about the necessity of medications ($\beta = 0.87$ [0.27, 1.47]) concerns about the negative effects of medication ($\beta = -0.91$ [-1.35, -0.47]), and beliefs that medications are harmful ($\beta = -0.50$ [-0.89, -0.10]). In addition, medication use self-efficacy significantly improved in intervention participants ($\beta = 1.0$ [0.23, 1.76]).

Discussion: The Living Well program was implemented successfully by peer coaches working with adults with diabetes residing in high-needs communities. The combined strategies of storytelling and peer support resulted in improved medication adherence, medication beliefs, and medication use self-efficacy in adults with diabetes.

BEHAVIORAL AUTOMATICITY MEDIATES THE ASSOCIATION BETWEEN EFFORTFUL CONTROL AND ADOLESCENT TYPE 1 DIABETES MANAGEMENT

Laura B. Cohen, B.A.¹, Tori Humiston, M.S.¹, Hema Y. Prahbu, B.A. in Psychology², Caroline Cummings, MA¹, Natalie E. Benjamin, M.S.³, Amy Hughes Lansing, Ph.D.¹¹University of Nevada, Reno, Reno, NV; ²University of Cincinnati, Cincinnati, OH; ³Marquette University, Milwaukee, WI

Daily management of type 1 diabetes requires frequent treatment-related behaviors that aid in regulating blood glucose levels (Chiang et al., 2018) and adolescents with type 1 diabetes experience significant challenges with following treatment recommendations (Farrell et al., 2004; Helgeson et al., 2010). Behaviors increasing effortful control have been repeatedly associated with improved adherence to treatment regimens and glycemic control (Berg et al., 2014; Lansing et al., 2016; Perez et al., 2016). However, research in adolescent type 1 diabetes management has yet to explore the intersection of habitual behavior and effortful control, despite evidence supporting the importance of behavioral automaticity for healthy living patterns (Galla & Duckworth, 2015) and the role of effortful control in the development of behavioral automaticity (Wood & Neal, 2007). The present study hypothesized that the association of high effortful control with better disease management would be mediated by behavioral automaticity for health behaviors in adolescents with type 1 diabetes. Participants consisted of adolescents diagnosed with type 1 diabetes ($n = 79$, M age = 15.1, 61% Female) who completed a multi-measure survey while attending a diabetes summer camp. Adolescents completed a modified Self-Report Behavioral Automaticity Index for Type 1 Diabetes (adapted from Gardner et al., 2012), the Self-Care Inventory, Revised (Weinger, et al., 2005), and the Effortful Control sub-scale of the Early Adolescent Temperament Questionnaire-Revised (Ellis & Rothbart, 2011). Data were analyzed using regression analysis. Results indicated a significant positive association between effortful control and disease management ($b = .394$, $t(74) = 3.48$, $p = .001$) and effortful control and behavioral automaticity ($b = .839$, $t(77) = 3.41$, $p = .001$). Additionally, a significant positive association was observed between automaticity and disease management ($b = .259$, $t(75) = 6.143$, $p < .001$). Moreover, the relationship between effortful control and disease management was no longer significant when controlling for automaticity ($b = .194$, $t(74) = 1.832$, $p = .071$), which is consistent with behavioral automaticity fully mediating the relationship between effortful control and disease management. These findings demonstrate the importance of targeting both habit formation and self-regulation systems to facilitate type 1 diabetes management and health outcomes in adolescence.

A DEMONSTRATION TO CAPTURE ADHERENCE TO FOOT SELF-CARE IN DIABETES: FINDINGS FROM ONGOING TRIALS TO PREVENT FOOT COMPLICATIONS

Amanda Loesch, B.S.¹, Andrew Nicholson, MSPH², Stephanie Rettig, MPH³, Lena Woo, BA⁴, Sundar Natarajan, MD, MSc⁵

¹NYU Medicine/VA NY Harbor Healthcare System, New York, NY; ²VA NY Harbor Healthcare System, New York City, NY; ³VA New York Harbor Healthcare System, New York, NY; ⁴VA NY Harbor Healthcare System, New York, NY; ⁵NYU School of Medicine, New York, NY

Background: Diabetes increases the risk for lower extremity amputation (LEA), which is preceded by diabetic foot ulceration (DFU) in >80% of cases. Adherence to foot self-care lowers the risk for such complications. Currently, an unbiased measure that accurately captures adherence to foot self-care behaviors does not exist.

Objective: To evaluate the validity of a foot self-care demonstration designed to assess proficiency in basic foot self-care practices using baseline data from primary prevention (diabetic neuropathy, no DFU; n = 406) and secondary prevention (previous DFU; n = 234) trials.

Methods: Participants, through free recall, verbally explained and/or demonstrated 13 routine foot self-care practices. Each item was scored as 0 (not done), 1 (done but not proficient) or 2 (done and proficient), for a score ranging from 0-26. Participants were dichotomized into proficient (P) or non-proficient (NP) groups based on their foot self-care proficiency (indicated by a score > the median). Inter-rater reliability was evaluated using intra-class correlations (ICC), convergent validity examined with the validated foot self-care skills survey, discriminant validity with the EuroQol and exploratory factor analysis (EFA) was performed. P and NP groups were compared using Fisher's exact and Wilcoxon tests.

Results: The mean proficiency score for the combined study sample (n = 640) was 8.38 (SD=3.11) and the median was 8 (range 0-22). The inter-rater reliability was 0.86 (p < .0001). Spearman's correlation with foot self-care skills score was 0.26 (p < .0001) while correlation with EuroQol was -0.01 (p=0.77). EFA indicated three latent factors: 1) foot barrier, 2) inspecting feet and 3) preparatory check, that could potentially correspond to distinct subscales. There was a greater percentage of proficient individuals among participants with a history of DFU as compared to those with no history of DFU (51.28% v 37.78%, p < .0001). Duration of diabetes (years) in P and NP individuals was 17.89 and 15.75 (p=0.0049) respectively. Finally, there was a higher percent of NP individuals living alone (P: 37.3 v NP: 62.7, p=0.04).

Conclusions: Our findings show that the demonstration instrument is valid and avoids self-report bias. This method is ideal for evaluating foot self-care because of the different elements involved. A longer duration of diabetes, previous DFU and not living alone were associated with increased proficiency.

STRESSPROFFEN - AN APP BASED STRESS MANAGEMENT PROGRAM FOR PATIENTS WITH CANCER: SHORT TERM EFFICACY FINDINGS FROM AN RCT

Elin Børøsund, PhD¹, Cecilie Varsi, PhD², Shawna S. Ehlers, PhD, LP, ABPP³, Matthew M. Clark, PhD, LP, ABPP³, Michael A. Andrykowski, PhD⁴, Lise Solberg Nes, Prof. LP PhD²

¹Center for Shared Decision Making and Collaborative Care Research, Oslo University Hospital, OSLO, Oslo, Norway; ²Center for Shared Decision Making and Collaborative Care Research, Oslo University Hospital, Oslo, Oslo, Norway; ³Mayo Clinic, Rochester, MN; ⁴University of Kentucky, Lexington, KY

Background: Many cancer patients will experience distress. A number of in-person psychosocial stress management interventions exist for cancer patients, but these types of interventions are not always available options during active medical treatment, or for patients that reside far away from a cancer center. A multi-disciplinary research team has designed and developed *StressProffen*, an app-based cognitive behavioral stress management intervention for patients with cancer, and *StressProffen* has been pilot-tested by cancer survivors.

Aim: To examine short term effects of using *StressProffen* (compared with usual care), in a randomized controlled trial (RCT) for patients diagnosed with cancer.

Method: In an RCT, 135 cancer patients were followed for 3 months. Participants were randomized to either: 1) The *StressProffen* intervention (n=66), or 2) a control group (n=69) receiving usual care. The *StressProffen* app-based program contained a face-to-face introduction session and ten app-based modules with stress management strategies including educational information and a variety of exercises (e.g., diaphragmatic breathing and meditation). Participants received follow-up phone calls after 3 and 6 weeks. Outcome measures were completed at baseline and at 3-months post intervention start, and included The Perceived Stress Scale (stress), the Hospital Anxiety and Depression Scale (anxiety and depression), and SF-36 (Health Related Quality of Life; HRQoL).

Results: Participants were mainly women (82%), age range 20-78 years old (mean 51.8) and represented a wide variety of cancer diagnoses, but with a majority breast cancer (49%). Simple t-test change scores showed that compared with the control group, the *StressProffen* intervention group had significant decrease in stress (p = .022; mean diff (MD) -3.0; 95% Confidence Interval (CI) -5.6 to -0.4). There was also an increase in HRQoL for the *StressProffen* intervention group for most sub-factors, and significantly so for Role-Physical (p = .039; MD: 15.6; CI: 0.8 to 30.7), Social Functioning (p = .035; MD: 8.9; CI: 0.6 to 17.2), Role-Emotional (p = .049; MD 16.7; CI: 0.1 to 33.7), and Mental Health (p = .009; MD: 7.1; CI: 1.8 to 12.4). There were no significant changes in anxiety or depression at the 3 month assessment.

Conclusion: This study demonstrates that an app-based cognitive behavioral stress management intervention can contribute to decreased stress and improved well-being for patients diagnosed with cancer.

3:45 PM-4:00 PM

MODELS OF TRAUMA, DEPRESSION AND SUICIDALITY IN
A SAFETY NET PRIMARY CARE SAMPLESamantha N. Mladen, M.S.¹, Allison Baylor Williams, M.S.¹, Sarah C. Griffin, MS, BASc², Paul B. Perrin, PhD¹, Bruce Rybarczyk, PhD¹¹Virginia Commonwealth University, Richmond, VA; ²Virginia Commonwealth University, Carrboro, NC

Background: Primary care is a vital component of the American healthcare system, particularly for patients with limited resources. However, there is little research on the interplay of trauma exposure, depression, and suicidality, particularly in high-risk primary care samples. The present study aimed to: 1) characterize the prevalence and nature of suicidality, depression, and trauma exposure in this sample; and 2) develop and test models of the relationships among suicidality, depression, and trauma exposure.

Methods: Patients ($n=207$) in a safety-net primary care clinic completed the Patient Health Questionnaire-9 (PHQ-9), Adverse Childhood Experiences Study (ACES) questionnaire, and Brief Trauma Questionnaire (BTQ). Participants (age $M=44.75$, $SD=11.62$), were 60% male, predominantly Black/African American (64%; 27% White/European-American, 9% Other), and overwhelmingly with low resources (69% reported an annual income $< \$5,000$, 98% an annual income $< \$30,000$).

Results: Half of patients reported at least four traumatic events ($m=3.86$ events; $SD=3.01$) childhood traumatic events and approximately 3 ($SD=2.09$) adult traumatic events. A majority of the sample (82.13%) reported clinically significant levels of depression and 43.5% endorsed suicidality. Trauma exposure exacerbated the relationship between depression and suicidality ($B = .01$, $\Delta R^2 = .02$, $p = .008$). Depression partially mediated the relationship between trauma exposure and suicidality (.04, 95% CI: [.02, .06]).

Discussion: These results call attention to the high prevalence of trauma exposure, depression, and suicidality in a high-risk primary care sample. They reveal a complex interplay between trauma, depression, and suicidality, whereby trauma exposure strengthens the link between depression and suicidality and depression partially mediates the relationship between trauma exposure and suicidality. These findings highlight the pervasiveness and complexity of suicidality in low-income primary care patients, underscore the importance of nuanced suicide assessment, and identify trauma and depression as potential treatment targets to reduce suicidality.

Paper Session 16

4:00 PM-4:15 PM

ASSESSING THE MENTAL HEALTH IMPACT OF 13 REASONS WHY:
A NARRATIVE LITERATURE REVIEWBeth L. Hoffman, MPH¹, Jessica G. Burke, PhD¹, Riley B. Wolynn, n/a¹, Brian A. Primack, MD, PhD², Jane M. Liebschutz, MD, MPH, FACP¹, Jaime E. Sidani, PhD, MPH, CHES¹, Sansea L. Jacobson, MD¹, Elizabeth Miller, M.D., Ph.D.³¹University of Pittsburgh, Pittsburgh, PA; ²University of Arkansas, Fayetteville, AR; ³Children's hospital of Pittsburgh, Pittsburgh, PA

Introduction: In 2017, Netflix released Season 1 of *13 Reasons Why*, a controversial series focused on the suicide of its teenage protagonist. Given concerns about the risk for suicide contagion because of the show's graphic depiction of suicide, multiple researchers have sought to determine if there were associations between the release of the program and various mental health-related outcomes such as youth negative affect and suicide rates. However, there has yet to be a systematic and comprehensive synthesis of this literature. This review aims to fill that gap.

Methods: We conducted literature searches in Medline, Ovid PsychINFO, and EbscoHost Communications & Mass Media Complete in August 2019. Reference lists of articles found through database searches were searched to identify additional relevant articles. Selected studies had to be related to *13 Reasons Why* and examine quantitative or qualitative data to assess a mental health-related outcome. Studies were classified according to (1) participant factors, (2) study design, and (3) outcomes assessed.

Results: Fourteen articles met selection criteria. Eleven (79%) assessed outcomes primarily in youth and/or young adults. Two used time series analyses to assess any changes in suicide rates among youth aged 10–17 and 10–19 after the release. Five (36%) examined the association between the release and other trends, such as hospital admission rates for self-harm/suicidal ideation and Google searches for suicide-related terms. Six (43%) used surveys to investigate the association between viewing patterns and outcomes; of these studies, five were cross-sectional and one was longitudinal. Findings from these studies demonstrated that, compared to the general population, youth and young adults with a history of depression or suicidal ideation were more likely to view the program alone and report that watching it worsened their mood and/or increased their risk of suicide.

Conclusion: Current research suggests an association between exposure to the program and increases in youth suicide and suicidal behavior. This research also raises concerns that high-risk youth may be particularly susceptible. Given that the program remains popular, with the official Season 3 trailer having been viewed 8.6 million times by its August 2019 release date, continued research is needed to explore its effects on youth further.

PEER SUPPORT BY TELEPHONE FOR HIGH RISK GROUPS AS A STRATEGY FOR SCALE-UP AND DISSEMINATION: GENERAL EVALUATION & LESSONS LEARNED

Megan S. Evans, MS¹, Edwin B. Fisher, PhD², Patrick Y. Tang, MPH³, Nivedita L. Bhushan, PhD, MA⁴, Dawn Dreyer Valovcin, MHSA⁵, Cherie Castellano, M.A. LPC⁶

¹University of North Carolina-Chapel Hill, Durham, NC; ²Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC; ³Peers for Progress, DURHAM, NC; ⁴University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁵Rutgers University, Piscataway, NJ; ⁶Rutgers University Behavioral Healthcare, Roseland, NJ

Peer support is associated with a variety of physical and mental health benefits. Beyond demonstrations of effectiveness, however, research is needed to identify ways in which peer support can be implemented in real world settings. One promising approach is through telephone peer support. Telephonic peer support services provided by Rutgers Health University Behavioral Health Care were evaluated. This organization serves a variety of high-risk groups including veterans, police, mothers of children with special needs, and child protection workers. The Reciprocal Peer Support Model—emphasizing four tasks: Connection & Pure Presence, Information Gathering & Risk Assessment, Case Management & Goal Setting, and Resilience Affirmation & Praise—guides the services provided. Evaluation included contact data from the years 2015-2016, interviews with peer supporters and callers of the programs, and selected case notes documenting interactions.

Over these two years, peer supporters made 64,786 contacts with 5,616 callers. The length of peer support relationships were determined by individual needs, with 22% lasting one month or less and 43% extending over one year. Callers reached out for various reasons, with 92% of cases reviewed receiving help with a psychosocial issue (i.e. interpersonal, mental health, workplace, traumatic incident) and an additional 62% receiving assistance with a basic needs issue (i.e. medical, housing, legal). Fifty-three percent received at least one referral. Voicemails accounted for 51% of contacts and were delivered in a way that emphasized the connection made and continued concern for the caller, thus representing substantive contact and not simply attempts to schedule it.

A variety of peer support benefits were identified, including accessing needed services, stress relief, normalization of clients' experiences, and reduced feelings of isolation. Clients also reported progress in a range of areas such as attending counseling, obtaining medical insurance for a child, and taking time off as a way to prevent job burnout. Diversity is a striking theme of these findings – diversity of caller needs, patterns of contact, types of support, and types of benefits. This diversity shows the flexibility of these services. Standing behind this flexibility, however, are standardized guidelines based on the Reciprocal Peer Support model as well as a robust IT platform that supports documentation and sharing among staff, creating continuity of 24/7 support.

ARE VIRTUAL STRESSORS A REALITY?

Anna M. Strahm, MS¹, Heidi A. Rued, M.S. Psychology², Clayton J. Hilmert, Ph.D.²

¹North Dakota State University, West Fargo, ND; ²North Dakota State University, Fargo, ND

Virtual reality affords new opportunities for eliciting psychophysiological stress responses in controlled environments. In the present study we compared the effects of a traditional Trier Social Stress Task (TSST; Kirschbaum, et al., 1993), with two versions of a virtual-TSST developed by our lab. Participants performed a five-minute speech and five minutes of oral arithmetic in one of three confederate audience conditions: (1) 2-confederates in-lab, (2) 2-virtual confederates, and (3) 200-virtual confederates. Virtual confederates were pre-recorded using a Vuze 4K 3D 360° Spherical VR Camera. Virtual audiences were presented to participants with an Oculus Rift headset. All confederates provided scripted non-positive feedback to enhance perceptions of evaluative threat in each condition. We measured psychological responses using the Stress and Arousal Checklist, in addition to physiological reactivity including salivary cortisol, systolic blood pressure (SBP) and diastolic blood pressure (DBP). A one-way ANOVA revealed that participant responses on the stress subscale of the Stress and Arousal Checklist did not differ between conditions ($p > .05$). However, there was a difference in reports of arousal ($p < .05$). Post-hoc Tukey LSD comparison revealed that participants in the 2-virtual confederates condition had lower arousal scores than those in the 200-virtual confederates condition. Mixed-model analyses were used to examine within subject physiological responses and compare them between the three conditions. There was a main effect of time on SBP and DBP such that values during the speech and math tasks, and the first recovery period were significantly higher than during baseline ($ps < .01$). Also, there was a main effect of time on cortisol such that values at 10 minutes post task were significantly higher than baseline ($p < .05$). There were no differences between conditions for physiological responses at any point ($p > .05$). These results suggest that the virtual-TSST protocols developed by our lab elicit psychophysiological stress responses similar to those elicited by the traditional, in-person, TSST. Use of virtual reality in the development of further stressor tasks may create more ecologically valid tasks for the participants recruited, as well as the benefit of being portable technology which can be used in situations where access to lab space may not be available.

3:30 PM-3:45 PM

RELATIONSHIPS BETWEEN PTSD SYMPTOMS AND DISINHIBITED EATING AND WEIGHT-RELATED CONCERNS: THE ROLE OF EXPERIENTIAL AVOIDANCE

Jennalee S. Wooldridge, PhD¹, Cara Dochat, M.S.², Niloofar Afari, PhD³, Herbert Matthew, PhD⁴¹University of California San Diego/VA San Diego, San Diego, CA; ²San Diego State University/University of California San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; ³VA Center of Excellence for Stress and Mental Health and Department of Psychiatry UC San Diego, San Diego, CA; ⁴VA San Diego Healthcare System, San Diego, CA

Disinhibited eating and post-traumatic stress-disorder (PTSD) commonly co-occur. Avoidance, a key feature of PTSD, is one potential mechanism that may explain this relationship. However, little is known about mechanisms relating PTSD and disinhibited eating, and much less has been examined in men relative to women. Avoidance, which is a key feature of PTSD and related to lower quality of life and greater psychopathology generally, is one candidate mechanism. Thus, the purpose of the current analysis was to: 1) examine the associations among PTSD symptoms and measures of disinhibited eating and weight-related concerns, including obesity-related quality of life and weight-related stigma, in a primarily male sample of veterans with overweight or obesity; and 2) determine whether experiential avoidance, a tendency to avoid unpleasant thoughts, feelings, and physical sensations, even when maladaptive, helps explain the relationship among PTSD symptoms and disinhibited eating and weight-related concerns. Participants were 89 veterans (76% male) with overweight or obesity enrolling in an intervention study to address eating and weight concerns. On average, participants were 57.2 years old ($SD = 10.0$) with a BMI of 37.4 ($SD = 7.3$). Bivariate correlations were used to examine relationships among PTSD symptoms (PTSD Checklist-Civilian; PCL-C), disinhibited eating symptoms (Binge Eating Severity Scale; BES), obesity-related quality of life (Obesity-Related Well-Being Questionnaire; ORWELL), weight-related stigma (Weight Self-Stigma Questionnaire; WSSQ), and experiential avoidance (Acceptance and Action Questionnaire II; AAQ-II). Separate linear regressions were used to examine relationships between PTSD symptoms with disinhibited eating symptoms, obesity-related quality of life, and weight-related stigma, respectively. Scores on the PCL-C, BES, ORWELL, WSSQ, and AAQ-II were all significantly correlated (p 's: $< .001 - .01$). Linear regression analyses indicated that higher PCL-C scores were related to higher scores on the BES, ORWELL, and WSSQ after controlling for confounding variables including BMI and ethnicity. Effect sizes were in the small-medium (WSSQ) and medium-large (BES, ORWELL) ranges. Further, AAQ-II fully mediated both the relationship between PCL-C and ORWELL ($B = .48$, $SE = .19$, 95% CI: .05, .82), and WSSQ ($B = .28$, $SE = .05$, 95% CI: .19, .38), but did not mediate the relationship between PCL-C and BES. In this sample, PTSD symptoms were associated with greater disinhibited eating symptoms, poorer obesity-related quality of life, and greater weight-related stigma. These findings suggest experiential avoidance should be considered in future interventions addressing PTSD and disinhibited eating and weight concerns in men and women. Longitudinal research is needed to better understand these relationships over time.

Paper Session 17

3:45 PM-4:00 PM

ASSOCIATION BETWEEN DECLINING INPATIENT PSYCHIATRY BEDS AND RISK FOR SUICIDE AMONG VETERANS

Ranak B. Trivedi, PhD¹, Bjarni Haraldsson, MS, BA², Joseph Simonetti, MD, MPH³, Peter J. Kaboli, MD, MS⁴¹Stanford/VA Palo Alto, Menlo Park, CA; ²VA, Iowa City, IA; ³Veterans Health Administration, denver, CO; ⁴Iowa City VAMC and University of Iowa, Iowa City, IA

Background: Suicide rates among Veterans have increased despite investment in mental health services in the Veterans Health Administration (VHA). We sought to examine the extent to which veteran-level characteristics, inpatient psychiatric beds, and community spending is associated with risk of death by suicide.

Methods: Veterans seen at a VHA primary care clinic between 1/1/2003 and 12/31/2016 were included. Patient data from the VA Corporate Data Warehouse were merged with cause of death data from the National Death Index Suicide registry. Other data sources were: the VHA Support Service Center (total VHA inpatient psychiatric beds and occupancy rates), Area Health Resources Files (civilian inpatient psychiatric beds and occupancy rates), and State Mental Health Agency (county-level data on mental health spending). Veteran-level analysis modeled the outcome as a binary suicide yes/no with a logit link. Relationships between veteran characteristics and suicide were tested using logistic regression. Facility-level analyses were conducted using a GLMM with a random intercept for parent station, and modeled the number of suicides per quarter with a Poisson distribution and log-link. Bed availability was categorized into quintiles, from lowest occupancy (highest availability) to highest occupancy (lowest availability).

Results: Of the 10,119,845 Veterans identified, 26,105 died by suicide during the study period. Compared to veterans aged 18-34 y, those aged 35-44, 45-54, and 55-64 y had increased odds of suicide ($OR = 1.14, 1.45, 1.25$, respectively), while veterans 65-74 had decreased odds of suicide ($OR = .76$). Higher odds of suicide were seen in male compared to female veterans ($OR = 2.9$), unmarried compared to married veterans ($OR = 1.84$), and veterans living in rural compared to urban areas ($OR = 1.2$). Black Veterans had lower odds of suicide ($OR = 0.26$) compared to Whites. Veterans diagnosed with bipolar disorder, major depressive disorder, schizophrenia, PTSD, and substance use disorder had 1.69, 1.50, 1.43, 1.63, and 1.44-times greater odds of suicide, respectively, compared to veterans without those diagnoses. Lower rates of suicide were observed for each additional 25 psychiatric beds/100,000 population ($RR = 0.87$) and each additional \$50 spent on mental health per capita ($RR = 0.97$). Rural VHA hospitals had greater relative risk of suicides than urban hospitals ($RR = 1.09$). Compared to VHAs in the lowest quintile of occupancy, those in the highest quintile had a 1.14 greater risk of suicide. OR s and RR s are significant at $\alpha = 0.05$.

Conclusions: Our novel findings are that lack of mental health bed availability is associated with a higher risk of suicide while greater community mental health investment is protective. Future work should clarify optimal levels of bed availability and mental health spending to increase the efficiency of allocating resources in the VHA and the community.

A MATTER OF LIFE AND DEATH AFTER WAR: HOW THE VA CAN HELP PREVENT VETERAN SUICIDES

Regina Villazor, n/a¹, Carlos Vincent Chua, n/a²¹Fors Marsh Group, Arlington, VA; ²Asian Development Bank, Mandaluyong, National Capital Region, Philippines

While suicide is a complex phenomenon that widely affects individuals from all walks of life, veterans are a particularly vulnerable population due to veteran-specific risks. These risks are the frequency, length, and danger of deployments; exposure to extreme stress; physical/sexual assault while in the service; and service-related injury.

To date, veteran-specific risks are inextricable occupational hazards, so the U.S. Department of Veterans Affairs (VA) is in a unique position to aid veterans in suicide prevention. The VA has different programs that aim to address veteran mental health issues, varying across states. While an evaluation of specific programs are usually conducted to justify spending, it will be informative to study the broad effects of public health expenditure from a macro-perspective.

This paper asks: will scaling resources help the VA reduce veteran suicides? If so, what is the optimal spending level? If not, what are the alternative policy actions that can address this issue? Through a panel estimation, this paper studies the relationship between veteran suicide by firearms and total VA expenditures and VA health expenditures, separately. Along with controls for socioeconomic characteristics of the veteran population, regional heterogeneity is accounted for through temporal interactions between 2005 and 2016.

This paper finds that there is no statistically significant relationship between expenditures and veteran suicides. Simply increasing funding at this point may be inefficient and ineffective in preventing veteran suicides. Alternatively, the paper finds that increases in veterans' VA healthcare utilization, income, and educational attainment reduce the rate of veteran suicides. For a percentage point increase in VA healthcare utilization, the rate of suicide by firearms decreases by 0.06 percentage points.

As a robustness check, the paper finds no potential policy endogeneity; thus the significant negative relationship between VA healthcare utilization and veteran suicides indicate that improving utilization rates can potentially prevent more suicides. This can be done through more active outreach and communication of available VA programs to veterans. However, it is important to note that, while statistically significant, the effect of utilization is still quite small. It would be imperative to examine the effectiveness of each program through evaluations, which will help the VA apply best practices to prevent veteran suicides.

The findings suggest that reducing veteran suicides will require more than just increased funding. There is already a promising mechanism in place for suicide prevention - what matters now is how the VA can fully harness this mechanism.

Paper Session 17

4:15 PM-4:30 PM

ROLE OF SLEEP APNEA IN THE RELATIONSHIP BETWEEN PTSD AND ADVERSE CARDIOVASCULAR EVENTS IN A NATIONAL VETERANS AFFAIRS SAMPLE

Lizabeth Goldstein, PhD¹, Shira Maguen, PhD², Daniel Bertenthal, MPH³, Beth Cohen, MD⁴, Ali El-Solh, MD, MPH⁵, Thomas C. Neylan, MD⁴¹San Francisco VA Healthcare System, San Francisco, CA; ²UCSF and SFVAMC, San Francisco, CA; ³San Francisco VA Health Care System, San Francisco, CA; ⁴University of California, San Francisco, San Francisco, CA; ⁵VA Western New York, BUFFALO, NY

The prevalence rate of posttraumatic stress disorder (PTSD) among veterans is estimated to be up to 20%. Previous research has shown that PTSD is associated with increased risk of several negative health outcomes, including adverse cardiovascular events. Obstructive sleep apnea (OSA) is more prevalent among Veterans with PTSD compared to the general US population; two recent studies found that among Veterans seeking PTSD treatment in Veterans Health Administration (VHA) PTSD clinics, 70-73% screened high likelihood for OSA. OSA itself is associated with numerous medical conditions, including hypertension, coronary artery disease, heart failure, and stroke. We sought to evaluate the extent to which sleep apnea may account for the relationship observed between mental health (MH) disorders, particularly PTSD, and negative cardiovascular outcomes. Using national VHA databases, we extracted data for Veterans seen at least twice over a 10-year period in VHA. Veterans were categorized by mental health status (PTSD, MH diagnosis other than PTSD, or no MH diagnosis), sleep apnea status (OSA or not), and incidence of adverse cardiac event. The sample consisted of 5.6 million Veterans, with average age of 61-years-old ($SD = 14$), and was 91% male and 78% Caucasian. Nineteen percent of the sample had a PTSD diagnosis, and 25 percent had another mental health diagnosis. Eighteen percent of the sample had an OSA diagnosis. After adjustment for age, compared with Veterans without MH or OSA diagnosis, Veterans with PTSD and OSA were much more likely to experience an adverse cardiovascular event over the studied decade (adjusted RR, 2.59; 95% CI, 2.58-2.61). This risk exceeded that of a PTSD diagnosis alone (adjusted RR, 1.63; 95% CI, 1.62-1.64) or OSA diagnosis alone (adjusted RR, 1.96; 95% CI 1.95-1.97). A similar pattern was observed for MH disorders other than PTSD and OSA: among those with both a MH diagnosis and OSA, the adjusted RR was 2.86 (95% CI, 2.84-2.87), and among those with a MH diagnosis alone, the adjusted RR was 1.74 (95% CI, 1.73-1.74). Results accounted for the interactions between sleep apnea and both other MH diagnosis and PTSD. In sum, the combination of OSA and MH diagnosis (PTSD or other) confers a substantial risk for adverse cardiovascular events. More detailed findings with results broken out by specific adverse cardiac outcome (identified by ICD-10 diagnosis codes) will be presented. We will review implications of this work and suggest next steps to improve the detection and treatment of OSA among veterans with PTSD and other MH disorders.

Paper Session 17

4:30 PM-4:45 PM

EFFECTS OF SOCIAL NETWORK CHARACTERISTICS ON MENTAL HEALTH OUTCOMES AMONG ARMY RESERVE AND NATIONAL GUARD SOLDIERS

Erin M. Anderson Goodell, PhD, ScM¹, D. Lynn Homish, M.S.², Gregory Homish, Ph.D.²¹Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ²University at Buffalo, The State University of New York, Buffalo, NY

Background: Previous civilian research has demonstrated that the social environment can affect one's own mental health through protective factors like greater closeness to peers as well as risk factors like exposure to peers' own depressive or self-injurious behaviors. Recent military work has examined the effects of peers on soldiers' substance use, but the literature is limited in its discussion of social-ecological risk and protective factors for soldier mental health outcomes. To address this gap, the current study examines associations between social network characteristics and current severity of soldiers' mental health symptoms.

Methods: Data are from Operation: SAFETY (Soldiers And Families Excelling Through the Years), a study of health of Army Reserve and National Guard (R/NG) soldiers and their partners. Analyses were based on 441 R/NG soldiers and 2,637 social ties. Outcomes of interest were generalized anxiety severity, overall and cluster-specific PTSD severity, and depression severity. Social network characteristics included closeness to ties, time spent with ties, ties' substance use, and ties' military involvement. Negative binomial regression models were used to examine relationships between social network characteristics and each soldier mental health outcome.

Findings: Greater numbers of illicit drug-using ties in the social network were associated with greater severity of anxiety as well as PTSD symptoms related to avoidance and hyperarousal. Regarding social ties' military service, greater numbers of ties who were in a soldier's unit were associated with decreased depression symptom severity. For ever-deployed soldiers, greater numbers of military ties were associated with risk for greater anxiety severity, avoidance-related PTSD symptoms, and depression severity, while greater numbers of unit member ties were protective of all three outcomes.

Conclusions: Social tie illicit drug use was associated with severity of multiple anxiety-related mental health outcomes, which may indicate soldiers' self-medication through use with social networks. Unit members appeared to serve protective roles against soldiers' negative mental health outcomes, reflecting the fact that unit members may better understand the specific military experience of the soldier and serve as a resource of support. Findings contribute to the understanding of social-ecological risk and protective factors that influence mental health outcomes in the military.

FAMILIAS SALUDABLES - A FAMILY-BASED APPROACH TO CHILDHOOD OBESITY PREVENTION: LESSONS FROM THE FIELD

Mara Bird, PhD¹, Diana Aguirre, MPH, CHES², Olga Korosteleva, Ph. D.³, Elisa Nicholas, MD, MSPH⁴, Melawhy L. Garcia, MPH, PhD⁵

¹Center for Latino Community Health, Evaluation and Leadership Training, Long Beach, CA; ²CSULB Center for Latino Community Health, Evaluation, Long Beach, CA; ³California State University, Long Beach, Long Beach, CA; ⁴The Children's Clinic, Serving Children & Their Families, Long Beach, CA; ⁵California State University Long Beach, Long Beach, CA

Background: Endemic to the current US population, obesity disparately affects Hispanic children and their families, especially children of middle income families whose parents have low levels of educational attainment. A family-based approach allows parents and their children to learn together to develop sustainable behaviors for a healthy life.

Methods: The study uses a randomized control design (2 group) with 5 repeated measurement points (pre, post, 3, 6, and 9-month). Survey data is self-report using bilingual paper instruments. Participants also provide anthropometric measures (e.g. height, weight, BMI) using portable Tanita SC portable bioimpedance scales and stadiometers. Various methods of recruitment are being tested: calling patients identified via Electronic Health Record diagnoses, direct physician referral, and public recruitment (in-person, flyers, and inter-agency sharing). Settings for the conditions include: clinics, health department, library, park-based community centers and churches. The 7-session intervention is based on three evidence-based interventions: KidShape 2.0, SPARK K-2 and 3-5 grade physical activity curriculum, and Sanos y Fuertes: Healthy and Strong. Intervention sessions are implemented in 2-hour segments once or twice per week by bilingual trained staff.

Results: A total of 69 child-parent dyads have enrolled in the intervention and 56 child-parent dyads in the control condition. Preliminary results show BMI percentile maintenance or improvement for the intervention, and maintenance or worsening for the control. There are significant reductions in sedentary time and increases in activity for children in the intervention. There are no statistically significant differences for fruit, vegetable, simple carbohydrate nor sugar-sweetened beverage consumption, or in time spent active as a family.

Discussion: Multifactorial reasons for rates of participation and attrition will be discussed overall and by sites and by group size. Finally suggested best practices will be presented to guide similar research.

Paper Session 18

3:45 PM-4:00 PM

MEAL PLANNING AS AN IMPORTANT BEHAVIOR CHANGE STRATEGY FOR DIETARY INTAKE AND OBESITY AMONG FAMILIES OF SCHOOL-AGE CHILDREN

Jayne A. Fulkerson, PhD¹, Melissa L. Horning, PhD, RN, PHN¹, Jennifer A. Linde, PhD¹, Sarah Friend, MPH, RD¹¹University of Minnesota, Minneapolis, MN

Purpose: Meal planning is thought to contribute to dietary quality and weight management. However, meal planning is often measured retrospectively (e.g., survey of typical week) and little is known about whether the proportion of meals planned in advance is associated with demographic, household, and mealtime characteristics or dietary intake and weight among families with school-age children. The present study aimed to assess these relationships using real-time measurements of whether meals were planned in advance to inform behavior change intervention research.

Methods: The present study analyzed NU-HOME 2017/2018 baseline data (n=105 families). Ecological momentary assessment surveys were randomly sent to parents on seven evenings over two-weeks to assess if the evening meal was made at home and if it was planned in advance. The proportion of meals planned in advance was calculated across the two-weeks using a cut-point of $\leq 50\%$ vs. $> 50\%$. Parent psychosocial surveys assessed demographic, household and mealtime characteristics and parent fruit/vegetable (FV) intake. Research staff conducted dietary recall interviews to assess child FV intake and measured child and parent height and weight (body mass index (BMI)). Chi-square/Fisher's exact/T-tests were used to examine associations of the proportion of meals planned in advance with parent and child outcomes.

Results: Compared to those planning $\leq 50\%$ of meals in advance, those planning $> 50\%$ were significantly more likely to be food secure, college educated and have higher mean scores for child's food fussiness, family meal routines, self-efficacy for preparing healthful meals and lower mean family chaos scores (p 's < 0.05). Those planning $> 50\%$ meals in advance reported significantly greater frequency of their child's plate half filled with FV and have higher mean parent daily FV intake (p 's < 0.05) than those who planned $\leq 50\%$ of meals in advance. No associations were found between the proportion of meals planned in advance and the number of children in the household, parent age, job status, work schedules, child cooking skills, child FV intake or parent/child BMI/BMI z-scores.

Conclusions: Findings suggest behavior change programs intending to assist parents with meal planning may promote healthful dietary intake but may need special focus on augmenting mealtime routines and self-efficacy while addressing food insecurity and family chaos.

PATTERNS OF EATING DISORDER PATHOLOGY AND PSYCHOPATHOLOGY IN RELATION TO WEIGHT AMONG CHILDREN IN FAMILY-BASED TREATMENT

Anne Claire Grammer, BA¹, John R. Best, PhD², Lauren A. Fowler, PhD³, Katherine N. Balantekin, PhD, RD⁴, Richard I. Stein, PhD⁵, Rachel Conlon, PhD⁶, Brian Saelens, PhD⁷, Robinson Welch, PhD⁸, Michael Perri, PhD⁹, Leonard Epstein, PhD⁴, Denise E. Wilfley, PhD³

¹Washington University in St. Louis, St. Louis, MO; ²University of British Columbia, Vancouver, BC, Canada; ³Washington University in St. Louis, St. Louis, MO; ⁴University at Buffalo, Buffalo, NY; ⁵Washington University School of Medicine, Saint, MO; ⁶University of Pittsburgh School of Medicine, Pittsburgh, PA; ⁷University of Washington / Seattle Children's Research Institute, Seattle, WA; ⁸Washington University in St. Louis, Clayton, MO; ⁹University of Florida, College of Public Health and Health Professions, Gainesville, FL

Background: Eating disorder (ED) attitudes and behavior and general psychopathology are commonly reported among children with overweight/obesity (OW/OB), yet few studies have examined their compounded impact on weight change during treatment. The current study characterized patterns of ED attitudes and behavior and general psychopathology in children with OW/OB and examined their impact on weight change following family-based obesity treatment (FBT).

Method: Children (n=172) with OW/OB participated in 4 months of FBT. Child-reported ED attitudes (i.e., shape concern, weight concern), ED behavior (i.e., loss of control [LOC] eating), general psychopathology (i.e., anxiety, depression), and child percent overweight (%OW) were assessed at baseline and month 4. Finite normal mixture modelling identified latent classes of ED attitudes/behaviors and general psychopathology at baseline. Multiple linear regression examined whether class membership correlated with changes in %OW from baseline to month 4, controlling for child age, sex, race, ethnicity, baseline %OW, and family socioeconomic status.

Results: Results supported a three-class structure: high general psychopathology and ED attitudes only (HIGH) [i.e., high shape and weight concerns, high anxiety and depression, low LOC, n=70]; high general psychopathology plus high ED attitudes and behaviors (HIGH+LOC) [i.e., high shape and weight concerns, high anxiety and depression, high LOC, n=59]; and low general psychopathology and ED attitudes and behaviors (LOW) [i.e., low shape and weight concerns, low anxiety and depression, low LOC, n=43]. All groups demonstrated clinically significant weight loss (defined as greater than a 9-unit change in %OW) from baseline to month 4, but there were group differences in change in %OW during FBT, such that the HIGH+LOC group demonstrated significantly less weight change from baseline to 4 months (-12.2, SE=1.0) compared to the LOW group (-16.1, SE=1.2, $p=.04$). No other significant group differences were observed.

Conclusions: FBT was robust to these forms of pathology, as across groups, children demonstrated clinically significant change in %OW following FBT. The magnitude of clinically significant weight change, however, may vary depending on patterns of pathology. Future research is needed to develop tailored treatment strategies to address the needs of children with concurrent ED attitudes and behaviors and general psychopathology.

Paper Session 18

4:15 PM-4:30 PM

STUDY DESIGNS INFLUENCE CONCLUSION FOR MEDIATED EFFECTS OF FOOD INSECURITY ON WEIGHT-RELATED PARENTING PRACTICES AND CHILD BMI

Eleanor T. Shonkoff, PhD¹, Tyler B. Mason, PhD², Genevieve F. Dunton, PhD, MPH², Christine H. Naya, MPH³¹Merrimack College, North Andover, MA; ²University of Southern California, Los Angeles, CA; ³University of Southern California, Pasadena, CA

Background: Paradoxically, children may be at higher risk for obesity when families experience food insecurity. One mechanism that could explain the link is use of controlling parental feeding practices (e.g., restriction, pressure to eat, demandingness). However, studies have found mixed results, possibly due to study design: using cross-sectional data to test mediational models. This study compares cross-sectional versus longitudinal models testing maternal concern for child weight and two feeding practices (restriction, pressure to eat) as mediators of the association between food insecurity and child body mass index (BMI).

Methods: Data came from a longitudinal study of mother-child pairs from southern California (n=202) with follow-up data collection every 6 months across 3 years. Children were M=10.12 (range 8-12) years at baseline, 67% Hispanic, and 51% female; mothers were M=41.24 years, and 59% had a college education or higher. Variables used were: household food insecurity (Six-item Short Form Food Security Survey Module - modified); parental food restriction, pressure to eat, and concern with child weight (Child Feeding Questionnaire); and child BMI (stadiometer & scale). Cross-sectional and longitudinal (i.e., baseline, 12 months, and 30 months) mediational models with multiple imputation were conducted in MPlus, controlling for child age and gender.

Results: Greater parental concern with child weight mediated the association between greater food insecurity and higher child BMI in cross-sectional models (indirect effect=.115, $p < .01$) but not longitudinal models (indirect effect=.000, $p = .960$). Higher food insecurity and greater restriction and greater pressure to eat were independently associated with child BMI in cross-sectional models (Brestriction=.23, $p < .01$, Bfood insecurity=.20, $p < .01$; Bpressure=-.39, $p < .01$, Bfood insecurity=.24, $p < .01$), but parental feeding practices were not significant mediators in cross-sectional or longitudinal models.

Conclusion: Cross-sectional models indicated that the link between food insecurity and higher child BMI is mediated by higher parental concern for child weight, and that parental restriction and pressure to eat are associated with child BMI. However, longitudinal models did not indicate significant associations or mediation. Mixed findings from previous research may be due to cross-sectional statistical mediational models rather than effects of substantive differences in parenting over time.

Paper Session 18

4:30 PM-4:45 PM

INVESTIGATING THE RELATIONSHIP BETWEEN PARENTAL WEIGHT STIGMA AND PARENTAL FEEDING PRACTICES

Joshua M. Gold, PhD, MPH¹¹University of Washington / Fred Hutchinson Cancer Research Center, Seattle, WA

Background: Past research has demonstrated a link between weight stigma (i.e., prejudicial attitudes or discriminatory behavior targeted at individuals who carry excess weight) and an individual's own weight-related behaviors and outcomes, but no study has examined how parental levels of weight stigma may affect weight-related parenting practices. The primary objective of this study was to examine the cross-sectional associations between parental levels of weight-based stigmatization and weight-related feeding practices.

Methods: A national sample of participants (N = 406) were recruited through Amazon's M-Turk crowdsourcing marketplace who had at least one child aged 5-10 and perceived themselves to be overweight or obese. Parental weight stigma was assessed using the Stigmatizing Situations Inventory and Weight Bias Internalization Scale. Restrictive feeding practices were measured using subscales from the Comprehensive Feeding Practices Questionnaire. Explicit parental modeling of eating behaviors were assessed using subscales from the Parental Modeling of Eating Behaviors Scale. Several exploratory variables (of note, parental concern about child weight) were also collected. Hierarchical linear regression was used to determine the extent to which parental weight stigma explained variance in feeding practices after adjusting for relevant covariates. *A priori* exploratory mediation analyses were tested within path models.

Results: Parent-reported weight stigma experiences (R^2 change = .076, $\beta = .293$, $p < .001$) and weight bias internalization (R^2 change = .013, $\beta = .128$, $p = .016$) significantly predicted restriction for weight scores. In contrast, only weight bias internalization significantly predicted restriction for health behaviors (R^2 change = .019, $\beta = .156$, $p = .006$). Weight stigma experiences were significantly associated with verbal modeling behaviors (R^2 change = .021, $\beta = .154$, $p = .005$). In exploratory analysis, concern about child weight significantly mediated the relationship between weight stigma, restrictive feeding practices, and verbal modeling.

Conclusions: Parental weight stigma was found to significantly predict restrictive feeding practices and verbal modeling of healthy eating behaviors. Furthermore, these relationships may be mediated by parental concern about child weight. These findings represent an important first step in understanding the intergenerational effects of weight stigma on weight-related parenting behaviors.

QUALITY OF LIFE THERAPY FOR PATIENTS WITH IMPLANTABLE CARDIOVERTER DEFIBRILLATORS: TREATMENT ENGAGEMENT AND ACCEPTABILITY

Allison J. Carroll, PhD¹, Lillian Christon, PhD, Licensed Psychologist², James R. Rodrigue, PhD, FAST³, Joseph L. Fava, Ph.D.⁴, Michael B. Frisch, Ph.D.⁵, Eva R. Serber, Ph.D.⁶

¹Feinberg School of Medicine, Chicago, IL; ²MUSC, Charleston, SC; ³Beth Israel Deaconess Medical Center, BOSTON, MA; ⁴The Miriam Hospital, Providence, RI; ⁵Baylor University, Waco, TX; ⁶Medical University of South Carolina, Charleston, SC

Background: Implantable cardioverter defibrillators (ICDs) save lives, but can also induce psychological distress among patients. Positive psychological constructs, including quality of life (QOL), are associated with improved outcomes among cardiac patients.

Methods: In this small randomized controlled NHLBI-funded study, ICD patients with elevated depression or anxiety symptoms were randomized to a 12-week positive psychology intervention (Quality of Life Therapy, QOLT; n=11) or an attention-matched control (Heart Healthy Education, HHE; n=10). At baseline and end-of-treatment, participants were administered the Quality of Life Inventory (QOLI) with 16 domains (e.g., health, family) to guide QOLT treatment targets as well as assess QOL outcomes. Participants and interventionists rated each session for engagement. Interventionists and the principal investigator (PI) audited 20% of sessions for treatment fidelity. At end-of-treatment, participants completed a Program Evaluation to assess intervention acceptability.

Results: The majority of participants attended all 12 sessions (15/21; 71%), with similar rates of complete attendance between QOLT participants (73%) and HHE participants (70%). Thirty-six percent of sessions were conducted by telephone (78/215 sessions), with a greater proportion of telephone sessions among HHE participants (48%) than QOLT participants (23%). Participants were highly engaged in treatment ($M=4.7/5$, $SD=0.3$), with good agreement between participants and interventionists ($ps < .001$). Likewise, treatment fidelity was high to the treatment protocols ($M=4.7/5$, $SD=0.5$), with excellent agreement between interventionists and PI ($ps < .001$). Eight QOLT and 10 HHE participants completed the Program Evaluation. Nearly all QOLT participants (88%) reported improved mental health whereas HHE participants (90%) reported improved physical health ($p=.001$). Improvements in overall QOL were reported among both groups, with greater improvements in QOLT participants ($d=1.02$) compared to HHE participants ($d=0.84$).

Conclusions: ICD patients found the positive psychology intervention to be an engaging and acceptable treatment for psychological distress. The majority of QOLT participants reported improvements in mental health. These pilot data support a larger-scale trial using QOLT among ICD patients to assess clinical outcomes and potential mechanisms underlying the relationship between positive psychological constructs and cardiovascular health.

3:45 PM-4:00 PM

EXPERIENCES OF YOUNG WOMEN WITH CHRONIC DISEASE: HEART DISEASE AND BREAST CANCER

Jacqueline H. J. HJ Kim, Ph.D.¹, Brittany L. Drake, M.A.², Eynav E. Accortt, Ph.D.³, Annette L. Stanton, Ph.D.¹, C Noel Bairey Merz, MD⁴, Irene S. Pollin, MSW⁵

¹UCLA, Los Angeles, CA; ²University of California, Los Angeles, Hawthorne, CA; ³Cedars-Sinai, Los Angeles, CA; ⁴Cedars-Sinai Medical Center, Los Angeles, CA; ⁵Children's Hospital, Washington DC (1975) Private Practice, Medical Crisis Counseling Clinic, Chevy Chase, MD (1980-1986) Established Medical Crisis Counseling Center, Washington Hospital Center, Washington, DC (1986), Chevy Chase, MD

Background: Young women's experiences with chronic diseases, especially the stereotypically "men's" diseases of the heart, are understudied. Young women's challenges might differ for chronic diseases less versus more commonly associated with women, for example, heart disease vs. breast cancer. Similarities across young women with chronic disease also might exist, given that chronic diseases are more normative in older age. Intersections of age, gender, and the experience of chronic disease require greater attention; accordingly, this qualitative study examined the narratives of young women with one of two diseases, heart disease or breast cancer, among the leading causes of mortality in women.

Methods: Semi-structured interviews were conducted with 20 women ($M_{age} = 45.2$, $SD = 8.6$; $n = 10$ with each disease). Inductive, thematic analysis was conducted; iterative coding and revision of candidate themes occurred through consensus.

Results: Four primary themes emerged: Resilience and Coping, Identity Integration, Implications of Chronic Illness Social Norms, and Personal Account of Lived Experience. Generally, diagnoses were a surprise to women. Challenges occurred when medical providers held a representativeness heuristic that heart disease and cancer occur in older women. Women were distressed when limited public knowledge resulted in unsupportive behaviors. Participants often were at the height of building careers, intimate relationships, and families, which were threatened by disease-related functional problems. Women typically used a combination of cognitive and behavioral coping strategies to integrate the illness experience with their sense of self. Relationships strengthened or changed; many found new social roles in service of others with chronic illness. Prominent experiences more salient to women with heart disease included: worsened self-image from disability, negative impact of invisibility (e.g., "can't tell from looking at me that I'm sick"), persisting isolation, and lack of professional support. Barriers reported by younger women with heart disease may reflect gender biases (e.g., atypical symptoms attributed to anxiety; no diagnosis with clear arteries).

Conclusion: Greater public awareness of heart disease and cancer in younger women, alongside structural support and connection with similarly challenged peers, are warranted. As advocacy for breast cancer awareness and action has increased over the past decades, so too are similar efforts for younger women with heart disease vitally needed.

4:00 PM-4:15 PM

PSYCHOLOGICAL DISTRESS AND ITS INCREASE PREDICT DETERIORATION IN MEDICAL ADHERENCE OVER 9 MONTHS IN HEART PATIENTS

Biing-Jiun Shen, PhD¹, Yunge Fan, M.A.¹¹Nanyang Technological University, Singapore, N/A, Singapore

Background: Psychological distress, including depression, anxiety, and perceived stress, is not only prevalent but also associated with poor clinical outcomes among patients with coronary heart disease (CHD). Medical nonadherence appears to be a potential pathway linking psychological distress and poor outcomes. This study aimed to examine whether different forms of psychological distress and its increase over time would predict greater deterioration in CHD patients' adherence to medication and overall treatment recommendations over 9 months.

Methods: Participants were 165 CHD patients (mean age = 63 [SD=8.65]) recruited from a community outpatient heart wellness program. They completed validated measures of psychological distress (depression, anxiety, and perceived stress), medication adherence, and adherence to specific medical recommendations (e.g., exercise, healthy eating, weight loss, stress reduction, etc.). Hierarchical multiple regression analyses were conducted to examine whether each distress variable and its increase over time would predict deterioration of patients' adherence to medication and treatment recommendations at 9 months. Given their correlations, depression, anxiety, and perceived stress were tested in separate models. All models were adjusted for respective adherence measure at baseline, age, gender, marital status, education, BMI, months in program, hypertension, and diabetes.

Results: For medication adherence, depression ($\beta = .15, p = .024$) and its increase ($\beta = .20, p = .003$) significantly predicted greater deterioration in medication adherence at 9 months, after adjusting for baseline adherence ($\beta s = .56$ to $.61, ps < .001$) and other covariates. Anxiety ($\beta = .18, p = .011$) and its increase ($\beta = .17, p = .016$) also predicted more deterioration in medication adherence at 9 months. However, baseline stress ($\beta = .10, p = .168$) and its change ($\beta = .05, p = .463$) were not significant predictors. For adherence to specific recommendations, both baseline depression ($\beta = -.20, p = .010$) and its increase ($\beta = -.15, p = .035$), baseline anxiety ($\beta = -.25, p = .001$) and its increase ($\beta = -.17, p = .018$), and baseline stress ($\beta = -.29, p < .001$) and its increase ($\beta = -.23, p = .002$), predicted greater deterioration in adherence to specific recommendations at 9 months, after adjusting for baseline adherence ($\beta s = .46$ to $.51, ps < .001$) and other covariates.

Conclusions: Both baseline psychological distress and its increase over time independently predicted greater deterioration in medical adherence over 9 months among CHD patients. The study demonstrated the importance of continuous monitoring of different forms of psychological distress among CHD patients. Behavioral interventions to reduce psychological distress may be promising for improving patients' medical adherence over time.

Paper Session 19

4:15 PM-4:30 PM

CONTEXT MATTERS: EXPLORING INTERVENTION DOSE AND OUTCOMES IN A PALLIATIVE CARE INTERVENTION FOR PATIENTS WITH HEART FAILURE

Rachel Wells, PhD, MSN, RN, CNL¹, J. Nicholas Dionne-Odom, PhD, RN², Andres Azuero, PhD², Sally Engler, MPH³, Harleah Buck, PhD, RN, FPCN, FAHA, FAAN⁴, Konda Keebler, DNP⁵, Keith M. Swetz, MD, MA⁶, Marie Bakitas, DNSc, CRNP², Sheri Tims, BSN, RN, CHPN⁷

¹University of Alabama at Birmingham, Hoover, AL; ²University of Alabama at Birmingham, Birmingham, AL; ³UAB School of Nursing, Birmingham, AL; ⁴University of South Florida, Tampa, FL; ⁵University of Alabama at Birmingham, Hueytown, AL; ⁶UAB School of Medicine, Birmingham, AL; ⁷UAB, Birmingham, AL

Background: A better understanding of perceived optimal intervention dose and dose experience is critical for early palliative care intervention development for the 6.5 million US adults living with advanced heart failure (HF). While previous palliative care intervention studies often reported improved patient QoL and resource use and lowered symptom burden, intervention designs, including dosing, vary widely. Moreover, less is known about participants' perspectives and experiences with intervention dose and its impact on outcomes.

Purpose: To explore ENABLE CHF-PC (Educate, Nurture, Advise Before Life Ends Comprehensive Heart Care for Patients and Caregivers; NCT02505425) participants' perspectives and experiences with dose attributes of a psychoeducational, multicomponent early palliative care intervention (an in-person outpatient palliative care consultation and 6 nurse-led, weekly psychoeducational telehealth sessions with monthly follow-up).

Methods: We conducted a one-on-one, semi-structured interviews qualitative study with ENABLE intervention participants. Perspectives were elicited on experiences with intervention dose attributes (amount, duration, frequency, and intensity), intervention content, general trial participation, and intervention impact on QoL and healthcare resource use. Interviews were transcribed verbatim and analyzed using constant comparative analysis.

Results: Analysis of 45 patient interviews generated 14 themes clustered around 3 categories: 1) impressions of the ENABLE CHF-PC intervention and dose attributes, 2) individual contexts, and 3) study outcomes. Dose attributes of duration, frequency, amount, intensity, timing, and delivery were frequently described, including the relationship on outcome change. While the intervention was well-received, participants varied on how much the intervention dose should be modified to influence outcome change. Participants also commonly described their study experience within a specific context. Dose attributes are filtered through 5 individual participant context (disease-related factors, family support, nurse coach relationship, logistical factors, emotions) prior to intervention initiation and during intervention delivery impacting individual outcome change related to the intervention experience. Participants also described overall study impact on their health-seeking behaviors, HF knowledge, provider communication, and non-healthcare relationships.

Conclusions: The intervention dose and experience, despite shared HF diagnosis, resonated differently with each participant. These differing perspectives of early palliative care intervention dose and design support the rationale of considering principles of precision medicine, adaptive interventions, and SMART trial design.

Paper Session 19

4:30 PM-4:45 PM

EXPERIENTIAL AVOIDANCE PREDICTS POSITIVE MOOD IN CARDIOPULMONARY REHAB PATIENTS

Jordan M. Ellis, MA¹, Emily P. Midgette, BA², Alexander J. Capiaghi, BS², Alexander M. Schoemann, PhD², Matthew C. Whited, Ph.D, Licensed Psychologist²

¹East Carolina University, San Antonio, TX; ²East Carolina University, Greenville, NC

Introduction: Despite the well documented preventative health benefits related to completing a cardiopulmonary rehabilitation program (CVPR) following a cardiac or pulmonary event, adherence remains suboptimal. Many factors for poor adherence and non-completion have been identified, and depression appears to be an important barrier to participation. Experiential avoidance, defined as unproductive efforts to reduce aversive emotional experiences, has been implicated as a mechanism related to the development and maintenance of depression, yet has been poorly researched in chronic disease populations as a treatment target. The purpose of the present study was to examine the longitudinal daily relationships between experiential avoidance and negative and positive affect utilizing a mobile ecological momentary assessment (EMA) approach, and to assess the feasibility of utilizing mobile EMA with CVPR patients. We expected that experiential avoidance would be associated with higher negative mood and lower positive mood.

Methods: Forty-seven CVPR patients were recruited within their first six CVPR monitored exercise sessions. Participants were prompted twice daily in the afternoon and evening for 14 days on their personal, or loaner, mobile devices using the Personal Analytics Companion (PACO) app. Participants completed a brief questionnaire consisting of assessed momentary experiential avoidance (5 items), negative mood (6 items), and positive mood (2 items). Multilevel modeling (MLM) was utilized to examine within-person within-prompt relationships between EA and mood, and lagged analyses were utilized to examine the bidirectional day-to-day relationships between EA and mood.

Results: Participants responded to 80% of EMA prompts and on average completed the assessment within 13 minutes of receiving the prompt. MLM analyses indicated that EA was significantly related to positive and negative mood within time points, in the hypothesized direction. Fixed effects from lagged analyses showed that EA predicted next day positive mood ($b = -.18, p < .01$), but positive mood did not predict next day EA. Lagged relationships between EA and negative mood were not significant, however these findings may be related to a floor effect observed in the measurement of negative mood.

Discussion: Mobile EMA monitoring appears to be a feasible approach to data collection for CVPR patients. Longitudinal relationships suggest that EA may be an important functional target for increasing positive mood in CVPR patients, and may also have implications for mood related barriers to program adherence and completion.

Paper Session 20

3:30 PM-3:45 PM

FATIGUE, AFFECT AND SEDENTARY BEHAVIOR AMONG BREAST CANCER SURVIVORS OVER TIME USING ECOLOGICAL MOMENTARY ASSESSMENTS

Bernardine M. Pinto, Ph.D.¹, Shira Dunsiger, PhD², Madison M. Kindred, Ph.D.³, David M. Williams, Ph.D.⁴

¹University of South Carolina, Columbia, SC; ²Brown University, Portsmouth, RI; ³Augusta University, Augusta, GA; ⁴Brown University School of Public Health, PROVIDENCE, RI

Sedentary behavior (SB) has been increasingly recognized as a risk factor for chronic disease. Cancer survivors report large volumes of SB in a typical day. Fatigue is one of the most common and debilitating sequelae that survivors experience and it can lead to increased SB. The goal of the current study was to examine the longitudinal relationship between fatigue, affect and SB in a sample of breast cancer survivors who reported data in real-time using Ecological Momentary Assessment (EMA) ($n=22$, mean age 51.5, 54.5% White, 59.1% working full-time; mean 2.45 years post-diagnosis, 13.6% cancer Stage 0, 27.3% Stage 1, 22.7% Stage 2 and 22.7% Stage 3). SB was assessed via accelerometry (Actigraph) and participants responded daily to one fixed and four random prompts via smartphone for 7-day periods at baseline, 3, 6, 9 and 12 months. Using a series of autoregressive, cross-lagged models, we tested the associations between affect, fatigue and SB. At baseline, average objectively measured sedentary time was 4601.0 min/week ($SD=174.0$) and remained stable over time. Models estimate the potential changes in affect, fatigue and SB over time, as well as the cross-lagged effects (e.g., “Does how I feel right now predict SB 3 hours from now?” and “Does SB right now predict fatigue at the next prompt?”). Models controlled for employment type as well as treatment (chemotherapy, radiation). Standardized coefficients were estimated and allow for the comparison of the strength of effects. Although SB did not change over time, there were significant cross-lagged effects of affect, fatigue and SB. Models of fatigue and SB suggest a trend for the cross-lagged effects of fatigue on SB such that greater levels of fatigue were associated with greater SB over the next 3 hours ($\beta=.08, p=.09$). There was also a significant association between current SB and future fatigue with greater time spent sedentary associated with higher levels of subsequent fatigue ($\beta=.11, p=.03$). More positively valenced affect earlier in the day was negatively associated with SB later in the day ($\beta=-.22, p<.001$) and this effect was stronger than effects of SB on future affective response ($\beta=-.13, p=.01$). Reducing SB among cancer survivors is clinically relevant and EMA approaches are a viable approach to examining antecedents of SB so that appropriate interventions targeting can be offered and evaluated.

Paper Session 20

3:45 PM-4:00 PM

SLEEP SCHEDULE VARIABILITY IS NOT ASSOCIATED WITH TREATMENT RESPONSE TO AN INTERNET-BASED CBT FOR INSOMNIA PROGRAM

Kelly M. Shaffer, PhD¹, Donald Hedeker, Ph.D.², Charles M. Morin, PhD³, Karen S. Ingersoll, PhD⁴, Frances Thorndike, PhD⁵, Lee M. Ritterband, PhD¹¹University of Virginia School of Medicine, Charlottesville, VA; ²University of Chicago, Chicago, IL; ³Laval University, Quebec, PQ, Canada; ⁴University of Virginia, CROZET, VA; ⁵Pear Therapeutics, Inc, Charlottesville, VA

Objectives: Cognitive-behavioral therapy for insomnia (CBT-I) emphasizes maintaining consistent bedtimes and rising times, but evidence is mixed regarding whether variability in an individual's sleep schedule is related to treatment outcomes. This secondary analysis tested 2 research questions: 1) does an Internet-based CBT-I program reduce within-subject (WS) variability in sleep schedule, and 2) does WS variability in sleep schedule predict self-reported insomnia remission?

Methods: Participants (N=303) were randomized to receive either an Internet-based CBT-I program (SHUTi: Sleep Healthy Using the Internet) or Internet-based patient education (PE). Participants reported daily bed- and rising times on 10 online sleep diaries collected over 2 weeks at baseline (prior to randomization) and post-assessment (9 weeks post-baseline at conclusion of intervention). Participants completed the Insomnia Severity Index at post-assessment and a 6-month follow-up; scores < 8 indicated insomnia remission. A novel two-stage data analytic approach through the freeware program MIXWILD was used to first estimate the random effects of participant-level bed- and rising time WS variability and tested the effect of condition. Next, participants' random effects were used as predictors in a logistic regression predicting insomnia remission at the following time point, controlling for condition.

Results: There were no differences in WS variability for bed- or rising times at baseline between participants randomized to SHUTi versus PE ($\tau=-0.02$, $p=.88$ and $\tau=-0.01$, $p=.93$, respectively). At post-assessment, SHUTi participants reported about 30% less bedtime and 32% less rising time variability compared to PE ($\tau=-0.35$, $p=.03$; $\tau=-0.39$, $p=.01$). Beyond the effect of condition, there were no associations between participants' bed- or rising time WS variability and their likelihood of reporting insomnia remission at the following time point, either from baseline to post-assessment, or from post-assessment to 6-month follow-up ($ps > .84$).

Conclusions: Internet-delivered CBT-I increases consistency in users' daily bed- and rising times; however, more consistent sleep schedules were not related to achieving or maintaining insomnia remission. These findings from a novel analytic framework question the clinical importance of common sleep hygiene rules as part of behavioral sleep insomnia treatments, and further research is warranted to identify mechanisms driving observed sleep improvements.

Paper Session 20

4:00 PM-4:15 PM

HEALTH EFFECTS OF ABUSE HISTORY AND MODERATING EFFECT OF PARENTING STRESS FOR MOTHERS WITH MENTAL DISORDERS

Victoria Behar-Zusman, PhD, Brian McCabe, PhD¹, Lila de Tantillo, PhD², Kristin Levoy, PhD, RN, MSN³¹Auburn University, Auburn, AL; ²Jacksonville University, Jacksonville, FL; ³University of Pennsylvania School of Nursing, Philadelphia, PA

Background: Mothering in the context of having a mental disorder is an understudied phenomenon requiring attention so that service providers can be responsive to the needs of mothers and families. Women with mental disorders are more likely to have experienced abuse during childhood or adulthood than the general population, and the health consequences of abuse are well documented. However, there is less research on how having a history of abuse may affect the health of mothers with mental disorders, or whether parenting-related stressors exacerbate the health consequences of abuse for these mothers. The study examined relationships between experiencing multiple forms of abuse (physical, sexual, emotional/psychological) across the lifespan and health indicators among mothers receiving outpatient behavioral health services. We also explored parenting stress (low parenting self-efficacy, child-related hassles, and caregiving load), as a moderator of the relationship between abuse history and maternal health.

Method: The study conducted secondary analysis of baseline data from a randomized trial with 172 predominantly Hispanic mothers. Health indicators included anxiety, depression, obesity, fatigue, pain, sleep disturbance, physical functioning, substance and cigarette use.

Results: Most (80%) mothers had experienced abuse, and those with abuse during childhood had 3.82 greater odds of experiencing abuse in adulthood. Mothers who experienced abuse in both childhood and adulthood reported more depression, sleep disturbance, and substance use. Number of abuse forms was related to anxiety, depression, fatigue, pain, sleep disturbance, and substance use. Moderation analysis indicated that caregiving load intensified the relationship between abuse history and maternal anxiety, depression, and sleep disturbance; child-related hassles intensified the relationship between abuse history and maternal fatigue and pain.

Implications: The study confirmed the high prevalence of abuse history and the deleterious effects of experiencing abuse on maternal health among women with mental disorders. We also extended the extant research by demonstrating that these effects are intensified by parenting-related stress. Service providers should routinely ask female clients about their abuse history and their caregiving-related stressors to deliver trauma-informed services addressing the consequences of abuse as well as parenting stress. Further research is warranted to develop and evaluate interventions tailored for mothers with mental disorders who are survivors of abuse to improve maternal and child wellbeing.

DAILY REPORTS OF SLEEP AND SMOKING ABSTINENCE: AN ECOLOGICAL MOMENTARY ASSESSMENT STUDY

Chaelin K. Ra, PhD¹, Emily Hébert, DrPH², Summer Frank-Pearce, PhD, MPH³, Rachel Moisiuc, BS², Adam Alexander, Ph.D.⁴, Darla E. Kendzor, PhD⁵, Karen L. Gamble, PhD⁶, Karen Cropsey, Psy.D.⁷, Michael S. Businelle, PhD⁵

¹University of Oklahoma Health Science Center, Oklahoma City, OK; ²Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK; ³Oklahoma Tobacco Research Center/University of Oklahoma Health Sciences Center, Oklahoma City, OK; ⁴Oklahoma Tobacco Research Center, Oklahoma City, OK; ⁵University of Oklahoma Health Sciences Center, Oklahoma City, OK; ⁶UAB, Birmingham, AL; ⁷University of Alabama at Birmingham, Birmingham, AL

Background: There is preliminary evidence that sleep duration and sleep quality are associated with smoking cessation. Yet, few studies have examined mechanisms linking sleep with smoking lapse.

Methods: Data from a pilot three-armed randomized clinical trial of a smartphone-based smoking cessation intervention among adults (N=81) were used to examine mechanisms linking sleep (i.e., hours of sleep each night, sleep quality) and smoking lapse. Participants were loaned a smartphone and asked to complete ecological momentary assessments (EMAs) one week pre-quit and the first 4-weeks following the quit attempt. EMAs assessed daily sleep and wake times, sleep quality, positive and negative affect, smoking urge, stress, and smoking status. Multilevel mediation models were conducted to estimate the associations between sleep, affect, urge, stress, and daily smoking status controlling for age, sex, education, race (White vs. non-White), intervention group, and heaviness of smoking at baseline.

Results: Participants were primarily male (51.2%), White (67.9%), 49.4 years old (SD=12.2), and completed 169 EMAs during the 4-week post-quit period on average. Paths from sleep duration and quality to positive affect, smoking urge, and stress ($\beta=-0.08\sim-0.09$, $p=.0001\sim.02$) and from positive affect, smoking urge, and stress ($\beta=-0.08\sim-0.18$, $p=.0001\sim.09$) to daily smoking status were significant. None of the direct effects between sleep quality and duration and daily smoking status were significant. However, the random indirect effects between sleep quality and smoking status via positive affect, smoking urge, and stress ($\beta=-0.02$, $p=.005$; $\beta=-0.02$, $p=.01$; $\beta=-0.01$, $p=.07$ respectively) were significant, suggesting complete mediation.

Conclusion: While sleep duration was related to psychosocial factors that have been previously associated with smoking lapse, there was no direct relationship between sleep duration and daily smoking status. However, results indicated that poor sleep quality may increase risk for smoking lapse through direct effects on positive affect, smoking urge, and stress. Future research should determine if interventions that focus on improving sleep quality during a smoking cessation attempt can increase cessation success rates.

AGREEMENT BETWEEN PERCEIVED AND PHYSIOLOGICAL STRESS IN PREGNANT WOMEN ACROSS A COGNITIVE-BEHAVIORAL INTERVENTION

Samanvitha K. Sundar, MS¹, Darius Tandon, PhD², Lauren Wakschlag, PhD³, Nabil Alshurafa, PhD³

¹Northwestern University, Evanston, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³Northwestern University, Chicago, IL

Adverse impacts of stress are known to be amplified during the prenatal period which is a normatively stressful period. Chronic exposure to even normative stress adversely affects both maternal and fetal health. Cognitive-behavioral therapy (CBT) interventions such as Mothers and Babies (MB) are well-established in improving maternal mental health, although we are not aware of existing studies that have attempted to augment CBT interventions with delivery of additional just-in-time content. This pilot study measured maternal physiological and perceived stress response in real time and used these data to deliver additional just-in-time content to fifteen pregnant women in their second trimester. Participants wore a novel miniaturized flexible device, Biostamp research Connect, measuring electrocardiogram (ECG) signals, and responded to at-most five ecological momentary assessments (EMAs) sent daily to report on perceived stress. The MB intervention contains 12 sessions where participants receive instruction from a facilitator in person or by phone teaching them to apply stress reduction techniques. Daily perceived stress responses to EMAs were measured using the average of responses to the Perceived Stress Scale (PSS-4). A machine learning model was built to estimate total minutes of physiological stress exposure from ECG signals from the wearable sensor. A perceived stress slope and physiological stress slope is calculated across the 12 weeks to signify an increase or decrease in perceived and physiological stress respectively. 9 out of 11 pregnant women showed a reduction in daily levels of physiological stress (4 out of the 15 did not provide sufficient sensor data), and 7 out of the 14 pregnant women showed reductions in daily perceived stress responses (1 participant did not adhere to EMA responses). 8 out of the 11 pregnant women showed agreement between slope of physiological and perceived stress. This study showed feasibility of a CBT-informed intervention augmented with JIT responses on reducing both physiological and perceived stress response. A small randomized trial is now underway (N=100) to test the impact of Wellness-4-2 on maternal wellbeing and downstream impact on infant neurodevelopment. Further study in larger samples is warranted to determine the efficacy of this, and similar interventions, and determine efficacy of a real-time intervention delivered only during detected stressful days.

LIFESTYLE REDESIGN OCCUPATIONAL THERAPY IN PRIMARY CARE: IMPACT ON HEALTHCARE UTILIZATION AMONG INDIVIDUALS WITH DIABETES

Beth Pyatak, PhD, OTR/L, CDE¹, Jesus Diaz, OTD, OTR/L², Megan Linderman, OTR/L³, Stacey L. Schepens Niemiec, PhD, OTR/L¹, Elissa S. Lee, OTS⁴, Khatira Mehdiyeva, MD, MPH¹, Elia Salazar, MPH⁵, Jeanine Blanchard, PhD, OTR/L¹, Jagruti Shukla, MD, MPH⁶, Josh Banerjee, MD, MPH, MS⁷

¹University of Southern California, Los Angeles, CA; ²USC, Los Angeles, CA; ³University of Southern California, Rancho Santa Margarita, CA; ⁴University of Southern California, Berkeley, CA; ⁵USC Chan Division of Occupational Science and Occupational Therapy, Los Angeles, CA; ⁶LAC+USC Medical Center/LA Department of Health Services, Los Angeles, CA; ⁷LAC+USC Medical Center, Los Angeles, CA

Background: An estimated 30.3 million people in the US have diabetes, with one in four health care dollars spent on caring for individuals with diabetes, at an annual cost of \$327 billion per year. As 72% of diabetes appointments take place in primary care, improvements in diabetes care in this setting may reduce the need for more costly specialty care and acute care services (emergency department [ED] visits and hospitalizations). As part of a hybrid effectiveness-implementation study conducted in a safety net primary care clinic within a large urban public health system, we assessed the impact of Lifestyle Redesign occupational therapy (LR-OT), an evidence-based lifestyle intervention, on acute care utilization among patients with diabetes.

Methods: Clinic patients with diabetes and HbA1c >9.0% were referred to the study using a randomized consent design in which patients were assigned to (a) be offered LR-OT services (up to 8 one-hour sessions) (n=73), or (b) serve as a no-contact comparison group (n=69). Patients' ED visits, hospitalizations, and length of inpatient stay were extracted from the EMR for 12 months prior to, and 12 months following, each patient's study enrollment date. Data were compared on an intention-to-treat basis.

Results: Acute care utilization decreased in the LR-OT group and increased in the control group in the 12 months following study enrollment, compared to the 12 months prior to enrollment. For ED visits, utilization decreased by 30.3% in the LR-OT group and increased by 18.9% in the control group (p=0.09). Hospitalizations decreased by 44.4% in the LR-OT group and increased by 11.1% in the control group (p=0.09). Average length of stay decreased by 0.1 days in the LR-OT group and increased by 1.3 days in the control group. We estimate the cost savings associated with these differences in acute care utilization at approximately \$5,100 per patient per year.

Discussion: Given the increasing incidence of diabetes and impetus for cost saving interventions, these data suggest that integrating LR-OT services in primary care may be effective at reducing costs associated with acute care utilization among individuals with diabetes. However, these findings are preliminary, as the study was not powered to detect statistical significance for healthcare utilization outcomes. Replication in a larger, fully powered randomized trial is needed to evaluate the robustness of the observed effects.

3:45 PM-4:00 PM

FEASIBILITY OF AN INTEGRATED APPROACH TO COORDINATE CARE ACROSS CLINICAL AND COMMUNITY SETTINGS TO PREVENT CHILDHOOD OBESITY

Jennifer S. Savage, PhD¹, Lisa Bailey Davis, D.Ed., R.D.², Samantha M. R. Kling, PhD, RD³, Holly Harris, BSc, PhD⁴, Jacob Mowery, BA⁵, Shawnee Lutchter, B.S. Exercise Science⁶, Michele Marini, MS¹

¹Penn State University, University Park, PA; ²Geisinger, Danville, PA; ³The Pennsylvania State University, San Jose, CA; ⁴The Pennsylvania State University, University Park, PA; ⁵Geisinger Health System, Danville, PA; ⁶Geisinger Health System, McEwensville, PA

Economically disadvantaged newborns receive care from pediatric primary care providers (PCPs) and Women, Infant and Children (WIC) nutritionists; however, care is not coordinated between settings. The feasibility of an integrated approach to coordinate care will be described. WIC-eligible caregivers and infants (n= 131) receiving pediatric care were recruited and randomized to the intervention (Savage, BMC Pediatrics, 2018) or control groups. The intervention included 1) Early Healthy Lifestyles (EHL), a parent self-assessment tool; 2) responsive parenting curriculum delivered by WIC and PCPs; and 3) data sharing and care coordination between settings facilitated by health information technology. Data sharing occurred bidirectionally between settings; from WIC to PCP (i.e., PCPs could view WIC data or vice versa) and care could be coordinated when PCPs interact with WIC data (or vice versa). The feasibility of sharing data to coordinate care was evaluated using the infant's electronic health record and WIC data management system. Results revealed that caregiver-infant dyads attended 459 (3.50±1.03/dyad) PCP and 296 (2.26±0.97/dyad) WIC visits over the 6-month intervention. Overall, parents completed the EHL prior to 53% (1.86±1.15/dyad) of the PCP visits. These data along with agreed upon elements were shared with WIC following 100% of PCP visits, and 50% of the time a WIC visit followed a PCP visit. Thus, there were 1.76±0.81 PCP to WIC care coordination opportunities per dyad. When this happened, WIC coordinated care at 67% of opportunities (1.18±0.85/dyad). Data were shared from 67% of WIC visits (1.5±0.95/dyad), and 59% of the time a PCP visit followed a WIC visit. Thus, there were 0.89±0.78 WIC to PCP care coordination opportunities per dyad. When this occurred, PCPs coordinated care at 44% of opportunities (0.39±0.58/dyad). Coordinating care between parents, clinical and community settings through patient-reported measures, data integration, and electronic data sharing is a feasible strategy. However, between-participant variability in timing, sequence and frequency of visits underscores the need for flexible approaches in pragmatic studies and longer intervention period to increase dose. Workflow integration is a key factor that enabled PCP data sharing while partial-integration limited WIC data sharing. PCPs and WIC used data received to coordinate care, but WIC nutritionists were more likely to do so than PCPs.

PATIENT AND PROVIDER PERCEPTIONS OF THE PATIENT-CENTERED CARE EXPERIENCE IN URGENT CARE SETTINGS

Danielle Blanch-Hartigan, PhD, MPH¹, David M. Murungi, PhD¹, Sandeep R. Purao, PhD¹¹Bentley University, Waltham, MA

There has been tremendous growth in the urgent care (UC) model of healthcare delivery. We sought to examine the communication experiences and quality of care perceptions of both patients who visited UC and the providers who practice in this setting.

Two surveys assessed: 1) patient perspectives: 402 Mechanical Turk respondents who had visited UC within the past year (52.7% male, modal age 25-34 yrs.); and 2) provider perspectives: 69 providers working in UC settings in the Southern United States (33.3% male, mean age = 43.6 years, SD= 9.28, 42% nurse practitioners, 33.3% physicians assistants, 21.7% physicians). Both patients and providers answered questions about their UC experiences on six core functions of patient-centered communication: fostering healing relationships, exchanging information, responding to emotions, making decisions, enabling patient self-management, and managing uncertainty (1=strongly disagree to 5=strongly agree) and reported on overall quality of care (1=poor to 5=excellent). In addition, both patients and providers compared their experience in UC to other healthcare settings.

89% of UC providers and 79% of patients reported excellent or very good overall quality in UC. Although UC patients (Mean=4.05, SD=.84) and providers (Mean=4.34, SD=.44) reported high levels of patients-centered communication across the 6 functions, patient responses showed potential areas for improvement. A sizeable proportion of UC patients did not agree these 6 functions were fulfilled, particularly in the areas of responding to patients thoughts and feelings (27%), involving patients in decisions making (27%), and managing uncertainty (23%). Over 90% of UC providers responded that they were meeting patient needs on these functions; the majority of UC providers perceived the same (58%) or better (30%) quality of care at UC compared to other healthcare settings. 33% of UC patients reported they would rather visit urgent care than their primary care provider. Providers who reported less burnout and greater empathy and patients who had more health-related self-efficacy experienced significantly greater patient-centered communication in UC.

Patients and providers seemed relatively positive about the communication and care experience in UC as compared to other healthcare delivery settings. As the UC model of healthcare delivery grows, it is important to identify areas of patient-centered care, such as addressing patient emotions and involving patients in decision-making, which can improve the care experience for UC patients.

BRIEF BEHAVIORAL ACTIVATION FOR DEPRESSIVE SYMPTOMS IN PRIMARY CARE: A MULTI-SITE RANDOMIZED CONTROLLED TRIAL

Jennifer Funderburk, PhD¹, Wilfred Pigeon, PhD², Robyn L. Shepardson, PhD¹, Laura Wray, PhD³¹VA Center for Integrated Healthcare, Syracuse, NY; ²Veteran Affairs, Canadaigua, NY; ³VA Center for Integrated Healthcare, Buffalo, NY

Depressive symptoms are commonly reported by primary care patients. Existing evidence-based brief psychotherapies for depression are not translatable within primary care for a variety of reasons, including the number and duration of appointments exceeding what is feasible within primary care and interventions not being designed for patients reporting a range of depressive symptoms from moderate to severe. Behavioral activation (BA), a component of cognitive-behavioral treatment for depression, is an ideal choice to examine for its efficacy in this setting as it has been found to be effective with difficult-to-treat populations and can be implemented by a variety of healthcare providers. BA uses values assessment and activity scheduling to engage patients in meaningful experiences. We will present results of a multi-site randomized controlled trial of a brief form of BA designed for primary care (BA-PC) comprised of two 30-minute appointments with two booster appointments. A total of 140 veterans (age M=53 SD=15.2 years; 91.4% male) from three primary care clinics were randomized to BA-PC or integrated primary care treatment as usual (TAU). All participants reported at least moderate depressive symptoms (≥ 10 on the Patient Health Questionnaire-9 [PHQ-9]). Participants completed assessments every 2 weeks throughout the 12-week trial. Mixed-level modeling showed participants in both TAU and BA-PC experienced significant declines in PHQ from baseline to week 3 ($p < .0001$), which was prior to receiving any treatment ($M=3.4$ weeks to first treatment in both conditions). Participants in the BA-PC condition continued to improve to week 12 ($p < .01$). However, we did not find an overall condition effect at week 12. Secondary analyses showed of those participants who still reported at least moderate symptoms after the initial assessment, 20.9% participants in TAU versus 43.6% in the BA-PC condition, $z(df=1)=-2.36$, $p < .01$, had PHQ-9 scores drop < 10 at week 12, a sign of no need for further treatment. Future research and clinical implications related to the impact of regular symptom assessments will be discussed.

Paper Session 21

4:30 PM-4:45 PM

THE IMPACT OF BRIEF INTERVENTIONS ON FUNCTIONING IN PRIMARY CARE: THE EFFECTIVENESS OF THE PRIMARY CARE BEHAVIORAL HEALTH MODEL

Kevin Wilfong, B.S.¹, Jeffrey Goodie, Ph.D., ABPP²¹Uniformed Services University of the Health Sciences, Rockville, MD; ²Uniformed Services University of the Health Sciences, Bethesda, MD

The limited scalability combined with limited opportunities for patients to receive evidence-based interventions in the current model of treatment for anxiety and depression creates a gap in access to adequate care. Primary Care Behavioral Health (PCBH) is one model of treatment in which behavioral health consultants (BHC) work directly with primary care providers. Beneficiaries (N = 5,402) of the military healthcare system seen by BHCs were assessed for functioning outcomes and the appointment characteristics. The study sample was predominately Caucasian, female, military dependents seen for 2 to 4 appointments. A reliable change index revealed that, of the 5,402 individuals analyzed, 52.55% showed *improvement*, 17.16% showed *reliable improvement*, 24.21% showed *deterioration*, 2.44% showed *reliable deterioration* and, 3.63% of the sample showed no change ($p < 0.05$). Of individuals with a *severe* BHM-20 GMH score at baseline, 81.50% showed some improvement at their final appointment, with 33.01% falling under *reliable improvement*. A mixed model analysis was used to determine the predictive value of appointment characteristics. All relations were significant ($p < 0.001$), except the between-subjects effect of appointment duration. Appointment duration revealed a negative within-subjects relation; individuals reported worse functioning at the start of atypically long appointments. Appointment interval revealed a negative between-subjects and positive within-subjects relation; individuals with longer mean time between appointments reported worse functioning but better functioning at appointments following an atypically long interval. Appointment number revealed a negative between-subjects and positive within-subjects relation; individuals with more appointments reported worse functioning outcomes but better functioning across appointments. In summary, the current study provides additional data to support the effectiveness of the PCBH model, to include a conservative measure of clinically meaningful change and the effect of appointment characteristics on functioning outcomes. One in six individuals with anxiety, depression, or adjustment disorder showed reliable improvement, with the greatest rates of reliable improvement in individuals with severe functioning at baseline and individuals with a greater total number of appointments reported worse functioning outcomes. Overall, these data support the effectiveness of time-limited care provided through the PCBH model.

USING PERCEPTUAL MAPPING TO UNDERSTAND PREP USE IN TRANS WOMEN BY PATIENT SELF-ADVOCACY: IMPLICATIONS FOR MESSAGE DEVELOPMENT

Sarah Bauerle, Bass, Ph.D. and MPH¹, D'Avanzo A. D'Avanzo, MS¹, Jesse A. Brajuha, MPH², Gutierrez Luis, MPH, MA³, Mohammed Alhajji, PhD(c), MPH⁴, Patrick J. Kelly, BSPH⁵, Jae M. Sevelius, PhD⁶

¹Temple University College of Public Health, Philadelphia, PA; ²Temple University, Philadelphia, PA; ³University of California, San Francisco, San Francisco, CA; ⁴Risk Communication Lab / College of Public Health/ Temple University, Philadelphia, PA; ⁵Temple University, Conshohocken, PA; ⁶University of California, San Francisco, San Francisco, CA

Background: US estimates indicate trans women are 34 times more likely to have HIV. Pre-exposure prophylaxis (PrEP) shows significant promise for reducing HIV risk, but trans women have low levels of use. Understanding unique barriers to PrEP use among trans women is important for reaching this at-risk population.

Methods: 128 trans women from Philadelphia and San Francisco were surveyed to assess perceptions about PrEP. A k-means cluster analysis using a modified patient self-advocacy (PSA) scale was conducted and then Perceptual mapping (multidimensional scaling) and vector modeling methods were used to create 3-dimensional maps to show how barriers and facilitators to PrEP use differed by group and potential message strategies for an intervention. This method is used in commercial marketing to assess highly targeted strategies for message development.

Results: Perceptual maps show conceptual differences about barriers and benefits of PrEP use between “engagers” (high PSA) and “avoiders” (low PSA). Message strategies for benefits of PrEP use were similar (“Makes me feel in charge”), but were dissimilar for barriers (Engagers were concerned about feeling less feminine if on PrEP and noted a preference for using condoms. Avoiders were concerned that even if they were on PrEP they would get “HIV anyway”). Both groups were concerned about the possible effect on hormones. Additional message strategies for engagers include addressing that they have worries about other “more important” things in life and a concern that their sex partners would think they would “give them HIV” if on PrEP. Importantly, both groups say that spending time in the trans community and that having sex is an important way to feel good about being a trans woman were important and could be emphasized in messaging.

Conclusions: These methods are useful in understanding trans women's unique PrEP perceptions and potential message strategies that could be embedded in communication and interventions. While conceptual differences were seen in those with high and low PSA, message strategies are similar, making it possible to target interventions to both groups.

A PRAGMATIC RANDOMIZED CONTROLLED TRIAL TO ACCELERATE DIFFUSION OF PRE-EXPOSURE PROPHYLAXIS FOR HIV PREVENTION

Lindsay Young, PhD¹, John Schneider, MD, MPH²¹University of Chicago, Los Angeles, CA; ²University of Chicago, Chicago, IL

Background: Despite clear efficacy of Pre-Exposure Prophylaxis (PrEP) in preventing HIV transmission, meaningful uptake in populations most likely to seroconvert has yet to occur. Newer network type interventions may be useful for PrEP implementation, particularly as the epidemic in the United States becomes more concentrated.

Methods: We tested a peer change agent Type I network intervention aimed at increasing early PrEP linkage to care among the network members connected to young Black men who have sex with men (YBMSM) experiencing high rates of HIV from 2016-2018. The intervention included a single half-day training and mini-booster sessions on how YBMSM can engage and motivate their network members to seek out and start PrEP. We randomly assigned 423 YBMSM in Chicago to receive the network intervention versus a time-matched control, with an independently collected primary surrogate outcome of PrEP referral and/or linkage to a PrEP orientation appointment among the Facebook network friends of YBMSM study participants.

Results: Each study participant in the trial had on average 1822 Facebook network friends. Over the 55-week observation period, there were 65 network members with observed PrEP referral or linkage to care. Network members with referral or linkage were more likely to be connected to study participants in the intervention arm than the control condition (aOR 1.50 (1.09-2.06); $p=0.012$). During the observation period PrEP referral was most likely to occur within 3 days of an intervention session compared to control OR 0.07 (0.02-0.013); $p=0.007$) resulting in 1-2 referrals of network members per session.

Conclusions: A peer change agent Type I network intervention was effective at diffusing PrEP through a social network of individuals highly susceptible to HIV. This low intensity intervention demonstrated network level impact in increasing PrEP referral and linkage to care among populations that have experienced limited PrEP care engagement in the United States. (Funded by the National Institute of Allergy and Infectious Diseases; ClinicalTrials.gov number, NCT 02896699)

4:00 PM-4:15 PM

ADDRESSING LIFE STRESSORS: RESULTS OF AN INDIVIDUALLY TAILORED INTERVENTION FOR PATIENTS WITH A HISTORY OF REPEAT STIS

Steven A. John, PhD, MPH¹, Nicole B. Carnegie, PhD², Immaculate Apchemengich, BS³, Lindsay Emer, PhD⁴, Lance S. Weinhardt, PhD⁵¹Medical College of Wisconsin, Milwaukee, WI; ²Montana State University, Bozeman, MT; ³University of Wisconsin-Milwaukee, Sacramento, CA; ⁴University of Wisconsin-Milwaukee, Milwaukee, WI; ⁵University of Wisconsin-Milwaukee, Milwaukee, WI

Background: HIV and sexually transmitted infection (STI) counseling and testing services focus on behavior change theory, but patients presenting with repeatedly acquired STIs indicate the need for more intensive services focused on broader, upstream life stressors inhibiting behavior change. We sought to test the efficacy of an individually tailored socio-contextual intervention focused on addressing life stressors to reduce repeat STI risk.

Methods: A Midwestern sample of STI clinic patients with a history of repeatedly acquired STIs ($n = 128$, $M_{age} = 29$ years, 65% male, 91% Black or African-American) were randomized to receive either the standard of care intervention or experimental, individually tailored strengths-based prevention case management with electronic health record chart review conducted at 12 months post-intervention to compare rates of incident STI. We used multiple imputation to support intent-to-treat and fully-adjusted logistic regression precision model analyses.

Results: Individuals who received the experimental intervention had a lower rate of repeat infection compared to the standard of care group at 12 months post-intervention (37% vs. 43%, respectively). After adjusting for baseline variable imbalances and precision variables, patients in the standard of care group had 2.37 times higher odds of repeat infection compared to those in the experimental group at 12 months post-intervention ($p = 0.065$). Individuals who scored higher in internal locus of control had significantly lower odds of subsequent STI (AOR = 0.91; $p = 0.046$). Higher score on the drug abuse screening test (i.e., DAST-10) was significantly associated with higher odds of subsequent STI (AOR = 1.47; $p = 0.002$).

Discussion: A supplemental, case management intervention had a meaningful intervention effect on reducing repeat STI risk among patients with a history of repeat infections in our underpowered analysis. Prioritizing socio-contextual needs is important when patients present with repeat infection. Combining this intervention strategy with STI partner referral services and substance use prevention and treatment programs should be tested in future implementation science research to further reduce the risk of repeatedly acquired STIs among STI clinic patients with a history of recurrent STIs.

TRAJECTORIES OF HIV RISK BEHAVIORS AND SUBSTANCE USE AFTER INITIATING PRE-EXPOSURE PROPHYLAXIS (PREP) IN A CLINICAL SETTING

Brooke Rogers, Ph.D., M.P.H.¹, Tyler B. Wray, Ph.D.², Philip Chan, M.D., M.S.¹, Christina T. Chu, B.A.³, Megan Pinkston, M.A., Ph.D.⁴, Siena Napoleon, MPH⁵, Sabrina H. Strong, MPH⁶, Matthew J. Murphy, MD, MPH⁷, Collette Sosnowy, PhD¹

¹Warren Alpert Medical School of Brown University, Providence, RI; ²Brown University School of Public Health, Providence, RI; ³The Miriam Hospital, Providence, RI; ⁴Warren Alpert School of Medicine of Brown University; Lifespan Physicians Group, Providence, RI; ⁵The Miriam Hospital, North Providence, RI; ⁶The Miriam Hospital, Providence, RI; ⁷Brown University, Providence, RI

Introduction: The past decade has been marked by significant advances in biomedical prevention of HIV including the use of antiretroviral medication as pre-exposure prophylaxis (PrEP). Several studies have identified patient and provider concerns that PrEP could result in “risk compensation” or an increase in several HIV risk behaviors. The purpose of this study was to evaluate that hypothesis by examining trajectories of alcohol, substance, and high-risk sexual behavior after initiating PrEP in a clinical setting.

Methods: Patients from a hospital-based clinic who identify as men who have sex with men (N=248) completed surveys at their PrEP visits, which occurred approximately every 3 months, per clinical guidelines. For this study, participants were followed for a maximum of 18 months after their first PrEP visit (up to 6 PrEP visits). Latent class growth analysis identified classes of trajectories in binge drinking, and illicit drug use, and condomless anal sex frequency.

Results: Best-fitting LGCA models identified 3 classes for trajectories of binge drinking (BIC=1826.97, LMR-LRT=43.12, $p = .021$, BLRT=45.73, $p < .001$, Entropy = 0.76), 2 classes for trajectories of illicit substance use (BIC=758.12, LMR-LRT=105.78, $p = .002$, BLRT=112.18, $p < .001$, Entropy = 0.92), and 2 classes for trajectories of sexual risk (BIC=5063.73, LMR-LRT=217.7, $p = .042$, BLRT=230.87, $p < .001$, Entropy = 0.97) over the initial 18 months of PrEP care. In that time, there were no significant increases in any of these risk behaviors. In fact, those with the highest use of alcohol use gradually reduced their use ($b_1 = -0.14$) after starting PrEP. The same downward trend was found for those with the highest illicit substance use to start ($b_1 = -0.2$). Those with a highest number of condomless anal sex partners saw a small, but non-significant increase in partners (by .83 partners).

Discussion: Findings demonstrated that alcohol use, illicit substance use, and sexual transmission risk behavior did not significantly increase after PrEP initiation. Concerns about increased risk after initiation are often cited as a barrier among providers and patients; however, our results directly contradict the risk compensation narrative. From a public health perspective, it may be helpful to use these findings to inform future clinical interventions and educational materials provided to patients.

ADAPTING A POSITIVE AFFECT INTERVENTION FOR MOBILE DELIVERY: DEVELOPMENT OF THE POSITIVELY HEALTHY APP BASED INTERVENTION

K. Marie M. Sizemore, PhD¹, Shannon S. Gray, M.A.², Carly Wolfer, BA³, Aria Tilove, BA³, Hyejin Park, BA⁴, Ali Talan, DrPH¹, H. Jonathon Rendina, PhD, MPH⁵

¹Hunter College, New York, NY; ²PRIDE Health Research Consortium, New York, NY; ³PRIDE Health Research Consortium at Hunter College, New York, NY; ⁴PRIDE Research Consortium, Palisades Park, NJ; ⁵Hunter College and The Graduate Center, CUNY, New York, NY

Background: Individuals living with HIV are disproportionately affected by stressful life events. Stress is not only associated with HIV progression, it is also linked to transmission risk behavior. In the United States, the majority of individuals living with HIV are sexual minority men (SMM) for whom sexual minority stress and HIV-related stress add to general life stressors to increase health risks. Studies show that mindfulness and positive affect buffer against stress for HIV+ individuals, however limited research has examined their potential health benefits for HIV+SMM. Moskowitz's (2014) Positive Affect intervention includes a mindfulness module, and has demonstrated efficacy in populations living with HIV. In our proof-of-concept pilot, we adapted the Positive Affect intervention for mobile app delivery.

Methods: The Positively Healthy app was designed as an ecological momentary intervention (EMI), and uses a just-in-time-adaptive-intervention (JITAI) delivery format. Participants were 22 HIV+SMM ($M_{age} = 37.82$; $SD = 10.52$), the majority were Black (31.8%) or Latino (31.8%). Participants completed a baseline assessment, where we introduced to app based intervention. Participants then completed a 90-day ecological momentary assessment (EMA). JITAI activities were triggered, based on reported stress in the EMA survey, at a 2:1 ratio. Over the 90 day intervention period, participants also received a daily positive message, and had access to on demand content in the app. After 90 days, participants completed a post-intervention assessment and focus group session, where we assessed feasibility and acceptability of the Positively Healthy app.

RESULTS. On average, participants reported feeling stressed 25/90 days. Participants responded to 82.1% of the intervention activities and viewed 62% of the positive messages over 90-day period. A review of our qualitative interview data indicated that the app based delivery was acceptable and feasible for HIV+SMM. However, participant feedback also revealed that our intervention content would benefit from further adaptation to enhance its cultural appropriateness for our target population. Our focus group data indicated that participants related most to the mindfulness content within the app, and they expressed interest in using the app in adjunct to a mindfulness-based practice (e.g. yoga).

Conclusion: Our proof-of-concept pilot findings suggest the mobile app is an acceptable and feasible platform for delivery. We note that this adaption did not include tailoring the intervention content to the unique needs of HIV+SMM. Future directions for this research include utilizing community input to further adapt the Positively Healthy app to maximize its relevance and acceptability for HIV+SMM. This formative research is a necessary first step in planning for a larger trial to test the efficacy of the adapted intervention.

HABLANDO CLARO: CLEAR TALK! APPLYING AN INTERGENERATIONAL APPROACH TO PREVENT HIV AMONG LATINAS

Melawhy L. Garcia, MPH, PhD¹, Natalia Gatdula, MPH¹, Lilia Espinoza, MPH, PhD², Erika Bonilla, MPH³, Mara Bird, PhD⁴, Britt K. Rios-Ellis, MS PhD⁵¹California State University Long Beach, Long Beach, CA; ²California State University, Fullerton, Fullerton, CA; ³Kaiser Permanente, San Jose, CA; ⁴Center for Latino Community Health, Evaluation and Leadership Training, Long Beach, CA; ⁵CSU Monterey Bay, Seaside, CA

Background: Hispanic/Latinos in the U.S. are disproportionately affected by HIV/AIDS. By 2016, Latino men who had sex with other men were the second most-affected subpopulation, and HIV diagnoses in Latino gay/bisexual men increased by 13%. Latinas who engaged in heterosexual contact were the fifth most-affected subpopulation. One in 6 are unaware of their HIV status. Despite public health efforts, Latinas experience a complex set of factors that place them at risk for infection. Risk factors include lack of access to health care, low socioeconomic status, traditional cultural norms (e.g., lack of sexual health communication), and low rates of HIV testing due to lack of knowledge and low perceived risk.

Objective: To test the efficacy of Hablando Claro: Clear Talk!, a culturally tailored intervention to reduce HIV infection risk among Latina adolescents (12-18 years old) and their female caregivers by increasing HIV knowledge, intergenerational sexual communication, and HIV testing.

Methods: Hablando Claro: Clear Talk! is an adaption of the evidence-based intervention Teen Health Project. Intergenerational dyads participated in one introductory session, two half-day sessions, and four monthly support groups led by trained community health workers. Intervention content, discussions, and activities based on Social Cognitive Theory focused on increasing: 1) HIV knowledge; 2) adolescent-caregiver communication about sex; and 3) HIV/STI risk reduction skills, self-efficacy, and testing. A one-group pretest-posttest design was used to assess the efficacy of the intervention. Assessments were self- or verbally administered prior to the sessions (pretest), immediately after (posttest), and three months after the intervention.

Results: Adolescents and their female caregivers (N=293) enrolled in the study. From pretest to three-month follow-up, HIV knowledge increased for adolescents and caregivers ($p < 0.001$ for each) and HIV testing increased significantly for adolescents ($p < 0.05$). Significant increases were observed for adolescent-caregiver sexual health communication as well as comfort in communicating about sex for both adolescents and caregivers ($p < 0.001$).

Conclusion: Our findings provide preliminary evidence that integrating sexual health and HIV risk-related knowledge with skills-based practice for Latina women and adolescents are effective components of a culturally tailored HIV prevention intervention for Latinas.

COMPARING VARIATIONS IN CHILDHOOD SEXUAL TRAUMA MEASURES IN PREDICTING ADVERSE HEALTH & FUNCTIONING OUTCOMES IN ADULTHOOD

Ashley Schuyler, MPH¹, Joseph Catania, Ph.D.¹¹Oregon State University, Corvallis, OR

Background: Research has linked experiences of childhood sexual trauma (CST) with adverse adult outcomes that span physical, psychological, and social domains of functioning. Differences in conceptualizing and measuring CST, however, have produced inconsistent results and inhibit the examination of basic trauma-related variables hypothesized to impact adult outcomes. In general, CST measurement lacks a conceptual grounding in established theoretical frameworks such as traumatic stress models. We compared a commonly used measure of CST (exposure) with a theoretically-derived measure of a key dimension of CST severity (i.e., duration; Hoier et al., 1992); measures are compared with regards to adverse adult outcomes across multiple domains. The majority of past studies are additionally impeded by the use of small/opportunistic samples with limited variation in outcome measures. We address this problem by using data from the National Sexual Health Survey (NSHS).

Methods: The NSHS is a national probability sample of U.S. adults (18-70 yrs.; N=6,537). Measures assessed perpetrator-specific sexual experiences in childhood (< 18 years) that involved the use of force or threats, the number of perpetrators, and the length of time over which the sexual trauma occurred with each perpetrator. We compared a dichotomous CST exposure measure to a multi-level measure of trauma duration. Controlling for background characteristics (age, race/ethnicity, gender, sexual orientation) we compared CST measures in the prediction of adverse outcomes across domains of physical (3 outcomes) and mental health (6 outcomes), intimate relationships (3 outcomes), & achievement (4 outcomes) (logistic regression & likelihood ratio tests).

Results: Relative to the CST exposure measure, the multi-level CST severity measure had significantly larger relationships to five adverse outcomes within two of the domains examined (mental health, achievement). Both measures had significant but similar relationships to all remaining outcomes. The multi-level variable showed significant dose-response relationships (i.e., greater duration with more adverse outcomes) in 7 models. Generally, those reporting the highest degree of CST severity demonstrated the largest effects. We observed both linear and non-linear relationships to adult outcomes.

Conclusions: The current findings suggest that a theoretically-derived measure of CST severity provides substantially more information about adverse outcomes in adulthood than more commonly used measures of CST exposure. The results also suggest that chronic traumatic stress related to CST should be studied in large heterogeneous samples where a wider range of outcomes and outcome values are employed. Integrating theoretical concepts to standardize CST measurement has important implications for screening and secondary prevention across the life span.

IDENTIFICATION AND CHANGES IN PERCEIVED STIGMA
INTERSECTIONALITY WITHIN A VIRTUAL COMMUNITY OF
YOUNG PEOPLE LIVING WITH HIV

Mary M. Step, PhD¹, Theodore Russell, BSPH², Steven A. Lewis, MBA, MPH³, Josh D. Kratz, MA⁴, Jennifer McMillen Smith, MSSA, LISWS⁵, Ann Avery, MD⁶

¹Kent State University, Kent, OH; ²Case Western Reserve University, Lakewood, OH; ³MetroHealth Medical Center / Case Western Reserve University, Cleveland, OH; ⁴The MetroHealth System, Tampa, FL; ⁵The MetroHealth System, Cleveland, OH; ⁶MetroHealth/ Case Western Reserve University, Cleveland, OH

Background: Intersectionality refers to the idea that multiple aspects of social identity (e.g., race, sexual orientation) can interact to create and maintain health disparities. The accumulated burden of these perceived stigmas may be key to addressing HIV disparities in linkage to care and viral suppression. *Positive Peers* is a smartphone application, that aims to provide young people living with HIV (YPLH) a supportive virtual community to counteract perceived stigma and ultimately better manage their illness.

Method: A mixed methods study that included survey and intensive interviewing modalities was conducted with out-of-care or newly diagnosed young people (18-34) living with HIV. Participants volunteered to download the *Positive Peers* mobile application to their phones and participate in a prospective observational study for 18 months. *Positive Peers* offers users multiple health management, tools and information, SMS communication functions, and frequently refreshed HIV relevant blogs and advice. Demographic data, medical record data, self-reports of perceived stigma were collected at enrollment, and prospectively at six, 12 and 18 months from baseline (n = 128).

Results: Interview transcripts revealed that most participants viewed themselves as outside the boundaries of mainstream society, and also as targets of discrimination and social exclusion. We detected the repeated theme that living with HIV created an additional layer of minority status to an existing intersectional social identity of being black and LGBTQ. Participants desired virtual space defined by inclusion and security and described *Positive Peers* as a non-discriminatory community consisting of people with similar life experiences. Fixed effects regression analysis showed a trend for decreased overall perceived stigma ($f = 3.62$, $p < .059$), and significant decrease in negative self-image ($f = 6.03$, $p < .015$) across the study period for all participants. On average the effect is small, but with some significant variation between participant ethnic groups, age, and disease status.

Discussion: Positive HIV status functions as a layer of intersectionality with race and sexual orientation that compounds the stigma perceived by YPLH. The *Positive Peers* mobile application provides a virtual space where disparity populations can normalize their experience. These data support the notion that technology interventions tailored toward disparity groups may be useful tools for reducing the burden of intersectional stigma and support HIV care outcomes.

RISK FACTORS OF CONSENSUAL AND SURVIVAL SEX IN A SAMPLE
OF HOMELESS AND FORMERLY HOMELESS YOUNG ADULTS

Eldin Dzibur, PhD¹, Harmony R. Rhoades, PhD², Danielle R. Madden, PhD¹, Brian W. Redline, BA¹, Sara Semborski, LCSW¹, Benjamin F. Henwood, PhD, MSW¹

¹University of Southern California, Los Angeles, CA; ²University of Southern California, SAN DIEGO, CA

Introduction: Daily recall methods have been successful in capturing sex events and understanding context and correlates in high-risk samples, such as young adults experiencing homelessness. Although homelessness among young adults is thought to be associated with risky sex, including exchanging sex for goods or services (i.e., survival sex), less is known about sex risk among young adults who have transitioned from homelessness to housing programs compared to those who remain homeless.

Objective: The objective of this study was to examine predictors of consensual and survival sex events in a sample of homeless and formerly homeless young adults.

Methods: Participants (N=123 housed, 109 homeless) were recruited from housing and service programs. Participants completed a questionnaire examining previous 90-day consensual and survival sex events, followed by a 7-day smartphone-based daily-recall regarding consensual and survival sex events. Age ($M=22.2$, $SD=2.3$), gender (54% male), race (42% Black), ethnicity (37% Hispanic), housing status, and relationship status (34% exclusively monogamous) were entered as covariates in logistic regressions predicting whether or not an individual had consensual sex or survival sex over the measurement period.

Results: Approximately 80% of participants reported consensual sex in the past 90 days, 28% reported consensual sex over 7 days, and 10% reported survival sex either in the past 90 days or over 7 days. Sex events in the past 90 days were positively associated with consensual sex during the week, and survival sex in the past 90 days was positively associated with survival sex during the week ($ps < 0.001$). Those in an exclusively monogamous relationship were more likely to report having any sex event during the week and more sex in the past 90 days than individuals in other relationships ($ps < 0.001$). Homeless participants were more likely to report survival sex during the week than participants in housing programs ($p < 0.01$).

Discussion: The study found that housing status may be protective against risky survival sex events, regardless of relationship status, indicating that supportive housing programs may provide a more stable environment. Although relationship status was an indicator for consensual sex events, exclusively monogamous relationships are thought to be low-risk. Future studies may seek to exclusively sample high-risk individuals, such as those in unstable relationships, to facilitate within-subject findings.

4:30 PM-4:45 PM

SCALING UP EVIDENCE-BASED TEEN PREGNANCY PREVENTION IN HIGH-NEED COMMUNITIES: THE KEEPING IT REAL TOGETHER INTERVENTION

Luanne Rohrbach, PhD, MPH¹¹University of Southern California, Los Angeles, CA

Introduction: Numerous factors facilitate the scale-up of evidence-based prevention interventions (EBIs) in community settings, including incorporating EBIs within existing systems, building organizational infrastructure and capacity for EBIs through training and technical assistance, establishing practitioner-scientist partnerships, and utilizing data systems to assess needs and evaluate impacts. Since 2010, the Teen Pregnancy Prevention Program, funded by the US Department of Health and Human Services, has sponsored efforts to scale up and evaluate EBIs that target sexual risk behaviors among youth. We describe the results of a multi-component project that scaled up an HIV/AIDS and pregnancy prevention intervention in schools and surrounding high-need communities located in Los Angeles County.

Methods: Over an 8-year period, we recruited 42 middle schools and 325 teachers to implement a comprehensive sexual health education program. Process evaluation data were collected from teachers, including student attendance, dosage, implementation fidelity, and program acceptance. School-based program implementation occurred in the context of a community-wide intervention that also included parent education, community mobilization, and disseminating information about youth-friendly clinics. To assess the effectiveness of the program in delaying sexual onset, we surveyed 9th-grade students each spring, from 2012 to 2019, in 10 high schools that project middle schools fed into (n=8000). Using a quasi-experimental design, we compared two groups of youth, those who received and did not receive the intervention during middle school.

Results: Our scale-up model focused on capacity building in program sites, including teacher training and regular technical assistant visits from project staff; identifying and supporting a lead teacher at each school; creating an on-line toolkit for resources and online process evaluation data reporting; regular meetings of a Teacher Advisory Board; and establishing a system for collecting outcome data.

Overall, the program reached more than 50,000 students. Outcome data showed that students who had received the intervention were less likely to report initiation of sexual activity by 9th-grade compared to students who did not participate. The program group also reported few pre-sexual behaviors and better outcomes on psychosocial variables hypothesized to be mediator of program effects.

Conclusions: Scale-up of evidence-based programs in community settings requires not only resources (both internal and external), but also a plan for building capacity, supporting implementation, collecting evaluation data, and sustaining implementation that is co-developed and endorsed by key community stakeholders.

EFFICACY OF A GENDER-RELEVANT TOBACCO CESSATION INTERVENTION AMONG LOW-INCOME WOMEN IN BRAZIL: RESULTS OF A RANDOMIZED TRIAL

Isabel C. Scarinci, PhD, MPH¹, Nadia Kienen, PhD, MPH², Sharina Person, PhD³¹University of Alabama at Birmingham, Birmingham, AL; ²Universidade Estadual de Londrina, Londrina, Parana, Brazil; ³University of Massachusetts Medical School, Worcester, MA

Background and Aim: The World Health Organization Framework Convention on Tobacco Control has identified understanding of women and their tobacco-related issues, as well as the need for the development of gender-relevant tobacco control efforts, a priority. We examined the efficacy of a theory-based, culturally- and gender-relevant Community Health Worker (CHW) intervention for low-income Brazilian women that augments the tobacco cessation program offered through the public health system (PHS). **Design:** Pragmatic group randomized controlled trial. **Setting:** Eight towns in a tobacco producing state in Brazil - Paraná. **Participants:** A total of 338 adult women current smokers recruited in the community were enrolled in the study between 2014-2017. **Intervention:** (1) Intervention (4 towns): 12 home visits by a CHW and scheduled appointment to attend the tobacco cessation program at the PHS; and (2) Control (4 towns): Scheduled appointment to attend the tobacco cessation program at the PHS. **Measurements:** The primary outcome was self-report abstinence at 7-month follow-up. An interviewer-administered questionnaire was administered at baseline and 7-month follow-up (e.g., demographics, depressive symptomatology, etc.) as well CO measurement.

Results: The overall retention rate at 7-month follow-up was 80.7% in the intervention group and 85.1% in the control group. Using intention-to-treat analysis, abstinence at 7-month-follow-up was 20% in the intervention group vs. 11% in the control group. Multivariable modeling showed that participants in the intervention arm had 1.88 times the odds of self-reported smoking cessation than control participants after adjustment for depressive symptomatology, self-efficacy, and having someone in the house that smokes. Only self-efficacy remained significant in the full model as a predictor of tobacco cessation. Replication of these analyses using the objective measure of CO at undetectable rates (cut-off score of 8ppm) yielded similar results.

Conclusions: A theory-based, culturally- and gender-relevant intervention delivered by trained CHWs can successfully promote tobacco cessation among low-income women.

EFFECTS OF AEROBIC EXERCISE ON PATTERNS OF QUIT BEHAVIOR AMONG WOMEN: RESULTS FROM THE QUIT FOR HEALTH RCT

David M. Williams, Ph.D.¹, Shira Dunsiger, PhD², Jessica A. Emerson, PhD³, Bess H. Marcus, Ph.D.⁴, Robert Miranda, PhD⁵, Peter Monti, PhD⁶, Michael Ussher, PhD, MSc, BA⁷

¹Brown University School of Public Health, PROVIDENCE, RI; ²Brown University, Portsmouth, RI; ³Miriam Hospital, East Providence, RI; ⁴Brown University, Sharon, MA; ⁵Brown University, Providence, RI; ⁶Brown U., Providence, RI; ⁷St George's, University of London, London, England, UK

Quit for Health was a randomized clinical trial designed to examine efficacy of aerobic exercise as an adjunct to smoking cessation treatment among women. Participants were randomized to 12 weeks of moderate intensity exercise (N=53) vs. 12 weeks of a video-based wellness program (N=52). Data were collected both at in-person sessions and via ecological momentary assessment (EMA) continuously over 12 weeks. The goal of analysis was to understand intervention effects on end of study cessation outcomes as well as patterns of quitting behavior over time. Longitudinal models implemented with Generalized Estimating Equations were used to assess group differences in bio-verified 7-day PPA at end of treatment. To further understand potential differences in quitting behavior over time, Latent Class models (LCMs) were used to identify patterns of real-time self-reported quit behavior over 12 weeks. Potential differences in the distribution of quitting patterns between-groups was assessed using ANOVA and associations between quitting pattern and smoking behavior at follow-up was examined using logistic regression. The overall sample consisted of 105 participants randomized to Exercise vs. Wellness. Participants were 42.5 years of age on average (SD=11.2), predominantly non-Hispanic (93%) with half reporting a college-level education. Participants smoked an average of 17.0 (SD=7.7) cig/day at baseline, with no significant between-group differences. Mean standardized nicotine dependence was -0.32 (SD=.98) at baseline, with significantly higher scores in Exercise vs. Wellness (p=.004). End of treatment outcomes indicate that at 12 weeks, 25% of Exercise participants had bio-verified 7-day PPA vs. 42% of Wellness participants (p=.10). LCMs supported 4 patterns of quit behavior. Specifically, 14% of participants quit by week 3 and had high probability of quitting through week 12 (*sustained quitters*); 49% of participants were *non-quitters*; 24% were *slow and steady quitters* (slope increased over time with high probability of quitting at week 11) and 13% had high probability of quitting at week 2 and a decline in quitting thereafter (*relapsers*). There were significant between-group differences in pattern (p=.04) with more Exercise participants in patterns characterized by slow and steady quitting behavior, which was, in turn, associated with continuous abstinence at 9-month (OR=1.16, 95% CI: 1.02-1.36) and 12-month (OR=1.08, 95% CI: 1.01-1.64) follow-up. In sum, while there was no direct effect of aerobic exercise on post-treatment (12-week) quitting behavior, engaging in exercise during quit attempts led to a more gradual pattern of quitting behavior, which was associated with continued smoking abstinence up to one year post-randomization.

PILOT RCT OF A TAILORED SMOKING CESSATION PROGRAM FOR PEOPLE LIVING WITH HIV IN THE WASHINGTON, D.C. METROPOLITAN AREA

Elexis C. Kierstead, MPH¹, Emily Harvey, MA², Denise Sanchez, n/a³, Kimberly Horn, EdD⁴, Cassandra A. Stanton, PhD, MS⁵, Charles Debnam, BA, MCHES, CTTS⁶, Lorien Abroms, n/a³, Freya Spielberg, MD, MPH⁷, Amy Cohn, PhD⁸, Tiffany R. Gray, DrPH, MPH⁹, Many Magnus, PhD, MPH¹⁰, Minal Patel, PhD, MPH¹, Raymond Niaura, PhD¹¹, Jessica Elf, PhD MPH¹²

¹Truth Initiative Schroeder Institute, Washington, DC; ²Henry M. Jackson Foundation, Arlington, VA; ³George Washington University, Washington, DC; ⁴Virginia Tech Carilion Fralin Biomedical Research Institute, Roanoke, VA; ⁵Westat, Rockville, MD; ⁶Community Wellness Alliance, Washington, DC; ⁷Dell Medical School, University of Texas, Austin, AUSTIN, TX; ⁸University of Oklahoma Health Sciences Center, Oklahoma City, OK; ⁹DC Department of Health, Landover, MD; ¹⁰Milken Institute School of Public Health at GW, Washington, DC; ¹¹New York University, New York, NY; ¹²Colorado State University, Fort Collins, CO

Introduction: The prevalence of smoking among people living with HIV (PLWH) in Washington, D.C. is double the national average, at 40%. The morbidity and mortality attributed to tobacco-related disease in PLWH in the U.S. currently outweighs that due to HIV infection. Smoking cessation is key to improving the health of PLWH, however cessation programs for this population have had mixed results. This study evaluated the preliminary efficacy of a pilot RCT of a tailored intervention (TI) for smoking cessation targeting PLWH.

Methods: The TI included one in-person counseling session and a 2-way text messaging program for 30 days and integrated aspects of minority stress theory, intersectional identities, and cognitive behavioral therapy. Standard of care counseling was the control (SC). The primary outcome was smoking cessation at 1 month. Secondary outcomes included changes in cigarettes per day (CPD) and self-efficacy. Intent-to-treat analysis was used.

Results: A total of n=25 participants were enrolled (11 TI, 14 SC); n=2 were lost to follow up. The median age was 54 (IQR: 48,58) and most participants were male (n=18, 72%), African American (n=19, 76%), and making less than \$20,000/year (n=19, 76%). Half the sample identified as a sexual minority (n=13, 52%). Although not significant due to low power, the TI arm had larger proportions of African Americans (n=10/11, 91% TI vs. n=9/14, 64% SC) and menthol smokers (n=10/11, 91% TI vs. n=11/14, 79% SC), and greater CPD at baseline (median [IQR]: 15 [6,20] TI vs. 9 [1,15] SC). Although not significant, a lower proportion quit in the TI group than the SC group (n=3, 27% TI vs. n=5, 36% SC). However, there were greater reductions in CPD in the TI arm (-10 [-19,-3] TI vs. -0.5 [-15,0] SC). Self-efficacy to quit increased in both arms, and this was a significant increase from baseline to follow-up in the TI (p-value: 0.04). African American participants were significantly less likely to quit than those who were another race (RR: 0.32, p-value: 0.03). Only 7(28%) had been advised to quit by a provider in the previous 12 months, and most (n=22/23, 96%) indicated they would like more integration of quit services in their HIV care.

Discussion: This new intervention shows potential efficacy for smoking cessation among PLWH. Larger sample size is needed to fully evaluate the efficacy of this approach. Strategies to attenuate the impact of race on quitting smoking in PLWH should be integrated into future interventions.

Paper Session 24

4:15 PM-4:30 PM

PREDICTORS OF SMOKING CESSATION ONE YEAR AFTER LUNG CANCER SCREENING WITHIN THE VETERANS HEALTH ADMINISTRATION, 2014-2018

Jaimee L. Heffner, PhD¹, Chelle L. Wheat, MPH, PhD², Paul Krebs, PhD³, Laura Feemster, MD⁴, Deborah E. Klein, MD⁵, Steven B. Zeliadt, PhD⁶¹Fred Hutchinson Cancer Research Center, Seattle, WA; ²Veterans Health Administration, Seattle, WA; ³VA San Diego Healthcare System, San Diego, CA; ⁴VA Puget Sound/University of Washington, Seattle, WA; ⁵Swedish Medical Group, Seattle, WA; ⁶VA Center of Innovation for Patient-Centered and Value-Driven Care, Seattle, WA

Background: Although the value of supporting smoking cessation as part of lung cancer screening is widely acknowledged, little is known about long-term cessation among screening patients in real-world treatment settings, including what characteristics are associated with quitting and whether screening results and tobacco treatment initiated at the time of screening predict long-term cessation. The objective of this study was to evaluate predictors of 1-year post-screening cessation outcomes within the largest integrated healthcare system in the US—the Veterans Health Administration (VHA).

Method: Administrative data from the VHA National Corporate Data Warehouse were used to identify Veterans who received a first low-dose CT (LDCT) for lung cancer screening between 2014 and 2018 and who had smoking Health Factors data available in the electronic medical record 9-15 months after LDCT. Multilevel modeling was used to evaluate individual demographic and clinical predictors of cessation after controlling for facility-level random effects.

Results: Of the 32,707 Veterans (95% male) identified as current smokers at the time of first screening, 5,129 (15.7%) were no longer smoking one year later. Predictors of cessation included older age, being unmarried; having more physical health conditions; absence of a trauma/stress-related disorder or a personality disorder; receiving first screening in 2018; and having suspicious screening findings (LungRADS=4) (all p-values < .05). Receipt of cessation treatment (behavioral and/or pharmacological; 18.2% of sample) was not a significant predictor of quitting (p=.072).

Conclusions: One-year quit rates within the VHA were comparable to those observed previously in clinical trials and cohort studies of lung cancer screening (i.e., 10-17%). Taken together with our previous finding that the cessation pharmacotherapies most commonly prescribed to Veterans undergoing LDCT were the least effective ones, the lack of association between receipt of treatment and long-term cessation may be due to gaps in connecting patients with the most effective treatment options, such as combination NRT. This suggests a need to examine how cessation support is being provided and to improve intervention effectiveness for this population. Screening recipients who are younger, married, have fewer physical health problems but greater mental health problems, and who have LungRADS scores < 4 may be particularly in need of additional quit support.

4:30 PM-4:45 PM

GUIDED IMAGERY FOR SMOKING CESSATION: IDENTIFYING KEY THEMES IN GUIDED IMAGERY SCRIPTS DEVELOPED BY SMOKERS WHO WANT TO QUIT

Peter Giacobbi, Ph.D.¹, Judith S. Gordon, PhD², Julie Armin, PhD², Uma Nair, PhD², Yessenya Barraza, n/a²¹West Virginia University Research, Morgantown, WV; ²University of Arizona, Tucson, AZ

Guided imagery is an enhanced visualization technique intended to help individuals achieve desired goals and outcomes, and evidence supports its use for smoking cessation. The use of guided imagery for tobacco cessation involves a collaborative approach between coaches and smokers to develop written scripts for smokers to use in the process of quitting. While evidence supports a tailored approach for guided imagery script development, identifying common themes across smoker-developed scripts could provide a more efficient and standardized approach to delivery. A novel, scalable method for delivering guided imagery interventions is via a telephone quitline model. In a recently completed trial, we developed and tested a telephone-based guided imagery smoking cessation program. Participants in the trial were recruited through a statewide quitline or community-based methods and then randomized to a guided imagery Intervention Condition (IC; n=56) or active behavioral Control Condition (CC; n=49). In the IC, the coach and participant collaboratively created guided imagery scripts which were then delivered by email as audio files for participants to practice between coaching sessions. The transcribed scripts of the 56 IC participants (64.2% female; mean age=49.6) were coded by members of the study team and analyzed using the constant comparison approach. The major purposes of each coaching session, as per the published protocol, were used as a framework to guide our analyses. Major themes included: 1) reasons and benefits of quitting (e.g., health, family); 2) identification of coping strategies for triggers (e.g., avoidance, exercise); 3) coping with cravings and withdrawal (e.g., accepting that craving will go away); 4) preparing to quit (e.g., preparing to be smoke-free); and 5) relapse prevention (e.g., living life smoke-free.). Exemplars of each theme will be reported. A more nuanced analysis of the scripts revealed themes that reflected cognitive (routine, habits, and changes in behavior), motivational (emotionally laden terms and confidence or self-efficacy messages) and future-focused thinking. These “higher-order” imagery themes align with previous cross-sectional and health behavior change trials. Results of the script analysis suggest ways to refine and standardize the GI scripts which could assist in the development of a smoking cessation script library and more rigorous efficacy testing using this cognitive technique.

ADAPTIVE GAMESQUAD: A NOVEL PHYSICAL ACTIVITY AND VIRTUAL HEALTH COACHING INTERVENTION FOR YOUTH WITH MENTAL HEALTH CHALLENGES

April B. Bowling, ScD, MA¹, James Slavet, PhD², Chelsea Hendrick, BS³, Phillip J. Nauta, B.S.⁴, Marilyn Augustyn, N/A⁵, Mediatrix Mbamalu, MD⁶, Carol Curtin, PhD, LICSW⁷, Linda Bandini, PhD⁸, Aviva Must, PhD⁹, Amanda E. Staiano, PhD, MPP, MSc³

¹Merrimack College School of Health Sciences, North Andover, MA; ²Marblehead Public Schools, Marblehead, MA; ³Pennington Biomedical Research Center, Baton Rouge, LA; ⁴Pennington Biomedical Research Center, Greenwell Springs, LA; ⁵BUSM, Boston, MA; ⁶Boston Medical Center, Boston, MA; ⁷E.K. Shriver Center, UMass Medical School, Worcester, MA; ⁸University of Massachusetts Medical School, Worcester, MA; ⁹Tufts University School of Medicine, Boston, MA

Background: Youth with mental health diagnoses (MHD) are at increased risk of unhealthy lifestyle behaviors such as low physical activity (PA), poor diet and sleep, and excessive screen use, contributing to elevated rates of overweight and chronic diseases. They also face barriers to participation in lifestyle/behavioral interventions due to depleted familial resources and competing treatment priorities. This study translated an existing, home-based exergaming and telehealth coaching program developed for youth with overweight/obesity (GameSquad) for use among youth with MHD. We assessed intervention feasibility, engagement, and changes in pre/post moderate-to-vigorous PA (MVPA).

Methods: Participants were recruited from special education and clinic settings and randomized to receive a 10-wk intervention or waitlist control. Intervention participants received an Xbox, 3 exergames, a Fitbit, and a challenge booklet prescribing 3 exergame challenges/wk. Up to 6 coaching sessions were conducted virtually through the Xbox with both child and parent present. Coaches helped participants set PA goals and provided education on nutrition, sleep hygiene and screen use. Process data including coaching and exergaming session participation and engagement were collected via REDCap and Fitbit downloads. 7-days of MVPA data pre and post the 10-week intervention were collected via Actigraph.

Results: Twenty-three participants (mean age 14.8 y, 82.6% male) were consented/assented (n=11 intervention, n=12 control). Equipment was successfully installed and utilized by all intervention participants, who averaged 5 of 6 planned coaching sessions. Including 4 who discontinued exergaming by week 5, participants completed 50% of planned exergame sessions and averaged 104.8 (+/- 72.6) min/wk of exergaming. Intervention participants decreased their daily MVPA less than control participants after the 10-week intervention (2.02 vs. 8.12 min/day, p=0.42). Technology challenges and lack of interest in exergames were the most commonly cited reasons for not completing planned exergame sessions. A majority (67%) reported enjoying coaching sessions and receiving useful healthy living tips.

Conclusions: Adaptive GameSquad is a feasible and promising intervention to improve PA and health knowledge among youth with MHD. Participants successfully engaged in virtual health coaching sessions. More game choices and better technology integration would likely improve PA engagement.

Paper Session 25

3:45 PM-4:00 PM

YOUTH AND YOUNG ADULT SUICIDE: DO STATES WITH GREATER BEHAVIORAL HEALTH TREATMENT CAPACITY HAVE LOWER SUICIDE RATES

Thomas Wickizer, Ph.D., M.P.H.¹, Evan Goldstein, MPP², Laura Prater, PhD³

¹College of Public Health, Ohio State University, Columbus, OH; ²Ohio State University, Columbus, OH; ³The Ohio State University College of Medicine, Grandview, OH

Background: Suicide is the second leading cause of death among youth and young adults. Significant risk factors for suicide include having a mood disorder such as depression, or a substance use disorder, or having firearms available and keeping them in the home. The aim of this study was to evaluate whether states with greater behavioral health treatment capacity have lower suicide rates among youth and young adults, compared with states having less treatment capacity.

Methods: We conducted a state-level time series cross sectional analysis (n=126), representing 45 states over 3 years, 2005, 2010 and 2015 (5 states had too few cases to warrant analysis). The outcome variable was the annual firearm suicides per 100,000 persons age 1-24. Two explanatory variables representing behavioral health treatment capacity were analyzed: 1) annual behavioral health workforce size (ABHW), and 2) number of facilities offering intensive outpatient substance use treatment (OSUT). Covariates included in the analysis were state population, %nonwhite, %male, unemployment rate, and number of FBI background checks, which served as a proxy for gun availability. Multivariable fixed-effects linear regression models were used to examine the association between the two explanatory variables and the suicide rate. The suicide rate and the explanatory variables were specified in log form, so the estimates can be interpreted as elasticities (% changes).

Results: The mean annual suicide rate increased by 25.4% from the 2005 mean rate of 2.95 suicides per 100,000. States with the highest suicide rates included Alaska, Montana and Wyoming. States with the lowest rates included Maryland, New Jersey and New York. On average, for every 10% increase in a state's ABHW, the suicide rate among youth and young adults decreased by 1.9% (p=.003). A similar estimate and significance level was found for the second explanatory variable representing OSUT.

Conclusion: There appears to be a small but statistically significant effect of behavioral health treatment capacity on the suicide rate for youth and young adults. There are many compelling reasons to increase access to mental health treatment and substance use treatment, but increasing that access is likely to have only a small effect on the major public health problem of youth suicide. Attention should focus on enacting appropriate policies to promote gun safety and limit the availability of guns. In addition, pediatricians and other physicians and clinicians should be encouraged to perform appropriate screening and assessment to identify youth and young adults who may be at risk for attempting suicide; and the medical community, more generally, should be encouraged to initiate advocacy activities to promote sensible, evidence-based policies to improve gun safety and limit gun availability.

4:00 PM–4:15 PM

AMIGAS LATINAS MOTIVANDO EL ALMA (ALMA): AN INTERVENTION TO REDUCE STRESS, DEPRESSION AND ANXIETY AMONG LATINA IMMIGRANT WOMEN

India Ornelas, PhD¹, Georgina Perez, MSW¹, Serena Maurer, PhD¹, Daron Ryan, MPH¹, Cynthia J. Price, PhD¹, Deepa Rao, PhD¹¹University of Washington, Seattle, WA

Background: Latina immigrant women are at increased risk for depression and anxiety due to the social, political and economic stressors that shape their lives in the United States. They also face many barriers to access mental health care, including lack of health insurance, language barriers, and stigma. Amigas Latinas Motivando el Alma (ALMA) is a community-based intervention designed to reduce symptoms of stress, depression and anxiety among Latina immigrant women and address known barriers to care.

Methods: The ALMA intervention was developed based on previous formative research, stress and coping theory, and existing evidence-based strategies. The intervention is currently being tested in a delayed intervention control trial (N = 200) in three community sites. Participants complete surveys at four time points to assess outcomes, including measures that assess their satisfaction with the program.

Results: The program aims to: (1) help women identify positive coping strategies they are already using to manage stress; (2) introduce new coping strategies (e.g. mindfulness techniques, body awareness, and social support); and, (3) provide resources for additional mental health support if needed. The 8-week intervention has been delivered at two community-based organizations, perceived as safe and welcoming environments. The sessions are co-led by instructors with expertise in social work, mindfulness and yoga. Average program attendance is 18 participants at each session, 66% of those initially recruited. Preliminary analyses (N = 43) suggest that women have high levels of satisfaction with the intervention. All participants receiving the program indicated that they would recommend it to others. Almost all participants reported that it helped them reduce stress, feel less isolated and improved their mental health.

Conclusions: Community-based mental health programs have potential to reach Latina immigrant women who might not otherwise seek mental health services. Future studies should assess the efficacy of these approaches.

Paper Session 25

4:15 PM–4:30 PM

TRAUMA EXPOSURE AND RATES OF ARREST IN AN URBAN SAMPLE OF PREGNANT WOMEN

Brenda Baker, Ph.D.¹¹Emory University, Atlanta, GA

Background: Women of the childbearing age make up the largest portion of the female justice-involved population, with approximately 3–5% entering a correctional setting pregnant. In addition, justice-involved women have significant histories of mental health conditions and trauma exposure. Conditions both known to impact rates of justice involvement.

Purpose: To describe associations between trauma exposure and trauma related psychopathology in pregnant, low socioeconomic status women who report justice involvement.

Methods: Pregnant women were randomly recruited from primary care and obstetric/gynecologic clinics at an inner-city medical center. Eligibility requirements included ability to give informed consent, have a working phone number, between the ages of 18–65, and ability to speak and read English. Participants completed a demographic form, and surveys including: Traumatic Events Inventory (TEI), Childhood Trauma Questionnaire-Short Form (CTQ-SF), Modified PTSD Symptom Scale (MPSS), and the Beck Depression Inventory (BDI). Participants were compensated \$15 for participating. Findings: Participants included 794 pregnant women. The mean age of participants was 25.8 + 5.7 years old, 39.3% had completed 12th grade, 21.5% had some college or technical school; 65.8% were unemployed. Only 9.1% of the sample reported a history of hospitalization for psychiatric reasons, and 11.5% reported a previous suicide attempt. Arrest was prevalent in the sample with 41.3% reporting at least one arrest. Statistical analysis indicated exposure to more types of childhood trauma was significantly associated with Post Traumatic Stress Disorder ($p < 0.001$), major depressive disorders MDD as adults ($p < 0.001$); additionally, a diagnosis of both PTSD ($p < 0.001$) and MDD ($p < 0.001$) was associated with increased rates of arrest. Childhood trauma exposure was significantly associated with increased rates of arrest ($p < 0.001$), while adult trauma was not significantly associated with arrest ($p = .229$).

Conclusions: Screening pregnant women in the prenatal care setting for trauma exposure and psychopathologies has the potential to identify women at higher risk for involvement in the justice system, to address mental health conditions and develop plans of care that potentially reduce involvement in the justice system.

CARE HEAD INJURY RACK CARD: DEVELOPED FOR ADVOCATES SERVING DOMESTIC VIOLENCE SURVIVORS WITH APPLICATION IN HEALTH SETTINGS

Julianna M. Nemeth, PhD¹¹The Ohio State University, Columbus, OH

Background: Head trauma and strangulation are common among domestic violence (DV) survivors. In Ohio, our research has documented that 81% of domestic violence survivors accessing advocacy services have experienced direct blows to the head, while 83% report strangulation. Until the CARE project, no tools existed to facilitate conversations with survivors about the health impact of such exposures.

Methods: In partnership with Ohio State University (OSU), the Ohio Domestic Violence Network (ODVN) secured a federal grant (2016-2019) to create and evaluate CARE (Connect, Acknowledge, Respond, Evaluate). Needs assessment focus groups at advocacy organizations serving DV survivors led to the development of CARE advocacy tools, including the Head Injury Rack Card (download at www.odvncares.org). Process evaluation focus groups (n=62) and outcome evaluation surveys (n=61) were completed by staff at DV organizations to facilitate our understanding of the impact of CARE on advocacy practice.

Process Evaluation Results: Staff cited widespread use of the CARE Head Injury Rack Card and reported the card normalized head injury among DV survivors and facilitated conversations about the impact of exposure on functioning. Advocates are not only using this tool, but also have shared and recommend its use in other settings: criminal justice (e.g. police, courts, jail), health (e.g. ERs, drug or mental health treatment), and service (e.g. children and job and family services, schools). One administrator noted, “The doctor in the ER called me and said he was very impressed with it. Because he...didn’t think he would look for those signs had she not taken that card with her.”

Outcome Evaluation Results: 62% of advocates reported using the CARE Head Injury Rack Card with survivors. Since participating in CARE, 68% and 58% of staff reported talking to survivors more often, 74% and 69% reported more comfort, and 73% and 67% reported more confidence in speaking with survivors about the potential impact of being hit in the head or strangled, respectively.

Discussion: 1 in 4 women will experience DV. The head and neck are the most common places targeted by perpetrators. The CARE Head Injury Rack Card could help transform the identification of the potential presence of traumatic and anoxic-hypoxic brain injury among DV survivors.

FEASIBILITY STUDY OF A BRAIN TRAINING PROGRAM IN SENIOR CENTER

Elizabeth Orsega-Smith, PhD¹, Brianna D. Wolfe, n/a², Nicolette M. Amato, n/a¹¹University of Delaware, Newark, DE; ²University of Delaware, Bear, DE

Background: The number of Americans 65 and older is expected to more than double in the next forty years, expanding to 88.5 million by 2060. Along with growth in the older adult population, there will be increases in the numbers of individuals with cognitive deficits. Therefore, it will be important to investigate programs that have the potential to delay the decline in cognition through brain stimulating activities.

Methods: An 8 week community-based brain training program was piloted with the goal to provide education about memory loss, to build cognition, stimulating peer support, and to provide skill building, and mentally challenging activities. During each 90 minute session, 10 independently living older adults were engaged in warm-up activities; such as word searches, crosswords, or trivia style games; followed by information and discussion about a particular artist (music or visual) or part of history, and completed an art project circling around the theme. These participants were mostly White/Caucasian (80%), female (90%), retired (80%) with a mean age of 70.5 (+7.5) years of age. All of the participants had a high school education or higher, with the majority (50%) completing some college.

Results: Pre and post program assessments of quality of life and cognition (SLUMS) showed significant improvements in SLUMS ($p < 0.001$). There were significant relationships between age and quality of life ($p < 0.05$), SLUMS and attendance ($p < 0.05$) and SLUMS and quality of life ($p < 0.05$).

Conclusions: The results of this feasibility study suggest that it is possible that brain training can engage older adults and may help to maintain cognition, with the potential to delay the decline of cognition. Overall, as aging progresses, cognitive declines become more prevalent. Therefore, proper brain stimulation programs implemented in independent living populations at risk for cognitive decline may delay the onset or progression of these aging diseases.

UNDERSTANDING ECOLOGICAL CONTRIBUTORS TO PHYSICAL INACTIVITY FACED BY RURAL AMERICAN INDIAN AND ALASKA NATIVE OLDER ADULTS

Maja Pedersen, MS¹, Diane K. King, PhD²¹University of Montana, Missoula, MT; ²University of Alaska Anchorage, Anchorage, AK

Introduction: American Indian and Alaska Native (AIAN) adults, who are aging in some of the most under-resourced, remote communities in the U.S., experience environmental and social barriers to engaging in physical activity (PA), a key determinant of healthy aging. AIAN older adults face pronounced health disparities including higher rates of poverty, chronic disease, disability, and all-cause mortality. Increasing PA to support healthy aging is extremely relevant for rural AIAN older adults given greater health risks and fewer services. Tailoring PA interventions to fit within the geographic- and social- context for rural AIAN seniors is critical to assuring their reach, adoption and sustainability.

Methods: We used multi-phased, community-engaged methods to (1) develop partnerships with AIAN communities in rural northwest U.S.; and (2) involve AIAN older adults in data collection to understand physical, social and cultural environmental supports and barriers to PA. Phase 1 methods followed recommendations for research with AIAN communities, including cultural training for investigators; hiring local staff to build research capacity; forming a community advisory board to align project activities with community priorities; and using formative research strategies such as listening sessions and interactive presentations. Phase 2 methods will include AIAN adults ages 55+, who will complete qualitative interviews and quantitative surveys to characterize social, cultural, and environmental factors that influence inactivity and PA. Our goal is to increase access to PA opportunities for AIAN older adults.

Results: Phase 1 findings from community sessions identified chronic disease-related supports (i.e., increased motivation for PA following diagnosis) and barriers to PA participation (i.e., inadequate outreach to involve older adults in multigenerational activities, few organized PA programs, and limited transportation). Phase 2 builds on these findings; themes of PA barriers and enablers across ecologic levels from 20 rural AIAN older adults will be presented, along with recommended strategies to increase PA opportunities.

Impact: Community-engaged methods used during formative and intervention development phases of research assure inclusion of diverse aging populations in public health efforts. Knowledge of social-ecological determinants of PA will inform implementation and intervention strategies that will reduce disparities and promote healthy aging.

PSYCHO-EMOTIONAL EFFECTS OF CHINESE CALLIGRAPHY HANDWRITING (CCH) INTERVENTION IN PERSONS WITH MILD COGNITIVE IMPAIRMENT

Yueh-Chuan Chien, n/a¹, An An Chao, PhD², Lin C. Chieh, assistant professor³, Yu-Chun Yen, n/a⁴, Henry S.R. Kao, Chair Professor⁵, Yu-Ting Shen, n/a⁶

¹National University of Tainan, Tainan, Tainan, Taiwan (Republic of China); ²Chung Yuan Christian University, Taiwan, Taoyuan City 325, Taoyuan, Taiwan (Republic of China); ³Tri-Service general hospital, Taipei City, Taipei, Taiwan (Republic of China); ⁴Taipei Medical University, Taipei, Taipei, Taiwan (Republic of China); ⁵The University of Hong Kong, New Taipei City, Taipei, Taiwan (Republic of China); ⁶Taipei Medical University, Taipei City, Taipei, Taiwan (Republic of China)

Background: Past research has shown that training by Chinese calligraphy handwriting (CCH) improves one's general cognitive functions, the cognitive abilities of people with mild cognitive impairment (MCI), improved spatial ability and picture memory of Alzheimer patients as well as a clinical case involving guided finger writing which caused a coma patient to have awakened after 10 years of unconsciousness. One common feature in the above studies was the use of distinctive visual-spatial properties of Chinese characters construction, i.e. the visual geometric properties of angularity, closure, symmetry and parallelism, that contributed to the subjects' perceptual and cognitive facilitation.

Objectives: No studies have examined the effects of calligraphy training with such geometric properties in the emotional and relaxation states of the normal or clinical patient groups. This pilot study tested this relationship among people with MCI.

Methods: A single-blind, randomized controlled trial was carried out in a sample of 23 participants aged 65-80 with Mini-Mental Status Examination (MMSE) scores at 24-27. Group 1 (N=11, high geometric characters) and Group 2 (N=12, low geometric characters) were trained for 8 sessions of brush writing, each lasting 50 minutes with one session per week for 8 consecutive weeks. We used the General Health Questionnaire (GHQ) as the psycho-emotional measures respectively before and after the whole treatment.

Results: The pre-post GHQ total scores showed a marginally significant result in favor of Group 1 ($p=0.08$), but no effect for Group 2. The pre-post difference of GHQ Anxiety sub-scores revealed a significant score reduction in Group 1 ($p=0.05$), but not in Group 2. A further comparison in the pre-post score difference between Groups 1 and 2 reached also marginally significant ($p=0.07$) in GHQ total scores and significant ($p=0.04$) in GHQ Anxiety sub-scores.

Discussion: The previous successful reduction of anxiety states by calligraphy treatment has been recorded mainly in the use of general (geometric and non-geometric mixed) writing characters. This study is to clarify the influence that geometric properties count for. The overall findings mark a modest beginning on advancing CCH loaded with geometric properties as an effective treatment to reduce anxiety. The findings have implications for developing similar geometric writing characters for treating anxiety disorders, stress-related and other psycho-emotional conditions.

DESIGNING A BEHAVIORAL INTERVENTION FOR AFRICAN AMERICANS WITH MILD COGNITIVE IMPAIRMENT AND HYPERTENSION

Kathy D. Wright, PhD,RN¹, Maryanna D. Klatt, PhD², Ingrid R. Adams, PhD RD LD LDE³, Christopher Nguyen, PhD⁴, Alai Tan, PhD¹, Douglas Scharre, MD⁵, Mion Lorraine, PhD,RN¹, Todd B. Monroe, PhD,RN¹

¹College of Nursing, The Ohio State University, Columbus, OH; ²Clinical Family Medicine, The Ohio State University, Columbus, OH; ³The Ohio State University College of Medicine, Columbus, OH; ⁴Department of Psychiatry & Behavioral Health, The Ohio State University Wexner Medical Center, Columbus, OH; ⁵The Ohio State University Wexner Medical Center, Columbus, OH

Uncontrolled hypertension (HTN) is a major risk factor for developing cognitive decline, Alzheimer's disease and related dementia disorders (ADRD). New guidelines for HTN management designate a systolic blood pressure < 130, but many African Americans with HTN do not achieve this target. The purpose of this pilot study protocol is to deliver a novel intervention, combining Mindfulness in Motion[®] and the Dietary Approaches to Stop Hypertension (DASH), to improve blood pressure self-care in African American (AA) older adults with mild cognitive impairment (MCI) and HTN. AAs aged 65 and older were randomized to mindfulness plus DASH, attention control (non-health related education delivered in 8-weekly group sessions) or control group (DASH diet pamphlet only). The Mindfulness in Motion (MIM) plus DASH intervention is delivered in 8-weekly group sessions of 6-10 participants. MIM includes mindful movements from chair/standing, breathing exercises and guided meditation. The DASH intervention uses a critical thinking approach that involves problem solving, goal setting, reflection, and developing self-efficacy. Both components are culturally tailored for older African Americans. Cognitive examination, diet and mindfulness practice surveys, and blood pressure are collected at baseline and 3 months. Seventy-five African Americans were screened and 38 were enrolled (women= 22; men= 7) and randomized to MIM DASH (n=13) attention control (n= 13) and control (n=12). Cohort I (n= 18) completed the study in June, 2019 and cohort II (n=20) will complete the study in November, 2019. Findings from this pilot study may provide the preliminary evidence that MIM plus DASH may improve blood pressure self-care in African Americans with MCI and HTN.

THE ASSOCIATION BETWEEN HERPESVIRUS REACTIVATION AND EXECUTIVE FUNCTIONING AMONG HEALTHY MIDDLE-AGED ADULTS

Hannah B. Short, N/A¹, Kyle W. Murdock, PhD²

¹The Pennsylvania State University, State College, PA; ²The Pennsylvania State University, University Park, PA

For many years, herpesviruses have been hypothesized to be associated with cognitive decline because they create life-long infections within neuronal cells in areas that are typically altered among those with Alzheimer's disease (AD). Previous work has demonstrated that those with AD and mild cognitive impairment (MCI) have greater herpesvirus reactivation (i.e., antibody titers) than healthy controls (Mancuso et al, 2014). Such findings suggest that poor immune control of the herpesvirus may contribute to cognitive decline; however, little is known about how herpesviruses may be associated with cognitive performance among healthy individuals. This is an important gap in the literature given that other forms of immune dysregulation (e.g., inflammation) are known to be associated with executive functioning (e.g., Wersching et al., 2010). In the present study, we examined the association between Epstein - Barr virus (EBV) antibody titers and performance on measures of executive functioning among a sample of 60 healthy and middle-aged adults ($M_{age} = 61.08$, $SD = 5.96$; 78.3% female) living in or near State College, PA. Each participant visit began at 8:00 am. After establishing informed consent, a phlebotomist engaged in a blood draw prior to participants completing a battery of neuropsychological tests. Measures of executive functioning included the Color-Word Interference Test to measure Inhibition (Delis, Kaplan, & Kramer, 2001), the Digit Span task to measure Updating/Monitoring (Wechsler, 2008), and the Wisconsin Card Sorting Test to measure Cognitive Flexibility (Heaton & PAR Staff, 2003). EBV antibody titers were measured by Microgen Laboratories via a standard protocol (Stowe, Ruiz, Fagundes, Stowe, Min, & Glaser, 2014). Results indicated that greater EBV antibody titers were associated with poorer inhibition ($r = -.38$, $p < .01$) and cognitive flexibility ($r = -.39$, $p < .01$). The association between EBV antibody titers and updating/monitoring was not significant ($r = -.16$, $p = .21$). These findings suggest that EBV reactivation may be associated with cognitive performance, even among healthy individuals. Therefore, herpesviruses may impact cognitive performance prior to the presentation symptoms of AD or MCI. Findings may also suggest that EBV reactivation could be an early indicator of AD/MCI risk, and thereby provide opportunities for early intervention; however, longitudinal research is clearly needed to test this possibility.

DEVELOPMENT OF A PROGNOSTIC AWARENESS QUESTIONNAIRE (PAQ) FOR PATIENTS WITH ADVANCED CANCER

Isabella I. Sereno, MAEd¹, Keri Brenner, MD², Joseph A. Greer, PhD¹, Vicki A. Jackson, MD, MPH¹, Elyse R. Park, Ph.D., MPH¹, Juliet Jacobsen, MD¹, Jennifer S. Temel, MD³, Areej El-Jawahri, MD⁴

¹Massachusetts General Hospital, Boston, MA; ²Stanford University, Stanford, CA; ³MGH, Boston, MA; ⁴Massachusetts General Hospital Cancer Center, Boston, MA

Background: Patients' perception of their prognosis plays an important role in their treatment decision-making in advanced cancer. However, no reliable, valid instruments currently exist to measure prognostic awareness comprehensively in patients with cancer.

Methods: We developed the PAQ using a sequential two-phase qualitative approach. During phase 1, we conducted five working groups with a transdisciplinary team of clinicians and researchers from oncology (n=2), psychology (n=2), psychiatry (n=1), and palliative care (n=3), as well as a survey development expert (n=1) to identify key domains of the PAQ. Using prior literature and consensus-driven process, the team then generated an item bank for each domain. During the second phase, we conducted cognitive interviews with 39 patients with advanced cancer to assess if the PAQ items are understandable, answerable, and interpretable as intended.

Results: The working groups identified the following domains that are critical to measure prognostic awareness: 1) cognitive understanding of prognosis (ability to understand goals of treatment and acknowledge the life-limiting illness), 2) emotional coping (capacity to process prognostic uncertainty and terminal prognosis), and 3) adaptive response (capacity to use prognostic awareness to inform life decisions). Data from cognitive interviews revealed that patients had an accurate understanding of the meaning of most PAQ items. Patients reported difficulty with binary response options for questions pertaining to coping with prognosis. They also expressed emotional difficulty answering numerous questions regarding their cognitive understanding of their prognosis. Some patients also reported the need to clarify the meaning of certain words such as 'cure' and 'prognosis.' We revised the PAQ items based on these findings by 1) replacing binary response options with agreement scales; 2) reducing the number of items focused on cognitive understanding of prognosis; and 3) defining 'cure' and 'prognosis' in the introduction to the PAQ.

Conclusion: We identified a novel conceptual framework to capture the complexity of prognostic awareness in developing the PAQ. We revised the PAQ based on cognitive interviews with patients with advanced cancer to ensure its content validity and readability. Future work should focus on further validating the PAQ by testing its psychometric properties including reliability and construct validity.

EHR-BASED PATIENT REPORTED OUTCOMES (PRO) SYMPTOM AND NEEDS MONITORING IN AMBULATORY ONCOLOGY: THE UHEALTH PRO PROGRAM

Heidy Medina, MPH¹, Jonathan Nysson, n/a², Madeline H. Krause, MEd³, William B. Hurwitz, M.A.³, Vandana D. Sookdeo, MD³, Neysari Arana, MPH⁴, Jessica MacIntyre, MSN, APRN, NP-C, AOCNP¹, Sofia Garcia, PhD⁵, Frank Penedo, PhD³

¹University of Miami, Miami, FL; ²University of Miami Hospital and Clinics, Miami, FL; ³Sylvester Comprehensive Cancer Center, Miami, FL; ⁴University of Miami, Sylvester Comprehensive Cancer Center, Miami, FL; ⁵Northwestern University, Chicago, IL

Background: There is growing interest in the inclusion of systematic monitoring of patient symptoms and practical and nutritional needs to deliver value-based care in ambulatory oncology settings. Routine monitoring that is integrated in the patient portal and connects in real-time with the electronic health record (EHR) can inform clinical care delivery and can improve patient engagement, as well as patient and system-level outcomes.

Methods: A concurrent mixed methods approach was used to assess initial acceptability and uptake of the UHealth PRO Program. We conducted a qualitative analysis of transcripts from a focus group among a patient advisory board (n=7). Additionally, 310 patients were assigned assessments from August–November 2019 through the EHR patient portal, which included PROMIS® computer adaptive tests (CATs) for anxiety, depression, fatigue, pain interference and physical function, selected items from the PRO-CTCAE to assess toxicities, the FACT-G7 to measure QOL, and a practical needs and nutritional needs checklist. Results were populated and alerts for scores above clinical thresholds for physical symptoms, depression, anxiety, and endorsed practical and nutritional needs were received by medical teams, social work or nutritionists, respectively.

Results: Qualitative data analysis from the focus group revealed five overarching themes which included: previous experience with the patient portal; usability and ability to navigate the patient portal and questionnaires; acceptability and functionality of questionnaires; and content-related suggestions. Most participants had used the patient portal—MyUHealth Chart before, and thought it was easy to navigate. Participants agreed that the UHealth PRO Program initiative was useful but only if feedback and referrals were obtained on a timely manner by their providers. Most preferred to complete assessments prior to their visit. Addressing lack of support during their cancer care experience was identified as a major concern that can be addressed by UHealth PRO. Within the test clinic, 125 (40.3%) of patients completed the assessments, among whom 41.6% were completed at home via the patient portal and 58.4% were completed in-clinic via the intake nurse/clinic staff. Of the 163 alerts received, the majority were for nutritional needs (33%), followed closely by practical needs (22%) and emotional distress (19%).

Conclusions: While these results demonstrate acceptability and feasibility in implementing the program, initial uptake of an EHR-based symptom screening tool was modest. Future work should promote patient engagement and educational awareness of the benefits of systematic monitoring to improve uptake.

EXPLORING CLINICIAN PERSPECTIVES ON HOSPITAL DISCHARGE PLANNING FOR PATIENTS WITH ADVANCED CANCER

Annemarie D. Jagielo, BA¹, Carlisle Topping, BA², Lara Traeger, PhD³, Daniel E. Lage, MD, MSc¹, Areej El-Jawahri, MD³¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital Cancer Outcomes Research Program, McMinnville, OR; ³Massachusetts General Hospital/Harvard Medical School, Boston, MA; ⁴Massachusetts General Hospital, Cambridge, MA; ⁵Massachusetts General Hospital Cancer Center, Boston, MA

Background: Acute hospitalizations and readmissions post hospital discharge represent a large portion of health care utilization at the end of life for patients with advanced cancer. Studies exploring factors contributing to these burdensome transitions of care at the end of life are lacking in oncology. We aimed to examine clinicians' perspectives on factors relevant to discharge decision making for hospitalized patients with advanced cancer and their impact on burdensome transitions of care.

Methods: Using a semi-structured interview guide, we conducted in-depth interviews with 13 clinicians providing care to hospitalized patients with advanced cancer at an academic medical center. Interviews explored clinicians' experiences with discharge planning for hospitalized patients with advanced cancer and their perspectives on factors contributing to prolonged hospitalizations, suboptimal discharge, and potentially burdensome transitions of care. We audio-recorded the interviews and transcribed them. Two study team members iteratively coded the transcript data and identified major themes, using a content analysis approach with attention to discrepant or unexpected data.

Results: We conducted interviews with thirteen clinicians including oncologists (n=4), case managers (n=2), social workers (n=2), physical therapists (n=2), and nurses (n=3). Across disciplines, participants cited inadequate communication between clinicians, the patient, and their families as a major barrier to adequate discharge planning. Lack of proactive planning for patients' discharge needs such as the need for intravenous medications or post-discharge services frequently resulted in delay in discharge. Ambiguous goals of care in patients with a limited prognosis and lack of timely communication of these goals between the inpatient team and the outpatient oncologist often resulted in impractical and suboptimal discharge plans. Many clinicians also perceived inadequate patient and family preparations and education regarding their post-discharge needs as a major contributor to hospital readmissions.

Conclusions: These findings highlight several gaps in timely communication between inpatient and outpatient clinicians, patients, and families, as major contributors to burdensome transitions of care at the end of life for patients with advanced cancer. Interventions to facilitate timely communication regarding discharge expectations, discharge needs, and goals-of-care between clinicians, patients, and families are needed.

Learning

Objective: To identify factors contributing to burdensome transitions of care at the end of life for hospitalized patients with advanced cancer in order to inform future interventions to improve their quality of end-of-life care.

FEAR OF CANCER RECURRENCE AND SLEEP IN COUPLES AT THE FIRST POST-TREATMENT MAMMOGRAM FOR EARLY-STAGE BREAST CANCER

Christine Perndorfer, M.S.¹, Emily C. Soriano, M.A.², Scott Siegel, PhD, MHCDS³, Rebecca Spencer, PhD⁴, Jean-Philippe Laurenceau, PhD²¹University of Delaware, Philadelphia, PA; ²University of Delaware, Newark, DE; ³Christiana Care Health System, Newark, DE; ⁴University of Massachusetts Amherst, Amherst, MA

Background: Sleep is a well-documented determinant of health in both the general population as well as in cancer survivors. While sleep disturbance is common in cancer survivors, its prevalence is greatest in individuals with breast cancer (BC). As such, it is critical to understand factors that underlie impaired sleep in these individuals. Few studies have examined a putative link between fear of cancer recurrence (FCR) and sleep disturbance in BC survivors. Moreover, research has not focused on the link between sleep and FCR among spouses of BC survivors. It also may be of particular interest to examine the relationship between FCR and sleep disturbance as couples enter potentially threatening phases of the survivorship trajectory, such as the first post-treatment mammogram (MMG).

Purpose: The present study examined the relationship between FCR and sleep disturbance in early-stage BC survivors and their spouses in the period surrounding survivors' first post-treatment MMG. Associations were examined between FCR and both daily sleep across the diary period as well as solely on the eve of the MMG, when FCR may be at its peak. Higher survivor and spouse FCR were hypothesized to predict reduced sleep quantity and quality and greater sleep onset latency (difficulty falling asleep) and wake after sleep onset for both themselves and their partners.

Methods: Couples coping with early-stage BC (N=57) reported sleep duration, quality, sleep onset latency, and wake after sleep onset each morning for 21 consecutive days spanning survivors' first post-treatment MMG. Three validated measures of global FCR were used to form latent survivor and spouse FCR factors. Average daily sleep outcomes as well as sleep on the eve of the MMG were regressed on both survivor and spouse FCR. Actor-partner interdependence modeling was used wherein associations between one participant's FCR and his/her own sleep (actor effects) and with his/her partner's sleep (partner effects) were estimated simultaneously in each model.

Results: Survivor FCR was associated with reduced average daily sleep duration and quality for themselves as well as reduced average sleep quality and greater average sleep onset latency for their spouse. Spouse FCR was associated with reduced average daily sleep duration for themselves. On the eve of the MMG, survivor FCR was associated with their own reduced sleep duration and quality as well as greater sleep onset latency for their spouse. Spouse FCR was associated with their own reduced sleep duration and quality as well as greater sleep onset latency and wake after sleep onset for their partner.

Conclusions: Findings supported individual and dyadic associations between FCR and sleep, addressing gaps in knowledge on FCR and health behaviors. FCR interventions may be a strategy for addressing sleep disturbance, and thereby long-term health for both BC survivors and their non-patient partners.

EVALUATING THE IMPACT OF DEPRESSION FUNCTIONAL LIMITATION AND SELF-RATED HEALTH ON SURVIVAL TIMES AMONG BREAST CANCER PATIENTS

Oluwaseun J. Adeyemi, MBChB, MPH, MWACS¹, Tasha L. Gill, MPH¹, Rajib Paul, PhD¹, Larissa Brunner Huber, PhD¹¹University of North Carolina at Charlotte, Charlotte, NC**Background:** Depression, functional limitations, and health status can create additional complexities in patients already diagnosed with breast cancer and thus shorten the survival time of these patients.**Purpose:** This study aims to assess the joint impact of self-reported depression, functional limitation, and self-rated health on survival times among breast cancer patients.**Methods:** Seventeen-year data from the Integrated Public Use Microdata Series - National Health Interview Survey (IPUMS-NHIS) were pooled and analyzed. Women who were ≥ 30 years old, diagnosed with cancer as an adult (i.e. ≥ 18 years), and who were interviewed within five years of diagnosis were included ($n=2,704$). The outcome variable was time to death. We computed hazard ratios (HR) using Cox-Proportional regression with symptoms of depression, self-rated health, and functional limitation from breast cancer as independent variables. Sociodemographic characteristics were included as potential confounders.**Results:** Age, race, educational attainment, marital status, and the poverty-income ratio were significantly associated with survival times of women with breast cancer ($p < 0.001$). Women with breast cancer who reported symptoms of depression had 17% (HR: 1.17; 95% CI: 1.00-1.37), and 19% (HR: 1.19; 95% CI: 1.00-1.37) increased risks of mortality in the unadjusted and adjusted models, respectively. Women with breast cancer who rated their health as poor had a 2-fold statistically significant increased risk of mortality (Adjusted HR: 2.01; 95% CI: 1.59-2.53) as compared to women with good to excellent health status. Similarly, women with breast cancer who rated their health as fair had nearly 1.5 times the risk of mortality compared to women who rated their health as good to excellent (Adjusted HR: 1.45; 95% CI: 1.20-1.75). Further, women with functional limitations from breast cancer had a 42% increased risk of mortality compared to women who did not report any functional limitation from breast cancer (Adjusted HR: 1.42; 95% CI: 1.16-1.72). This finding was also statistically significant.**Conclusions:** Symptoms of depression, fair and poor self-rated health and functional limitations from breast cancer significantly shorten the survival times of breast cancer patients. A holistic approach to treatment that includes mental health therapy and assistance with functional ability may be beneficial in improving quality of life and reducing mortality risks among these patients.

FACTORS ASSOCIATED WITH SOCIAL FUNCTIONING AMONG YOUNG ADULT CANCER SURVIVORS AFTER HEMATOPOIETIC CELL TRANSPLANTATION

Casey Walsh, PhD¹, Jean Yi, PhD², Abby Rosenberg, MD, MS, MA³, Marie-Laure Crouch, PhD², Karen L. Syrjala, PhD²¹University of Washington, Seattle, WA; ²Fred Hutchinson Cancer Research Center, Seattle, WA; ³Seattle Children's Research Institute, Seattle, WA**Background:** Adolescent and young adult (AYA) long-term hematopoietic cell transplantation (HCT) survivors face unique medical and psychosocial challenges that can compromise social functioning. We examined the impact of physical and social-emotional factors on the social functioning of AYAs post-HCT. We hypothesized that physical factors would explain the majority of the variance in social functioning and that social-emotional factors would explain additional variance, after controlling for potential sociodemographic covariates.**Methods:** This secondary cross-sectional analysis included HCT recipients from the INSPIRE study trial [NCT00799461] who received their first transplant between the ages of 15-39. Assessments included social functioning (SF-36 social functioning; SF), fatigue symptom inventory (FSI), cancer and treatment distress (CTXD), chronic graft versus host disease (cGVHD), physical functioning (SF-36 physical functioning; PF), and social support (ENRICHED ESSI). We used hierarchical multiple linear regression to identify factors associated with SF at the baseline assessment, with the first block including sociodemographic covariates significant at $P < .10$ in univariate testing, the second block including physical factors (fatigue, physical function, and cGVHD), and the third block including social-emotional factors (social support and cancer-related distress).**Results:** Participants ($N=293$) were 52% male and 90% white, non-Hispanic, with a mean current age of 40.3 years (SD 8.0). SF mean was 48.4 (SD 10.5), below age-adjusted norms ($t=-13.6$, $P < .001$). Univariate testing of covariates found sex, race, income, and cGVHD associated with SF. In the first block, income contributed significantly to the regression model, $F(3, 242)=3.27$, $p=.02$ and accounted for 4% of the variance in social functioning. Introducing the physical factors in the second block explained an additional 49% of the variance and this change in R^2 was significant, $F(6, 239)=44.27$, $p<.01$. Adding social-emotional factors in the final block explained an additional 9% of the variance in social functioning and this change in R^2 was also significant, $F(8,237)=47.13$, $p<.01$. In the final model, only fatigue and cancer-related distress were significant predictors of social functioning. Cancer-related distress uniquely explained 28% of the variance in social functioning. Together, all variables in the final model explained 61% of the variance in social functioning.**Conclusions:** Physical factors explained the majority of the variance in social functioning. Contrary to our hypothesis, social support was not significantly associated with social functioning, which could be due to the brief SF assessment tool used. Cancer-related distress and fatigue were most strongly associated with social functioning, suggesting important areas for clinical intervention with AYAs post-HCT.

EFFECTS OF THE PRESENCE OF A COMPANION ON ENCOUNTERS BETWEEN BLACK CANCER PATIENTS AND THEIR NON-BLACK ONCOLOGISTS

Amy K. Otto, PhD¹, Maija Reblin, PhD¹, Lauren M. Hamel, PhD², Lee Ellington, PhD³, Felicity K. Harper, PhD⁴, Susan Eggly, PhD²

¹Moffitt Cancer Center, Tampa, FL; ²Wayne State University/Karmanos Cancer Institute, Detroit, MI; ³University of Utah, Salt Lake City, UT; ⁴Karmanos Cancer Institute/Wayne State University, Detroit, MI

Background: Research has demonstrated that the presence of a family caregiver or other companion during a patient's medical encounter can influence the dynamics and oncologist perceptions of the encounter. Most prior studies have focused on non-Hispanic white patients; however, patient-provider interactions are affected by race, with poorer communication in racially-discordant interactions—particularly between Black patients and non-Black providers. This study aimed to examine the effects of the presence of a companion on encounters between Black patients and their non-Black oncologists.

Method: Data were collected as part of a larger intervention study conducted by Eggly et al. (2017). Participants were 115 Black cancer patients (93% female; 88% breast cancer) who had a video-recorded clinical encounter with one of 20 participating non-Black oncologists. Of these patients, 47% ($n=54$) had a companion present. Encounters were observed and coded for patient active participation, physician patient-centered communication, and encounter length. After the encounter, patients reported their perceptions of the treatment recommended by the oncologist, and oncologists reported their perceptions of the patient. To account for the nested nature of the data (patients within oncologists), multi-level models were conducted in which the presence or absence of companions predicted patient and oncologist behaviors and perceptions, as well as length of encounter, controlling for study intervention arm.

Results: Oncologists spent more time with accompanied patients ($B=5.52$, $p=.016$), used more patient-centered communication with them ($B=0.18$, $p=.037$), and perceived them as having more social support ($B=0.73$, $p<.001$) compared to unaccompanied patients. While observers did not rate unaccompanied patients as participating more actively, physicians reported that accompanied patients asked more questions ($B=0.35$, $p=.031$). Patient perceptions of the treatment recommended by the oncologist did not differ based on the presence or absence of a companion.

Discussion: Results suggest that bringing a companion to appointments with a non-Black oncologist may be beneficial to Black patients; oncologists perceive these patients to be more activated and have greater social support, which could potentially influence treatment recommendations. Having a companion present was also associated with more patient-centered communication, which has previously been linked with improved outcomes.

DOES SEXUAL DISRUPTION MEDIATE ASSOCIATIONS BETWEEN PERCEIVED COPING AND QUALITY OF LIFE IN BREAST & PROSTATE CANCER SURVIVORS?

Emily A. Walsh, B.A.¹, Molly Ream, B.A.¹, Chloe Taub, MA¹, Erica R. Nahin, M.S.¹, Hannah Fisher, MS², Jason Dahn, PhD³, Lara Traeger, PhD⁴, Bruce R. Kava, MD⁵, Frank Penedo, PhD⁶, Michael H. Antoni, Ph.D.⁷

¹University of Miami, Miami, FL; ²University of Miami, Durham, NC; ³Miami VA Healthcare System, Miami, FL; ⁴Massachusetts General Hospital/Harvard Medical School, Boston, MA; ⁵University of Miami Miller School of Medicine Urology Service, Miami, FL; ⁶Sylvester Comprehensive Cancer Center, Miami, FL; ⁷University of Miami, Coral Gables, FL

Background: Men with prostate cancer (PC) and women with breast cancer (BC) experience relationship challenges as a result of their treatment. Decrements in sexual functioning and quality of life (QOL) are well documented; however, limited work has evaluated whether illness-related sexual and intimacy disruption mediates the relationship between perceived coping and QOL in a relatively large and well characterized sample of PC and BC survivors.

Methods: PC ($n=260$) and BC ($n=179$; stages 1-2) survivors who were enrolled in stress management RCTs were assessed prior to randomization. The Psychosocial Adjustment to Illness Scale-Sexual Relationship subscale (PAIS) measured illness-related sexual and intimacy disruption, the Functional Assessment of Cancer Therapy-General (FACT-G) assessed QOL, and the Measure of Current Status (MOCS) captured perceived coping abilities. Differences between cancer groups were tested and followed by a Sobel test within each group to examine if illness-related sexual and intimacy dysfunction explains to association between perceived coping and QOL.

Results: PC survivors were older (PC $M=65.4$, $SD=7.6$; BC $M=50.2$, $SD=9.2$), further from diagnosis (PC $M=15.6$ mos, $SD=6.9$; BC $M=1.8$ mos, $SD=7.7$) and treatment (PC $M=10.3$ mos, $SD=4.5$; BC $M=0.8$ mos, $SD=0.8$), and reported greater QOL (PC $M=86.3$, $SD=14.2$; BC $M=80.2$, $SD=14.4$). BC survivors had greater annual income (MPC $M=51.0$, $SD=50.2$; BC $M=85.9$, $SD=74.2$), education (PC $M=13.8$ yrs, $SD=3.3$; BC $M=15.6$ yrs, $SD=2.5$), illness-related sexual/intimacy disruption (PC $M=13.5$, $SD=3.6$; BC $M=14.6$, $SD=1.6$) and coping ability (PC $M=62.9$, $SD=11.3$; BC $M=94.8$, $SD=12.9$). All p 's $< .05$. Greater perceived coping ability for BC and PC predicted greater QOL ($F(1,178)=46.9$, $p<.001$; $F(1, 259)=18.6$, $p<.001$). Illness-related sexual and intimacy disruption mediated the relationship between perceived coping and QOL for PC (Sobel test statistic=1.97, $SE=0.034$, $p=0.049$) but not for BC survivors (Sobel test statistic=.622, $SE=.01$, $p=0.53$).

Conclusions: Although women presented with greater sexual and intimacy disruption, this characteristic did not mediate the effects of perceived coping on QOL. For men, sexual and intimacy disruption did mediate the effects of coping on QOL. These differences could suggest that illness-related disruption applies differently within PC and BC. Interventions targeting the role of coping on sexual function and QOL may be more relevant in PC, and perceived coping may protect QOL through different pathways in BC.

DISEASE-SPECIFIC AND GENERAL HEALTH-RELATED QUALITY OF LIFE PROFILES AMONG MEN WITH ADVANCED PROSTATE CANCER

Blanca Noriega Esquivas, MD, MSPH¹, Tae K. Lee, PhD², Patricia I. Moreno, PhD³, Rina S. Fox, PhD, MPH³, Betina Yanez, PhD⁴, Sara M. St. George, PhD², Frank Penedo, PhD⁵

¹University of Miami - Miller School of Medicine, Doral, FL; ²University of Miami Miller School of Medicine, Miami, FL; ³Northwestern University Feinberg School of Medicine, Chicago, IL; ⁴Northwestern University, Chicago, IL; ⁵Sylvester Comprehensive Cancer Center, Miami, FL

Background: Androgen-deprivation therapy is a common treatment for advance prostate cancer. Despite its effectiveness, androgen-deprivation therapy is associated with physical and psychological side effects that can negatively impact health-related quality of life (HRQOL). Limited work has described HRQOL profiles in advance prostate cancer patients on androgen-deprivation therapy. This study identified distinct HRQOL profiles among men with advance prostate cancer; and examined sociodemographic and psychosocial factors that may be associated with subgroup membership.

Methods: 192 men diagnosed with advanced prostate cancer (stage III/IV) who received androgen-deprivation therapy at least once within the past year participated in this study. Participants self-reported sociodemographic, mental and physical health characteristics (e.g. anxiety, depression, fatigue, comorbidities). Disease-specific HRQOL was assessed with the Expanded Prostate Index Composite measure; while general HRQOL was measured using the Functional Assessment of Cancer Therapy - General (FACT-G). We used a latent profile analysis (LPA) to identify subgroups of men with distinct disease-specific HRQOL profiles and relate these LPA groups to a diverse set of correlates. All analyses were conducted in Mplus (v.8.3).

Results: Overall, participants had a mean age 68.7 ± 0.6 years. The majority were married (67%), non-Hispanic white (56%), and retired (57%). We identified two distinct disease-specific HRQOL profiles: lower levels of the hormonal, bowel, sexual, and urinary disease-specific HRQOL domains (12%) vs. higher levels of disease-specific HRQOL domains (88%). Significant correlates of the identified low disease-specific HRQOL profile were age ($OR = 0.86$, $95\%CI = 0.78-0.94$), metastatic disease ($OR = 0.32$, $95\%CI = 0.07-1.08$), and active coping ($OR = 1.8$, $95\%CI = 1.27-2.56$). Compared to the high disease-specific HRQOL subgroup, men in the low disease-specific HRQOL subgroup were younger, poorer, unemployed, had more comorbidities, reported higher levels of anxiety, depression, stress, and fatigue. Additionally, men in the low disease-specific HRQOL reported lower levels of general HRQOL as evidenced by lower physical ($M = 18.2$ vs. 23.8), emotional ($M = 16.7$ vs. 20.7) and functional well-being ($M = 16.5$ vs. 20.9) (all p 's $< .05$).

Conclusions: These findings provide a greater understanding of determinants of poor disease-specific and general HRQOL in men with advanced prostate cancer on androgen-deprivation therapy. Our findings may contribute to developing health promotion programs that create more targeted/profile-based interventions. Further research is needed to assess longitudinal trajectories of these profiles and their impact on disease-specific and general HRQOL among this population.

DIFFERENCES IN COPING AND APPRAISAL AMONG WOMEN WITH BREAST CANCER: A CLUSTER-ANALYTIC APPROACH

Yuh Cheng, BS¹, Jyun-Hong Chen, Ph.D.¹, Ashley W. Wang, Ph.D.², Cheng-Shyong Chang, MD³, Wen-Yau Hsu, PhD⁴

¹Soochow University, Taiwan, Taipei, Taipei, Taiwan (Republic of China); ²Soochow University, Taiwan, Taipei City, Taipei, Taiwan (Republic of China); ³Chang Bing Show Chwan Memorial Hospital, Changhua, Changhua, Taiwan (Republic of China); ⁴National Chengchi University, Taipei, Taipei, Taiwan (Republic of China)

Objectives: Despite research has established the role of coping strategies in the occurrence of posttraumatic growth (PTG), little is known about the ways in which different cancer patients may combine the use of several coping strategies in response to cancer impact appraisal. The aims of this study are to generate distinctive profiles of coping among women with breast cancer (BCa), and to test whether coping profiles are related to their psychological adjustment.

Methods: BCa survivors ($N = 322$; $M_{age} = 46.99$, $SD = 8.76$, range = 25-72) were assessed within four months post-surgery. The assessment battery included the Brief COPE, perceived cancer impact (sum score of threat, harm, disturbance, impact, control, challenge, and importance), the Hospital Anxiety and Depression Scale, the SF-36 Health Survey (quality of life; QoL), and the Affects Balance Scale (positive affect; PA).

Results: (Aim 1) five clusters of participants were identified. Women in cluster 1 (Fighting group; $n = 84$) demonstrated the highest level of all kinds of coping. Women in cluster 2 (Ms. 'Close Enough'; $n = 84$) reported averaged levels of all kinds of coping. Women in cluster 3 (Fatalism; $n = 29$) adopted relatively low levels of coping with the exception of greater use of acceptance coping. These three groups appraised cancer experience as highly impactful. Women in cluster 4 (Engagement group; $n = 95$) adopted high levels of self-sufficient coping. Women in cluster 5 (Low coping group; $n = 30$) reported the lowest coping efforts and perceived higher controllability of cancer. The latter two groups appraised cancer experience less impactful.

(Aim 2) We evaluated differences among clusters with respect to demographic characteristics and psychological adjustment. Cluster 1 and 4 reported highest PA and lowest depression, but cluster 1 reported greater anxiety and lower QoL than cluster 4. Cluster 5 was older in age compared with the others as well as lower anxiety and PA. Cluster 3 reported the greatest depression and anxiety and lowest QoL, followed by cluster 2.

Conclusions: Women with BCa can be classified in five groups according to the patterns of coping strategies and appraisal. Coping profiles were differentially related to psychological adjustment. Overall, these findings suggest that research should move from coping strategies to coping profiles in order to provide a deeper understanding of BCa adjustment.

6:15 PM-7:30 PM

FACTOR STRUCTURE AND CONCURRENT VALIDITY OF THE POSTTRAUMATIC GROWTH INVENTORY AMONG TAIWANESE BREAST CANCER SURVIVORS

JUNG-HSUAN KUAN, BS¹, Ashley W. Wang, PhD², Cheng-Shyong Chang, MD³, Wen-Yau Hsu, PhD⁴¹Soochow University, Taiwan, Taipei, Taipei, Taiwan (Republic of China);²Soochow University, Taiwan, Taipei City, Taipei, Taiwan (Republic of China);³Chang Bing Show Chwan Memorial Hospital, Changhua, Changhua, Taiwan(Republic of China); ⁴National Chengchi University, Taipei, Taipei, Taiwan (Republic of China)

Objectives: The first aim of this study is to determine the dimensions of the Posttraumatic Growth Inventory (PTGI) among Taiwanese cancer survivors. Through literature review, we examine whether the PTGI comprises a unitary dimension or five domains (Relating to Others, New Possibilities, Personal Strength, Spiritual Change, and Appreciation of Life), or four domains (Self, Spiritual, Life orientation, and Interpersonal). Second, if there is more than one dimension, we examine whether different psychosocial correlates, including cancer impact, psychological distress, and coping variables emerge when examining the subdomains of the PTGI.

Methods: Breast cancer survivors ($N = 354$; $M_{age} = 47.45$, $SD = 8.74$, range = 25–71) were enrolled one year after their surgery. They completed measures of perceived impact and challenge, the Brief COPE (self-sufficient, socially-supported, and avoidant coping), and the Hospital Anxiety and Depression Scale as well as the PTGI as part of a larger study on breast cancer adjustment. Confirmatory factor analyses were used to determine factor structure of the PTGI. Partial correlations controlling for age and education were adopted to examine psychosocial correlates of domains of PTGI.

Results: A 5 factors with 1 higher-order factor best fitted the data, indicating the PTGI was multidimensional as well as a general factor. We, then, explored the difference of the psychosocial correlates of the PTGI subdomains. Partial correlations revealed that self-sufficient coping was among the most significant correlates of all PTGI subdomains ($r = .51-.60$, $p < .001$), followed by socially-supported coping ($r = .31-.51$, $p < .001$). Moreover, specific correlates were found for each domain. Greater use of avoidant coping was associated with greater spiritual change ($r = .21$, $p < .001$). Greater perceived cancer challenge was associated with greater spiritual change ($r = .13$, $p < .05$). All domains but spiritual change were negatively associated with depressive symptoms ($r = -.15 - -.25$, $p < .05$). Anxiety was negatively associated with new possibility and appreciation of life ($r = .12$ and $.15$, $p < .05$).

Conclusions: While the PTGI can be understood as a unitary dimension, five facets each was associated with specific psychosocial correlates. Findings highlight a more complex model of PTG implicated in Taiwanese breast cancer survivors' experience of positive changes.

6:15 PM-7:30 PM

DEVELOPMENT OF A NEW PATIENT REPORTED OUTCOME FOR DEPRESSION IN OLDER ADULTS WITH CANCER

Rebecca M. Saracino, PhD¹, Rebecca Tutino, BA¹, Laura C. Polacek, MA¹, Kara Buda, MA², Caraline Demirjian, MPH¹, Christian Nelson, PhD¹¹Memorial Sloan Kettering Cancer Center, New York, NY; ²The Graduate Center, City University of New York, New York, NY

Background: Older adults with cancer (OACs) are less likely than any other age group to be appropriately diagnosed with depression, in part due to the overlap of depression criteria with cancer and treatment sequelae, the effects of physical aging, and the unique presentation of depression in older adults more broadly (i.e., absence of traditional mood symptoms). This multiphase measure development study sought to create a new patient reported outcome (PRO) to screen for depression in OACs.

Method: Phase 1 included qualitative interviews with experts in geriatric psychiatry in oncology ($N=8$) and depressed and non-depressed OACs ($N=26$; i.e., 70+) to develop a conceptual understanding of depression in this patient group based on a phenomenological qualitative approach. Thematic Content Analysis (TCA) of interview content by a trained coding team was utilized to generate candidate items for the new PRO. In Phase 2, these items underwent cognitive interviewing with OACs ($N=10$) to clarify wording, response options, formatting, and item selection. Phase 2 results were also synthesized and reviewed by a trained coding team.

Results: Phase 1 TCA results identified major and minor themes characterizing the prominent depressive symptoms experienced by OACs such as: anhedonia, reduction in social relationships, decreased meaning and purpose, lack of usefulness, feeling like a burden, and irritability. In Phase 2, cognitive interviewing revealed consistency among participant preferences. Participants preferred to have the scale instructions repeated within each item to increase recall ease, and the 5-response option format and length of the measure were acceptable. Consensus emerged for item preference as well. For example, participants preferred “the things I did were worthwhile” to “the things I did were valuable” and “I became irritated more easily” to “I was irritable.”

Conclusions: The phenomenology and component symptoms of depression in OACs diverges from the items that traditionally comprise self-report depression scales. Sole reliance on existing depression screening measures for OACs will continue to yield poor sensitivity and specificity, failing to identify OACs with clinically significant symptoms. This ongoing study will result in a new PRO that is uniquely suited for OACs. Phase 3 is underway and includes further refinement of the measure based on its preliminary psychometric properties and clinical utility.

EFFECTS OF SOCIAL ISOLATION AND CONSTRAINTS ON PSYCHO-SOCIAL SYMPTOMS EXPERIENCED BY STEM CELL TRANSPLANT PATIENTS

Joseph Martinez, N/A¹, Taylor Schulte, n/a², Lauren A. Whitmore, MA³, Amanda Belanger, B.S.³, Christine M. Rini, PhD⁴, Kristi Graves, PhD⁵¹Cornell University, Yonkers, NY; ²Georgetown Lombardi Comprehensive Cancer Center, Cancer Prevention and Control Program, Washington, DC; ³Cancer Prevention and Control, John Theurer Cancer Center, Hackensack University Medical Center, Hackensack, NJ; ⁴Northwestern University Feinberg School of Medicine, Chicago, IL; ⁵Georgetown University, Washington, DC**Background:** Hematopoietic stem cell transplantation (HSCT) is a treatment for hematological malignancies and its use is expected to increase fivefold by 2030. We were interested in identifying specific factors that may be associated with depression and anxiety among patients with hematological malignancies prior to HSCT. Based on the critical role of caregivers for patients undergoing HSCT, we examined whether social isolation or social constraints were associated with anxiety or depression prior to transplant.**Methods:** The current research is part of a multisite randomized clinical trial evaluating the effects of expressive helping to reduce physical and emotional symptoms in HSCT patients. We collected data on social constraints, social isolation, anxiety (measured by the GAD-7) and depression (measured by the CES-D) before transplant, around the time of hospital admission. We analyzed our data using bivariate analysis and multivariate linear regression.**Results:** We recruited 95 adult cancer patients (45% women, mean age = 55.5 years (SD = 12.35 years)) prior to transplant. Results indicate that higher levels of social constraints were significantly associated with higher levels of both anxiety and depression ($p < .001$). Moreover, findings suggest higher social isolation was related to higher anxiety and depression ($p < .000$). Of note, 47% of participants reported experiencing severe levels of depression. Younger age was significantly associated with higher anxiety ($r = -.41$, $p = .000$) and higher depression ($r = -.27$, $p = .009$). After controlling for age and gender, social isolation remained significantly associated with depression ($B = 0.53$, $p = .000$); $R^2 = .35$, $F(3,91) = 15.92$, $p = .000$) and social constraints remained significantly associated with anxiety ($B = 0.32$, $p = .002$); $R^2 = .28$, $F(3,84) = 10.49$, $p = .000$).**Conclusion:** Individuals with strong social support, meaning low social constraints and low feelings of isolation, appear to have lower levels of anxiety and depression. HSCT is a physically and emotionally demanding treatment. Our findings suggest the importance of implementing interventions prior to and during transplant to aid in symptom management in this vulnerable patient population.

MISPERCEPTION OF CANCER RISK AND ITS ASSOCIATION WITH INFORMATION SHARING MOTIVES AMONG WOMEN AT LOW RISK FOR BRCA MUTATIONS

Jingsong Zhao, MPH¹, Colleen M. McBride, PhD¹, Yue Guan, PhD, ScM, CGC¹¹Emory University, Atlanta, GA**Introduction:** The vast majority of women who complete family history screening will be at low risk for carrying a *BRCA1/2* mutation. Yet, whether women share this information with family members who could benefit is largely unknown. In this brief report, we explore whether women share information about being at low risk for *BRCA1/2* with others, and whether their level of understanding is associated with motives for sharing the result.**Methods:** We identified women in mammography clinics who completed a brief family history screen. Those screened as low risk for *BRCA1/2* mutations were asked to complete a one-time online survey between June 2016 and January 2017. The analyses of t-tests and chi-square tests were performed in 2019.**Results:** One-third (43/147) of women shared their low risk results with someone in their social network. The risk information was shared most often with a first-degree female relative to express feelings of relief (76%, 32/42). Women whose cancer risk perception was inconsistent with their screen result reported the most motives to share results with their relatives.**Conclusions:** The communication needs of women who are at low risk for carrying a *BRCA1/2* mutation, the majority of women screened, are underexplored. While these findings warrant replication, they suggest that women who misperceived their cancer risk may be most inclined to share their results with others, which may foster miscommunication in the broader family network.

EFFECTS OF A SMARTPHONE-BASED INTERVENTION ON CANCER KNOWLEDGE AND COPING AMONG LATINA BREAST CANCER SURVIVORS

Laura B. Oswald, PhD¹, Sharon H. Baik, PhD², Joanna Buscemi, PhD³, Diana Buitrago, BA⁴, Alejandra Perez-Tamayo, MD⁵, Judith Guitelman, n/a⁶, Frank Penedo, PhD⁷, Betina Yanez, PhD⁴

¹Moffitt Cancer Center, Tampa, FL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³DePaul University, Chicago, IL; ⁴Northwestern University, Chicago, IL; ⁵University of Illinois, Chicago, IL; ⁶ALAS-Wings, Chicago, IL; ⁷Sylvester Comprehensive Cancer Center, Miami, FL

Objective: Despite documented psychosocial disparities, few evidence-based interventions have been adapted to promote optimal survivorship among Latina breast cancer survivors (BCS). To address this need, we developed the *My Guide* smartphone application for Latina BCS. *My Guide* was culturally adapted for Latinas and designed to target breast cancer knowledge, coping behaviors, and cancer-related self-efficacy, which have been identified as modifiable intervention targets. In a randomized controlled trial, *My Guide* was compared to an attention-control and culturally adapted health promotion application, *My Health*. This presentation describes the longitudinal effects of *My Guide* and *My Health* on the intervention targets and explores differential experimental condition effects by average weekly application use during the six week study.

Methods: Latina BCS who had completed primary cancer treatment for early-stage breast cancer were randomized 1:1 to use *My Guide* or *My Health* for six weeks in their preferred language (English or Spanish). Assessments of breast cancer knowledge, coping behaviors, and cancer-related self-efficacy occurred at baseline, six weeks (post-intervention), and eight weeks. Linear mixed effects modeling was used to assess differences in changes in intervention targets over time between study conditions, controlling for language preference and education.

Results: Participants ($N = 78$) were an average of 52.54 years old ($SD = 11.36$), and most were born outside of the United States (71%) with Spanish as their preferred language (64%). There were no significant group x time effects on the outcomes of interest. However, women in both conditions had improved breast cancer knowledge over time. Women in both conditions identified as high application users (i.e., an average of at least one hour of application use per week) reported increased use of positive reframing and religious coping. In addition, high users in *My Guide* reported less self-blame than high users in *My Health*. There were no effects on cancer-related self-efficacy, though self-efficacy was high in this sample at baseline.

Conclusions: This was the first study to test culturally informed and evidence-based smartphone applications designed specifically for Latina BCS. Preliminary findings suggest that greater use of the applications resulted in favorable outcomes, and Latina BCS may benefit from smartphone application-based programs designed to improve cancer survivorship.

MEETING THE PSYCHOSOCIAL NEEDS OF BREAST CANCER SURVIVORS: EXAMINING ACCESS TO RESOURCES IN RURAL APPALACHIAN OHIO

Shannon E. Nicks, PhD, MPH¹, Annie Printy, Bachelor of Science², Leann Tulisak, B.S.³, Nicolette Coovert, N/A⁴, Kristin H. Schuller, Ph.D.¹

¹Ohio University, Athens, OH; ²OU-HCOM, Hinckley, OH; ³Ohio University Heritage College of Osteopathic Medicine, Athens, OH; ⁴Ohio University, The Plains, OH

Background: Social support is integral to cancer patients' physical and mental health, quality of life and well-being. Cancer patients often experience diminished social support, leaving survivors vulnerable to isolation, poor adherence to care and worse health outcomes; this is particularly true among breast and gynecological cancer survivors who experience greater psychosocial distress and lowered quality of life compared to other cancer survivors. However, survivors and clinicians may not always recognize diminished support and identify resources to help meet these support needs. This process may be particularly challenging in rural communities where health care access issues, limited resources, socioeconomic burdens and cultural factors may exacerbate negative effects of diminished social support.

Methods: To examine ways rural, Appalachian breast and gynecological cancer survivors' psychosocial needs are met, we conducted 10 key-informant interviews with health care and social service providers serving these patients. Interviews were audio-taped, transcribed and analyzed using a consensus coding process with 2 independent coders to generate themes.

Results: Patient care is often affected by financial constraints, low health literacy, unreliable transportation, and limited specialized mental health services; and available support programs are not maximally utilized by survivors. Furthermore, providers affirmed adequate care but suggested needed improvements, including increasing the quantity and diversity of support services, increasing patient awareness of available services, and advocating for increased funding.

Conclusions: Findings highlight gaps in supportive care that negatively influence cancer survivors' ability to access support services and provide a foundation for providers to enhance patient-centered care, placing increased emphasis on psychosocial well-being.

EXPLORING CAREGIVERS' OF PATIENTS WITH PRIMARY BRAIN TUMORS EXPERIENCES WITH AND NEEDS RELATED TO SEIZURE MANAGEMENT

Deborah Ejem, PhD, MA¹, Paula P. Warren, MD², J. Nicholas Dionne-Odom, PhD, RN¹, Louis B. Nabors, MD¹, Richard A. Taylor, DNP, CRNP, APN-BC³, rebecca L. edwards, DNP, APRN, ACNP, AOCNP, ACHPN⁴, Marie Bakitas, DNSc, CRNP¹

¹University of Alabama at Birmingham, Birmingham, AL; ²The Hattiesburg Clinic, HATTIESBURG, MS; ³University of Alabama School of Nursing, Birmingham, AL; ⁴UAB School of Nursing, Middletown, CT

Family caregivers of persons with primary brain tumors report high levels of distress. Information is limited, however, regarding family caregivers' experiences and needs concerning the risk and management of seizures in this population. In this qualitative descriptive study, we conducted one-on-one interviews to describe the experiences of family caregivers' of persons with primary brain tumors who have had *and* who have not yet had a seizure. We sought information on how they coped with this issue and what information they needed regarding management of out-of-the-hospital seizures. We conducted 15 interviews using study-specific interview protocols; 10 caregivers with seizure experience and 5 caregivers without seizure experience. Caregivers were, on average, 52 years old, predominately white (93.3%), college graduates (66.7%), and were employed full-time (53.3%). The relationship between caregiver and care recipient was spouse (46.7%), other family member (46.7%), and friend (6.6%). Most caregivers provided care everyday (46.7%) and for more than 8 hours per day (33.3%). Themes emerged around three major domains: 1) caregiver challenges regarding seizures, 2) desired resources/information about seizures, and 3) timing of delivery of these resources. Caregivers often reported being fearful of seizures and the majority (93%) expressing difficulty with knowing when to call EMS. In terms of desired resources, opinions were split between preferring written materials versus online resources with most participants (87%) stating that videos or graphics detailing seizures would be helpful. In terms of delivery timing, most (66.7%) thought that training should come after diagnosis versus at the time of diagnosis citing reasons such as too much other information to absorb and overall inability to focus. Future studies will use this information to develop and pilot a seizure-focused supportive caregiver intervention that is tailored and caregiver-directed and that can be incorporated into standard neuro-oncology clinical practice.

6:15 PM-7:30 PM

OPTIMISM AND CURABILITY PERCEPTION AMONG PATIENTS WITH ADVANCED, INCURABLE CANCER

Login George, PhD¹, Barry Rosenfeld, PhD², Allison Applebaum, PhD³, William Breitbart, MD³

¹Memorial Sloan Kettering Cancer Center, Belleville, NJ; ²Fordham University, Bronx, NY; ³Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Maintaining positive expectations of the future (i.e., an optimistic outlook) is highly psychologically adaptive, and clinicians and family members often encourage patients with cancer to maintain positive expectations. However, given research showing that in certain contexts optimism may be associated with less desirable outcomes (Gibson & Sanbonmatsu, 2004), this study examined whether patients who are more optimistic held more unrealistic, inaccurate perceptions regarding the curability of their cancer?

Methods: Baseline data of 230 patients with advanced, incurable cancer participating in a psychotherapy clinical trial were examined. Patients completed a measure of optimism and pessimism (Life Orientation Test-Revised). Patients also reported on whether their cancer was incurable (0), unlikely curable (1), likely curable (2), or curable (3). Several measures of psychological well-being and distress were also assessed (e.g., Hospital Anxiety and Depression Scale).

Results: Patients with higher optimism held stronger perceptions of their cancer as curable ($r = .20, p < .01$). Pessimism was unrelated to curability perception ($r = .01, p = .94$). Adjusted analyses showed that the association between optimism and curability perception existed independent of psychological distress and well-being (e.g., depression symptoms; psychological quality of life; $b = .06, p = .03$).

Discussion: The psychologically adaptive feature of positive expectations of the future was associated with more inaccurate, unrealistic curability perceptions. Results may be indicative of the challenge patients face in maintaining optimism while coming to grips with the incurability of their cancer. Future research should examine if helping patients identify new, more realistic targets to have favorable expectations about (e.g., symptom control) could help maintain optimism, while also facilitating realistic expectations and informed decision-making and planning (Jackson et al., 2013).

DIFFERENCES IN PSYCHOLOGICAL WELLBEING BASED ON CANCER TYPE DURING CANCER DIAGNOSIS

Kate E. Dibble, M.A.¹, Sinead M. Sinnott, M.A.², Keith Bellizzi, PhD, MPH¹, Ofer Harel, PhD¹, Tara Sanft, MD³, Rajni Mehta, MPH³, Lindsey Behlman, n/a⁴, Katherine Gnall, B.A.¹, Kaleigh Ligus, M.A.¹, Emily Fritzson, B.A.¹, Crystal L. Park, PhD⁵

¹University of Connecticut, Storrs, CT; ²University of Connecticut, HYDE PARK, MA; ³Yale School of Medicine, New Haven, CT; ⁴Yale Cancer Center, New Haven, CT; ⁵University of Connecticut, Storrs Mansfield, CT

Background: Cancer diagnosis and treatment generate a myriad of stressors for patients and their social circles. Active/primary treatment can last several years and introduce persistent challenges. Past studies have indicated existence of high levels of clinically significant symptoms of depression, anxiety, fear of recurrence (or progression), as well as lower levels of physical and mental health, with greater role limitations and social functioning. We aim to determine differences in psychological wellbeing based on type of cancer patients have.

Methods: This study is a preliminary analyses of baseline data collected using the Rapid Case Ascertainment (RCA) at Yale Cancer Center to identify newly diagnosed cases of colorectal, breast, and prostate cancers from local hospitals. Approved and consented participants complete a questionnaire inquiring about illness comorbidities, social support, self-efficacy, optimism, emotion regulation, anxiety/depression, spirituality, meaning of cancer, and coping.

Results: Preliminary baseline sample characteristics indicate that participants ($n=159$) had a mean age of 57.4 years and an average household income of \$97,079.15 ($SD=83,430.85$). The majority of the sample are female ($n=94$, 65.7%), are college educated ($n=86$, 61.5%), Caucasian ($n=124$, 78.5%) are non-Hispanic/Latino ($n=120$, 90.2%), married ($n=90$, 64.7%) and working full-time ($n=59$, 41.5%) or retired ($n=34$, 23.9%). Most were diagnosed with breast ($n=95$, 60.9%) or prostate cancer ($n=47$, 29.6%), followed by colorectal cancers ($n=14$, 9.0%). Overall, patients with prostate cancer showed higher levels of self-efficacy, spirituality, and physical functioning relative to those with breast or colorectal cancer. Those with breast cancer showed stronger coping, emotional processing, and responses to stressful experiences, often seen as an aspect of resiliency. Those with colorectal cancers were better at regulating emotions, but had more depression, anxiety, and PTSD symptoms than those with other types of cancer.

Conclusion: This research adds important information to the field of psychosocial considerations for individuals in active treatment. Outcome variables vary widely by cancer type, especially for those with colorectal cancers having more psychological symptomology than the other two types. Colorectal cancer survivors may experience increased distress because these individuals are often in a “watchful waiting” period rather than active treatment, prompting greater uncertainty about the future, testing resiliency. Additional research is required to understand this phenomenon and if it occurs in larger samples over time.

FEASIBILITY OF A REMOTE BASED EXERCISE PILOT RCT IN MEN WITH METASTATIC PROSTATE CANCER: RESEARCH IN PROGRESS FROM THE CHAMP STUDY

Stacey Kenfield, ScD¹, Erin Van Blarigan, ScD¹, Charles Ryan, MD², Alexander Bang, BS¹, Neil Panchal, MS, ACSM-CPT¹, Rebecca Graff, ScD¹, Imelda Tenggara, n/a¹, Brooke Schultz, MS¹, Anthony Luke, MD, MPH¹, Kyle Zuniga, B.S.³, Robert U. Newton, BHMS(Hons), MHMS, PhD⁴, Hala T. Borno, MD¹, Rahul Aggarwal, MD¹, Terence Friedlander, MD¹, Vadim Koshkin, MD¹, Andrea L. Harzstark, MD⁵, Eric Small, MD⁶, June Chan, ScD¹

¹UCSF, San Francisco, CA; ²University of Minnesota, Minneapolis, MN; ³Columbia University Vagelos College of Physicians and Surgeons, San Francisco, CA; ⁴Edith Cowan University, MULLALOO, Western Australia, Australia; ⁵Kaiser Permanente Medical Center, Oakland, CA; ⁶UCSF Helen Diller Family Comprehensive Cancer Center, San Francisco, CA

Background: Aerobic and resistance exercise may improve prostate cancer clinical and quality of life outcomes. No randomized controlled trials (RCTs) have published on the safety and feasibility of exercise in men with metastatic castration-resistant prostate cancer (mCRPC).

Methods: CHAMP is an ongoing pilot RCT examining the feasibility of a 12-week remotely delivered exercise intervention in mCRPC patients. Men are recruited from UCSF patient lists and doctor referrals (outside referrals allowed). Select enrollment criteria include: Eastern Cooperative Oncology Group (ECOG) performance status of 0-1; clearance to undergo a maximal Steep Ramp exercise test on a cycle ergometer and to complete vigorous aerobic and resistance exercise training; no history of hypertension that is not well controlled; cardiologist clearance, if warranted; English-speaking; and living within 3-hours drive unless referred by MD. Participants are randomized (1:1:1) to aerobic exercise 3X/week, resistance exercise 3X/week, or control. The study protocol initially specified supervised exercise, but distance to come on site for training was a barrier to accrual. We thus developed a remote exercise program (Sept 2017) wherein all men complete their exercise prescription at a local exercise facility and visit UCSF at baseline & post-12 weeks. They complete pre- and post-exercise session surveys, wear heart rate monitors during exercise sessions, and are contacted once/week by an exercise physiologist. We present study population characteristics and comment on preliminary adherence to the exercise programs.

Results: As of 8/21/19, 443 patients were assessed for eligibility; 292 (66%) were not eligible. Another 122 patients were excluded due to oncologist's discretion ($n=78$), declined participation ($n=21$), and inability to contact ($n=23$). 25 patients have been randomized to date (9 aerobic, 8 resistance, and 8 control; 3 supervised, 14 remote). Follow-up is 96%; 20 patients completed the 12-wk study; 1 person withdrew because he moved out of state. Median age is 72, range: 51-84; median BMI is 28.7 kg/m², range: 22.6-36.7; and median time from diagnosis to enrollment is 10.5 years, range: 0.9-26.3. Three are African American, 2 are Asian, 19 are white, and 1 is other race. 80% have a 4 yr university education or higher, 84% are married or in a civil partnership, 8% are current smokers, and 32% are past smokers. Men have metastases to bone (72%), lymph node(s) (52%), and lung (8%). Overall, men travel a median of 36.8 miles one way to UCSF. The 14 remote intervention participants travel a median of 87.5 miles (range: 14-280) one way to UCSF. Men who completed the 12-week remote intervention in CHAMP attempted 98% of prescribed workouts. Of the sessions they attempted, they completed 78% as prescribed. No safety concerns have been identified.

Conclusions: A remote exercise intervention is feasible among men with mCRPC.

6:15 PM-7:30 PM

GEOSPATIAL ANALYSIS OF INVASIVE LUNG CANCER BURDEN IN TENNESSEE, 2005-2015

Xiaohui Liu, PhD¹, Bonita Salmeron, BA², Faustine Williams, PhD, MPH, MS³, Francisco A. Montiel Ishino, PhD, MPH, CPH⁴, Anna Napoles, PhD, MPH³¹NIH-NIMHD, Bethesda, MD; ²NIH/NIMHD, Towson, MD; ³NIH/NIMHD, Bethesda, MD; ⁴NIH-NIMHD, North Bethesda, MD

Purpose: Lung cancer (LC) is the second most commonly diagnosed cancer and the leading cause of cancer related deaths for both men and women in the United States (U.S). Previous research has demonstrated that the Appalachian region, which extends from parts of New York to Mississippi, experiences elevated cancer risk and disproportionate burden compared to the non-Appalachian region. In terms of specific cancers, the geographic differences in LC rates are attributed to greater tobacco use, poverty, low literacy and less use of healthcare services. Tennessee is one of the largest and most diverse states in Appalachia in terms of race/ethnicity, income and location (rural vs. urban) and 52 out of 95 of its counties are considered Appalachian. The goal of this analysis is to examine the geographic variations in invasive LC incidence in Tennessee between Appalachian and non-Appalachian counties.

Methods: Age-adjusted invasive LC incidence rates per 100,000 population were calculated using data from the Tennessee State Department of Health from 2005 to 2015. This data was imported into ESRI ArcGIS 10.7 to generate incidence maps by county, sex and age.

Results: A total of 56,655 invasive LC cases were used for analysis based on data completion with an average age of 67.46. Of those cases, 56.1% (31,776) were males and 43.9% (24,879) females. For race, 88.3% (50,002) identified as white, 11.1% (6,276) as black and 0.7% (377) as other races. In terms of place at diagnosis, 53.2% (30,139) occurred in Appalachian counties and 46.8% (26,516) in non-Appalachian counties. The overall geographic distribution displayed clusters of the highest age-adjusted rates (1140.84-1329.61/100,000) in the largely rural, Northern Appalachian portion of Tennessee along the border of Kentucky. The same pattern is seen when aggregating by sex, however the highest age-adjusted rates for males are 1508.77-1743.48/100,000 compared to females with 900.11-1217.88/100,000.

Conclusions: The results indicate a disparity between Appalachian and non-Appalachian counties in LC incidence in Tennessee. Incidence of the highest rates occurs in predominantly rural counties of the state, particularly those Appalachian counties that border Kentucky. Future analysis will take into account environmental exposures, smoking rates and socioeconomic status.

BIOPSYCHOSOCIAL FACTORS, GUT MICROBIOTA, AND METABOLIC SYNDROME IN CANCER CAREGIVERS

Jennifer Steel, PhD¹, Lin Huang, MS², David Geller, MD¹, Hannah Cheng, BS², Ritambhara Pathak, BS², Yisi Wang, MPH², Shyamal Peddada, PhD²¹University of Pittsburgh School of Medicine, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA

Background: Caregiving is associated with increased risk of cardiovascular disease (CVD). However, the mechanisms linking caregiving with CVD have not been elucidated. The aims of this study were to begin to explore the biopsychosocial and gut microbiota predictors of metabolic syndrome, an intermediate endpoint for CVD, in cancer caregivers.

Methods: Caregivers were recruited from an outpatient oncology clinic. Caregivers were administered a battery of questionnaires. Fecal samples were collected to obtain data on gut bacteria. Metabolic syndrome was based on five criteria including abdominal girth, high density lipoprotein, triglycerides, glucose, and blood pressure. Mild metabolic syndrome included caregivers who met three of the five criteria while severe metabolic syndrome included those who met all five of the criteria. Descriptive statistics, analysis of composition of microbiomes (ANCOM), and order restricted inference (ORIOGEN) were used to test the hypotheses.

Results: Of the 30 caregivers included in the study, the majority were female (73.3%), Caucasian (93.3%), the spouse or intimate partner of the patient (83.3%), and the mean age of caregivers was 60.4 years. A total of 59.3% of the caregivers met the criteria for metabolic syndrome (MetS). Microbial diversity was lower in caregivers with poor patient-caregiver relationship quality (Williams' type test statistics=1.99, p=0.0349). A 12-fold increase in the abundance of *Clostridium citroniae* (ANCOM-BC= 3.44, p < 0.001) and an 11-fold increase in the abundance of *Parabacteroides distasonis* (ANCOM-BC=2.77, p=0.006) was observed among caregivers with severe metabolic syndrome when compared to those who had mild metabolic syndrome. There was a 15-fold increase in the abundance of *Akkermansia muciniphila*, among caregivers with mild metabolic syndrome compared to those who had severe metabolic syndrome (ANCOM-BC=2.72, p=0.03). *Anaerostipes* spp. was present in caregivers with mild metabolic syndrome but absent among caregivers with severe metabolic syndrome (Structural zero according to ANCOM-BC, p< 0.001). We observed that several species of the genera *Bacteroides* were highly abundant among caregivers with high levels of depressive symptoms or with poor patient-caregiver relationships quality. Caregivers with high diversity of taxa also tend to have higher levels of IL-6 (F(1,29)=5.25, p< 0.05).

Conclusion: *Clostridium* Spp and *Akkermansia muciniphila* are important in the maintenance of metabolic homeostasis and has been linked to CVD. We plan to test the direct and indirect links between psychosocial and behavioral factors, gut bacteria, and metabolic syndrome in a larger sample. If similar findings are observed, psychosocial interventions and nutritional supplements targeting these gut bacteria, may be recommended to reduce the risk of metabolic syndrome and CVD in cancer caregivers.

CANCER PATIENTS' UNDERSTANDING OF AND COMFORT WITH SEXUAL ORIENTATION AND GENDER IDENTITY (SOGI) QUESTIONS

Smita Banerjee, n/a¹, Koshy Alexander, MD¹, Chasity B. Walters, PhD, RN¹¹Memorial Sloan Kettering Cancer Center, New York, NY

Cancer disparities exist among sexual and gender minority (SGM) cancer patients. Collecting sexual orientation and gender identity (SOGI) data is important in providing individualized care. These data are not included in prominent cancer registries, such as the National Cancer Institute's Surveillance, Epidemiology, and End Results Program, the nation's leading source of information on cancer incidence, mortality, and survival. Furthermore, despite recommendations by the National Academy of Medicine, the US Department of Health and Human Services, and the Joint Commission, SOGI data are not routinely collected in healthcare settings. Research on patients' willingness to disclose SOGI data using standardized approaches for disclosure in healthcare stem primarily from primary care and emergency department settings. The present study extends that work to cancer care and utilizes a cross-sectional survey to assess cancer patients' understanding of SOGI terms, their comfort with recommended questions, and their preferred way to communicate this information to healthcare providers. Between May-July 2018, 225 oncology patients at an NCI-Designated Comprehensive Cancer Center were provided a paper-and-pencil survey at check-in, and 169 (75%) patients completed the survey. Overall, participants reported favorable perceptions (including clarity of questions and answer choices, ease of answering questions, comfort in sharing information about gender, and willingness to provide personal information on a hospital form) regarding answering SOGI questions, as evidenced by average scores in the range 4.36-4.53 (on a 1-5 Likert scale, with higher scores indicating more favorable perceptions). A varied distribution of responses was found for preferred mode of asking SOGI questions - approximately 70% participants reported a preference for verbal questions to them about their gender and 69% for or verbal questions to them about sex at birth. Online reporting, on the other hand, was the preferred mode for asking pronoun questions (42%) and sexual orientation questions (42%). These findings reveal high acceptability of SOGI data collection, and varied preferences for ways to communicate SOGI information to healthcare providers. The invisibility of SGM populations in the context of cancer is directly attributable to the lack of SOGI data collection. Cancer care institutions need to encourage SOGI disclosure in order to provide equitable care to all cancer patients.

6:15 PM-7:30 PM

VARIANCE IN MODE OF DETECTION FOR BREAST CANCER BY BREAST DENSITY AND STAGE AT DIAGNOSIS

Susanna N. Basappa, BS¹, Lila J. Rutten, PhD¹¹Mayo Clinic, Rochester, MN

Introduction and Background: Mammography is reported to have an overall sensitivity of 87% according to the Breast Cancer Surveillance Consortium (BCSC). However, evidence from more recent screening and population-based studies in Europe indicate that a significant proportion of patients come into care with breast cancer symptoms, which in turn trigger diagnosis rather than regular screening mammography. Women with breast cancer symptoms often have late stage cancer at diagnosis. This implies that previous negative mammograms are false negatives, and that screening mammography alone was insufficient for currently symptomatic women.

Specific Experimental Aims: In a US population-based cohort of women who have developed breast cancer, we will 1) determine the variance in mode of detection for breast cancer, and 2) determine if mode of detection varied in this population by breast density and by stage at diagnosis.

Methods: We identified a cohort of 386 women with a diagnosis of first time breast cancer (using ICD codes) within the Rochester Epidemiology Project (REP), which has 98.5% patient coverage in the selected 7 county area of attainment. We randomly sampled 90 women from this cohort and performed chart review to collect outcome variables and potential covariates. These data were collected in REDCap, and reported with descriptive statistics.

Results: Within our current cohort (n=90), 23% (21/90) had DCIS, 43% (39/90) had non-advanced cancer, and 33% (30/90) had advanced cancer. This is consistent with literature that suggests that one third of all breast cancers are found at late stage. For women with DCIS, 95% (20/21) were found with screening mammography, compared to only 72% (28/39) of non-advanced and 53% (16/30) advanced. This suggests that screening mammography is more successful in identifying DCIS but may more frequently miss early and especially later stage breast cancer. Approximately 50% (43/86, with 4/90 of unknown density) had dense breasts, which corresponds well with BCSC data indicating this of 47% in the normal screening population. Screening mammography was the mode of detection for 67% (29/43) women with dense breasts, and 81% (35/43) of women with non-dense breasts. This is consistent with the literature that suggests that women with dense breasts have a sensitivity decrease of 10-29% with screening mammography.

Conclusions: These data suggest that our population reflects both the breast density rate and the rate of advanced cancers found in the national population, and that there is a strong likelihood that for women with dense breasts or non-DCIS, screening mammography alone may not be sufficient to detect breast cancer. This disparity from the literature may be due to misattribution of mode of detection for breast cancer, especially in later stages of disease where the true mode of detection is more likely to be symptoms than screening mammography.

6:15 PM-7:30 PM

ANXIETY AND DEPRESSION SYMPTOMS AMONG CAREGIVERS OF STEM CELL TRANSPLANT RECIPIENTS PRIOR TO TRANSPLANT

Ashley M. Nelson, PhD¹, Jamie M. Jacobs, PhD², Joseph A. Greer, PhD¹, Jennifer S. Temel, MD³, Areej El-Jawahri, MD²¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital Cancer Center, Boston, MA; ³MGH, Boston, MA

Background: Stem cell transplant (SCT) is a potentially curative therapy for patients with hematologic malignancies that involves prolonged hospitalization, intensive follow-up, and considerable risk of morbidity and mortality. Family and friends caring for SCT recipients experience substantial caregiving burden as they prepare for SCT which may impact their psychological distress; yet, little research has described the extent of this distress. The goals of the present study were to characterize rates of anxiety and depression symptoms immediately prior to SCT and their relationship with certain domains of quality of life (QOL) and caregiving burden.

Methods: We conducted a secondary analysis of cross-sectional data to investigate study aims. Caregivers completed study questionnaires (i.e., Hospital Anxiety and Depression Scale [HADS] and CareGiver Oncology QOL) prior to SCT. Scores >8 on the HADS anxiety and depression subscales indicate clinically significant symptoms. We selected eight domains from the CareGiver Oncology QOL, which is a multidimensional tool of caregiving burden and QOL, including social support, physical wellbeing, self-efficacy, coping, leisure time, financial stability, private life concerns, and caregiving burden. Multiple regression models adjusting for age, sex, caregiver relationship, and SCT type (autologous and allogeneic) were used to examine associations between these domains and caregivers' anxiety and depression symptoms.

Results: A total of 193 caregivers (age $M = 57$ years, 70% female, 52% allogeneic transplant) were included. A majority of participants were caring for a spouse (80%), parent (8%), or child (5%). On average, caregivers reported more anxiety ($M = 7.04$, $SD = 3.94$) than depression symptoms ($M = 4.18$, $SD = 3.49$), with 47% and 16% endorsing clinically significant anxiety and depression symptoms, respectively. Low social support, worse physical well-being, poor self-efficacy and coping, less leisure time, as well as higher financial distress, private life concerns, and caregiving burden were associated with higher caregiver anxiety symptoms ($ps < .05$). These quality of life domains were also associated with higher caregiver depression symptoms in the same directions ($ps < .05$), with the exception of self-efficacy ($p > .05$).

Conclusions: Caregivers of SCT recipients experience substantial anxiety and depression symptoms prior to SCT. Impairments across multiple QOL domains are associated with caregivers' psychological distress prior to SCT. Psychosocial interventions designed to manage transplant and caregiving expectations, improve coping, reduce caregiving burden, and improve QOL are critically-needed for caregivers prior to transplant.

6:15 PM-7:30 PM

PERCEPTIONS AND EXPERIENCES OF WOMEN TESTING POSITIVE FOR BRCA1/2 GENETIC MUTATIONS: A QUALITATIVE ANALYSIS

Kate E. Dibble, M.A.¹, Laura K. Donorfio, PhD¹, Preston A. Britner, PhD¹, Trane Kessler, n/a¹, Valentina Atehortua, n/a¹, Annika R. Anderson, n/a¹, Jason Chan, n/a¹, Keith M. Bellizzi, PhD, MPH¹¹University of Connecticut, Storrs, CT

Background: Individuals testing positive for the *BRCA1/2* genes, or hereditary cancer mutations, are 33-55% more likely to develop breast and ovarian cancers before the age of 70. Genetic counseling for suspected *BRCA1/2* mutations is recommended for individuals with an increased risk of having a mutation, which is dependent on a number of personal, family, and clinical variables. Unfortunately, very little research exists regarding women's perceptions and experiences of undergoing genetic counseling in the United States.

Methodology: The current study is a cross-sectional, qualitative analysis of the experiences of women who have tested positive for either (or both) *BRCA1/2* genetic mutations within the past five years. Participants were recruited from four major online support groups for women with these genetic mutations. Participants provided email addresses or scheduled an appointment online through the private study Facebook page. Interviews were scheduled and completed through participant's choice of phone call or Skype interview. Foci of interviews ascertained how participants viewed their experience of genetic counseling and how counseling could be enhanced in the future. Thematic analyses were completed by two independent coders for each interview to create major themes across participants.

Results: A total of 34 participants completed the interview, answering questions related to family history, genetic counseling experience, and emotional impact of results. Interviews ranged from 5.30 to 37.02 minutes in duration ($M=19.52$). Six major qualitative themes were identified: Family Reaction/Support ($n=29$), Emotional Reaction ($n=33$), Perceived Risk ($n=34$), Preventive Measures ($n=34$), Healthcare System ($n=34$), and Future Recommendations ($n=31$). Specific observations present in participant interviews regarding these particular areas were categorized into one of the six major themes above. Negative psychological responses, financial/insurance issues, therapeutic needs, treatment information, and guidance were the primary sources of stress within this sample, whereas positive subthemes included empowerment, self-advocacy, and active cancer awareness.

Conclusion: It is apparent that there are both positive and negative perceptions and experiences relating to familial reaction/support, doctor/patient communication, insurance coverage, available patient resources, and genetic counseling experience as a whole. Although some aspects may project positivity, results suggest a need for future research and education for genetic counselors and others providing care for women being tested for *BRCA1/2* mutations.

A MODEL EXPLAINING TREATMENT ADHERENCE AND TREATMENT DECISIONAL DISTRESS IN BREAST CANCER SURVIVORS TAKING ADJUVANT THERAPY

Keith Sanford, Ph.D.¹, Alannah S. Rivers, B.A., M.A.², Gary Elkins, Ph.D.³, Janet S. Carpenter, PhD, RN, FAAN⁴, Kevin L. Rand, Ph.D.⁵, Rebecca Bartlett Ellis, PhD, RN, ACNS-BC⁶

¹Baylor, Waco, TX; ²Baylor University, WACO, TX; ³Baylor University, Waco, TX; ⁴Indiana University, Indianapolis, IN; ⁵Indiana University-Purdue University Indianapolis, Indianapolis, IN; ⁶Indiana University School of Nursing at Indianapolis, Indianapolis, IN

Although adjuvant hormone therapy is lifesaving for breast cancer survivors, it requires taking oral medication daily for five years, and due largely to treatment side effects, approximately 40% of women are non-persistent within two years. Programs to increase adherence to adjuvant therapy have consistently failed to produce significant effects and have not typically addressed the distress women experience about treatment decisions. To advance the field, it is crucial to begin by developing an empirically-supported model identifying malleable and modifiable mechanisms that shape both treatment adherence and treatment decisional distress.

To develop such a model, we first drew from existing theoretical work on treatment adherence to identify a pool of potentially important variables, then conducted psychometric work with general medical samples to reduce the pool to a set of variables that were distinct, could be assessed with high validity, and were robustly associated with adherence. This process resulted in 8 key variables: 2 attitude variables (perceived benefit of treatment, and perceived burden of treatment), 4 interpersonal variables (alliance with a physician, understanding medical information from a physician, and negative and positive interactions with significant social support persons), and 2 stress-response variables (perceived stress and financial stress). Based on this, we proposed a model where interpersonal and stress-response variables predict both treatment adherence and decisional distress, and where all the effects of these variables on adherence are mediated by the two attitude variables and by decisional distress.

To provide a preliminary test of this model, 130 breast cancer survivors were recruited via marketing research panels to complete an online questionnaire. The sample included 80 women currently taking adjuvant hormone therapy and 50 women formerly taking adjuvant therapy responding to questionnaire items by recalling their previous experience. The questionnaire included multi-item scales, validated in previous research, assessing all model variables and side effect/symptom severity. Based on the model, treatment adherence was expected to correlate with 9 variables, and decisional distress with 7, and all but one of these were significant. The model also suggested 18 possible mediational pathways, and all but five were significant. Although further work is needed to test the model in a longitudinal study of women recently prescribed adjuvant therapy, these preliminary results are promising, and this line of research may lead to novel interventions to increase treatment adherence and reduce decisional distress.

QUALITY ASSESSMENT OF CLINICAL PRACTICE GUIDELINES IN PSYCHOSOCIAL ONCOLOGY USING THE AGREE II TOOL

Catherine Bergeron, MA¹, Michelle Azzi, MA¹, Sarah Mackay, BSc¹, K. Watkins-Martin, MA Counselling Psychology (2019)¹, Adina Coroiu, PhD², Annett Korner, PhD¹

¹McGill University, Montreal, PQ, Canada; ²Harvard TH Chan School of Public Health, Montreal, PQ, Canada

Background: The use of science in clinical practice is integrated into the professional and ethical obligations of psychologists; however, recent findings suggest that psychologists often fail to keep up-to-date with current research and neglect to use evidence-based approaches. A recent effort to close this science-practice gap has been through the use of clinical practice guidelines (CPGs). CPGs are evidence-based tools designed to help healthcare professionals implement best-care practices and have been developed for a wide variety of settings, including psychosocial oncology. Despite the recognition that psychosocial factors have an important impact on the quality of life of cancer patients, patients often report that their psychosocial needs are not sufficiently addressed in treatment. Access to good-quality CPGs targeting cancer-related psychosocial challenges would help ensure that psychologists are well-equipped to address these needs. However, the quality of CPGs currently available in psychosocial oncology is unknown. In the present study, the quality of psychosocial oncology CPGs was assessed using the AGREE II method.

Methods: A total of 17 CPGs were evaluated independently by 4 trained appraisers using the AGREE II instrument. The AGREE II consists of 23 items across the 6 domains: scope and purpose, stakeholder involvement, rigor of development, clarity of presentation, applicability, and editorial independence. Based on appraiser ratings, each domain is given a score, with 0% indicating lowest possible quality and 100% indicating highest possible quality. An overall quality score is calculated based on individual domain scores, with 60% being the cutoff for acceptable CPG quality.

Results: The average score for overall quality across the 17 CPGs assessed was 77%, with only two CPGs falling below the acceptability cutoff of 60%. Average scores across the 6 domains ranged from 93-35%, with the highest score being 93% for Scope and Purpose and the lowest score being 35% for Applicability. Of the 17 CPGs, 14 were recommended for use in their current state by appraisers.

Conclusions: These findings suggest that most currently available psychosocial oncology CPGs are of good quality and, as such, have the potential to aid psychologists in addressing the psychosocial needs of cancer patients. Future research should seek to investigate CPG use among psychologists working in psychosocial oncology settings.

Skin cancer is the most common type of cancer, accounting for over half of all cancers diagnosed. The primary risk factor for skin cancer is ultraviolet radiation (UVR) exposure. UVR exposure is therefore essential to assess, including as an outcome of skin cancer preventive interventions. However, it is unknown to what extent the act of monitoring UVR exposure may be associated with behavioral or attitudinal changes (e.g., cancer worry, perceived risk). The goal of the current study was to assess potential reactivity associated with wearing a UVR monitoring device.

Ninety-seven parents (77% biological mothers) and their 97 children (mean age=12.7, SD=2.7) were asked to wear a UVR monitoring device called Shade on their clothing during a two-week period. Participants completed a questionnaire at baseline and study exit about skin cancer prevention behaviors such as wearing sunscreen, sunburn, tanning, and attitudinal changes such as cancer worry and perceived risk. Items were asked on a 5-point Likert scale from “never” to “always.” To explore potential reactivity associated with wearing a UVR monitoring device, changes in outcomes from baseline to exit were examined using analysis of covariance (ANCOVA), controlling for the season at time of enrollment.

Analyses indicated little change in the outcomes of interest (UVR exposure measured from the device, and per child self-report, parent self-report, and parent report on child on skin cancer prevention behaviors, tanning, sunburn, perceived risk, cancer worry, and response efficacy) from baseline to exit. Some significant changes in skin cancer preventive behaviors over time were found, including in long sleeve and pants wearing. For example, per parent-report about their child, long sleeved shirt wearing increased significantly between time points ($F(1.0, 84.0) = 4.3, p=.04$). However, these changes reflect small and not clinically significant changes in means levels of these behaviors (e.g., $M=1.85$ at baseline, $M=2.16$ at exit).

Our findings provide initial evidence that use of a UVR monitoring device among parents and children does not result in significant changes in UVR exposure, skin cancer prevention behaviors, or attitudes. Future studies could further assess potential reactivity associated with use of wearable UVR monitoring devices, and account for other factors that may impact reactivity such as child age, time spent outdoors, and geographic location. These findings suggest that objective UVR exposure measured via a UVR monitoring device such as the Shade device could be used as an outcome in skin cancer prevention interventions.

PLATFORM TYPE AND CANCER-RELATED CONTENT INFLUENCE SOCIAL SUPPORT ON SOCIAL MEDIA AMONG YOUNG ADULT CANCER CAREGIVERS

Echo L. Warner, MPH¹, Andrew Wilson, PhD, MStat², Lee Ellington, PhD², Ye Sun, PhD², Kristin G. Cloyes, PhD, MN, RN², Austin R. Waters, HBS³, Taylor Nelson, N/A³, Anne C. Kirchhoff, PhD, MPH²

¹Huntsman Cancer Institute, Salt Lake City, UT; ²University of Utah, Salt Lake City, UT; ³Huntsman Cancer Institute/University of Utah, Salt Lake City, UT

Background: Young adult cancer caregivers (YACC) use social media during their cancer experiences to seek social support from online communities. We studied the extent to which social media platform type and presence of cancer-related content in social media posts influenced the social support offered in response to YACC's posts during the first six months of caregiving.

Methods: Eligible YACC aged 18-39 were caring for a cancer patient diagnosed between 6 months to 5 years prior, spoke English and used social media at least once per week. YACC completed an interview and survey, then gave permission for their social media posts to be collected retrospectively from six months following the patient's diagnosis. We collected original posts from YACC's Facebook and/or Instagram profiles and all responses to these posts. Original posts and responses were manually coded for the presence of five types of social support (emotional, information, validation, companionship, instrumental). Support variables were transformed to depict the proportion of responses per post that contained each type of social support. Using mixed-effects models, we compared the distributions of each type of social support offered in response to YACC's original posts by platform type (Facebook vs. Instagram) and cancer-related content (no vs. yes). Summary statistics were calculated for YACC sociodemographics, patient cancer factors, and social media use.

Results: We analyzed N=1,527 social media responses from N=33 YACC. YACC were 70.6% female, 91.2% non-Hispanic White, and 85.3% employed. YACC were most commonly caring for a spouse/partner (52.9%), or a parent (23.5%). The most common type of social support offered was emotional (72.1%), followed by information (20.4%) and validation (17.2%). There were significantly more responses that contained emotional support on Instagram compared to Facebook ($\beta = 0.25$, Standard Error(SE) = 0.09, $p = 0.007$). There were significantly more responses with cancer-related content that contained validation support ($\beta = 0.20$, SE = 0.07, $p = 0.002$), but fewer responses containing emotional ($\beta = -0.17$, SE = 0.07, $p = 0.02$) and instrumental support ($\beta = -0.06$, SE = 0.02, $p = 0.001$) compared to posts without cancer-related content.

Conclusions: Future interventions for YACC should consider how platform features and user characteristics (e.g., close vs. weak ties) change the nature of social support offers. Clinicians and supportive care personnel can guide YACC on strategies that are most likely to result in supportive social media responses. For example, YACC may benefit from guidance on which platforms are set up for users to conveniently offer different types of support, and caution about the overuse of cancer-related terms which may lead to diminishing social support over time.

HIGH REPRODUCTIVE CONCERNS ASSOCIATED WITH FERTILITY COUNSELING: A CROSS-SECTIONAL STUDY OF YOUNG ADULT MALE CANCER SURVIVORS

Julia H. Drizin, MA¹, Brian Whitcomb, PhD², Tung Chin Hsieh, MD³, Jessica R. Gorman, PhD, MPH⁴¹Oregon State University, Philomath, OR; ²University of Massachusetts, Amherst, MA; ³UCSD, San Diego, CA; ⁴Oregon State University, Corvallis, OR

Background: Reproductive concerns are common among young adult cancer survivors. Fertility consultation (FC) has been proposed as a possible intervention strategy, but the relationship between FC and reproductive concerns among young adult (YA) male survivors has not been established.

Purpose: This study examined the association between FC and multiple dimensions of reproductive concerns among YA male cancer survivors.

Methods: One hundred and seventy YA male cancer survivors (age 18 to 35) across the United States completed a cross-sectional, online survey between 2016 and 2018. Participants reported demographics, receipt of FC, and reproductive concerns. Reproductive concerns were measured multidimensionally using the Reproductive Concerns after Cancer-Male scale. We used log binomial regression to examine the association between FC and high reproductive concerns across multiple domains.

Results: In multivariate analyses adjusting for desire for children, FC was associated with higher likelihood of having at least one high reproductive concern (RR 1.4, 95% CI 1.2-1.7, $p < .001$). Across subscales, FC was associated with greater likelihood of having high concerns about fertility potential (RR 1.7, 95% CI 1.0-3.0, $p = .06$), achieving pregnancy (RR 3.5, 95% CI 1.3-9.5, $p = .01$), their (potential) child's health (RR 1.5, 95% CI 1.1-2.2, $p = .02$), and disclosing infertility to a partner (RR 2.7, 95% CI 1.8-4.1, $p < .001$). In contrast, associations were not observed between fertility consultation and likelihood of high concerns about personal health (RR 1.4, 95% CI 0.5-3.8, $p = .48$) or acceptance of infertility (RR 1.8, 95% CI 0.8-3.9, $p = .14$).

Conclusions: YA male cancer survivors who received FC were more likely to have high reproductive concerns than those who did not receive FC. Men who seek out FC after cancer diagnosis may need additional continued support for their reproductive concerns. Research is needed to identify strategies to alleviate these concerns among this population.

LONGITUDINAL STUDY COMPARING ORAL CURCUMIN AND AGE GROUP ON CANCER-RELATED FATIGUE IN BREAST CANCER PATIENTS

Julia E. Inglis, Ph.D., R.D.¹, Luke J. Peppone, Ph.D., M.P.H.², Michelle C. Janelins, Ph.D., M.P.H.¹, Amber S. Kleckner, PhD³, Charles E. Heckler, PhD, MS¹, Jon F. Strasser, MD⁴, Howard M. Gross, MD, FACP⁵, Thomas M. Anderson, D.O. / FACRO / FAOCR⁶, Gary R. Morrow, Ph.D., M.S.¹¹University of Rochester Medical Center, Rochester, NY; ²University of Rochester MEDical Center, Rochester, NY; ³University of Rochester, Rochester, NY; ⁴Medical Director Radiation Oncology/ Helen F Graham Cancer Center, Christiana Care Health System, Wilmington, DE; ⁵Dayton Physicians Network/ NCORP Board of Directors, Dayton, OH; ⁶Columbus - NCORP, Columbus, OH

Background: Patients with breast cancer undergoing radiation therapy commonly experience cancer-related fatigue (CRF) symptoms. Oral curcumin is a biologically active component from turmeric with anti-inflammatory properties that may reduce symptoms of CRF. Age is also thought to be a factor in patient-reported symptoms; older patients may under-report symptoms. Although to our knowledge, research on the impact of age on CRF is limited. The goal of this study was to evaluate whether oral curcumin supplementation or age has an effect on CRF in patients with breast cancer.

Methods: In a phase II nationwide randomized controlled trial in the NCI Community Oncology Research Program (NCORP) network, female breast cancer patients receiving radiation therapy were randomized to 2 g capsules of curcumin powder three times (6 g)/ day (n=341) or placebo (n=337) starting at Day 1 of radiation therapy to one week post-radiation. Compliance was measured by weekly pill counts. Patients were further divided by age group: younger age (< 60yrs, n=386) vs. older age (≥60 yrs, n=292). CRF symptoms were assessed at pre-radiation (baseline), post-radiation, one-week post-radiation and one-month post-radiation using the Symptom Inventory Questionnaire. Multivariate regression analyses evaluated differences in CRF at each time point, controlling for baseline CRF, cancer stage and previous cancer treatment.

Results: There were 678 total participants. Those in the younger age group reported more CRF symptoms at the end of radiation therapy ($p=0.025$; 95% C.I. 0.068, 0.983). One week post-radiation therapy, the younger group continued to trend towards higher CRF symptoms ($p=0.107$; 95% C.I. -0.074, 0.761). Older patients receiving curcumin supplementation reported less CRF at the end of radiation therapy than younger patients receiving curcumin ($p=0.021$; 95% C.I. 0.119, 1.422). There was no difference in CRF symptoms between the curcumin and the placebo arm at any time point throughout the study.

Conclusion: Younger patients reported greater CRF in this study. Oral curcumin potentially benefitted older patients more than younger patients receiving supplementation. There were no statistically significant reported differences in symptoms of CRF from oral curcumin supplementation vs. placebo. More research is needed on the impact of curcumin supplementation and age on symptoms in patients with breast cancer. Older patients may under-report CRF symptoms.

BUILDING A PEER SUPPORT PROGRAM FOR PATIENTS WITH ESOPHAGEAL CANCER

Taylor Schulte, n/a¹, Sunnie Kim, MD², Julia H. Rowland, PhD³, Jennifer Bires, MSW, LICSW, OSW-C³, Kristi Graves, PhD⁴

¹Georgetown Lombardi Comprehensive Cancer Center, Cancer Prevention and Control Program, Washington, DC; ²University of Colorado Cancer Center, Aurora, CO; ³Smith Center for Healing and the Arts, Washington, DC; ⁴Georgetown University, Washington, DC

Background: Existing peer support programs have been implemented and tested predominately in women with breast cancer. Little research has been done with esophageal cancer (EC) patients, despite a growing population of survivors and a rapidly changing treatment landscape. Peer support programs may provide benefit through individual connections and experiences for patients with newly diagnosed EC.

Purpose: We sought to better understand the needs of EC patients during diagnosis, treatment and survivorship to develop a curriculum to train EC survivors to provide peer support to newly diagnosed patients.

Methods: We conducted two parallel phases: elicitation of input from expert stakeholders and individual qualitative, semi-structured interviews with EC survivors. In the first phase, we convened stakeholders from different disciplines representing medical oncology, psychosocial oncology, social work, thoracic surgery and patient advocates. We elicited input regarding the planned curriculum topics and identified content important to EC survivors. We then reviewed existing peer support resources to identify successful delivery models of peer mentoring among cancer survivors. In the second phase, we conducted qualitative interviews with EC survivors to learn about their experiences, factors that influenced quality of life and opinions about a peer support program.

Results: Input from 11 stakeholders resulted in a curriculum for a 5-hour in-person training workshop. Curriculum content included modules on adaptation to cancer, defining the role of a peer mentor, boundary setting, communication skills and self-care. We interviewed 8 male and 2 female EC survivors at an average of 32 months after diagnosis. 9/10 survivors indicated that a one-on-one peer support program could be useful. Respondents felt that information from peers was critical for anticipating side effects, learning about nutrition during treatment and after surgery, and the support of knowing they are not alone. We used these results to revise the training curriculum and to date have conducted 2 peer mentor training sessions with 7 EC survivors. Trainings were well received by mentors in terms of content, length and format.

Conclusions: A peer mentor program appears to be of interest and a needed resource for patients with newly diagnosed EC. We will evaluate the effectiveness of a pilot program by collecting patient-reported quality of life outcomes from the mentors and mentees before and 6-months after mentor-mentee matching.

NAVIGATING SEXUAL HEALTH IN CANCER SURVIVORSHIP FROM A DYADIC PERSPECTIVE

Jessica R. Gorman, PhD, MPH¹, Ellie Smith, MA¹, Julia H. Drizin, MA², Karen S. Lyons, PhD³, Marie Harvey, DrPH, MPH¹

¹Oregon State University, Corvallis, OR; ²Oregon State University, Philomath, OR; ³Boston College, Chestnut Hill, MA

Objective: Young adult (YA) breast cancer survivors experience myriad and persistent sexual health difficulties following cancer treatment. Strategies for managing these difficulties often focus on individual cancer survivors, but couples navigate life after cancer as a dyad. Using the Theory of Dyadic Illness Management as a guiding framework, this qualitative study examined how YA couples appraise, communicate about, and manage their sexual health and intimate relationships after cancer.

Methods: We conducted concurrent, individual telephone interviews with 25 YA female breast cancer survivors and their male partners. We utilized a thematic, inductive analysis to examine individual interviews, followed by analysis within- and across-couples to identify dyadic themes. We explored how themes mapped on to the Theory of Dyadic Illness Management to build a conceptual framework specific to the sexual health challenges of YA couples living with cancer.

Results: Our analysis revealed five themes: 1) Shared understanding of physical and psychological challenges of sexual health after cancer; 2) Navigating role shifts and changes to sexual relationship; 3) Getting through it as a team; 4) Maintaining open communication; and 5) Wanting services and support for partners/caregivers and couples. Both survivor and their partners articulated physical (e.g., painful sex, decreased libido) and psychological (e.g., guilt, self-consciousness) challenges to their sexual health in survivorship. Gender differences emerged, where women more often described a sense of “duty” to engage sexually than men did. Couples described a shift in roles throughout survivorship that either strengthened relationships or created a “wedge.” Couples identified “open communication” and strategies for “working as a team” as critical in order to navigate these challenges, but perceived a need for more support and resources. Most participants advocated for couple-focused and online services.

Conclusion: Many YA couples experience complex sexual health challenges after cancer. There is no “one size fits all” solution, as individuals and couples cope with and manage these challenges in different ways. Study results can inform couple-focused strategies to improve the experience for both survivors and their partners, such as creating shared understanding of sexual health after cancer and improving communication skills.

6:15 PM-7:30 PM

A POPULATION-BASED EVALUATION OF DELAY IN SURGICAL INVASIVE CANCER TREATMENT

Francisco A. Montiel Ishino, PhD, MPH, CPH¹, Peter T. Ajayi, B.A.², Faustine Williams, PhD, MPH, MS³¹NIH-NIMHD, North Bethesda, MD; ²NIH/NIMHD, Rockville, MD; ³NIH/NIMHD, Bethesda, MD

Purpose: Variations in cancer stage at presentation and treatment care exist in the U.S. by race/ethnicity, geography, and socioeconomic status (SES). Previous studies have found that black and non-Hispanic whites are more likely to be diagnosed at a later stage and delay the initiation of treatment. Early detection of cancer and treatment greatly improves a person's prognosis as well as survivorship outcomes. Specifically delaying surgical treatment for breast cancer (BC) more than 30 days and prostate cancer (PC) more than 90 days may lead to present late-stage cancer diagnosis and delay treatment may affect survival. The purpose of this study was to assess the impact of sociodemographic factors and SES on treatment delay among BC and PC patients.

Methods: A total of 28364 BC and 14294 PC cases were obtained from the Tennessee Department of Health Cancer Registry for patients diagnosed from 2005 to 2015. A logistic regression was utilized to model the likelihood of treatment delay and assess unique contributions of race/ethnicity, SES (a composite area-based measure), demographic variables, and cancer stage.

Results: Median time gap between diagnosis and surgical treatment was 28 and 61 days for BC and PC, respectively. Race/ethnicity was associated with delayed BC treatment; non-Hispanic blacks were at 1.2 odds (95% CI: 1.1-1.3) and Hispanics were at 1.4 odds (95% CI: 1.1-1.9) of delaying compared non-Hispanic whites. Those living in Appalachian counties were 1.2 odds (95% CI: 1.1-1.2) of delaying compared to those living in non-Appalachian counties. Those with distant (0.6 OR; 95% CI: 0.5-0.8) and regional (0.9 OR; 95% CI: 0.9-0.9) cancers were less likely to delay compared to those with localized cancer. SES was associated with delay such that a one-unit increase led to a 1.02-fold increase in the odds of being in the delay category. Concerning PC, relationships were similar to that of BC; however, Hispanics (0.8 OR; 95% CI: 0.5-1.5) did not significantly differ in delay compared to non-Hispanic whites and a one-unit increase in SES led to a 0.60-fold decrease in the odds of being in the delay category. Regardless of cancer type, increased age was associated with reduced treatment delay.

Discussion/Conclusion: The contributions of SES and sociodemographic factors on health disparities may vary depending on the type of cancer. Overall findings are suggestive that being of disadvantaged background (e.g., non-Hispanic black) in Tennessee is likely to increase the delay in surgical cancer treatment compared to those of advantaged backgrounds. Findings support the need to investigate the relationships between race/ethnicity, SES, and receiving timely cancer treatment for BC and PC.

6:15 PM-7:30 PM

SHORT AND LONG-TERM BARRIERS AND FACILITATORS OF SSE AMONG INDIVIDUALS WITH MELANOMA

Adina Coroiu, PhD¹, Chelsea Moran, MA², Catherine Bergeron, MA³, Annett Korner, PhD³¹Harvard TH Chan School of Public Health, Montreal, PQ, Canada; ²University of Calgary, Calgary, AB, Canada; ³McGill University, Montreal, PQ, Canada

Background: Melanoma can be lethal if not detected early and treated. Early detection can be facilitated via skin self-examination (SSE) and as such, SSE is part of melanoma follow-up care for individuals with a prior history, who face a life-long risk of reoccurrence. The objective of the current study was to identify short- and long-term predictors of SSE among melanoma survivors to inform future prevention interventions in high-risk groups.

Method: This is an observational study with longitudinal assessments conducted with adult melanoma patients in active follow up care. Socio-demographic and medical information (time since diagnosis, cancer stage) was collected at enrolment. Hypothesized psychosocial predictors of SSE (knowledge about melanoma early detection, intentions and self-efficacy about SSE, distress, and coping) were assessed at 3 months post a standardized dermatological education session on skin cancer preventive behaviours, including SSE.

Primary Outcome Measures: Behavioral outcomes, comprehensive SSE (checking up to 5 body areas in the last 3 months) and optimal SSE (checking the entire body/5 body areas at least monthly in the last 3 months) and were assessed at 3, 12, and 24 months post. T-tests and chi square analyses assessed changes in outcomes from 3-24 months. Linear and logistic regression models examined the association between predictors and the primary outcomes.

Results: Comprehensive SSE did not decrease significantly from 3 (M=2.7, SD=1.1) to 12 (M=2.6, SD=1.2) and 24 months (M=2.4, SD=1.2), with the strongest predictor at all time-points being intentions to perform SSE. Other significant predictors of comprehensive SSE included male sex, SSE self-efficacy, melanoma stage, and reliance on medical advice at 3 months post; and melanoma stage, (lower) education, and SSE self-efficacy at 12 and 24 months post. No other variables were associated with comprehensive SSE.

Optimal SSE was higher at 3 months (59%) compared to 12 (46%) and 24 months (34%) post the standardized dermatological education session. Significant predictors of optimal SSE were SSE self-efficacy, SSE intentions, biological sex at 3 months post; SSE self-efficacy and reliance on medical advice at 12 months post; and (lower) education and SSE self-efficacy at 24 months post. No other variables showed an association with optimal SSE.

Conclusions: This study showed that melanoma survivors in active follow up maintain SSE behaviour over time, but rates of SSE performed in agreement with medical recommendations are higher immediately post intervention and decrease somewhat over a 24-month period. Further, the strongest psycho-social predictors of SSE, intentions and self-efficacy, are highly amenable to change via motivational interviewing and goal-setting health interventions.

PERCEPTIONS OF FOLLOW-UP CARE AMONG BREAST CANCER SURVIVORS: ASSOCIATIONS WITH COMMUNICATION AND TRUST IN MEDICAL CARE

Jessica N. Coleman, BA¹, Gretchen Kimmick, MD, MS², Francis J. Keefe, PhD¹, Hayden B. Bosworth, PhD¹, Linda M. Sutton, MD¹, Lynda Owen, PhD, CCRP³, Vicky Gandhi, BS¹, Rebecca A. Shelby, PhD¹

¹Duke University, Durham, NC; ²Duke University Medical Center / Duke Cancer Institute, Durham, NC; ³Duke Cancer Network, Durham, NC

It is important to better understand factors that impact beliefs about cancer surveillance in order to increase engagement in follow-up care among breast cancer survivors. Medical mistrust and poor patient-provider communication may be key modifiable factors that are associated with suboptimal surveillance adherence, yet few studies have investigated these factors. Cross-sectional data were analyzed from breast cancer survivors ($N=100$) who received care at community hospital-based oncology clinics. Participants had Stage I-III breast cancer, were two to five years post-treatment, and had a mean age of 62 years ($SD=11$). The sample identified as White (43%), Black (36%), and American Indian (21%). Approximately 30% of the sample had a high school education or less, 41% had vocational training/some college, and 29% had a college degree or higher. Participants completed validated measures of perceived breast cancer surveillance utility (e.g., efficacy, benefits and costs of follow-up care) and mammography benefits, communication with health care providers, trust in physician, and medical mistrust. Separate hierarchical linear regressions were conducted for perceived surveillance utility and mammography benefits. Each model included communication with health care providers, trust in physician, and medical mistrust as independent variables. Covariates were included based on bivariate analyses. Provider communication, trust in physician, and medical mistrust explained 30% of the variance in perceived surveillance utility, controlling for race and education, $F(7,92)=9.48$, $p<.001$. Race and education did not explain significant variance in perceived utility. Provider communication, physician trust, and medical mistrust did not account for significant variance in perceived mammography benefits, controlling for education, $F(5,94)=1.90$, $p=.10$. Having a college degree or more education explained significant variance in perceived mammography benefits ($\beta=.23$, $p=.04$, $s^2=.04$). Results suggest that breast cancer survivors' beliefs about surveillance utility are associated with quality of provider communication, trust in physician, and medical mistrust. Improving provider communication and trust may be critical to increase perceived cancer surveillance utility and in turn, improve surveillance adherence among breast cancer survivors. Further research is needed to better understand perceived mammography benefits, considering education and additional psychosocial predictors.

A SYSTEMIC REVIEW OF SURVIVORSHIP CARE PLAN USE BY RACIAL AND ETHNIC MINORITY BREAST CANCER SURVIVORS

Marquita W. Lewis-Thames, MS, MPH, PhD¹, Shaila Strayhorn, PhD, MPH², Timiya S. Nolan, PhD, APRN-CNP³, Yamilé Molina, MS, MPH, PhD²

¹Washington University School of Medicine, St. Louis, MO; ²University of Illinois at Chicago, Chicago, IL; ³The Ohio State University, Columbus, OH

Purpose: Racial and ethnic disparities in breast cancer survival rates persist in the United States. While breast cancer 5-year survival rates for non-Hispanic White women are 90%, for African-American and Hispanic women, survival rates are 80% and 88%, respectively. Optimizing post-treatment survivorship care communication, especially through survivorship care plans (SCPs), may improve survivorship rates for minority breast cancer survivors. Understanding associated nuances and concerns of SCP implementation to racial and ethnic minority women is critical to address these disparities. The purpose of this systematic review is to thematically assess the implementation of survivorship care to female racial/ethnic minority breast cancer survivors as it relates to their preparation for survivorship care, the preferred practices for the delivery of a SCP, and the associated content to improve an understanding of survivorship care.

Methods: We screened studies from PubMed, Ovid-Medline, and CINAHL databases through April 2019, and identified eligible manuscripts using the PRISMA guidelines for a systematic review. Eligible manuscripts investigated breast cancer post-treatment survivorship care from study samples with at least 25% minority (e.g. African-American/Black, Hispanic, Asian) representation. Themes were assessed for survivorship care implementation for racial/ethnic minority breast cancer survivors. This review only extracted and analyzed information related to the post-treatment to end-of-life period of breast cancer survivors.

Results: Of 14 selected manuscripts, the investigations included diverse study designs that reported findings from over 12 different ethnic groups. Four key themes emerged. The first theme demonstrates that survivors were uncertain about survivorship as a stage in the cancer continuum; as some survivors were told they had transitioned to survivorship care while receiving treatments. Second, describes an approval of- and need for- SCPs and related materials. Third, survivors reported uncertainty about managing survivorship care resulting from confusion about recurring cancers and recommended follow-up clinic visits. Fourth, survivorship care information should be delivered in a healthcare setting with more care coordination, quality of life, and culturally relevant content in SCPs.

Conclusion: Identified themes revealed post-treatment survivorship communication and care coordination is often confusing. This uncertainty has implications on self-care management and adherence to necessary care. Findings provide insight on likely strategies to improve post-treatment communication and ultimately survivorship outcomes for minority breast cancer survivors.

DEVELOPMENT, PRODUCTION, AND ACCEPTABILITY OF A THEORY-BASED COMIC BOOK FOR HPV VACCINE PROMOTION FOR EAST AFRICAN ADOLESCENTS

Isabelle Celentano, MPH¹, Rachel L. Winer, PhD, MPH², Sou Hyun Jang, Ph.D.¹, Anisa M. Ibrahim, MD¹, Farah B. Mohamed, MPH, MSW³, Fanaye Gebeyaw, MA/MPH⁴, John Lin, BA⁵, Ahmed A. Ali, PharmD⁶, Victoria Taylor, MD MPH⁷, Linda K. Ko, PhD⁷

¹University of Washington, Seattle, WA; ²University of Washington School of Public Health, Seattle, WA; ³Seattle & King County Public Health, University of Washington, Somali Health Board, Renton, WA; ⁴King County Public Health, Mukilteo, WA; ⁵DEPARTMENT OF EPIDEMIOLOGY / UNIVERSITY OF WASHINGTON, SEATTLE, WA; ⁶Somali Health Board, Kent, WA; ⁷Fred Hutchinson Cancer Research Center, Seattle, WA

Background: HPV vaccine uptake is low among East African adolescents in the US. Adolescents' preferences influence vaccine decisions, yet few interventions exist that address adolescents' beliefs about HPV vaccines. Comic books are promising tools for communicating HPV vaccine information because it can both educate and entertain. We describe a multi-step process on how to create and evaluate a theory-based comic book among East African adolescents.

Methods: The comic book development was a multi-step process that included formative research with focus groups, creation of theory-based messages, and assessment of the comic book acceptability. First, we convened three separate focus groups in Somali, Amharic and Tigrinya (n=30) with East African mothers in Washington State to identify themes to inform the production of the comic book. Second, we conducted message mapping to operationalize the themes into theory-based messages. Third, we assessed the acceptability of the comic book, appeal, and message relevance among East African adolescents aged 14-17 years (n=134) using open-ended questions.

Results: The comic book incorporated socio-cultural themes, information needs, and suggestions for information flow that emerged from the focus groups. The comic book story followed a plot that focused on an adolescent main character and consisted of three scenes: 1) adolescent HPV vaccine education by a health professional in a classroom setting; 2) discussion of HPV vaccine beliefs and experiences among adolescent peers; and 3) communication with parents about HPV vaccine and intent for vaccination. Five themes emerged on comic book acceptability: overall appeal, structure, characters, story and content, and messages. The comic book appealed positively to most adolescents (92/111 comments; 82.9%). Comments about comic book structure noted liking the graphics (17/57; 29.8%) and ease of comprehension (22/57; 38.6%). Adolescents responded positively to ethnic representation (24/51; 47.1%), diversity of the characters (7/51; 13.7%), the story's educational focus (92/96; 97.9%), the use of humor (34/96; 35.4%), and flow of information among peers (31/96; 32.3%). The importance of HPV vaccines (82/98; 83.7%), seeking social support (43/98; 43.9%), and information about HPV and cancer (33/98; 33.7%) were messages noted as most important.

Conclusion: We used a multi-step process to create a culturally-tailored comic book on HPV vaccines that East African adolescents found to be both educational and entertaining. Further evaluation will focus on the impact of the comic book on HPV vaccination knowledge and intentions.

DAILY SOCIAL INFLUENCES ON PHYSICAL ACTIVITY AMONG MIDLIFE WOMEN WITH CVD RISK: AN ECOLOGICAL MOMENTARY ASSESSMENT STUDY

Danielle Arigo, Ph.D. in Clinical Psychology¹, Megan M. Brown, B.S.¹, Kristen Pasko, B.S.¹, Emily Vendetta, n/a¹, Laura Travers, M.S.¹, Adarsh Gupta, D.O.², M. Cole Ainsworth, Ph.D.¹, Danielle Symons Downs, Ph.D.³, Joshua M. Smyth, PhD⁴

¹Rowan University, Glassboro, NJ; ²Rowan School of Osteopathic Medicine, Stratford, NJ; ³Penn State University, University Park, PA; ⁴Pennsylvania State University, University Park, PA

Midlife women with elevated cardiovascular risk experience specific social influences on physical activity (PA), including perceptions of social events (i.e., positive/negative interactions) and social comparisons (i.e., self-evaluations relative to others). Existing data on these influences describe differences between individuals; although useful, this masks within-person change and temporal relations between social experiences and PA. Such information could inform improvements to tailored PA programs by targeting for whom and when specific interventions are needed. The current study used ecological momentary assessment (EMA) to capture relations between midlife women's perceptions of social experiences and PA in their natural environments. Participants were 40 midlife women with elevated cardiovascular risk (e.g., high blood pressure; MAGE=51, MBMI=34.4 kg/m²) who engaged in EMA for 10 days. Social perceptions were assessed via electronic surveys (5 semi-random times per day) and PA was assessed via waistband accelerometer. Daily summaries were calculated for the quantity/quality of social interactions, number/type of social comparisons, sedentary time, and time spent in light and moderate-to-vigorous activity (MVPA). Results showed high compliance with EMA (88% surveys, 98% accelerometer wear days) and significant day-to-day variability in social experiences and PA (ps< 0.001). One additional positive interaction per day was associated with significantly more sedentary time and less light PA. In contrast, a 1-unit increase in the intensity of negative interactions (rather than number of events) was associated with 23 fewer minutes of sedentary time per day. Across types of comparison, women engaged in 7 additional minutes of light PA, 4 additional minutes of MVPA, and 27 fewer minutes of sedentary time on days without (vs. with) comparisons. However, an increase of 1 downward comparison per day (i.e., comparing to someone "doing worse") was associated with 4 additional minutes of MVPA and 12 fewer minutes of sedentary time per day (all ps< 0.05). Findings show that EMA is sensitive to daily variation in midlife women's social perceptions and PA and reveals important daily relations. Specifically, that certain social experiences may facilitate their PA (e.g., downward comparisons), whereas others may present barriers (e.g., positive interactions). Downward comparisons may motivate women to continue healthy habits such as PA to prevent becoming like a worse-off other; positive interactions may distract from healthy habits, though they confer other health benefits. Further examination of time-sensitive relations between social experiences and PA will help to identify optimal targets for PA interventions that are tailored to the needs of midlife women.

POSTTRAUMATIC DEPRECIATION PREDICTS REPEAT HOSPITALIZATION IN CONGESTIVE HEART FAILURE PATIENTS

Sharon Y. Lee, M.S., M.A.¹, Crystal L. Park, PhD², Lucy Finkelstein-Fox, M.S.¹, Sinead M. Sinnott, M.A.³, Katherine Gnall, B.A.¹¹University of Connecticut, Storrs, CT; ²University of Connecticut, Storrs Mansfield, CT; ³University of Connecticut, HYDE PARK, MA

The health benefits of perceived posttraumatic growth (PPTG) for cardiac patients have been widely touted, although the validity of these claims has yet to be established. Some evidence suggests that, in cardiac patients, PPTG is related to greater health services engagement, reduced likelihood of another cardiac event, and lower levels of heart attack morbidity. While PPTG is an attractive construct, its predictive validity is inconclusive, as many measures elicit a positive response bias. Furthermore, research demonstrates that individuals can experience both positive and negative changes in the face of life-threatening illnesses. The construct of posttraumatic depreciation (PTD; negative life changes resulting from a stressful life event) has yet to be studied as a risk factor for poor health-related outcomes in the context of cardiac conditions, such as congestive heart failure (CHF). Frequency of repeat hospitalization is a particularly important outcome among CHF patients, given its economic, medical, and psychological toll. Of note, no study has examined whether and how PTD affects repeat hospitalization among CHF patients. The present study seeks to fill this gap by testing the following hypotheses with a longitudinal sample of 191 CHF patients (64% male; $M_{age}=68.6$ years): (H1) lower PPTG and greater PTD at baseline will predict a greater likelihood of hospitalization at 6-month follow-up and a greater number of CHF-related hospitalizations in the subsequent 5 years; and (H2) lower PPTG and greater PTD at baseline will be particularly detrimental for patients who had a CHF diagnosis for a longer time. Hierarchical logistic and linear regression with moderation analyses were conducted. PPTG and PTD showed a moderate inverse relationship ($r=-.29$, $p<.001$). H1 was partially supported in that greater PTD predicted a greater likelihood of hospitalization at 6-month follow-up ($OR=4.32$, 95% $CI[1.26, 14.85]$, Wald $\chi^2=5.39$, $p<.05$; Nagelkerke $R^2=.11$) and a greater number of CHF-related hospitalizations at 5-year follow-up ($\beta=.19$, $p<.05$; $R^2=.07$, $F(5,175)=2.80$, $p<.05$), after accounting for age, gender, and ejection fraction. However, PPTG was not a significant predictor of either hospitalization outcome. Furthermore, H2 was partially supported in that greater PTD was particularly deleterious for patients diagnosed with CHF for a longer time in predicting the total number of CHF-related hospitalizations by the 5-year follow-up ($\beta=.02$, $p<.01$; $R^2=.16$, $F(7,162)=4.25$, $p<.001$). Length of time for diagnosis did not interact with PTD to affect the likelihood of hospitalization at 6 months. Results suggest that, while positive and negative changes related to CHF are not mutually exclusive, PTD may be a more important psychosocial intervention target in terms of reducing hospitalization risk, particularly for patients diagnosed with CHF for a longer time.

IMPROVING MEDICATION ADHERENCE AMONG PATIENTS WITH HYPERTENSION: THE ROLE OF USING HEALTH BEHAVIORAL THEORIES

Mona Nili, n/a¹, Rowida Mohamed, n/a¹, Kimberly M. Kelly, n/a¹¹West Virginia University, Morgantown, WV

Background: One in three American adults has hypertension. The control of this highly prevalent disease is still far from adequate. Using antihypertensive medication is the most efficient strategy for hypertension control. However, adherence to antihypertensive medications is a major problem in the treatment of hypertension. About half of the patients who use antihypertensive medications are not adherent to their treatment. Several randomized clinical trials (RCTs) interventions have endeavored to improve adherence to antihypertensive medications, and some used health behavioral models/theories. However, the utility of using health behavioral models/theories in improving adherence to antihypertensive medications remains unknown.

Objectives: The objectives of this systematic review are to describe RCT interventions to improve antihypertensive medications adherence that used behavioral theories; assess type and extent of used theory; discuss the implications for practice and research.

Methods: This systematic review was prepared based on Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines. The PubMed, Scopus, Ovid MEDLINE, CINAHL, PsycINFO databases were searched for randomized clinical trial articles published in English, from 1979 to 2019. Two independent reviewers searched, screened abstracts and full-text of articles, extracted data, assessed risk of bias and use of model/theory by using the Theory Coding Scheme.

Results: A total of 815 articles were identified, 632 abstracts were screened, and 34 full-text articles were fully reviewed. The final review included 13 studies with 7,030 participants. The interventionist profession was nurse or pharmacist in the all included studies. Motivational Interviewing, Social Cognitive Theory, and Self-Regulation Model were the most common types of models/theories. Six studies used a single model/theory, and four studies measured constructs of model/theory. Among the included studies, two studies reported significant improvement in medication adherence.

Conclusions: Health behavioral models or theories can improve medication adherence among adults with hypertension, but this review did not find extensive support. More RCTs are needed that utilize health behavioral models/theories to their full extent in interventions to improve medication adherence among adults with hypertension.

Durant, MD, MPH¹, Rodney Tucker, MD MMM⁴, Kathryn L. Burgio, PhD⁷, Jose Tallaj, MD¹, Keith M. Swetz, MD, MA⁸, Salpy V. Pamboukian, MD MSPH¹, Marie Bakitas, DNSc, CRNP¹

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Hoover, AL; ³University of Alabama at Birmingham, Hueytown, AL; ⁴UAB, Birmingham, AL; ⁵UAB School of Nursing, Birmingham, AL; ⁶Dell Medical School, The University of Texas, Austin, TX; ⁷University of Alabama at Birmingham and Department of Veterans Affairs, Birmingham, AL; ⁸UAB School of Medicine, Birmingham, AL

Background: Palliative care (PC) for advanced stage heart failure (HF) is recommended by national organizations and guidelines, however there are few tested integrated HF PC models.

Research Objectives: Determine the effect of a nurse coach-led, PC telehealth intervention (ENABLE CHF-PC) on advanced HF patients' quality of life (QOL) and mood over 32 weeks.

Methods: Intervention (INV) vs. usual HF care (UC) randomized clinical trial (August 2016-October 2018) at a tertiary academic and Veteran's Affairs Medical Center serving high proportions of rural and African American (AA) patients. NYHA Class III/IV HF patients received UC or ENABLE CHF-PC consisting of an in-person PC consultation and 6 weekly nurse-coach psychoeducational telephonic sessions and monthly follow-up for 1 year. Primary outcomes were QoL (Kansas City Cardiomyopathy Questionnaire [KCCQ] & [FACIT-pal-14]) and mood (Hospital Anxiety Depression Scale [HADS]) over 32 weeks.

Results: Of 415 patient participants, mean age was 64, 53% male; 55% AA; 26% rural; 46% < high-school education; 75% reported having a caregiver; 47% reported reduced QoL (KCCQ clinical summary score ≤ 50). Over 32 weeks, trends favored INV group (mean KCCQ improved 5.1 points (± 1.4 SD) INV versus 2.7 (± 1.3) UC; mean FACIT-pal-14 improved 1.8 (± 0.6) INV vs 0.9 (± 0.6) UC; HADS-anxiety decreased equally in both groups (± 0.1) and HADS-depression decreased -0.9 (± 0.3) INV vs -0.5 (± 0.2) UC; however there was not a clinically significant improvement in INV group QOL and mood compared to UC (all p's > 0.05).

Conclusion: The lack of a clinically significant improvement in the INV relative to UC group may be explained by relatively high mean baseline QOL and mood scores. The high proportion of AA participants suggests acceptability of early PC in this population.

Implications: This study can inform timing and PC use in minority populations. Targeting HF patients with worse QOL/mood may be the most effective use of early palliative care.

THE ASSOCIATION BETWEEN HEALTH LITERACY AND MORTALITY IN THOSE WITH HEART FAILURE

Tyler Kuhn, B.S.¹, Mary Dolansky, PhD, RN², John Gunstad, Ph.D.¹, Richard Josephson, MD², Joel W. Hughes, PhD, FAACVPR¹

¹Kent State University, Kent, OH; ²Case Western Reserve University, Cleveland, OH

Introduction: Over 6 million Americans over the age of 20 are currently diagnosed with heart failure, which imposes complex self-care regimens for patients to manage. The Heart Failure Society of America has recommended the consideration of health literacy in heart failure management and encourages tailoring heart failure intervention strategies around health literacy. Low health literacy can impair heart failure management, and an association between low health literacy and increased mortality has been reported. The current study examined the association between tested health literacy and mortality in heart failure patients using two tests of health literacy and examined the role of cognitive functioning in that relationship in patients with heart failure. It was hypothesized that health literacy scores would predict all-cause mortality in those with heart failure and that cognitive functioning would attenuate the relationship between health literacy and mortality in heart failure.

Methods: Study participants were 372 patients with systolic heart failure recruited from two separate hospital systems in Northeast Ohio. Health literacy was tested using the Rapid Estimate of Adult Literacy in Medicine [REALM] and the Medical Term Recognition Test [METER]. Cognitive functioning was tested using the Modified Mini-Mental State [3MS]. Both cardiovascular and all-cause mortality data were obtained through December 2014, providing a median 2.9-year follow-up on death records.

Results: Multiple cox proportional hazards regressions were used to analyze whether the METER, REALM, and the 3MS predicted mortality in those with heart failure. Neither METER nor REALM scores predicted mortality. However, cognitive functioning did significantly predict mortality in regression models using both the METER ($B = -.07$; HR, .94 [95% CI, .89-.98]; $p < .01$) and REALM ($B = -.07$; HR, 0.94 [95% CI, .90-.97]; $p < .01$). Cognitive functioning also improved total model fit in both the METER ($\Delta\chi^2 = 9.20$, $p < .01$) and REALM ($\Delta\chi^2 = 9.77$, $p < .01$) models.

Discussion: When cognitive function was considered, no relationship between health literacy and mortality was observed. Further research is needed to determine the boundary conditions for the association between health literacy and mortality in those with heart failure.

HEALTH LITERACY AS A PREDICTOR OF ILLNESS BELIEF ACCURACY AMONG ADULTS WITH HEART FAILURE

Heather Neifert, BA¹, Tony Vehovec, PhD, RN², Mary Dolansky, PhD, RN², Nancy Albert, PhD³, Richard Josephson, MD², Joel W. Hughes, PhD, FAACVPR¹

¹Kent State University, Kent, OH; ²Case Western Reserve University, Cleveland, OH; ³Cleveland Clinic, Cleveland, OH

Introduction: Health literacy is associated with health knowledge and education, and lower health literacy is associated with less accurate illness beliefs among patients with a variety of chronic health conditions. In a 2017 study by Kumar and colleagues, among patients presenting to the emergency department with acute heart failure (HF), lower health literacy was associated with lower accuracy of HF illness beliefs. We sought to explore previous findings in a larger sample of community-dwelling adults with HF with reduced ejection fraction (HFrEF) recruited from cardiology clinics.

Methods: Adults with HFrEF (N=300) completed two measures of health literacy, the Rapid Estimate of Adult Literacy in Medicine (REALM) and Medical Term Recognition Test (METER). Scores were combined to create an index score of health literacy. Patients also completed the Survey of Illness Beliefs in HF to assess the accuracy of illness beliefs about the treatment and prognosis of HF. Hierarchical linear regression was used to determine the relation between health literacy and accuracy of illness beliefs controlling for sex, age, race, education level, and illness comorbidities.

Results: Age, race, education, and illness comorbidities had significant effects on illness belief accuracy ($F [5, 294] = 5.65, p < 0.01, R^2 = 0.09$). After controlling for these variables, health literacy improved total model fit ($F [1, 293] = 4.78, p < 0.05, R^2 = 0.10$) and was a significant positive predictor of accuracy on the Survey of Illness Beliefs ($B = 0.02 [p < 0.05]$). The mean score on the Survey of Illness Beliefs was 2.91 (SD = 0.30), indicating overall inaccurate illness beliefs within the sample.

Discussion: Lower health literacy was associated with less accurate HF illness beliefs. These findings extend prior research to a larger sample of outpatients with HFrEF, broadening the implications of Kumar and colleagues' work. Given that health literacy predicts self-care quality among patients with HF and that accurate illness beliefs are associated with better treatment adherence among patients with HFrEF, these findings may have implications for interventions that alter perceptions associated with inaccurate illness beliefs to improve HF treatment outcomes.

DEVELOPMENT AND VALIDATION OF A PARENTAL EMPOWERMENT SCALE AMONG HEAD START PARENTS

Roger Figueroa, PhD, MPH, MSc¹, Cristina Gago, MPH, CHES², Jacob P. Beckerman-Hsu, MPH³, Alyssa Aftosmes-Tobio, MPH⁴, Janine Jurkowski, PhD, MPH⁵, Kirsten Davison, PhD⁴

¹Cornell University, Ithaca, NY; ²Harvard University, Boston, MA; ³Harvard TH Chan School of Public Health, Boston, MA; ⁴Boston College, Chestnut Hill, MA; ⁵University at Albany School of Public Health, Rensselaer, NY

Empowerment is the ability to navigate one's own resources and relationships, and it likely influences health behavior change. However, few health-related empowerment measures for parents are available and/or these lack thorough validity and reliability testing. This is important given the emerging success of empowerment-focused, family-based childhood obesity interventions. Our research team developed a survey to measure health-related parental empowerment using theoretical constructs from empowerment-relevant theories. The survey included 21 items across 3 hypothesized dimensions including resource empowerment, critical awareness, relational empowerment. This study tested the content validity of the scale in a low-income sample of parents with preschool-aged children using principal component analysis (PCA), exploratory factor analysis (EFA), and confirmatory factor analysis (CFA), respectively. The instrument was administered to a sample of parents (n=826; 87% mothers) from 23 Head Start centers in Greater Boston. The resulting data were randomly split into two equal samples and a combination of exploratory and confirmatory analyses were used to test the scale. Using the first half of the sample, Principal Component Analysis yielded three component factors (eigenvalues = 8.30, 2.90, 2.00). EFA results indicated all items loading significantly onto each of the hypothesized parental empowerment dimensions ($\beta > .60; p < 0.01$). Individually, indicators in the resource empowerment dimension explained 23.77% of its variance, indicators in the critical awareness explained 23.12% of its variance, and indicators in the relational empowerment explained 16.00% of its variance. The hypothesized factor structure for three sub-scales was subsequently confirmed using confirmatory factor analysis with the second half of the sample ($\beta > .55; p < 0.01$). Fit indices met minimum criteria (CFI = .94-.99; RMSEA = .04-.10; SRMR = .01-.04) and all scales demonstrated acceptable internal consistency ($\alpha = .83-.89$). Results support the initial validity of a brief survey measuring parent empowerment for child health in a sample of low-income parents of preschoolers. Future research will examine the validity of the factor structure across language and parent gender along with the predictive validity of the scale in reference to behavior change.

IMPACT OF PARENTING STYLES ON ADOLESCENT HEALTH BEHAVIORS

Kristen Adams, BS¹, Rachel Tillery, PhD¹¹St. Jude Children's Research Hospital, Memphis, TN

Objective: The primary objective was to examine profiles of adolescent perceptions of caregiver physical activity and dietary parenting styles and examine how these profiles relate to adolescent fruit/vegetable intake and daily physical activity.

Methods: A secondary analysis was conducted from the FLASHE study. Adolescents (N= 1737) completed web-based surveys of physical activity and dietary behaviors. They also answered questions on physical activity and dietary parenting styles. Latent profile analysis was conducted to identify patterns of parenting styles. The three-step approach was used to examine predictors (i.e. age, gender of the adolescent, gender of the caregiver) and outcomes (i.e. adolescent physical activity and fruit/vegetable intake) of profiles.

Results: A 4-class solution was determined to be the best fit to the data. The uninvolved parenting style profile (9.4%) showed significantly less adolescent fruit and vegetable intake and lower levels of physical activity than all other profiles. The encouraging but less collaborative profile (14.3%) and the moderately encouraging and collaborative profile (46.3%) did not have significantly different fruit and vegetable intake and physical activity levels from each other but both showed higher levels than the uninvolved. The highly involved parenting style profile (30.0%) had higher adolescent fruit and vegetable intake and demonstrated more physical activity than all other profiles.

Conclusion: The results of the analysis revealed important implications supporting existing literature that parenting styles play a role in adolescent health behaviors such as diet and physical activity. This information should be considered when developing interventions aimed at improving adolescent health behaviors.

INFLUENCE OF PARENT SUPPORT AND MODELING & ADOLESCENT PSYCHOSOCIAL CONSTRUCTS ON ADOLESCENT PHYSICAL ACTIVITY & WEIGHT

Cardella Leak, MPH¹, Brook E. Harmon, RD, PhD¹, Kristoffer Berlin, PhD², Latrice C. Pichon, PhD, MPH, CHES³¹University of Memphis, Memphis, TN; ²The University of Memphis, Memphis, TN; ³The University of Memphis School of Public Health, Memphis, TN

Obesity rates continue to rise in the US with adolescents (12-19 years old) having the highest prevalence (20.6%) across all age groups. Research highlights the importance of physical activity (PA) in reducing adolescent obesity disparities. While factors at multiple levels of influence affect adolescent PA behaviors, parents are particularly influential at the interpersonal level. They are typically adolescents' first exposure and gatekeepers to both direct and indirect PA behaviors through their support and modeling of PA. These parent factors as well as individual-level factors such as adolescent self-efficacy and their perception of parent support affect adolescent PA-related behaviors. However, they have been less examined as well as health outcomes such as adolescent weight.

Using parent-adolescent dyad data (n=1644) from the Family Life, Activity, Sun, Health, and Eating (FLASHE) study, associations between parent PA support and PA modeling and adolescent moderate-to-vigorous physical activity (MVPA) and weight (BMI z-scores) were examined. All data were self-reported and collected using online surveys. Structural equation modeling was used to examine the pathways and associations between factors.

Parent PA modeling and adolescent weight (Est.=−0.036; p =0.001) as well as modeling and adolescent MVPA (Est.=0.040; p< 0.001) were statistically associated via a pathway mediated by self-efficacy. Adolescent PA self-efficacy also was associated with adolescent MVPA (Est.=0.035; p< 0.001) and adolescent weight (Est.=−0.105; p< 0.001) independent of parent variables. Parent PA support was directly associated with adolescent weight, but in a positive direction (Est.=0.117; p=0.007). No statistically significant associations were seen with adolescent perception of parent PA support or between adolescent MVPA and weight.

Overall, these findings can be used in multiple ways to not only assess the influence parental factors have on adolescent MVPA and weight, but to guide the type of components used in behavioral interventions. In particular, the findings suggest using parent PA modeling as well as adolescent PA self-efficacy as targets for behavioral interventions aimed at increasing adolescent MVPA and lowering adolescent weight. Ultimately, the association of parental factors with adolescent psychosocial constructs, behaviors, and health outcomes highlights the importance of using family-based interventions to positively impact the health of adolescents and their families.

A RANDOMIZED COMPARISON TRIAL ADDRESSING FAMILY EATING PRACTICES: AN INTERACTIVE FAMILY-BASED HEALTHY WEIGHTS PILOT STUDY

Megan Perdew, Bachelor's of Science in Nutrition Applied Sciences¹, Patti-Jean Naylor, PhD¹, Sam Liu, Ph.D.¹¹University of Victoria, Victoria, BC, Canada

Background: Childhood obesity is one of the most widespread public health challenges associated with unhealthy dietary habits. Family-based interventions can be an effective strategy to manage childhood obesity. However, numerous factors (e.g. community needs, program adaptability, and available resources) are often overlooked in current family-based interventions. Thus, our team worked with local stakeholders to develop the Family Healthy Living Program (FHLPP), a “made in B.C.” evidence-informed 10-week intervention representing the local context in terms of its current clinical and public health messaging.

Objective: Evaluate the efficacy of the FHLPP in improving self-reported nutrition outcomes for parent feeding practices and children's dietary behaviors.

Methods: Participants were parents (n=87) and their children (n= 97) aged 8-12 years who had a BMI ≥ 85th percentile for age and sex. Families were randomized to either the 10-week FHLPP or a waitlist control group. The FHLPP provided a blended intervention consisting of 10 weekly sessions, 4 community activities and an online platform with interactive activities. Validated self-report questionnaires were used to evaluate parent and child nutrition outcomes, which include: parent feeding practices, the home food environment, family healthy eating (HE) habits and identity, regulation of child's HE behaviors and parents' cooking self-efficacy. The child nutrition outcomes include dietary behaviors, attitudes, outcome expectations and self-efficacy related to HE. Intention-to-treat protocol were used. Repeated measures analysis of variance (ANOVA) (2x2) was used to compare with-in and between-group changes.

Results: Fifty-four families completed the study. Relative to controls, parents in the intervention condition significantly improved their parent feeding practices (mean= 6.01, SD = 0.92, $d = 0.60$, $p = 0.04$), total parent support of child's HE (mean= 10.63, SD=1.19, $d = 0.63$, $p = 0.04$) and regulation of child's HE (mean= 14.02, SD= 3.59, $d = 0.65$, $p = 0.04$) at follow up. No between group changes in child nutrition outcomes were observed.

Conclusions: Family-based interventions tailored to a community's needs and resources can improve parent feeding practices and parents' ability to support their children's HE behaviors. Nonetheless, future research should explore innovative engaging delivery agents that educate families about ways to improve dietary behaviors and create a home environment that supports children's HE behaviors.

ADVERSE CHILDHOOD EXPERIENCE AND CHILD'S MENTAL HEALTH: EXAMINING THE ROLE OF PARENTING STRESS AND FAMILY RESILIENCE

Jalal Uddin, PhD¹, Md. Helal Uddin, MSS (Sociology)², Najwa Alharbi, PhD³, Md Belal Hossain, MA⁴, Serra S. Hatipoglu, MA⁵

¹University of Alabama at Birmingham, Birmingham, AL; ²East West University, Dhaka, Dhaka, Bangladesh; ³Umm Al-Qura University, Mecca, Makkah, Saudi Arabia; ⁴Oklahoma State University, Stillwater, OK; ⁵University of Alabama at Birmingham, Winter Park, FL

Introduction: Adverse childhood experiences (ACE) have a robust impact on children's health outcome. However, it is less clear how parental stress and resilient resources affect the ACE-health relationship. The study examined the associations between ACE and child's mental health and behavioral disorders and tested the mediating and moderating role of parental stress and family resilience.

Methods: This study used data from the 2016-17 National Survey of Children's Health (NSCH). The analysis included 44,684 children aged 6-17 years. Outcomes were binary measures of whether a child was ever diagnosed with 1) any mental health issues and 2) ever diagnosed for and currently have any attention-deficit/hyperactivity disorder (ADHD). The analysis used survey weights and controlled for potential confounders.

Results: There is a strong association of ACE with both outcomes of children's mental health. In the adjusted models, each additional ACE score was associated with increased risk for any mental health issues (OR=1.33, $p < 0.01$) and ADHD (OR=1.21, $p < 0.01$). The inclusion of parental stress accounted for a mediation of 62% of the total effect of ACE on any mental health and 26% of the total effect of ACE on ADHD outcome. The associations of ACE with any mental health and ADHD were modified by the family resilience and connection index (FRCI). The associations between ACE and mental health outcomes were less strong for children with higher scores in FRCI.

Conclusions: The results demonstrated that parental stress acts as a potential mechanism through which ACE impacts a child's mental health. Family resilience and connection appears to buffer the negative effect of ACE. These results have implications for clinical practices and intervention programs with children and adolescents experienced severe child abuse and maltreatment.

YOUNG CHILDREN'S KNOWLEDGE OF THE FARM-TO-TABLE CYCLE

Emma L. Monnin, n/a¹, Allison Kiefner-Burmeister, Doctor of Philosophy in Psychology², Emma Studer, n/a³, Emilee Bradley, n/a², Ashley Oakley, n/a¹, Julia M. Snell, n/a¹, Madison Schloemer, n/a², Liana Burk, n/a¹

¹University of Findlay, Findlay, OH; ²The University of Findlay, Findlay, OH; ³The University of Findlay, Bloomville, OH

Young Children's Knowledge of the Farm-to-Table Cycle

Childhood obesity is at its highest rate in history (Suchindran, North, Popkin, & Gordon-Larson, 2010). Having knowledge of food is the base to choosing between healthy and unhealthy items, which is one form of behavioral obesity intervention (Oowski, Goranzon, & Fjellstrom, 2012; Sigman-Grant et al., 2014). In order for children to become healthier, food health education needs to begin early and be reiterated often. Teaching children about food allows them to choose healthier items and have a more complete understanding about what is beneficial for their bodies (Contento, Randell, & Basch, 2002; Wiseman & Harris, 2015). Parents report a clear desire for their children to have knowledge of food origins, but these conversations do not always happen (Bray, Zambrano, Chur-Hansen, & Ankey, 2016). When asking children about the health of various foods, especially by the age of five or six, they are generally able to distinguish between things that are healthy and unhealthy (Story, Nannery, & Schwartz, 2009). However, the literature is lacking in the assessment of child knowledge of food origins.

The current pilot study used visual aids to evaluate children's knowledge of the farm to table cycle (i.e., identification of foods on the farm, as a base ingredient, and at the store). Participants (fifteen children, Mage = 7.10 (1.49), range = 4-10, 60% male, mean parent BMI = 29.14 (9.40), 73% of parents higher than high school education) in the American Midwest were presented with three versions of 10 types of non-meat based foods. The three stages showed the food (1) on the farm when naturally grown, (2) as a simplified ingredient, and (3) on the shelf of a grocery store. Participants were given a picture of the grocery product (yogurt) and asked to choose the original farm photo of the product (cow). They were then asked what the product looked like in between the farm and grocery photo (milk). Each photo was chosen from a group of three randomly selected options. The number of correct and incorrect matches were documented. Participants correctly matched a food to its three pictures 85.19% of the time, with no relationship found between age and correctness ($r = -3.89, p = .152$).

This pilot study of a new, hands-on, method of food origin assessment shows that children may be more aware of food origins than previously thought. This method may work to stimulate food origin conversations with families and enhance health-based conversations with young children.

3-YEAR DEVELOPMENTAL TRAJECTORIES OF BEHAVIORAL WELL-BEING IN ADOLESCENTS AND CARE STAFF RESIDING IN RESIDENTIAL CARE HOMES

Rainbow T.H. Ho, PhD, REAT, BC-DMT, AthR, RSMT/E, CGP, CMA¹, Ted C.T. Fong, PhD², Joyce Fong, BSocSc²

¹Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral Health, Hong Kong, N/A, Hong Kong

Introduction: Young residents in child care homes are prone to psychological distress out of their complex background in their original families and are in need of intensive counseling service. Social workers in the care homes are often preoccupied with enormous workloads to work with the residents for in-depth emotional issues. Under the existing service, residents have to wait for a long time to see a clinical psychologist. We examines the efficacy of adding a counselor post in foster care home setting on the residents and existing staff in Hong Kong.

Research Design: This longitudinal study was conducted in collaboration with four local NGOs in Hong Kong from 2016 to 2019. A total of 113 social workers and 381 residents aged from 5 to 18 were recruited in the residential care homes from the NGOs. The four counselors hired in the NGOs provided continuous individual counseling sessions for counselees who completed the Counselor Rating Form before and after counseling. Assessments were performed on the residents' behavioral problems via their superintendents and levels of burnout and role ambiguity/conflicts via validated measurement scales. Latent growth modeling evaluated the temporal changes in the variables.

Results: The counselees reported a significant increase ($d = 0.51, p < 0.01$) in counselor rating. Residential care workers displayed overall stable trends in role ambiguity/conflict and burnout during the study period with significant inter-individual variations in temporal changes. Controlling for baseline, changes in role ambiguity/conflicts significantly and positively predicted changes in work burnout ($\beta = 0.26 - 0.45, p < 0.01$) and client burnout ($\beta = 0.30 - 0.42, p < 0.01$). The residents displayed piecewise decreasing trajectories in internalizing, externalizing, and total problems across the ten assessment waves, with substantial declines over the first 9 months.

Conclusions: The current findings suggest that the counseling service could have a beneficial effect in reducing the counselees' emotional and behavioral problems and ameliorating social workers' levels of burnout over time. Future studies are needed to evaluate the linkage between temporal changes in staff burnout and counselees' behavioral problems.

Acknowledgments: This work was supported by the Keswick Foundation Limited. The Keswick Foundation Limited was not involved in study design, in the collection, analysis, and interpretation of data, or in the writing of this abstract. We would like to thank Ms. Kathy Chau, Ms. Irene Cheung and the staff of the four residential care homes for their help with data collection and study coordination and the counselees for their participation in the study.

EATING NETWORK CHARACTERISTICS OF LOW-INCOME MOTHERS, AND LINKS TO DIETARY HABITS

Sydney Miller, B.S.¹, Aimee Fata, MPH², Sarah-Jeanne Salvy, PhD², Kayla de la Haye, PhD¹¹University of Southern California, Los Angeles, CA; ²Research Center for Health Equity, Cedars-Sinai Medical Center, West Hollywood, CA

Introduction: Unhealthy dietary patterns are prevalent in low-income populations and cause many adverse health outcomes. The social context of eating embodies many sources of influence on dietary patterns, however, less understood is the role of eating partners—i.e., one's "eating network"—on dietary intake and automated eating habits. This study uses social network analysis to examine low-income mothers' eating networks, exploring how eating network size, closeness, and support, are associated with food intake and habits.

Methods: Data are from an ongoing childhood obesity prevention trial that enrolls low-income mothers and their infants. These analyses focus on mothers' (N=32; M age=28; 74% Latina) frequency and habit strength (Gardner et al., 2012) of sugar-sweetened beverage, fried food, fruit, and vegetable intake as outcomes; and mothers' social network characteristics as predictors. Standard personal network measures were used to list and characterize 15 of the mothers' social ties, and compute: the proportion of their network who were eating partners (i.e., eating network), and the proportion of their eating network that were family, emotionally close ties, and providers of health support. Regression models tested for associations between network characteristics and (1) mothers' food intake, and (b) habit strength, for each food type, controlling for age and weight status.

Results: Mothers with larger eating networks consumed significantly less fried food ($p=0.03$) and had weaker fried food habits ($p=0.04$) and stronger vegetable intake habits ($p=0.05$). Within the eating network, having a greater proportion of family was associated with stronger fruit intake habits ($p=0.04$), and a greater proportion of close ties was associated with weaker fried food habits ($p=0.04$). Within the eating network, increased health encouragement was associated with lower fruit ($p=0.01$) and vegetable ($p=0.04$) intake.

Conclusion: These findings align with previous research and theory, and suggest that for low-income mothers, having larger eating networks is associated with stronger and healthier dietary habits. Having more family and close ties among eating partners is also associated with some healthier habits, and eating partners appeared to be responsive to unhealthy eating patterns (low fruit and vegetable intake) by providing health encouragement. Family-based eating interventions may want to leverage and foster mothers' social networks.

COMMUNITY VIOLENCE IN THE BAHAMAS: UNCOVERING THE IMPACT OF SHAME AND VENGEFULNESS

Breanna Abram, M.A.¹, Gillian Grannum, Ph.D.², Irina Rivera, M.A.³, Patrick Jacques, M.A.⁴, David Allen, M.D., M.P.H.⁵, Alexis D. Abernethy, Ph.D.⁶¹Fuller Graduate School of Psychology, Pasadena, CA; ²Wellspan Philhaven, Ephrata, PA; ³Fuller School of Psychology, Culver City, CA; ⁴Fuller School of Psychology, Pasadena, CA; ⁵Renascence Institute International, Ltd., Pasadena, CA; ⁶Fuller Theological Seminary, Pasadena, CA

The negative psychological and physical health outcomes associated with community violence have become an increasing research emphasis for social scientists. Communities in the Bahamas have endured notable suffering from the effects of community violence, especially since the 1980's cocaine epidemic. This study is a secondary analysis of a larger, collaborative project that explored the effects of shame on social rehabilitation in 30 community-based groups in the Bahamas. Participants were 57% women and ranged from 11-79 years of age. The aim of this study was to examine whether a hypothesized internal process (e.g., shame) would influence one potential correlate of community violence (i.e., hostility) depending on the degree of vengefulness and forgiveness. Two moderation analyses were conducted to test whether vengefulness and forgiveness would moderate the relationship between shame and hostility. After controlling for age and education, internal shame ($b = .15$, $t(361) = 7.52$, $p < .001$; $b = .18$, $t(361) = 8.61$, $p < .001$) and vengefulness ($b = .34$, $t(361) = 5.19$, $p < .001$) yielded significant direct effects on hostility. Forgiveness did not have a direct effect on hostility. While vengefulness was found to significantly moderate the relationship between shame and hostility ($\Delta R^2 = .006$, $\Delta F(1, 361) = 3.87$, $b = -.007$, $t(361) = -1.97$, $p < .05$), forgiveness was not found to be a significant moderator. Future studies might explore how addressing shame and vengefulness might enhance interventions aimed at equipping communities to address the harmful effects of violence.

SPIRITUAL WELL-BEING BUFFERS THE EFFECT OF ANXIETY ON PHYSICAL WELL-BEING IN NEWLY DIAGNOSED CANCER SURVIVORS

Alix G. Sleight, PhD, OTD, MPH, OTR/L¹, Pat E. Boyd, PhD¹, William Klein, PhD², Roxanne Jensen, PhD¹¹National Cancer Institute, BETHESDA, MD; ²National Cancer Institute, NIH, Bethesda, MD

Background: Individuals newly diagnosed with cancer are at risk for heightened anxiety and declining physical well-being. Anxiety may be lessened among cancer survivors who report experiencing a greater sense of life meaning and being at peace, subcomponents of spiritual well-being. To date, the protective nature of spiritual well-being in early cancer survivorship has been understudied.

Objective: To assess the extent to which spiritual well-being moderates the relationship between anxiety and physical well-being in a diverse, community-based cohort of newly diagnosed cancer survivors.

Methods: A secondary data analysis was conducted using the Measuring Your Health (MY-Health) study cohort. MY-Health recruited cancer survivors within 6-13 months of diagnosis with colorectal, lung, NHL, breast, gynecologic, or prostate cancers (n=5506) through 4 SEER cancer registries in 3 states. Life meaning and peace were assessed using the 8-item subscale of the Spiritual Well-Being Scale (FACIT-Sp-12). Anxiety was measured with a 11-item PROMIS® Anxiety short form, and physical well-being was assessed using the 7-item subscale of the Functional Assessment of Cancer Therapy-General (FACT-G). Multiple linear regression models were used to assess relationships among variables. A moderation analysis was conducted using PROCESS (Model 1; Hayes, 2019).

Results: Life meaning/peace was negatively correlated with anxiety, $b = -0.56$ ($p < 0.001$) and positively correlated with physical well-being, $b = 0.43$ ($p < 0.001$) after adjusting for race, education, income, and age. A significant interaction between life meaning/peace and anxiety was found ($p < .001$) after including covariates, such that the magnitude of the negative relationship between anxiety and physical well-being decreased as life meaning and peace increased. Specifically, those lower (-1 SD) in life meaning and peace demonstrated a stronger negative relationship between anxiety and physical well-being, $b = -0.34$ ($p < .001$), whereas those higher (+1 SD) in life meaning and peace demonstrated a weaker (though still significant) negative relationship between anxiety and physical well-being, $b = -0.25$ ($p < .001$).

Conclusion: Clinical interventions that foster a greater sense of life meaning and peace in newly diagnosed cancer survivors may protect against declines in physical well-being associated with early cancer survivorship. Given that anxiety often cannot be fully attenuated in newly diagnosed cancer survivors, further research is needed to assess how spiritual well-being may buffer the negative effect of anxiety on physical well-being. Ultimately, these findings point to potential benefits of a clinical focus on increasing life meaning and peace for cancer survivors as they transition into follow-up care.

A CONGREGATIONAL HEALTH NEEDS ASSESSMENT TOOL AND FINDINGS

Brook E. Harmon, RD, PhD¹, Emily Rose San Diego, MA², Veronica Calvin, MPH³, Lauren McCann, LMSW, CCLS⁴, John B. Smith, B.A.⁵, Fedoria Rugless, Ph.D.⁶, Latrice C. Pichon, PhD, MPH, CHES⁷, Terrinieka W. Powell, PhD⁸, Rachel T. Davis, BA⁹, Sterling C. McNeal, B.S.¹⁰, Lottie Minor, M. Ed.¹¹, Bettina Campbell, MSW¹²

¹University of Memphis, Memphis, TN; ²University of Memphis School of Public Health, Cordova, CA; ³Methodist Le Bonheur Healthcare, Cordova, TN; ⁴Methodist Le Bonheur Community Outreach, Memphis, TN; ⁵Methodist LeBonheur Healthcare, Arlington, TN; ⁶Church Health/ University of Memphis, Memphis, TN; ⁷The University of Memphis School of Public Health, Memphis, TN; ⁸Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ⁹Church Health, Nashville, TN; ¹⁰Church Health, Memphis, TN; ¹¹National Faith Based Mobilization Network, Memphis, TN; ¹²YOUR Center, Flint, MI

Faith-based organizations (FBOs) are important partners in developing and implementing health promotion programs for their communities. Assessing the health needs of these communities first can identify important issues to be addressed. Therefore, tools that assess a broad spectrum of physical, mental, and social needs are needed. The Mid-South Congregational Health Survey was developed through a community collaboration and assesses needs related to physical and mental health as well as social determinants of health. Congregations served by two healthcare institutions within the greater Memphis, TN area implemented the survey between February and July 2019. Associations between needs and age, sex, race, and educational level were examined using logistic regressions while adjusting for congregation size. Congregation leaders and members ($n=617$) from 76 congregations completed the survey. The average age was 54.74 ($SD=15.83$) and most participants identified as African American (86%), female (69%), and having less than a college degree (57%). Frequently reported needs were anxiety/depression (66%), high blood pressure/stroke (65%), stress (64%), affordable healthcare (61%), and youth programs (59%). Individuals 55 years or older were more likely to report high blood pressure/stroke ($OR=1.79$, 95% CI: 1.16, 2.39) as a need, but less likely to report anxiety/depression ($OR=0.44$, 95% CI: 0.30, 0.65), stress ($OR=0.63$, 95% CI: 0.43, 0.90), and youth programs ($OR=0.59$, 95% CI: 0.41, 0.85) as needs compared to individuals under 55 years of age. African Americans were more likely to report high blood pressure/stroke ($OR=3.55$, 95% CI: 1.96, 6.42), affordable healthcare ($OR=2.91$, 95% CI: 1.62, 5.24) and youth programs ($OR=3.25$, 95% CI: 1.78, 5.93) as needs compared to Whites. Individuals with a high school education or less were less likely to report stress ($OR=0.43$, 95% CI: 0.24, 0.79) as a need compared to individuals with college degrees. Congregation members identified interconnected needs across the spectrum of health. Thus, programs that addresses physical health (i.e., high blood pressure, stroke), mental health (i.e., anxiety, depression, stress), and social determinants of health (i.e., affordable healthcare, youth programs) holistically versus individually are needed. Future efforts should test the survey with diverse populations to verify findings across a variety of FBOs and to help develop targeted programs.

FACTORS DETERMINING PARTICIPANT PREFERENCE FOR MINDFULNESS-BASED CANCER RECOVERY VS. TAICHI/QIGONG IN ONGOING MATCH STUDY

Devesh Oberoi, n/a¹, Andrew I. McElmnan, BA (Hons.) Psychology¹, Katherine-Ann L. Piedalue, BA², Hassan Pirbhai, BComm¹, Linda E. Carlson, PhD¹

¹University of Calgary, Calgary, AB, Canada; ²Cumming School of Medicine, Calgary, AB, Canada

Purpose: Partially randomized, participant-preference trial design is often recommended for studies assessing the effectiveness of behavioral interventions where participants cannot be blinded to the intervention. In our ongoing randomized preference-based multi-site (Calgary, AB, and Toronto, ON) integrative-oncology trial, the MATCH study, which investigates the effectiveness of mindfulness-based cancer recovery (MBCR) vs. Taichi/Qigong (TCQ) and waitlist control in cancer survivors, we found more participants chose to join TCQ compared to MBCR. However, little is known about the factors that determined preference for the intervention. The current study seeks to explore participants' reasons for their preference for these two behavioral interventions.

Methods & Analysis: Participants in the ongoing MATCH study having a preference were included. Participants rated their expectations from their preferred program, and program acceptability and perceived benefits from the preferred program on a 5-point Likert scale. Furthermore, a subsample participated in open-ended, semi-structured interviews which queried expectations from the preferred program, direct or indirect experience with the intervention and personal factors influencing their preference. Interviews were tape-recorded, transcribed verbatim and analyzed using thematic analysis with mixed deductive and inductive coding.

Results: A total of 347 people have participated in the MATCH study so far at the Calgary site, with 135 preferring TCQ, 92 preferring MBCR, and 120 having no stated preference. Twenty-two people were included in the interviews. Data analysis is currently underway; participant's socio-demographic characteristics will be presented using descriptive statistics and the results of the thematic analysis will be presented as themes highlighting reasons for participants' treatment preference.

Implications: Findings from this study will inform researchers about the views and past experiences of MATCH study participants that guide their preference for these two mind-body therapies. Identification of reasons guiding participant preference may help inform patient-centered decision-making and care in the design of future behavioral trials.

DEPRESSION SYMPTOMS AND MINDFULNESS: A NETWORK ANALYTIC APPROACH

Grant Jones, B.A.¹, Mary-Ann Dutton, PhD², Amanda J. Shallcross, MPH, ND³, Richard McNally, PhD¹

¹Harvard, Cambridge, MA; ²Georgetown, DC, DC; ³New York University, New York, NY, NY

Network analysis is an analytical technique that allows one to look at the symptoms constitutive of a given mental disorder, and allows one observe their relationships between one another. In clinical psychology more broadly, network analysis has gained attention specifically in the realm of interventions, as it allows one to view how interventions impact symptom relationships. One intervention that network analysis has not yet been used to examine is mindfulness meditation, an intervention that has gain much attention in recent years. Using two datasets (Georgetown, N= 126; NYU, N= 92) from two randomized controlled trials on the effect of mindfulness meditation on depression and PTSD symptoms, we examined how a meditation intervention impacts the networks of these disorders. For both PTSD and Depression symptoms, those assigned to the active treatment condition had no significant changes to their networks. However, when one looks closely at the networks of the responders versus non-responders to meditation treatment for depression symptoms, one sees that the responder network at baseline is significantly less dense than the network for non-responders. Furthermore, at the endpoint of the study, the difference in density becomes even more pronounced. Ultimately, this analysis could provide valuable insight into how meditation alleviates depression symptoms. Limitations of this analysis include low N, impacting network stability, as well as differing measurements of depression across data sets. Future directions include repeating these analysis on larger meditation data sets.

SHARED DECISION MAKING IN COMPARATIVE EFFECTIVENESS RESEARCH USING CLUSTER RANDOMIZATION: EARLY FINDINGS FROM PCORI.

Allison Rabinowitz, MPH¹, Jess Robb, MPH¹, Theresa Kim, PhD MS¹, Arpi Terzian, PhD¹¹PCORI, Washington, DC

Background: Decision aids and shared decision-making (SDM) approaches help clinicians and patients work together to make decisions on treatment plans that balance the benefits and harms with patient preferences and values. Gaps in clinical evidence can make it difficult to know which decision aids and SDM methods are most effective. The Patient-Centered Outcomes Research Institute (PCORI) supported cluster randomized controlled trials (RCTs) to bridge the evidence gap and improve patient-centered health care. To inform best practices for engaging patients and providers in SDM, we examined PCORI-supported cluster RCTs to 1) Identify effective interventions and 2) Compare study characteristics of cluster RCTs that reported positive findings with those that reported null findings.

Methods: Two program staff independently read and manually abstracted information from final research reports on all cluster RCTs managed by PCORI's Comparative Effectiveness and Decision Science Program (CEDS) and completed by January 2019. Staff double-coded data on cluster-specific study characteristics such as number of arms, number of clusters per arm and average number of participants per cluster. A senior staff member reviewed and resolved discrepancies.

Results: There were 16 completed cluster RCTs, representing trials from earlier funding cycles. Of the 16, 10 focused on SDM, involving over 21,000 patients. Study populations ranged from parents of children with minor head trauma deciding whether to use computed tomography to women attending family planning clinics seeking contraceptives to patients from racial and ethnic minority groups with serious mental illness deciding which medication to use. The proportion of trials defining clusters at the clinic level was 60%; 40% defined clusters at the provider level. The proportion of cluster RCTs with more than two arms was 30%. Overall, the average number of clusters was 39 (range: 4 – 172), average number of patients per cluster was 129 (range: 4 – 430) and average population served was 2,150 (range: 92 – 9,030). The proportion reporting null findings was 40% (n=4). These trials reported clusters at the clinic level and tended to be larger in scale, reporting the highest number of patients per cluster and highest number of patients served. Reasons for null findings included failure to implement the intervention and low fidelity to the full intervention dose.

Conclusions: Monitoring can identify clinical efficiencies in cluster RCT design and conduct, an important policy and funding issue. Results from our efforts to systematically classify trial-specific metrics can strengthen the evidence base in SDM and support increased uptake of research.

PARENT RACE AND BODY SIZE IMPACT HOW PROVIDERS GATHER INFORMATION FOR TYPE 1 DIABETES TREATMENT DECISION-MAKING FOR A CHILD

Xuan Zhu, PhD¹, Jeph Herrin, PhD², Ron Lam, n/a³, Michelle van Ryn, PhD, LMFT, MPH⁴, Seema Kumar, MD¹, Manpreet Mundi, MD¹, Richard O. White, MD⁵, Sean M. Phelan, PhD, MPH¹

¹Mayo Clinic Rochester, Rochester, MN; ²Yale School of Medicine, New Haven, CT; ³Flying Buttress Associates, Ltd., Charlottesville, VA; ⁴Oregon Health & Science University (OHSU) School of Nursing, Portland, OR; ⁵Mayo Clinic Florida, Jacksonville, FL

Provider bias about race and body size has been shown to contribute to disparities in treatment decision-making and patient health outcomes in adult care; however, the impact of these biases on pediatric care is understudied. Treatment decision-making for type 1 diabetes in children is particularly prone to the influence of provider bias because of the lack of unambiguous and universal clinical guidelines. Providers are expected to tailor insulin therapy recommendations to patients' and caregivers' personal and social characteristics because while certain treatments (e.g., insulin pump therapy) may lead to better glycemic control and have a lower risk of complications, they place a greater burden on caregivers and require patients to have more technical and cognitive skills. One pathway through which provider bias may impact type 1 diabetes treatment decision-making for children is by causing providers to gather information about the patient and the caregiver that is consistent with stereotypes and biases. This biased collection of information can then lead to different treatment decisions. Using simulated patient interactions, we tested whether parent race and body size impact how providers ask questions about the patient and the parent.

A 2 (parent race: Black, White) by 2 (parent body size: obese, normal) between-subjects survey experiment was conducted with 420 US pediatric endocrinologists. Participants viewed a vignette describing a 10-year old girl with type 1 diabetes and poor glycemic control who is currently on a moderately intense insulin regimen. The vignette was illustrated with an artist's drawing of the girl and her mother in a clinic setting. Parent race and body size were manipulated so that the mother was either Black or White and either had obesity or a normal weight. The girl and mother's race was matched. After viewing the vignette, participants chose questions to ask the mother and/or patient from a predetermined list. Comparisons were controlled for provider BMI.

Providers who viewed the normal weight (vs. obese) mother drawings asked more questions ($p = .003$). Specifically, more questions about diabetes knowledge, diet and exercise, dosing, injecting, storage, and complications were asked in the normal weight (vs. obese) mother conditions ($.001 \leq p\text{-values} \leq .042$). In addition, there were race by body size interactions on the number of dosing and complications questions asked, such that providers in the normal weight (vs. obese) Black mother condition asked more questions about dosing ($M = 4.8$ vs. 3.8 , $p = .005$) and complications ($M = 1.5$ vs. 0.8 , $p = .001$), while the number of questions asked did not differ between the White mother conditions.

These findings suggest that provider perceptions about race and body size can influence how providers gather information about patients, which may contribute to variations in treatment decision-making and patient health outcomes.

“TAKE CHARGE, GET CURED”: TESTING A MHEALTH HCV TREATMENT DECISION TOOL FOR METHADONE PATIENTS FOR ACCEPTABILITY AND EFFICACY

Sarah Bauerle, Bass, Ph.D. and MPH¹, Amy Jessop, PhD, MPH², Muhamed Gashat, MD, MPH³, Jesse A. Brajuha, MPH⁴, Mohammed Alhajji, PhD(c), MPH⁵, Monika Burke, MPH⁶, Carine Wellington, CHES, MPH(c), n/a⁷, Nicole Ventriglia, CHES⁸

¹Temple University College of Public Health, Philadelphia, PA; ²Western Michigan University, Ardmore, PA; ³HepTrec, Philadelphia, PA; ⁴Temple University, Philadelphia, PA; ⁵Risk Communication Lab / College of Public Health/ Temple University, Philadelphia, PA; ⁶HepTREC, Philadelphia, PA; ⁷George Washington University, Philadelphia, PA; ⁸Fox Chase Cancer Center, Coatesville, PA

Background: Hepatitis C (HCV) is a highly prevalent infection in current and former IV drug users. Current estimates indicate that over 70% of those in methadone maintenance treatment programs (MMTs) have HCV, but only 11% have initiated treatments despite availability of new treatments that are easily tolerated and can cure infection in about 8 weeks.

Methods: We conducted a pilot randomized equivalency trial at four Philadelphia, PA MMTs to test acceptability, feasibility and promise of efficacy of our “Take Charge, Get Cured” mobile health (mHealth) treatment decision tool, developed through extensive formative work that included methadone patients’ input and targeted directly to concerns of methadone patients with Hepatitis C (HCV). We compared its impact on perceptions and knowledge about HCV and HCV treatment, decisional conflict, intention to and actual initiation of HCV care to a web-based Cochrane-reviewed, non-targeted HCV decision tool. Subjects (n=122) were randomized, administered baseline questionnaires, interacted with the targeted or non-targeted decision tool on an electronic tablet, and answered post-test questions. After 3-months subjects (n=93; 76%) were surveyed for follow up.

Results: “Take Charge, Get Cured” users were more likely to report the tool helped with decision making and demonstrated greater improvement in knowledge, decisional conflict, and intention to be treated for their HCV infections than users of the non-targeted decision tool. They were significantly more likely to say the targeted tool was helpful, that they would recommend it to others, and was helpful. At three month follow up, targeted group participants were more likely to say the tool helped them make a better decision about treatment and prepared them to talk to their doctor about what matters most to them about treatment. No differences were seen in actions to initiate HCV care, but more targeted group participants reported talking to their doctors about HCV treatment.

Conclusions: Results indicate a highly targeted mHealth decision tool is an important strategy to affect perceptions and knowledge of HCV treatment that lowers decisional conflict about initiating treatment, key components in decision making. We believe this highly acceptable and feasible intervention could be utilized in clinical settings to address the important barriers to initiating HCV treatment in a vulnerable population.

BREAST CANCER WORRY IN HIGH RISK WOMEN OFFERED PREVENTIVE THERAPY: A UK MULTICENTRE PROSPECTIVE STUDY

Kelly E. Lloyd, BSc, MA¹, Louise H. Hall, PhD², Samuel Smith, PhD²

¹University of Leeds, LEEDS, England, UK; ²University of Leeds, Leeds, England, UK

Background: Worry about developing breast cancer is associated with cancer prevention behaviours, such as uptake of preventive therapy. However, the direction of this relationship has been questioned. The Cognitive-Social Health Information Processing model suggests there may be an inverted U-shaped relationship between worry and uptake, whereby moderate levels of worry are most strongly associated with uptake. Few prospective studies have been conducted to test this theory.

Aims: 1) Assess levels of breast cancer worry in women considering preventive therapy; 2) identify the socio-demographic and clinical factors of women who experience high breast cancer worry; 3) examine whether there is an inverted U-shaped relationship between worry and uptake; and 4) assess changes in worry over time.

Method: Women at increased risk of breast cancer were recruited from 20 clinics across England (n=408). Self-reported uptake of prophylactic tamoxifen was assessed three months later (n=258, 63.2%). Breast cancer worry (‘I worried about developing breast cancer’; ‘My worries about breast cancer interfered with my daily activities’) was assessed at baseline and three months using a 4-point Likert scale. In the pre-registered primary analysis, participants who reported ‘Not at all’ or ‘Rarely’ to both worry questions were classified as ‘low worry’. Participants who reported ‘Sometimes’ were classified as ‘medium worry’, and those who reported ‘Often’ were classified as ‘high worry’. Pre-registered sensitivity analysis was undertaken which increased the threshold for the classification of high worry (‘Sometimes’ or ‘Often’).

Results: In total, 39.5% of respondents reported medium worry at baseline and 21.2% reported high worry. Ethnic minority women were more likely to report high worry than white women (OR=3.02, 95% CI=1.02, 8.91, p=0.046). Women who were educated to below degree level were more likely to report high worry than those with higher education (OR=2.29, 95% CI=1.28, 4.09, p=0.005). No association was observed between worry and uptake of tamoxifen, although fewer respondents with medium worry at baseline initiated tamoxifen in the primary analysis (low worry=15.5%, medium=13.5%, high=15.7%). In the sensitivity analysis, participants presenting with medium worry (‘Rarely’) reported the highest uptake of tamoxifen (19.7%). At three months, women’s mean worry scores had significantly reduced from 4.09 out of 8 at baseline to 3.72 at follow up (p < 0.001).

Conclusion: We found weak evidence to support the ‘inverted U-shaped’ theory, although the worry-uptake relationship was affected by the categorisation of worry. Standardised reporting of the classification of worry is warranted to allow transparent comparisons across cohorts. Ethnic minority women and those with less education may need additional support to reduce cancer-related worry when considering preventive therapy.

ILLNESS PERCEPTIONS, DEPRESSIVE SYMPTOMS, AND TYPE 1 DIABETES MANAGEMENT AMONG LATINO AND NON-LATINO WHITE EARLY ADOLESCENTS

Maria D. Ramirez Loyola, M.A.¹, Deborah J. Wiebe, PhD, MPH¹¹University of California, Merced, Merced, CA

Illness perceptions may impact depressive symptoms and type 1 diabetes (T1D) management during early adolescence. Prior research has focused on non-Latino Whites (NLW), despite evidence that different ethnic/racial groups perceive illnesses differently. Further, assessments of illness perceptions have not considered how others are involved in illness management (e.g., perceived parental control) nor perceptions of illness-related self-conceptions (e.g., if T1D is smoothly integrated into one's self-concept). Such perceptions may be important during adolescence when parental involvement in T1D declines and teens are developing a stable sense of self-identity. We used survey methods to examine ethnic differences in illness perceptions—including T1D-related perceptions of self and others—and their associations with outcomes among Latino and NLW early adolescents. Participants aged 10-15 ($N = 118$; 54% Female; 48% Latino; $M_{age} = 13.24$) completed survey measures of illness perceptions, depressive symptoms, and adherence. HbA1c was collected from medical records. Results revealed that Latinos perceived less personal control over T1D ($t(111) = -1.995$, $p = .049$) and viewed T1D as less chronic ($t(93) = -2.540$, $p = .013$), but these perceptions were unrelated to outcomes. Interestingly, higher perceived parental control was associated with lower depressive symptoms ($\beta = -2.858$, $SE = .940$, $p = .003$), and trended toward higher adherence ($\beta = .208$, $SE = .107$, $p = .053$). Higher perceived illness integration was associated with lower (better) HbA1c ($\beta = -.409$, $SE = .142$, $p = .005$), better adherence ($\beta = .178$, $SE = .063$, $p = .006$), and lower depressive symptoms ($\beta = -2.614$, $SE = .534$, $p < .001$). Conversely, higher perceived illness severity was associated with higher (worse) HbA1c ($\beta = .511$, $SE = .182$, $p = .006$), poorer adherence ($\beta = -.263$, $SE = 0.79$, $p = .001$), and increased depressive symptoms ($\beta = 2.310$, $SE = .717$, $p = .002$). Although there were no significant differences in these associations across ethnic groups, these findings demonstrate the importance of illness perceptions in the management of depressive symptoms and T1D during early adolescence. Taken together, these results highlight the need to consider illness perceptions associated with the self, as well as others, when examining associations with health outcomes in future research.

DIABETES-RELATED TOPICS DISCUSSED IN MEDICAL VISITS FOR ADOLESCENTS AND YOUNG ADULTS WITH TYPE 1 DIABETES

Connie I. Wong, BA¹, Jamie S. Neiman, MA¹, Diane Polyakov, BA¹, Giuliana Centofanti, n/a¹, Meredith Rose, LGSW, ML¹, Maureen Monaghan, PhD, CDE¹¹Children's National Hospital, Washington, DC

Objective: Diabetes health care providers provide essential behavioral health information to adolescents and young adults (AYAs) with type 1 diabetes during routine diabetes care. This study utilized audio recordings of diabetes clinic visits to identify content discussed in routine diabetes care and associations among key demographic and clinical characteristics and clinical content.

Methods: 28 AYA participants (M age = 17.58 years \pm 1.06; 54% female; 43% non-Hispanic white) and 7 health care providers (HCPs) participated in a longitudinal study of health communication and had up to 4 routine diabetes clinic visits audio recorded (65 total visits recorded; M visits per participant = 2.32 visits; M duration = 21.62 minutes). Clinic visits were transcribed and coded by trained coders to categorize all content. Chi-square tests of independence were performed to examine the relation between gender and frequency of topics discussed, and between parent/guardian presence and frequency of topics discussed.

Results: Across participants, the following topics were discussed in at least one visit: Objective Indicators of T1D Health 100.0%; Adherence 100.0%; Environment (e.g. family, school, work) 96.4%; Lifestyle (e.g. diet, physical activity, sleep) 82.1%; Transition to Adult Diabetes Care 10.7%; Sexual Health 10.7%; Substance Use (e.g. alcohol, drugs, nicotine) 10.7%. A parent/guardian was present in 64.6% of visits. The relation between gender and Transition to Adult Diabetes Care was significant, $\chi^2(1, N = 65) = 4.13$, $p < .05$. Transition was more likely to be discussed in visits with female AYAs. Parent/guardian presence was significantly associated with discussions of Sexual Health and Substance Use, $\chi^2(1, N = 65) = 8.69$, $p < .01$; $\chi^2(1, N = 65) = 4.72$, $p < .05$, respectively. Sexual Health and Substance Use were both more likely to be discussed in visits without a parent/guardian.

Discussion: Results suggest that topics relevant to diabetes care such as transition to adult diabetes care, sexual health, and substance use are not routinely discussed during medical visits, particularly when a parent/guardian is present. Standard templates in electronic medical records of topics for HCPs to discuss, as well as time alone between AYAs and HCPs without a parent/guardian, may help facilitate more frequent discussion of these topics.

IMPACT OF DINING WITH DIABETES, A COMMUNITY BASED DIABETES MANAGEMENT PROGRAM ON CONFIDENCE TO MANAGE THE DISEASE IN OLDER ADULTS

Katie E. Greenawalt, MS¹, Stacy Reed, MS²¹Penn State University, Lebanon, PA; ²Penn State University, Lancaster, PA

Introduction: According to the American Diabetes Association, over 30 million Americans (about 1/10 people) have diabetes, with type 2 diabetes (T2D) being the most common form of the disease, accounting for over 90% of all cases. Research indicates that group-based diabetes self-management education can result in improvements in clinical, lifestyle, and psychosocial outcomes for persons with T2D. The present research sought to evaluate if subjective confidence to manage diabetes was reflected in objective biomarker measures of hemoglobin A1c and blood pressure readings from pre to 3-months post program in a group of older adults who completed an evidence-based diabetes self-management program.

Methods: Dining with Diabetes (DwD) is a community-based diabetes self-management program for adults with T2D or pre-diabetes. A series of 4 weekly, 2-hour classes and a follow-up class held 3 months post program were conducted based on the social cognitive theory. The program offered food demonstrations and tastings, physical activity, and group-based discussions about diabetes management. Topics included (1) common tests to know, (2) carbohydrates, sweeteners and fiber, (3) fats and sodium, and (4) medication and goal setting. Data collection occurred at the first and last DwD class (3-month follow-up). Self-reported variables included demographics and psychosocial factors (confidence to manage diabetes, diabetes knowledge, and habits related to diabetes management). Clinical outcomes were determined by Hemoglobin A1C and blood pressure.

Results: Study participants (N=21) were mostly female (90.5%), Caucasian (100%) and older adults (mean age = 75 +/- 6.1). 3-month outcomes revealed a significant increase in confidence to manage diabetes scores ($p < .05$). Clinical outcomes indicated a significant reduction in systolic blood pressure ($p < .05$). No significant differences were found in mean diastolic blood pressure or A1c levels. Post program, 90% of participants stated that the class had a positive impact on their health.

Conclusion: These pilot results suggest that the Dining with Diabetes program may contribute to an increase in confidence among older adult women to manage their Diabetes. These findings are tangentially supported by the significant reduction in systolic blood pressure at 3 months. While confidence is a strong predictor of healthy behaviors, causality cannot be inferred from these results. Should these preliminary findings be supported in additional DwD studies, such evidence could be used to inform a larger and more diverse randomized controlled trial in the future.

6:15 PM-7:30 PM

FEASIBILITY OF TEXT MESSAGE SLEEP ASSESSMENT IN AFRICAN-AMERICANS AND LATINOS WITH TYPE 2 DIABETES

Alana Biggers, MD, MPH¹, Julia Henkins, MPH¹, Isaye Barton, MD¹, Lisa K. Sharp, PhD¹, Ben Gerber, MD, MPH², Colin Hubbard, PhD¹¹University of Illinois at Chicago, Chicago, IL; ²University of Illinois at Chicago - Department of Medicine, Chicago, IL

Background: Since 2017, the American Diabetes Association recommends sleep assessment in people with type 2 diabetes (T2DM). However, only 43% of primary care providers ask their patients about sleep, and accurate sleep assessment is challenging. Paper-based sleep diaries are often incomplete, illegible, or subject to hoarding (multiple days completed at once). Text messaging (TM) may provide an inexpensive and convenient method for sleep assessment. This pilot study evaluated the feasibility of a TM sleep diary among a minority population with T2DM. We compared TM-derived sleep parameters with those obtained by actigraphy.

Methods: A convenience sample of 40 participants with uncontrolled T2DM from an urban, academic medical center was recruited from a concurrent randomized, controlled trial of a mhealth diabetes self-management program. Participants first completed an in-person interview assessments of sleep quality (Pittsburgh Sleep Quality Index, PSQI, with scores ≥ 5 suggestive of poor sleep). Participants then wore an Actiwatch (Philips) for seven days during both wake and sleep intervals. During those seven days, patients received scheduled TMs every day at 10:00 AM via a custom app (mytapp). Participants responded to 10 sleep assessment TMs individually, with message content adapted from the Consensus Sleep Diary. TM responses were double-coded and adjudicated by an independent researcher. Spearman rank correlations between sleep parameters from TMs and actigraphy were computed. Bland-Altman plots were created to determine agreement and bias.

Results: Of the 40 patients enrolled, 32 were female, 34 were African-American, and 6 were Latino. The mean age was 52.2 years (standard deviation [SD] 8.2), mean hemoglobin A1c was 8.98 (SD 1.5), and mean PSQI score 7.6 (SD 3.6). All 40 patients wore the Actiwatch and 39 completed TM sleep diaries. With a maximum of 70 TM replies possible, median non-response rate was 4.5 (interquartile range [IQR] 2.0-13.5). Total sleep time (TST) was similar between actigraphy and TM (median 383 vs. 393 min. respectively [$rs=.71$, $p < .01$]). Sleep onset latency (SOL) for actigraphy and TM was median 25.3 vs. 27.5 min. [$rs=.56$, $p < 0.01$]. Wake after sleep onset (WASO) was higher from actigraphy than TM (median 46.3 vs. 6.0 min. [$rs=.28$, $p=.08$]). Bias (mean of difference) estimates were: TST -18.3 (95% CI [-41.5, 5.0]), SOL -2.5 [-13.3, 8.2], and WASO 37.1 [28, 46.3].

Conclusion: TM is a novel and feasible method for sleep assessment. There was a strong correlation between TM and actigraphy in total sleep time evaluation and a moderate correlation between TM and actigraphy in sleep onset latency evaluation. The value of other sleep parameters obtained via TM remains uncertain. Accurate knowledge of sleep duration and quality, which have a known relationship with glycemic control, is important in diabetes management.

INCREASING ENGAGEMENT AND RETENTION IN THE NATIONAL DPP LIFESTYLE CHANGE PROGRAM: A HUMAN CENTERED DESIGN APPROACH

Alexis Williams, MPH, MCHES, NBM-HWC¹, Judith McDivitt, PhD¹, Erin E. Malone, MPH², Kimberly Hames, MBA, MSBA³¹Centers for Disease Control and Prevention, Chamblee, GA; ²Deloitte Consulting, Atlanta, GA; ³Deloitte Digital, Raleigh, NC

The National Diabetes Prevention Program lifestyle change program (LCP) is a research-based program with proven efficacy at helping people with prediabetes reduce their risk for developing type 2 diabetes. This structured program encourages moderate weight loss and other healthy lifestyle changes among participants, lowering their risk of type 2 diabetes, heart attack, and stroke. Program evaluation indicates that participant weight loss outcomes are improved by increased attendance and completion of the program, and retention is key to program recognition by the CDC and reimbursement by payers. While participant retention in the LCP is an imperative for programs it has been a challenge. This project aimed to gather insights about participant engagement in the LCP that can be applied to increase engagement and retention. It used a Human-Centered Design (HCD) approach, which is an evidence-based, data driven method for understanding people's needs and motivations in order to design effective solutions that meet those needs. Data collection methods included literature review; in-depth interviews with LCP program administrators, coaches and participants; and observations of LCP sites. Qualitative data analysis of the findings identified major themes and recommendations for supporting participant engagement. Results indicated that participants are engaged in the LCP when they connect authentically with their coach, offer and seek support from their peers, and are absorbed in the program curriculum and activities. This poster will describe the HCD approach, as well as findings related to participant engagement needs, the attributes and behaviors of engaging lifestyle change coaches, and the elements of an engaging class. Recommendations for supporting increased participant engagement in the National DPP and similar chronic disease lifestyle change programs, as well as areas for future research will be discussed.

TRANSLATING A RIGOROUS RESEARCH INTERVENTION FOR USE IN ROUTINE CLINICAL CARE: THE PATRIOT RANDOMIZED CLINICAL TRIAL (RCT)

Zoe Finer, University of Michigan, B.S.¹, Sangmin Hyoun, EdM², Andrew Nicholson, MSPH³, Sundar Natarajan, MD, MSc⁴¹VA NY Harbor Healthcare System / NYU Medicine, New York, NY; ²Veterans Affairs, New York, NY; ³VA NY Harbor Multiple Health Behaviors, New York City, NY; ⁴NYU School of Medicine, New York, NY

Background: PATRIOT is a RCT testing if a personalized behavioral intervention (PBI) reduces foot lesions in adults with diabetes. The PBI is a comprehensive phone-based intervention that targets multiple behaviors related to foot self-care, foot self-monitoring, diet, and other diabetes-related behaviors.

Objective: To translate the PATRIOT intervention for clinical implementation based on feedback from the current PATRIOT interventionists and a clinical nurse care manager.

Methods: We examined the average time interventionists spent preparing for and delivering counseling calls in PATRIOT. We conducted semi-structured qualitative interviews with the current intervention team (n=5) on how to implement the intervention in a clinical setting. We also conducted a semi-structured interview with a VA nurse care manager to understand current clinical workflow and potential challenges to implementation. We analyzed interviews using thematic analysis to obtain understanding of how PATRIOT can be implemented in clinical care.

Results: A total of 406 individuals were randomized with 203 participants assigned to receive the PBI. The average time to prepare for counseling calls was approximately 10 minutes and average call length was 23.69 minutes (SD=12.81). Key themes that emerged from interviews around changes needed for implementation were: technology integration to optimize efficiency in clinical care, prioritizing foot self-care over foot temperature monitoring, and emphasizing patient-centeredness. All interventionists felt calls should be less scripted and more conversational to enhance personalization and give patients the ability to troubleshoot barriers and create SMART goals most pertinent to them. Interviewees also discussed foreseeable challenges for clinical implementation and two key themes emerged: retention of health behavior theories after intervention translation and competing priorities among the multidisciplinary care team. Implementation of PBI should fit into clinical workflow to ensure success.

Conclusion: Simplifying PBI increases feasibility for clinical implementation. Integrating PBI into clinical care will promote preventive health among vulnerable patients, ultimately leading to better health outcomes. Future directions to integrate the PATRIOT intervention into the clinical setting should utilize a formal process of toolkit development and evaluation of toolkit implementation along with effectiveness.

WHEN BELONGING BACKFIRES: DISCRIMINATION PREDICTS TYPE 2 DIABETES RISK AMONG COLLEGE STUDENTS HIGH IN SOCIAL BELONGING

Maryam Hussain, PhD¹, Jacqueline N. Hua, n/a¹, Angela E. Johnson, MA², Bianca M. Hinojosa, MA¹, Jennifer L. Howell, PhD¹¹University of California, Merced, Merced, CA; ²University of California Merced, Merced, CA

Almost one-third of college students are affected by obesity, putting them at increased risk for metabolic disease. Emerging research implicates experiences of discrimination—a form of psychosocial stress—as one factor that can exacerbate metabolic disease risk. The aim of the present study was to replicate and extend earlier findings linking discrimination to increased metabolic disease. Specifically, in addition to examining the link between discrimination and metabolic disease risk, we examined whether social belonging—a known buffer against the negative health effects of psychosocial stressors—might moderate this relationship. In the link between discrimination and metabolic disease risk, social belonging might serve one of two moderating roles. Social belonging is a known buffer against the negative health effects of psychosocial stressors, suggesting that belonging should weaken the relationship between discrimination and metabolic disease risk. Alternatively, research on social exclusion suggests that people are most distressed when they experience social exclusion from groups with which they highly identify. In this way, feeling strongly that one belongs but regularly experiencing social threat in the form of discrimination should exacerbate the relationship between discrimination and metabolic disease.

Participants from a Hispanic serving institution ($N = 160$, 60.9% Hispanic/Latino/a, 63% female) completed items assessing their comparative (for their age and gender) risk for type 2 diabetes (e.g., family history, waist size, physical activity, diet). Participants also reported on the frequency with which they experienced discrimination on campus. Finally, participants rated the extent to which they felt a sense of belonging on campus. Supporting the social exclusion hypothesis, more frequent discrimination was related to higher comparative type 2 diabetes risk only among those who had high campus social belonging (+1 SD) but not among those who reported low campus social belonging (-1 SD). These findings highlight the negative metabolic health implications for students who experience social exclusion in the form of discrimination in an environment they had perceived as one of belonging.

EXAMINING PREDICTORS OF SELF-CARE EMPOWERMENT INTERVENTION DROPOUT IN JAPANESE PATIENTS WITH TYPE 2 DIABETES

Asuka Kato, PhD, MPH¹, Kazuhiro Yoshiuchi, MD, PhD², Ryo Suzuki, MD, PhD³, Toshimasa Yamauchi, MD, PhD³, Takashi Kadowaki, MD, PhD³, Hideki Hashimoto, MD, DrPH¹

¹The University of Tokyo, School of Public Health, Department of Health and Social Behavior, Bunkyo-ku, Tokyo, Japan; ²The University of Tokyo, Graduate School of Medicine, Department of Stress Sciences and Psychosomatic Medicine, Bunkyo-ku, Tokyo, Japan; ³The University of Tokyo, Graduate School of Medicine, Department of Diabetes and Metabolic Diseases, Bunkyo-ku, Tokyo, Japan

Objective: Growing evidence reveals that culturally-tailored empowerment programs positively influence diabetes behavior changes while improving self-efficacy, diabetes self-management (e.g. diet, exercise), and treatment outcomes (e.g. BMI, hemoglobin A1c). However, little is known about the factors associated with dropouts of empowerment programs. Examining clinical, psychosocial, and socioeconomic factors related to dropouts is a necessary first step to developing an effective culturally-tailored empowerment program. We examined the predictors of self-care empowerment intervention dropout among Japanese patients with type 2 diabetes through a pre-post study.

Methods: We recruited inpatients who attended a structured diabetes education program at one university hospital in Tokyo, Japan. Inclusion criteria were as follows: (1) diagnosed with type 2 diabetes, (2) aged 20-65 years, (3) not undergoing treatment with either psychiatric or eating disorders, and (4) native Japanese speaking. The self-care empowerment intervention was a follow-up program after the hospitalization. It consisted of a total of 10 weeks, with patients watching a video composed of narrative stories in the social context to make diabetes behavior changes at home once per week. Pre- and post- intervention assessments were based on a patient self-reported questionnaire. It included the General Self-Efficacy Scale, the Rosenberg Self-Esteem Scale, Patient Activation Measure (PAM-13), hemoglobin A1c, BMI, and socioeconomic status at the point of pre-intervention. PAM-13 was used to assess patients' activation levels for self-care.

Results: Out of 22 patients, a total of 17 patients participated in the self-care empowerment intervention (participation rate; 77.3%). Eleven patients completed the whole 10-week intervention, while 6 patients had dropped out (retention rate; 64.7%). There were significantly more dropouts in newly diagnosed patients with type 2 diabetes (mean diabetes duration: 1.2 years vs. 12.1 years, $p = 0.006$). The dropouts had higher patient activation for self-care than those who completed the intervention (PAM-13: Level 3 vs. Level 2). However, other clinical and psychosocial parameters associated with dropouts had no differences in BMI ($p = 0.83$), self-esteem ($p = 0.97$) and self-efficacy ($p = 0.28$) with those who completed the intervention.

Conclusion: Special attention and additional support to the vulnerable individuals with newly diagnosed with type 2 diabetes but yet higher patient activation for self-care should be incorporated into developing and implementing a culturally-tailored self-care empowerment program.

SEX DIFFERENCES IN EDUCATIONAL INEQUALITY IN DIABETES PREVALENCE IN THE UNITED STATES (2001-2016)

Jalal Uddin, PhD¹, Gargya Malla, MBBS, MPH¹, Sha Zhu, PhD¹, Leann Long, PhD², Verna Keith, PhD¹, April Carson, PhD, MSPH, FAHA¹

¹University of Alabama at Birmingham, Birmingham, AL; ²The University of Alabama at Birmingham (UAB), Department of Biostatistics, Birmingham, AL

Background: Health disparities research has long documented a robust educational gradient in morbidity and mortality and acknowledged the protective role of education in health. However, it is less clear if the magnitude of the protective effect of higher education has changed over time and whether there is a differential effect across race/ethnicity and sex. This study examined the association of education with prevalent diabetes and tested whether this association is modified by sex, race/ethnicity, and survey year.

Data and Methods: This analysis included 35,118 non-institutionalized adults aged 20 or older from the National Health and Nutrition Examination Survey (NHANES) 2001-2016. Diabetes was defined as HbA_{1c} ≥ 6.5% and/or the use of any glucose-lowering medication. Multivariable logistic regression with survey weights was used to obtain odds ratios (OR) for the association of education with prevalent diabetes. Interaction terms for education with race/ethnicity, sex and survey year were included in models.

Results: The age-adjusted prevalence of diabetes increased from 6.9% in 2001-2002 to 12.5% in 2015-2016. In 2015-2016, adults with less than high school education had a higher prevalence of diabetes (18.4%) than adults with a college education (9.6%). Additionally, the prevalence of diabetes in 2015-2016 was higher among men (13.7%) than women (11.4%) and differed by race/ethnicity (11.3%, 17.6%, 14.2%, and 12.3% in whites, blacks, Hispanic, and other, respectively). The education-diabetes association was modified by sex ($p=0.06$) but not race/ethnicity or survey year. After adjustment for sociodemographic factors, health behaviors, and health conditions, those with college education versus less than high school education had a lower diabetes prevalence, and this association was stronger among women (OR=0.57, 95% CI=0.46-0.70) than men (OR=0.73, 95% CI=0.57-0.93).

Conclusions: The inverse educational gradient with diabetes prevalence was stronger among women than men, suggesting potential differential returns in the social stratification of health.

SOCIAL SUPPORT, DIABETES DISTRESS & SECURE ATTACHMENT IN TYPE 2 DIABETES

Victoria Jonas, B.A.¹, Claire J. Hoogendoorn, Ph.D.², Steven A. Safren, Ph.D.³, Jeffrey S. Gonzalez, Ph.D.²

¹Ferkauf Graduate School of Psychology, New York, NY; ²Ferkauf Graduate School of Psychology, Bronx, NY; ³University of Miami, Coral Gables, FL

Background: Type 2 diabetes (T2D) is prevalent in the US, and the difficulties of living with this illness can result in significant emotional distress. Social support may be protective for decreased distress, improved health and quality of life in T2D, but not everyone may benefit from social support in the same way. Attachment style, characterized by comfort in connectedness with others, may be an important factor influencing the effect of available social support. This study examined associations between social support and diabetes distress (DD), and evaluated moderating effects of secure attachment on this relationship.

Methods: We screened 114 adults with T2D (M(SD), age = 55.7(9), 86% white, 59% male, M(SD), HbA_{1c} = 8.5(1.6) for N=109), for potential entry into a trial of cognitive behavioral therapy for adherence and depression. Social support satisfaction and network size, total DD, as well as DD subscales for emotional burden, physician-related distress, regimen-related distress and interpersonal distress were assessed via validated questionnaires. Multivariable linear regressions tested associations between social support and DD, controlling for age, gender and depression symptom severity. Moderation analyses examining the role of secure attachment were run with the same covariates.

Results: A negative bivariate relationship was found between support satisfaction and total DD ($r = -.21$, $p = .02$), but did not remain significant in the adjusted model. Among DD domains, higher support satisfaction was bivariately associated with less interpersonal distress ($r = -.40$, $p < .001$), remaining significant in adjusted analyses ($\beta = -.38$, $p < .001$). Older age was independently associated with less DD in all adjusted models. There were no significant relationships found between network size and total DD or DD subscales. Secure attachment was not associated with DD. Contrary to our hypothesis, secure attachment was not found to be a moderator of relations between social support and DD.

Conclusions: Support satisfaction was associated with lower total DD and diabetes-related interpersonal distress. Results suggest that secure attachment may be irrelevant to the relationship between social support and DD. Future research should examine these associations in larger samples of people with diabetes. This study contributes to a relatively small body of work examining attachment in diabetes, as well as a larger literature on protective psychosocial factors for diabetes-related distress in T2D.

ADAPTING A COOKING, FOOD BUDGETING, AND NUTRITION INTERVENTION FOR A RURAL COMMUNITY OF AMERICAN INDIANS WITH TYPE 2 DIABETES

Meagan Brown, MPH¹, Caitlin Hawley, MSPH², Corrine M. Huber, Master of Science³, India J. Ornelas, PhD⁴, Lyle G. Best, MD⁵, Anne N. Thorn-dike, MD, MPH⁶, Shirley A.A. Beresford, PhD⁴, Jason G. Umans, MD, PhD⁷, Amanda Fretts, PhD MPH⁴

¹University of Washington School of Public Health, Seattle, WA; ²Cardiovascular Health Research Unit, Seattle, WA; ³Missouri Breaks Industries Research, Inc., Timber Lake, SD; ⁴University of Washington, Seattle, WA; ⁵Missouri Breaks Industries Research Inc, Watford City, ND; ⁶Harvard Medical School/Massachusetts General Hospital, Boston, MA; ⁷MedStar Health Research Institute, Hyattsville, MD

Introduction: Type 2 diabetes is a leading cause of morbidity and mortality among American Indians (AIs) in the United States (US). Most existing interventions in AI communities focus on diabetes prevention, but few are designed to optimize diabetes management. Although a healthy diet is a key component of managing diabetes, few interventions address underlying contextual factors that inhibit individuals' ability to eat healthy foods. The Cooking for Health Study is a randomized controlled trial designed to test the effectiveness of a culturally-tailored food budgeting, purchasing, and cooking intervention on improving diet quality and cardio-metabolic health among AI adults with diabetes who reside in a large AI community in the North-Central US. The curriculum (print and video) is adapted from Cooking Matters, an evidence-based healthy eating program utilized by SNAP-Ed and USDA My Plate. This formative project examined curriculum adaptations needed to target AI adults with diabetes in a rural and resource-limited setting.

Methods: Two focus groups of AI adults with diabetes were conducted to (1) identify necessary adaptations to Cooking Matters; and (2) inform the development of new materials that address barriers to healthy diet identified in previous pilot work, including low literacy/numeracy and food budgeting skills. Participants were recruited using flyers, social media, and by word-of-mouth. Focus groups lasted 90 minutes, and were audio-recorded and transcribed. Transcripts were coded by two analysts using a coding scheme based on the focus group guide and an inductive, constant comparison approach. Queries of codes were reviewed for themes.

Results: Participants (n=14) ages ranged from 40-59 years old; 11 (79%) were female. Identified themes revolved around curriculum content and ways to incorporate culture and family into the intervention. Participants suggested adding content on mental health to address the stress of living with diabetes. Additionally, participants provided ideas on how to include AI culture (e.g., traditional foods, language) in the curriculum. Participants were also interested in learning how to prepare child-friendly foods and involving the whole family in cooking.

Discussion: Healthy cooking interventions for AIs with diabetes should include content on traditional culture and ways to involve family in cooking, as well as mental health and well-being. Cooking Matters will need adaptations to be more relevant and effective in this AI community.

RECRUITMENT OF MINORITY FAMILIES TO BEHAVIORAL CLINICAL TRIALS: IDENTIFYING HARD-TO-RECRUIT FAMILIES

Jillian T. Rhind, B.S.¹, Deborah Ellis, Ph.D.², April Idalski Carcone, Ph.D., MSW¹, Jill Weissberg-Benchell, Ph.D.³, Meredyth A. Evans, Ph.D.⁴, Mohammad Alwazeer, M.D.⁵, Colleen Buggs-Saxton, Ph.D., M.D.¹

¹Wayne State University School of Medicine, Detroit, MI; ²Wayne State University, Detroit, MI; ³Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; ⁴Ann & Robert H. Lurie Children's Hospital of Chicago, Chicago, IL; ⁵Ascension St. John Hospital, Detroit, MI

Minority youth with type 1 diabetes (T1D) are at risk for poor illness management and suboptimal glycemic control. Despite this, almost no clinical trials have targeted this high-risk population. In light of barriers to enrolling minority families into clinical trials, information is needed to characterize level of effort needed to effectively conduct such outreach and to understand the characteristics of families who are hardest to enroll. The study purpose was 1) to describe the level of effort needed to enroll urban African American adolescents with T1D and their parents into a clinical trial testing an ehealth intervention targeting illness management and 2) to investigate differences between families who were "hard-to-recruit" versus "easy-to-recruit" during initial recruitment and enrollment. Hard-to-recruit (HTR) was defined as those whose initial recruitment letter was returned due to an incorrect address, who had disconnected/ incorrect phone numbers or who no-showed for a scheduled recruitment visit. The study was conducted at five Midwestern pediatric diabetes clinics in Detroit and Chicago. Participants were 127 African American adolescents with T1D. Mean youth age was 13.4 years and parent age was 42.4 years. 53% of youth and 89% of parents were female. Mean youth HbA1c was 11.4%. On average, 8.8 contacts (phone calls, texts, letters) were needed to enroll families. HTR families (N=44, 35%) required almost twice as many contacts ($p < .01$). 17% of the sample required a face-to-face contact from research staff during a diabetes clinic visit to successfully enroll them. HTR families were not significantly different from ETR families on diabetes characteristics (duration of illness, insulin regimen, or HbA1c). Parent-reported family characteristics including level of disorganization in the home and diabetes-related family conflict also did not differentiate HTR from ETR families. No significant differences were found for most demographic factors (youth age, caregiver age, or caregiver education). However, HTR families had significantly lower annual family income than ETR families (\$27,700 vs \$37,600, $p < .05$). Findings demonstrate the high level of outreach efforts required by research staff to recruit urban high-risk minority families into clinical trials. The hardest to recruit families are characterized by barriers to enrollment related to poverty and may require novel approaches in order to increase their participation in research.

DIALOGUE ANALYSIS DURING A COGNITIVE REHABILITATION INTERVENTION FOR PEOPLE WITH DIABETES: ARE WE REALLY PATIENT-CENTERED?

Heather E. Cuevas, PhD, ACNS-BC¹, Sharon Carter, DNP, RN¹¹The University of Texas at Austin, Austin, TX

Background: The importance of discourse in patient learning in health education is uncontroversial, but the positive effects of discourse in online interventions are understudied and can only be expected if the instruction meets certain quality requirements. The purpose of this project was to analyze the online classes of a cognitive rehabilitation intervention for people with type 2 diabetes to determine to what extent the classes had characteristics of productive discourse.

Methods: Ten adults with T2DM and two interventionists participated in an 8-week intervention that combined classes held via webinar with online home-based computer training. The Generalized Medical Interaction Analysis System, based in Speech Act Theory, was used to analyze the discourse. Transcripts of the classes (n=8) were coded using a coding manual, two trained coders, and atlas.ti software. The unit of analysis was a completed speech action or “utterance.” Two main codes were assigned: a speech act code (questions, representations, logistics, socializing) and a topic code. The codes were subcoded to describe the utterances further (e.g. comprehension, emotions, checking understanding).

Results: The number of statements varied between classes and percentages were calculated for the individual categories. Most interventionist statements and questions were representative (55%) (e.g. “Insomnia can cause cognitive problems”); checking for understanding (30%) (e.g. “is that clear?”); and expressing empathy (15%) (“That must have been hard”). Interventionist feedback on participant statements consisted of explanation or observation (52%); evaluation of the participant response (21%); and problem-solving (14%) (“Let’s see what else we can do”). Most feedback was short restatements of the participants’ statements and evaluations (e.g. “correct”) or comments for further reflection (e.g. “have you thought about this?”). Problem solving dialogue included questions that elicited participants’ values/preferences (48%).

Discussion: The discussions overall were characterized by a high percentage of open-ended questions, short participant responses, and interventionist feedback that was participant-centered. The pattern of interventionists’ behavior was consistent with motivating positive behavioral change. Future interventions should include components of discourse evaluation and examinations of relationships to adherence and clinical outcomes.

EVALUATING A BEHAVIORAL COMMITMENT PROGRAM TO SUSTAIN ENGAGEMENT IN A DIGITAL DIABETES MANAGEMENT PLATFORM

Robert J. Ellis, PhD¹, Emma Townley-Smith, B.S. Engineering, Stanford University², Kay Kappaganthu, PhD¹, Bobbie A. James, MStat³, Jesse A. Bridgewater, PhD⁴, Bimal Shah, MD, MBA¹¹Livongo Health, Mountain View, CA; ²Livongo Health, Menlo Park, CA; ³Livongo Health, Mountain View, CA; ⁴Livongo, San Jose, CA

Objective: Sustaining participant engagement in digital lifestyle change programs is both crucial and difficult. A “5-day Challenges” behavior change program was implemented to an existing diabetes (DM) management platform (Livongo) with the hypothesis that an intention to change health behaviors will improve the frequency of blood glucose (BG) checks via a cellularly connected meter and associated mean BG values over three consecutive 30-day periods (“Post1”, “Post2”, “Post3”) relative to a 30-day “Pre” period.

Methods: 136,626 individuals enrolled in Livongo for at least 30 days were given the opportunity to participate. Of those, 8,258 expressed interest, and were presented with a sequence of five 5-day activities (eating vegetables, drinking water, walking more, sleeping well, and reducing stress). 3,982 completed at least one of the 25 Challenge steps (Participants), and 4,276 completed 0 Challenge steps (Initiators). All other individuals were classified as Controls. For evaluation, Initiators and Controls were matched to Participants based on key demographic traits, frequency of BG checking, and other program activity during the Pre-period using a 1-to-1 exact matching method. The Pre-period was defined as the 30 days prior to the date of the first Challenge step for Initiators and Participants, or prior to 2019-05-15 for Controls.

Results: After matching, each cohort had 3,308 individuals. At Post1 and Post3 relative to Pre, the percentage of each cohort achieving ≥ 5 checks was +10.9 points (i.e., 90.2% at Post1 vs 79.3% at Pre; McNemar’s test p -value < 0.001) and -1.3 points ($p = 0.080$) for Participants; +3.4 points and -7.1 points for Initiators (both $p < 0.001$); and -4.9 points and -12.3 points for Controls (both $p < 0.001$). Similar trends were observed for achieving ≥ 10 checks or performing any program activity, revealing initial improvement and sustained engagement over time among Participants vs. Initiators and Initiators vs. Controls. A significant decrease in mean BG from Pre to Post3 was larger among Participants (mean: -5.1 mg/dl, 95% CI: [-6.5, -3.7]) than Initiators (-4.1 mg/dl [-5.5, -2.7]); Controls saw a non-significant change (-0.7 mg/dl [-1.9, +0.6]).

Conclusions: The “5-day Challenges” mobile-based behavior change protocol significantly and positively impacted blood glucose checking frequency—a key index of program engagement—and was associated with significant reductions in mean blood glucose relative to baseline.

DYADIC ASSOCIATIONS BETWEEN BODY MASS INDEX AND INCIDENT DIABETES IN MIDDLE AGED AND OLDER ADULTS

Rachel J. Burns, PhD¹¹Carleton University, Ottawa, ON, Canada

Body mass index (BMI) is positively associated with the risk of developing type 2 diabetes (T2D). Although romantic partners influence each other's health outcomes, links between partner's BMI and the development of T2D have not been examined. Therefore, the purpose of this study was to test dyadic associations between BMI and the development of T2D in middle-aged and older adult couples over 8 years. Data came from both members of 950 couples in the Health and Retirement Study. Neither partner had diabetes at baseline (2006). Body mass index was based on objective measurements of height and weight at baseline. Diabetes status was assessed at baseline and two follow-ups (2010, 2014) via blood samples; individuals with hemoglobin A1c levels at or above 6.50% were classified as having diabetes. The actor-partner interdependence model for binary outcomes was used to examine dyadic associations between BMI at baseline and the development of T2D during follow-up. After adjusting for covariates (age, education, ethnicity, marriage duration, physical activity), a significant actor effect was observed, such that one's BMI at baseline was positively associated with one's own odds of developing T2D during follow-up (OR = 1.08, $p < .001$). A significant partner effect was also observed, such that the BMI of one's partner at baseline was positively associated with one's own odds of developing T2D during follow-up, above and beyond one's own baseline BMI (OR = 1.04, $p = .003$). These associations were not moderated by sex. This pattern of results held when BMI was coded categorically (not overweight/obese vs. overweight vs. obese). In conclusion, every one unit increase in partner's BMI at baseline was associated with a 4% increase in one's own odds of developing diabetes during the next 8 years, above and beyond one's own BMI at baseline. Although research largely examines *intrapersonal* risk factors for chronic health conditions, such as T2D, these results suggest that *interpersonal* risk factors are a promising avenue of research. These results also highlight an opportunity to develop theoretical models that specify how and when partner characteristics are linked to physical morbidity.

DIET QUALITY AND WEIGHT-RELATED EXPERIENTIAL AVOIDANCE FOLLOWING TREATMENT FOR WEIGHT-LOSS AND DISINHIBITED EATING

Brian H. Blanco, MSW¹, Jennalee S. Wooldridge, PhD², Cara Dochat, M.S.³, Herbert Matthew, PhD⁴, Kathryn M. Godfrey, PhD⁵, Jennifer Salamat, BS⁴, Niloofar Afari, PhD⁶

¹VA San Diego Healthcare System/University of California San Diego, San Diego, CA; ²University of California San Diego/VA San Diego, San Diego, CA; ³San Diego State University/University of California San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; ⁴VA San Diego Healthcare System, San Diego, CA; ⁵ChristianaCare Center for Provider Wellbeing, Newark, DE; ⁶VA Center of Excellence for Stress and Mental Health and Department of Psychiatry UC San Diego, San Diego, CA

Obesity/Overweight is a major public health issue. Diet quality and weight-related experiential avoidance (EA) may serve as barriers to weight loss. Weight-related EA includes attempts to avoid thoughts and situations that remind one of their weight and is related to disinhibited eating. In a recent randomized controlled trial, Veterans completed 4 weeks of Acceptance and Commitment Therapy or behavioral weight-loss (BWL) treatment for disinhibited eating following participation in the VA's weight management program and were followed up for 6 months. The aims of this secondary data analysis were to examine 1) if there was improvement in diet quality from baseline to 6-month follow up; 2) relationships between demographic characteristics, weight-related EA at baseline and post-treatment, and diet quality at follow up; and 3) whether changes in weight-related EA during treatment were related to change in diet quality at follow up. Veterans (N=68; Mage=57 years; MBMI=38 kg/m²) completed food frequency questionnaires at baseline and 6-months, which were used to generate a diet quality score on the healthy eating index-15 (HEI-15). Weight-related EA was assessed using the Acceptance and Action Questionnaire for Weight-Related Difficulties Revised (AAWQR) at baseline and post-treatment. Two-way mixed ANOVAs revealed no treatment group differences on either HEI-15 or AAWQR; HEI-15 score significantly declined from baseline (M=69.8) to 6-month follow up (M=67.3; $p < .001$) and AAWQR total and subscale scores significantly improved from baseline to post-treatment ($ps < .005$). Correlation analyses revealed several significant negative correlations with HEI-15 at 6-months including AAWQR total at baseline ($r = -.26, p = .03$) and post-treatment ($r = -.25, p = .04$) and AAWQR subscales representing weight as a barrier to living ($r = -.24, p = .048$) and self-stigma ($r = -.28, p = .02$) at post-treatment. Regression analyses examined sex, baseline BMI, and post-treatment AAWQR, controlling for baseline AAWQR and HEI-15, as predictors of HEI-15 at 6 months. Male sex ($b = -5.15, p = .04$), but not post-treatment AAWQR, was associated with HEI-15 at 6 months. We found that greater weight-related EA was associated with lower diet quality cross-sectionally, but changes in EA during treatment did not predict changes in diet quality at follow up. Additional research is needed to determine how best to improve and sustain dietary behavior in behavioral interventions for obesity and disinhibited eating.

EXAMINING ASSOCIATIONS AMONG PARENT REPORTED CHILD HEALTH BEHAVIORS AND CHILD HEALTH STATUS, AND BMI IN PRE-ADOLESCENT GIRLS

Manuela Jaramillo, BS¹, Daniella Marchetti, MS², Zachary Goodman, MA¹, Maria M. Llabre, PhD³, Patrice G. Saab, PhD¹¹University of Miami, Coral Gables, FL; ²University of Miami, miami, FL; ³University of Miami/Jackson Health System (SSO), Coral Gables, FL

Introduction: Improving healthy eating behaviors in children is important since child health predicts cardiovascular disease in adulthood. Previous longitudinal research shows a negative relationship between breakfast consumption and BMI, and a positive relationship between fast food consumption and BMI in pediatric populations. This study examined the association of parent report of child health and health behaviors with child BMI in ethnically diverse middle school aged girls.

Methods: 340 middle-school aged girls ($M = 11.8$ years; 91% minority) were participants in a larger study emphasizing the importance of healthy lifestyle. Participants' BMI (kg/m^2) was calculated after measuring height and weight ($M = 21.4$, $SD = 4.97$). Parental rating of child health status was determined by response to the question "How would you describe your child's health?" Approximately 46% of parents reported their child's health as "very good" or "excellent." Parents reported the average days/week that their child consumed breakfast ($M = 5.96$, $SD = 1.79$) and fast food ($M = 1.49$, $SD = 1.18$).

Results: Two regression models were conducted controlling for child age and maternal education. In model 1, predictors were child breakfast and fast food consumption and the outcome was parent reported child's health. There was a significant association between child breakfast consumption ($\beta = .143$, $p = .008$) and fast food consumption ($\beta = -.195$, $p < .001$) with parent reported child's health. In model 2, predictors were child breakfast and fast food consumption and parent reported child's health and the outcome was child BMI. There was a significant association between parent reported child's health with BMI ($\beta = -.306$, $p < .001$).

Conclusion: The findings indicate that both breakfast and fast food consumption are associated with parent reported child's health and that parent reported child's health is associated with BMI. Identifying parent-modifiable child health behaviors (like providing children with breakfast and limiting fast food consumption) that predict child BMI and overall health is important for the purpose of interventions in clinical practice. Pediatricians can educate parents on the health benefits of regular breakfast consumption and infrequent fast food consumption to ultimately improve child weight status, health, and develop sustainable health habits.

DOES STRESS DERAIL MOTIVATION FOR HEALTHFUL EATING IN PREGNANCY AND POSTPARTUM?

Jan T. Mooney, M.A.¹, Tonja R. Nansel, Ph.D.², Leah M. Lipsky, Ph.D.²¹Health Psychology PhD Program, University of North Carolina at Charlotte, Charlotte, NC; ²Social and Behavioral Sciences Branch, Division of Intramural Population Health Research, Eunice Kennedy Shriver National Institute for Child Health and Human Development, Bethesda, MD

Although women report motivation for healthful eating during pregnancy, their adherence to US dietary guidelines is low. Qualitative data have shown that pregnant women may relax effortful control over eating behaviors to reduce stress during pregnancy; thus, stress may override motivation to eat healthfully. According to self-determination theory, autonomous (internal) sources of motivation are more closely related to health behaviors than controlled (external) sources of motivation, suggesting that autonomous motivation may be able to buffer the potential adverse effect of stress on diet quality. This study examined associations of diet quality with stress, autonomous motivation, and controlled motivation during pregnancy and postpartum. Participants in the Pregnancy Eating Attributes Study completed multiple 24-hour diet recalls and validated measures of perceived stress and motivation for healthful eating (analytic sample: $n = 282$ pregnancy; $n = 190$ postpartum). Hierarchical multiple regressions tested associations of diet quality (Healthy Eating Index-2015) with stress, motivation (autonomous and controlled motivation entered simultaneously), and their interactions, controlling for age, education, race/ethnicity, and income. Diet quality was not associated with stress in pregnancy or postpartum ($b = -.003$, $p = .98$ and $b = .02$, $p = .88$, respectively). Autonomous motivation for healthful eating was significantly greater during pregnancy (4.51 ± 1.14) versus postpartum (5.24 ± 1.25 , $t(184) = 2.61$, $p = .01$), but controlled motivation was unchanged. Diet quality was strongly associated with autonomous motivation during both periods ($b = 3.33$ and 3.57 , $p < .001$, respectively), but was not associated with controlled motivation ($b = -.38$, $p = .58$ and $b = .53$, $p = .57$, respectively). Interaction terms were nonsignificant and provided minimal improvement to model fit. Although negative point estimates for all interaction coefficients suggested that stress may attenuate the relationships between motivation and diet quality, all 95% confidence intervals were inclusive of zero. The elevation of autonomous motivation during pregnancy and its' association with diet quality is consistent with qualitative findings that pregnant women perceive eating healthfully as beneficial to their baby and suggests the potential utility of approaches to foster autonomous motivation.

HOUSEHOLD FOOD WASTE REDUCTION: LESSONS LEARNED IN A FIRST-OF-ITS-KIND INTERVENTION

Christopher Wharton, PhD¹, Maricarmen Vizcaino, PhD¹, Andrew Berardy, PhD¹, Adenike Opejin, MS¹¹Arizona State University, Phoenix, AZ

Introduction: Wasted food in the home represents a multipronged problem of food management. Food waste impacts household finances and represents missed opportunities to eat healthful foods, especially because the largest proportion of consumer food waste comprises fruits and vegetables. Wasted food rotting in landfills also greatly contributes to emissions of methane, a potent climate change gas. Research suggests household food waste is largely preventable, and as such changing behaviors in ways that can reduce food losses at home could contribute to healthier eating, stabler home finances, and reduced environmental impact simultaneously. Because this area of research is relatively new, only limited literature exists exploring behavior-related issues such as motivations and barriers to reducing food waste. And, to the best of our knowledge, no published research exists detailing methods for conducting household food waste intervention studies specifically.

Methods: We recently completed a first-of-its-kind intervention focused on reducing food waste at the household level. We recruited fifty-three households, which participated in a 5-week intervention leading to significant reductions in wasted food, which were associated with changes in related theoretical behavioral constructs. Throughout the intervention, our team gathered information on what worked, what did not, and what could be improved in future studies. This abstract presents those lessons learned by offering ideas on methodology, process, and participant interaction.

Results: Successes included designing understandable methods for participants to collect food waste using bins and scales, as well as making food waste collection straightforward by offering a clear definition of what ‘counted’ as waste. However, we identified opportunities to improve training processes both in terms of efficiency and repeatability. And participant data reporting, though conducted with a simple online interface, required a change in process mid-study to ensure consistency. We also found that exploring multiple food-related values as motivations, rather than a singular approach (such as focusing solely on health) proved vital to engaging participants in reducing food waste over time. We noted, however, that it was important to capture as much contextual data as possible as family events, parties, cooking mistakes, and eating out, among other issues, played a considerable role in impacting food waste patterns.

Discussion: Lessons learned from this unique pilot study provide useful insights for others interested in developing interventions that assist individuals in food waste reduction. Offering understandable processes and methods, motivations, and clear data reporting schemes, along with the equipment necessary to repeat the process consistently, can aid in developing larger and better interventions in the future.

DEMOGRAPHIC AND CULTURAL CORRELATES OF TRADITIONAL EATING AMONG ALASKA NATIVE MEN AND WOMEN AT RISK FOR CARDIOVASCULAR DISEASE

Mark A. Sanders, MS¹, Marily Oppezzo, PhD, MS, RDN², Jordan D. Skan, M.S.³, Derek Searcy, BA⁴, Mariah A. Knox, BA⁴, Neal Benowitz, MD⁵, Matthew Schnellbaecher, MD⁴, Judith J. Prochaska, PhD, MPH⁶¹Stanford University School of Medicine, San Francisco, CA; ²Stanford University, Mountain View, CA; ³Alaska Native Tribal Health Consortium, Anchorage, AK; ⁴Alaska Native Tribal Health Consortium, Anchorage, AK; ⁵University of California, San Francisco, San Francisco, CA; ⁶Stanford University, Stanford, CA

Background: Traditional foods are a way to connect with and celebrate culture, transmitted across generations. In Alaska’s Norton Sound region, the traditional diet with marine sources of omega three polyunsaturated fats is thought to be protective against cardiovascular disease (CVD). Yet, the increased availability of processed foods from the lower 48 has shifted traditional eating patterns, with a concurrent rise in risk of CVD. This study seeks to understand traditional eating practices among Alaska Native men and women in Norton Sound and its relationship with cultural correlates and demographic factors.

Methods: As part of the HEALTHH project (Healing and Empowering Alaskan Lives Toward Healthy-Hearts), 299 Alaska Native men and women from the Norton Sound region of Alaska who are at-risk for CVD were recruited and surveyed at baseline. A 38-item food frequency questionnaire (FFQ) was developed to assess dietary intake for the past 7 days. The measure included nine foods defined as traditional and common to the region (e.g., wild berries, moose, salmon, seal or whale oil). Response options ranged from “Did not eat it this week” (coded 0) to “More than twice each day” (coded 14). A “traditional foods index” was computed as servings of traditional foods divided by total servings of assessed foods. The index was non-normally distributed, and thus nonparametric tests were conducted to examine associations.

Results: The median traditional foods index was 17% (IQR: 9%-30%), indicating that among the foods included in the FFQ, weekly consumption of traditional foods made up about a fifth of reported diet. A Mann-Whitney U test found significant difference ($U=9052$, $p=0.043$) between the median traditional foods index in participants completing the questionnaire in the summer months (May–September, 19.42%) compared to the winter months (October–April, 14.92%). Those in smaller communities (< 1000 residents) had a higher median traditional food index (18.65%) than those in the larger community of Nome (~3800 residents) (12.95%, $U=6022.5$, $p=0.041$). Spearman correlations were significant for tests of association between the traditional foods index and age [$r=.27$, $p<0.001$], community connectedness [$r=.19$, $p=0.002$], community standing [$r=.15$, $p=0.015$], and traditional language comprehension [$r=.199$, $p=0.001$]. Language fluency [$r=.03$, $p=0.658$] and cultural identification [$r=.07$, $p=0.234$] were not significantly correlated with the traditional foods index.

Conclusion: A greater proportion of traditional foods in one’s diet among Alaska Native men and women was found in the summer months, in smaller communities, and among older individuals. Traditional eating was positively correlated with community connectedness, community standing, and traditional language comprehension. Further research is needed to examine how these findings may influence CVD and other health outcomes.

THE INFLUENCE OF MINDFUL EATING AND/OR INTUITIVE EATING APPROACHES ON DIETARY INTAKE: A SYSTEMATIC REVIEW

Hannah Grider, BS¹, Hollie Raynor, PhD, RD¹¹University of Tennessee, Knoxville, TN

Background: Research on restrained eating has led to the belief that an eating style that relies on physiological cues of hunger and fullness may enhance dietary outcomes as compared to an eating style that relies on cognitive control. Two types of interventions have been developed to assist with the development of an eating style that relies on cues of physiological need. These interventions focus on mindful eating (ME) and intuitive eating (IE). This systematic review examined how ME and IE interventions influence dietary intake, and how well the interventions influenced ME and IE by reporting outcomes when they were assessed with a validated tool.

Methods: The selection of literature followed the PRISMA systematic review process, in which PubMed, CINAHL and PsycINFO databases were searched. Studies were included if they met the following criteria: randomized trial design, in which one arm was an intervention with an ME or IE component and there was at least one other arm that was a control or active comparison; enrolled participants were of a healthy weight or with overweight or obesity and were at least 18 years of age; and outcomes of energy intake and/or diet quality were reported at baseline and post-intervention.

Results: A total of 14 studies, represented by 15 articles, were included, which were comprised of 9 ME interventions and 5 IE interventions. Eight studies, representing 9 articles, reported on energy intake, with six studies reporting no significant differences between groups. Twelve studies, representing 13 articles, reported on diet quality, with 7 studies reporting no significant differences between groups. Four studies measured ME and IE with a validated tool, which revealed ME or IE interventions did not consistently increase ME or IE.

Conclusion: Overall, evidence suggests that ME and IE interventions do not influence dietary intake; however, future research using validated tools to measure ME and IE is needed. Without the measurement of ME or IE, it is hard to conclude whether participants adopt the ME and IE approaches, and what effect these interventions have on dietary intake.

DOES SELF-WEIGHING WITH FEEDBACK ASSIST WITH THE SELF-REGULATION OF ENERGY BALANCE BEHAVIORS?

Genevieve Prushinski, BS¹, Hollie Raynor, PhD, RD¹¹University of Tennessee, Knoxville, TN

Background: Self-monitoring of diet, physical activity, and/or weight is an important component of weight management. Self-weighing with feedback, in which the feedback is aligned with action of self-weighing, appears to enhance weight management. However, the frequency of self-monitoring weight with feedback has yet to be examined thoroughly in experimental settings, and it is unclear what diet and/or physical activity behaviors occur following self-weighing with feedback. The purpose of this investigation was to examine the effects of frequency of self-weighing combined with feedback on dietary intake and physical activity.

Methods: This study randomly assigned 22 young adults (21.8 ± 3.1 yrs, 23.1 ± 2.3 kg/m², 81.8% female, 72.7% white), seeking to maintain their weight to one of three conditions: daily weighing with feedback, weekly weighing with feedback, or no weighing control. Participants in the daily and weekly weighing groups were provided with Bluetooth scales and instructed to weigh themselves one time per day or one time per week, respectively, for four weeks. Participants received feedback either daily (daily weighing group) or weekly (weekly weighing group) on their change in weight and a suggestion of how to increase or decrease their energy balance by 150 calories in order to maintain their current weight. Diet (24-hr recalls), physical activity (accelerometry), weight, self-esteem, mood, eating attitudes, and unhealthy weight control behaviors were measured at baseline and follow-up.

Results: Participants in the weighing groups gained significantly ($p < 0.05$) less weight (-1.4 lbs ± 3.0) than the no weighing control group (2.8 lbs ± 3.3). Weight changes were -0.4 lbs ± 1.1 for the daily weighing group, -2.4 lbs ± 4.0 for the weekly weighing group, and 2.8 lbs ± 3.3 for the no weighing group, and post-hoc comparisons showed that the weight change in the weekly weighing group was significantly ($p < 0.05$) less than the no weighing control. Analyses of covariance showed no significant differences in energy intake or physical activity, self-esteem, mood, eating attitudes, and unhealthy weight control behaviors, between groups at follow-up.

Conclusion: Results suggest that self-weighing with feedback has no harmful effects and may be useful for weight control, especially weekly weighing with feedback, among adults of a healthy weight seeking to maintain their weight.

CHANGES IN TODDLER DIET QUALITY IN A FAMILY WELLNESS PROGRAM: A PILOT RANDOMIZED CONTROL TRIAL

Tracey Ledoux, PhD, RD, FAND¹, Aliye B. Cepni, BS², Ashley Taylor, BS in Psychology¹, Christine A. Crumbley, PhD¹, Debbie Thompson, PhD¹, Norma Olvera, Ph.D.¹, Daniel O'Connor, PhD¹, Nancy E. Moran, Ph.D.⁴

¹University of Houston, Houston, TX; ²University of Houston, Sugar Land, TX; ³USDA/ARS; Baylor College of Medicine, Houston, TX; ⁴Baylor College of Medicine, Houston, TX

Background: Poor diet quality increases the risk of obesity, diabetes, heart disease, and some types of cancers. Diet habits begin developing in early childhood and track through life. There is a need for wellness programs to help toddlers (i.e., 12-36 months) adopt lifelong healthy eating habits.

Purpose: This study's purpose was to determine the preliminary effect of a family wellness program on fruit and vegetable (FV), snack, and sugar sweetened beverage (SSB) intake among toddlers.

Methods: Families were recruited from the community and randomly assigned to an experimental wellness program called the Families Understanding Nutrition and Physically Active Lifestyles (FUNPALs) Playgroup or a usual care program called the Healthy Toddler Parent Group (HTPG). The FUNPALs Playgroup, largely based on Social Cognitive and Family Systems Theories, aimed to improve toddler diet by helping parents create a healthy home environment. FUNPALs Playgroup behavior change strategies included facilitator modeling and experiential learning delivered within a playgroup setting. The HTPG aimed to improve toddler diet by teaching parents dietary recommendations for toddlers through facilitator instruction and group discussion within a parent group setting. Both groups received 10 weekly sessions and completed pre (T1) and post program (T2) measurements. Snacks and SSB intake were assessed with the Kids Bite Food Frequency Questionnaire (FFQ), which has been validated for preschool age children (Aguilar et al., 2014). FV intake was assessed with the Kids Bite FFQ and with skin carotenoid concentration measured by non-invasive reflection spectroscopy, which is a biomarker of dietary carotenoid rich FV. Repeated measures ANOVAs were conducted to test group differences on FV, SSB, and snack intake from T1 to T2.

Results: The sample (n=50) comprised toddlers ($M_{age} = 27$ months, 58% males) and parents ($M_{age} = 31.7$ years, 84% female), who identified as predominantly Non-Hispanic white (44%), Hispanic/Latino (38%), and/or African American (32%). There was an interaction effect on SSB intake [Wilk's Lambda = .802, $F(1, 36) = 8.87, p = .005$] indicating a greater decrease in SSB consumption from T1 to T2 among FUNPALs Playgroup toddlers compared to HTPG toddlers. There was a main effect of time on skin carotenoid levels [Wilk's Lambda = .864, $F(1, 33) = 5.206, p = .029$]. Both groups showed increased skin carotenoid concentrations from T1 to T2. Per Cohen (1988), the effects on SSB consumption (partial eta squared = .20) and skin carotenoids (partial eta squared = .14) represent large effects. No interaction or main effects on parent-report (FFQ) snack or FV consumption were found.

Conclusions: This study provides preliminary evidence that a family wellness playgroup program may have a large positive effect on toddler diet quality. Next steps are to test the FUNPALs Playgroup in a fully powered RCT.

RELATIONSHIPS BETWEEN FOOD PREPARATION QUALITY AND SOCIO-DEMOGRAPHIC FACTORS AMONG A DIVERSE SAMPLE OF AMAZON MTURK WORKERS.

Margaret P. Raber, DrPH¹, Karen Basen-Engquist, PhD¹

¹University of Texas MD Anderson Cancer Center, Houston, TX

Background: The promotion of home food preparation skills is an increasingly popular approach to public health nutrition. However, little research has examined modern cooking practices in the population and how cooking quality relates to socio-demographic variables. This limits the development and effective distribution of healthy cooking initiatives. Low-cost self-report assessment tools of cooking behavior are needed to understand cooking practices across the population. The Healthy Cooking Index (HCI) has shown promise as a method for quantifying nutrition optimizing food preparation practices, but requires further development and testing in a larger sample.

Objective: The purpose of this communication is to describe the development of a self-report questionnaire mapped to the HCI and investigate relationships between HCI practices and socio-demographic variables in a sample of Amazon MTurk workers.

Methods: The HCI consists of a series of cooking behaviors with the ability to positively or negatively impact the nutritional quality of home-prepared foods. HCI self-report questions were developed with a group of community members, trained in citizen scientist research practices. The HCI questionnaire (HCIQ2) was then combined with demographic and comprehension variables and distributed to a sample of adults via Amazon's MTurk platform. Cooking frequency and comprehension variables were assessed and summative healthy cooking scores calculated based on the HCI. Relationships between HCI score and demographic variables were examined using ANOVA and Independent Sample T-test methods.

Results: Almost all MTurk respondents (n=436) reported understanding all of the questions in the survey (98.7%) and few noted issues with the questionnaire content (1.8%). Most respondents reported cooking a meal at home within the last 2 days (90%), with the majority noting lunch or dinner as the main meal (79%). Demographically, participants were mainly from the US and India, young (18-35) (75%), educated (76% with Bachelor degree or higher) and employed full time (81%). The mean HCI score of the sample was 2.31 (-1 to 8). Factors that impact HCI score include meal type (dinner > breakfast $p=.03$) and country of respondent (US > India=.05). No other demographic variables were associated with HCI scores.

Conclusions: The HCIQ2 is a feasible self-report data collection tool for use in the general population. Resulting HCI scores are influenced by meal type prepared and country of respondent, variables that should be factored into future analysis using the HCI. A deeper understanding of HCI behaviors in the population will be useful in future research examining cooking practices relative to biological correlates of health.

COOKING QUALITY IS ASSOCIATED WITH SUCCESSFUL WEIGHT LOSS AMONG OVERWEIGHT/OBESE PARTICIPANTS IN A WEIGHT LOSS INTERVENTION.

Margaret P. Raber, DrPH¹, Karen Basen-Engquist, PhD¹, Leticia A. Gatus, DrPH, MPH², Thuan Le, MPH¹¹University of Texas MD Anderson Cancer Center, Houston, TX; ²MD Anderson Cancer Center, Houston, TX

Background: Home cooking is associated with favorable body weight and diet quality, yet few studies have examined modern cooking habits beyond general frequency. Not all home cooking is equally healthy, thus research examining home cooking *quality* (as opposed to only *quantity*) and health outcomes is timely and will support the development and integration of cooking components into lifestyle interventions. To measure home cooking quality we developed The Healthy Cooking Index, based on extant evidence and pilot testing.

Objective: The purpose of this communication is to examine the Healthy Cooking Index scores of participants in a worksite weight loss intervention and evaluate associations between cooking quality and weight loss success.

Methods: This analysis examined 192 overweight/obese participants in the Vibrant Lives weight loss program. Vibrant Lives consisted of 16 lessons received by mail or email over 26 weeks. Program content was based on the Diabetes Prevention Program and focused on physical activity, portion control, and reducing dietary fat. Self-reported demographic information, height and weight were collected at baseline. Height, weight, and cooking behaviors as assessed by the Healthy Cooking Index Questionnaire (HCIQ2), were collected post-intervention. HCIQ2 scores were calculated for each participant and examined relative to weight loss success using Pearson correlation coefficients and ordinary least squares linear regression, with self-reported demographic variables added as covariates.

Results: Most participants were female (89%) and White (42%) or Hispanic (40%). The majority (83%) reported cooking a main meal at home within the last 2 days. HCIQ2 scores were negatively correlated with weight change (post - pre weight in lbs) (Pearson Correlation Coefficient = -.2244; $p=.002$). The regression model showed for every 1 positive HCIQ2 point change, there is a weight change difference of -1.341 lbs ($p=.003$) suggesting healthier cooking practices may support weight loss in this population.

Conclusions: This is the first study to examine the quality of home cooking behaviors relative to weight loss success during an intervention period. This study is limited by the homogenous sample. Further research is needed to understand variability in cooking quality across the population and transmission of healthy cooking education in an intervention context.

EFFECTS OF CORRECTING VACCINE MISINFORMATION: FACTORS THAT INFLUENCE VACCINE MISPERCEPTIONS

Christopher Calabrese, MPH¹, Jieyu Featherstone, MA¹, Jingwen Zhang, PhD¹¹UC Davis, Davis, CA

As health misinformation continues to spread online, researchers have examined the effects of fact-checking on reducing people's misperceptions despite mixed evidence for effectiveness. In particular, the rise of vaccine misinformation online has contributed to peoples' misperceptions about specific vaccines. With vaccine hesitancy being a top public health concern, it is important to first understand what factors, such as epistemic beliefs or partisan media sources, influence misperceptions about vaccines, and whether misinformation corrections reduce these misperceptions. To address this issue, we conducted a large-scale, online experiment to test the effects of correcting vaccine misinformation (correction vs. none) among five different vaccines (Influenza, HPV, MMR, TDAP, and Zika) on vaccine misperceptions. In addition, we assessed participants' need for evidence, faith in institutions, trust in medicine, conspiracy beliefs, perceived vaccine knowledge, and frequency of partisan media use. Findings indicate that the misinformation corrections significantly reduced vaccine misperceptions related to the Influenza ($b = -.52$, $p = .04$), TDAP ($b = -.37$, $p = .05$), and Zika ($b = -.82$, $p = .006$) vaccines. These corrections did not influence misperceptions surrounding the MMR and HPV vaccines. Conspiracy beliefs were a significant predictor for misperceptions among all five vaccine types ($p < .001$). However, the use of partisan media as a health information source did not influence people's vaccine misperceptions. Our findings suggest that correcting vaccine misinformation online may reduce people's vaccine misperceptions. With vaccine misinformation still prevalent online, it is important for researchers to focus on corrections to reduce the impact it may have on vaccine misperceptions. Further, health professionals should focus on interventions to address users' conspiracy beliefs surrounding vaccines. Future research should examine the effects of other correction methods to combat vaccine misinformation online.

EFFECT OF DIFFERENT PARTICIPANT CONTACT MODALITIES ON THE ADHERENCE TO A DIGITAL MINDFULNESS INTERVENTION

Joanna Guan, BA¹, Julie Vaccaro, BS¹, Sarah M. Fisher, BA², Elena Fromer, BS¹, Jonathan Torres-Espinoza, BS¹, Stefanie E. Mayer, PhD¹, Elissa S. Epel, PhD¹, Aric Prather, PhD¹

¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA

Introduction: Digital interventions address many current barriers to mental health services such as cost-effectiveness and accessibility. Increasing evidence from studies on digital mindfulness meditations supports a dose-response effect in improving stress and mental health outcomes. While research has shown that participant contact (vs. no contact) increases treatment adherence, it is unknown whether the type of contact matters. Here, we examined data from an 8-week digital mindfulness program on work-related stress and tested whether actively engaging participants or simply reminding them to meditate improved treatment adherence.

Methods: Eligible participants (n=1,128) were randomly assigned to either a digital HeadspaceTM application (n=544) or a waitlist control (n=584) condition. Those assigned to the digital meditation intervention were asked to meditate for 10 min/day over 8 weeks. Participants in this group who had not meditated in the prior 2 weeks (n=468) were contacted by the research team. Participant contact was categorized into those who actively engaged with the research team via either a motivational interviewing style phone conversation or text message response (“engaged”) and those who received a reminder to meditate via voicemail or text message but did not actively engage with the research team (“reminded”). We used independent sample t-tests to examine whether the two different contact modalities had an effect on treatment adherence as measured by the number of completed meditation sessions in the 2 weeks following contact.

Results: Of 468 contacted participants, 182 were contacted once, 145 twice, and 141 three or more times during the 8-week intervention period. For participants who were contacted only once, there was a significant effect of contact modality on treatment adherence, such that those who were actively engaged by the research team completed more meditation sessions in the subsequent 2 weeks than those who were simply reminded ($p = .015$). However, this effect was no longer significant for participants who were contacted twice ($p = .554$) or three or more times ($p = .145$).

Discussion: Our data suggest that treatment adherence to a digital mindfulness intervention could be significantly increased if researchers engaged participants early on. Participants who have recurrent adherence problems may require different strategies for reengagement. These results inform future retention and reengagement strategies for digital interventions that allow researchers to increase the effectiveness of digital programs.

HOW HASHTAGS #EATINGFORTWO AND #EATINGFOR2 ARE USED ON INSTAGRAM: A CONTENT ANALYSIS OF PREGNANCY POSTS

Valeria Herrera, BS, RDN¹, Emily Zimmer, Student², Brooke Libby, MPH³, Madison Bracken, MA⁴, Tiffany A. Moore Simas, MD, MPH, MEd⁵, Sherry Pagoto, PhD⁶, Molly E. Waring, PhD⁶

¹University of Connecticut, Hartford, CT; ²University of Connecticut, Monroe, CT; ³University of Connecticut, Groton, CT; ⁴University of Connecticut, West Hartford, CT; ⁵UMass Medical School/UMass Memorial Health Care, Upton, MA; ⁶University of Connecticut, Storrs, CT

The idea that pregnant women should be “eating for two” may contribute to overeating and subsequently excessive gestational weight gain. The majority of young women use Instagram, and pregnancy is a common topic of discussion. Social media posts may influence perceived norms for eating during pregnancy. We examined Instagram posts that included “eating for two” hashtags to understand the extent to which they may be conveying unhealthy dietary habits during pregnancy. We sampled public English-language Instagram posts about diet, physical activity, or weight gain in pregnancy that included #eatingfortwo or #eatingfor2 in fall 2018 and extracted post data from the Instagram API using Python. We reviewed the post image, text, hashtags, and the user’s profile to conduct a content analysis to identify themes of how these hashtags were used; we also coded whether the user was pregnant and whether accompanying images depicted a pregnant woman (100% double-coded; 85–99% agreement; consensus reached via discussion). Of the 201 pregnancy posts sampled, 39 were no longer accessible at the time of content analysis, resulting in an analytic sample of 162 posts. The majority (73%) of posts were posted by pregnant women, and 30% of posts included a photo of a pregnant woman. Posts fell into six themes: attempting to eat healthy/consume needed nutrients for the baby (25%), encouraging/sharing overeating or unhealthy dietary intake (9%), specifically referencing pregnancy cravings (8%), blaming the baby for unhealthy or excessive intake (2%), actively refuting the idea that “eating for two” means drastically higher calorie intake during pregnancy (1%), and posts not referencing energy intake or healthfulness of pregnancy diet (55%). Posts were posted by 130 users (92% posted 1 post) with median 559 followers (IQR: 238–1388; range: 21–1712601); 12% had 10,000+ followers. All posts were liked (median [IQR]; range: 40 [23–61]; 5–10714 likes per post) and 71% were commented on by at least one other account (median [IQR]; range: 2 [1–5]; 1–286 users per post with others commenting). Instagram posts that include #eatingfortwo or #eatingfor2 include both healthy eating intentions and promotion of eating behaviors that may contribute to excessive gestational weight gain. Future research should explore how Instagram posts influence perceived eating norms during pregnancy and how this platform could be leveraged to disseminate evidence-based public health nutrition messaging.

INTERVENTIONS FOR PROBLEMATIC SMARTPHONE USAGE IMPROVE WELL-BEING

Robert M. Montgomery, M.A. Candidate¹, Abraham Rutchick, Ph.D.²¹CSU Northridge, Los Angeles, CA; ²CSU Northridge, Department of Psychology, Northridge, CA

Smartphones occupy more time and attention than ever before. Although the scientific study of smartphone usage is still in its early stages and contains numerous ambiguities and contradictions, a growing body of research suggests that smartphone use can be problematic. The present study experimentally examined the efficacy of an intervention package designed to help users reduce problematic usage by promoting more intentional interaction with their devices. Specifically, the impact of the intervention was measured for a variety of outcomes including subjective well-being, objectively measured smartphone usage and problematic smartphone usage. A sample of 174 participants (75.3% female, 54.6% Hispanic or Latino) aged 18 to 51 ($M=23.49$) were randomly assigned to either an active usage monitoring group (control, $n = 93$) or to concurrently implement three settings changes (treatment $n = 81$): (1) turn off most notifications, (2) move all non-tool applications from the homescreen, and (3) turn the phone to grayscale. The three-week treatment period was preceded by a three-week baseline period during which usage data was collected. Participants in both conditions monitored their usage with smartphone applications. Relative to the control condition, participants in the treatment condition reported improvements in self-reported physical health, $F(1,172)=10.44$, $p=.001$, and mental health $F(1,172)=3.99$, $p=.047$, and reduced automaticity of phone use $F(1,172)=4.173$, $p=.043$, from pre- to post-intervention. Additionally, for the treatment group, reductions in automaticity mediated reductions in smartphone addiction, anxious attachment, and distraction. Notably, neither daily minutes of phone use nor the number of times the phone was unlocked was impacted by the intervention package. It therefore appears possible to achieve a more deliberate style of smartphone usage through the implementation of simple settings changes without restricting usage and with positive implications for subjective well-being. Exploratory results from a four-week follow up also support this conclusion. Participants who implemented interventions throughout the follow up period retained treatment gains, whereas those who reverted to their normal settings did not. These findings contribute to an emerging literature that demonstrates the importance of considering not only the content and quantity of technology use, but also the manner in which it is used.

ECOLOGICAL MOMENTARY ASSESSMENT OF AFFECTIVE RESPONSE DURING PHYSICAL ACTIVITY: DIFFERENCES BY SUBJECTIVE WELL-BEING

Bridgette Do, MPH¹, Tyler B. Mason, PhD², Sydney Miller, B.S.², Genevieve F. Dunton, PhD, MPH²¹University of Southern California, Santa Monica, CA; ²University of Southern California, Los Angeles, CA

Physical activity promotion remains a national priority for research and intervention. Affective response during physical activity may influence the likelihood of engaging in future activity. However, there is considerable between-variation in how individuals emotionally respond to physical activity. An individual's overall trait-like affect profile (e.g., subjective well-being) may partially explain this variation. However, prior studies on affective response during physical activity have not addressed this question. The current study utilized ecological momentary assessment (EMA) to examine within-subject differences in affective response during physical activity in naturalistic settings by subjective well-being. Participants included 114 adults ($M_{\text{baselineage}} = 40.3$, 72% females) who completed three semi-annual EMA measurement bursts that each lasted four continuous days. Participants responded to eight random EMA survey prompts a day on a smartphone; surveys assessed current activity level (i.e., physically active vs. not physically active), positive affective response (i.e. happy, cheerful, calm/relaxed), and negative affective response (i.e., tense/anxious, stressed, sad/depressed, frustrated/angry). Paper questionnaires assessed trait-like positive affect (i.e., subjective well-being using the Satisfaction With Life Scale) at the beginning of each measurement burst. Separate multi-level models examined whether burst-level subjective well-being moderated the within-subject associations between activity level and concurrent affective response, controlling for day of the week, time of day, gender, age, and activity intensity (measured by a waist-worn Actigraph GT2M accelerometer). Negative affective response during physical activity (vs. non-physical activity) was lower when individuals had greater subjective well-being ($p < 0.01$). However, subjective well-being did not moderate differences in positive affective response during physical activity (vs. non-physical activity) ($p > 0.05$). Individuals with low subjective well-being may be especially vulnerable to experiencing physical activity negatively, and therefore may not benefit from exercise interventions that seek to reduce trait-like negative affect (e.g., depression). For individuals with low subjective well-being, interventions should consider prescribing activities that maximize positive affective response in order to increase adherence and support behavior maintenance.

EVALUATING THE IMPACT OF TIME, DEMOGRAPHIC, AND SOCIAL EFFECTS ON COMPLIANCE TO EATING EVENT-TRIGGERED EMA SURVEYS IN FAMILIES

Brooke M. Bell, B.A.¹, Abu Sayeed Mondol, MS², Meiyi Ma, n/a², Ridwan Alam, n/a², Ifat A. Emi, n/a², Kayla de la Haye, PhD³, John Lach, PhD⁴, John Stankovic, PhD⁵, Donna Spruijt-Metz, MFA, PhD³

¹University of Southern California, Beverly Hills, CA; ²University of Virginia, Charlottesville, VA; ³University of Southern California, Los Angeles, CA; ⁴The George Washington University, Washington, DC; ⁵University of Virginia, Earlysville, VA

Background: Novel data collection methodology such as ecological momentary assessment (EMA) can be used to collect data in context and in real-time. Despite its advantages, participant noncompliance is a potential limitation to using EMA. Compliance to EMA prompts can vary among different populations, and a recent review indicates that compliance rates for youth are suboptimal. Additionally, the evaluation of compliance to EMA methodology used in family-based studies has not yet been examined. This study proposes to evaluate the impact of (i) time, (ii) demographic, and (iii) social factors on compliance to event-triggered EMA surveys in a family-based study.

Methods: The Monitoring and Modeling Family Eating Dynamics (M2FED) study installed a cyber-physical system, which incorporated wearable sensors and smartphones, for a 2-week period in multiple family homes. In each family, there were 3 or more multi-generational participants (aged 11 years and up), each of whom wore a smartwatch that automatically detected eating events occurring in the home. An event-based EMA sampling protocol was used to send brief surveys to participants' smartphones shortly after an eating event was detected. For this study, the unit of analysis was every eating event-triggered EMA survey that was sent to and received by participants' smartphones throughout the span of the study (n=591). Compliance was recorded as "1" if the survey was answered, and as "0" if the survey was not answered. Logistic regression models were used to determine whether time (time of day: morning/afternoon/evening), demographic (gender: male/female; family role: parent/child), and social factors (whether *another* participating family member *j* had answered a survey that had been received within 15 minutes of focal person *i*'s survey) affected the likelihood of a survey being answered.

Results: The data in this study come from 19 families (total of 55 participants), the majority of whom identified as Hispanic or Latino (60.0%). 591 eating event-triggered surveys were sent and received. On average, the mean participant compliance rate was $M=71.5\%$ ($SD=28.8\%$, $Min=0\%$, $Max=100\%$). An EMA survey was 2.4 times as likely to be answered if another family member had answered a survey within 15 minutes ($p=0.0037$). Time of day, gender, and family role were not significant predictors.

Conclusion: These results suggest that family members and other social relations may be leveraged to increase compliance in future EMA studies.

EFFECTS OF GAMIFYING PHYSICAL ACTIVITY ON MOTIVATIONS TO BE PHYSICALLY ACTIVE: A CLUSTER RANDOMIZED CONTROLLED TRIAL

Kristen L. Wilburn, DPT¹, Chih-Hsiang Yang, PhD², Gabrielle Turner-McGrievy, PhD, RD², Ricarda K. Pritschmann, M.S., CHES³, Danielle E. Jake-Schoffman, PhD³, Courtney Monroe, PhD, EP-C⁴

¹Arnold School of Public Health, University of South Carolina, Columbia, SC; ²University of South Carolina, Columbia, SC; ³University of Florida, Gainesville, FL; ⁴Arnold School of Public Health, University of South Carolina, Columbia, SC

In contrast to controlled motivations (i.e., extrinsic and introjected), autonomous motivations (i.e., intrinsic, integrated, and identified), are more consistently associated with regular physical activity (PA). Gamification is increasingly being leveraged as a promising strategy to promote PA, but its impact on motivation for PA remains underexplored. This study examined the effect of adding gamification elements to a theory-based PA intervention on changes in motivations among insufficiently active adults. Participants were randomized as self-selected teams of 3-8 individuals to a 12-week technology-mediated PA intervention (TECH: n=59 participants; 12 teams) or the same intervention plus a real-time PA competition and gamified challenge characterized by a storyline, levels, and points (TECH+G; n=57 participants; 12 teams). Linear mixed effects models were fitted to test baseline to 12-week and 1-year changes in motivations (Behavioral Regulation in Exercise Questionnaire-3; score range: 0[low]-4[high]). For context, both groups had similar increases in mean accelerometer-measured daily steps and minutes of moderate-to-vigorous physical activity from baseline to 1-year. At baseline, participants (M age=40.1±10.3 years; 78% female) had low-to-moderate levels of intrinsic (TECH: 1.8±0.9; TECH+G: 2.3±1.0), integrated (TECH: 1.4±0.9; TECH+G: 1.6±1.0), and identified (TECH: 2.4±0.8; TECH+G: 2.7±0.7) motivations. Both groups had significant increases ($ps < 0.05$) from baseline to 12 weeks in intrinsic (TECH: 0.2±0.7; TECH+G: 0.2±0.5), integrated (TECH: 0.3±0.7; TECH+G: 0.5±1.0), and identified (TECH: 0.3±0.9; TECH+G: 0.2±0.8) motivations, with no between group differences ($ps > 0.05$). Relative to baseline, integrated motivation was significantly higher at 1 year (TECH: 0.2±0.7; TECH+G: 0.4±0.8, $ps < 0.05$), with no between group differences ($p > 0.05$). A significantly greater increase in introjected motivation was observed for TECH vs. TECH+G from baseline (1.7±1.0 vs. 1.9±1.0) to 1 year (2.2±1.1 vs. 1.9±1.0), $p < 0.01$. Adding gamification elements to a technology-delivered PA intervention among teams of adults with existing social ties improved autonomous motivations in the short-term, albeit not to a greater extent than the same intervention without gamified elements. Notably, gamification did not prompt increases in controlled motivations for PA. Testing the effect of specific gamification elements that may best enhance autonomous motivations for PA is warranted.

A VIRTUAL GENETIC COUNSELOR FOR BREAST CANCER GENETIC RISK COMMUNICATION

Shuo Zhou, MS¹, Timothy Bickmore, PhD²¹Northeastern University, West Roxbury, MA; ²Northeastern University, Boston, MA

Introduction: Effective genetic risk communication has been increasingly important for disease prevention and behavior change. Yet understanding and acting on genetic risks can be challenging due to the complexity of the information, especially for individuals with limited health literacy or numeracy. Many individuals do not have access to genetic counselors due to various logistical barriers. We developed a computer animated virtual genetic counselor for hereditary breast cancer, and conducted a pilot study to assess its feasibility and acceptability.

Methods: We conducted a quasi-experimental study with 12 female participants, aged 21-63 years; 41.7% white, 25% Hispanic, 16.7% black, & 16.7% Asian; and 16.7% with limited health literacy (based on the Newest Vital Sign). Participants were asked to interact with the virtual counselor in a single 30-minute session. Measurements included post-test satisfaction and intent to follow the recommended guidelines for breast cancer screening (single item 7-point scales), and pre-post breast cancer genetics knowledge (range 1-11).

Results: Participants' post-treatment scores for the composite knowledge scale (mean=9.8, SD=0.9) significantly increased compared with their pre-treatment scores (mean=4.9, SD=2.2), paired $t(11) = -7.01$, $p < .001$. Participants were satisfied with the virtual counselor (mean=6.2, SD=0.6), and the counseling experience (mean=6, SD=0.7). They liked the virtual counselor (mean=5.6, SD=0.9), trusted her (mean=6.1, SD=1.0), were willing to continue working with her (mean=5.5, SD=1.1), and found her knowledgeable (mean=6.4, SD=0.5). One-sample Wilcoxon signed rank tests demonstrated that all single item median scores were significantly greater than neutral scores of 4 ($p < .01$ for all scales).

When asked how much information they received during the session, participants' ratings (mean=4.1, SD=0.8) indicated it was just right: neither too much nor too little (based on one sample Wilcoxon tests, $p < .01$). Participants were willing to follow the recommended guidelines for breast cancer screening (mean=6, SD=0.9), and willing to talk more about genetic risks with their doctor (mean=6.5, SD=0.7). These scores were also significantly greater than neutral scores of 4 ($p < .01$ for all scales).

Conclusion: Our results show that the virtual genetic counselor is well accepted, and is effective in educating participants about breast cancer genetics. Future research will focus on dynamically tailoring dialogue to participants' personal traits and comprehension assessed during the interaction.

FEASIBILITY OF USING 'SMARTER' METHODOLOGY TO UNDERSTAND PRECIPITATING CONDITIONS FOR PEDIATRIC MIGRAINE EPISODES

Mark A. Connelly, PhD¹, Madeline Boorigie, BA, CCRP²¹Children's Mercy Kansas City, Kansas City, MO; ²Children's Mercy, Kansas City, MO

Background: and Aims: Migraine is a common neurological disease often beginning in childhood for which recurring episodes of often debilitating headaches are thought to be potentially triggered by certain stimuli. Identifying the conditions that suggest an episode of migraine may be forthcoming is a requisite step toward developing next generation "just in time" behavioral treatments with the capacity to prevent migraine attacks. Toward this end, in this study we aimed to first evaluate the feasibility in children of a methodology (Sensor-based Mobile Assessment and Real-Time Ecological Reporting) that may have potential for identifying precipitating conditions for migraine occurrence.

Method: In a sample of 30 consenting youth ages 10-17 with migraine recruited through a headache clinic, smartphones supplemented with a wrist-worn biosensor were used to collect contextual data over a period of 4 weeks. Self-reported data were collected in 4 epochs per day using custom real-time reporting software and included information on headache (e.g., time of onset, intensity), lifestyle (e.g., perceived level of physical activity and stress), and environment (e.g., perception of light and noise level). Data derived from the wearable biosensor included information on autonomic arousal and physical activity, and built-in sensors on participants' phones were used to indicate location and to quantify the sensory environment (e.g., ambient noise and light levels). Participant acceptability via an end-of-study survey, and implementation fidelity of the SMARTER methodology, were assessed to evaluate feasibility.

Results: Complete self-report data were obtained on a mean of 88% of days ($SD = 22.4\%$) and at a mean of 77% of moments ($SD = 24.5\%$). Data from the wearable biosensor were obtained for a mean of 18.7 hours per day worn ($SD = 2.3$ hours), with participants on average wearing the sensor on 21 days ($SD = 9.9$). Objective data on sensory environment (ambient light and sound) and other environmental conditions (temperature, precipitation, and air pressure) derived from built-in phone sensors could only be obtained from 17-73% of participants' own phones. Most participants (64-100%) responded with at least "somewhat agree" to questions about acceptability of the study methods, but 18-23% indicated difficulties with burden and remembering to wear the sensor. All but one participant (97%) endorsed interest in being able to receive a notification about when a migraine might occur.

Conclusions: A contemporary data sampling approach comprising ambulatory sensors and real-time reporting appears to be acceptable to most youth with migraine and may enable novel methods of predicting and preventing symptom occurrence in the future. However, use of built-in sensors on children's own phones for passive data collection appears to be unlikely to produce adequately reliable data for building predictive models.

USING A USER-CENTERED CLINICAL DESIGN SUPPORT TOOL TO REDUCE HIGH COST MEDICATION UTILIZATION

Felicia Mendoza, n/a¹, Sara Chokshi, DrPH², Lisa Anzisi, BS, RPh, MS, PharmD, BCPS³, Adam Szerencsy, DO⁴¹NYU Langone Health, New York, NY; ²NYU Langone School of Medicine, New York, NY; ³NYU, New York, NY; ⁴NYU Langone Health, Lake Success, NY

Background: Per capita spending on prescription drugs is the highest in the United States amongst all other countries. As value-based programs continue to shape the evolution of healthcare systems, new payment models that reward cost reductions in medication spending are emerging. Clinicians are key drivers in prescribing high-cost medications and may be unknowingly prescribing generic formulations that are more expensive than their brand alternatives. The electronic health record (EHR) can be leveraged to point clinicians to more cost-effective options. Previous studies indicate medication cost transparency EHR alerts can reduce prescriptions for high-cost medications, but little evidence shows which alerts are the most effective. User-centered design is an approach that can be employed to impact the effectiveness of such clinical decision support system.

Objective: The purpose of this study was to determine if a user-centered clinical decision support tool delivered at time of prescription led clinicians to reduce their utilization of high-cost medications.

Materials and Methods: The tool was deployed to ambulatory practices, including primary and specialty care clinics, across a single health system from October 2017 through January 2018. Utilizing principles of user-centered design, tool development incorporated considerations of provider motivations around prescribing behavior and analysis of current workflows. Four high cost medications classes were selected for the alert based on similarities to available lower cost alternatives. The tool featured a modification in the standard provider and system-level medication preference list, removing high-cost agents and substituting them with lower cost alternatives, and an alert that suggested lower cost alternatives when a medication among 4 high cost medication classes were ordered.

Results: Three of the four medication classes showed a reduction in utilization post intervention. As expected, acceptance rates of lower cost alternatives were higher when a direct match of dose and frequency existed. There was no significant difference in acceptance rates between primary care providers and specialists.

Conclusion: Findings suggest that clinical decision support can be effectively leveraged for reducing prescription of high cost medications and provide a framework for future implementation. Further research is needed to understand the gaps in disparate claims data.

MULTIMORBIDITY AND USE OF MHEALTH TO TRACK PROGRESS ON HEALTH GOALS: RESULTS FROM THE HEALTH INFORMATION NATIONAL TRENDS SURVEY

Camella Rising, PhD, MS, RDN¹, Roxanne Jensen, PhD², Richard P. Moser, PhD³, April Oh, PhD, MPH⁴¹National Cancer Institute, Division of Cancer Control and Population Sciences, Behavioral Research Program, Health Communication and Informatics Research Branch, Rockville, MD; ²National Cancer Institute, Rockville, MD; ³National Cancer Institute/Behavioral Research Program, Rockville, MD; ⁴NIN/NIC/BRP/HCIRB, Rockville, MD

Background: Many U.S. adults, especially those ≥ 50 years old, have at least one chronic medical condition. Using mhealth technologies such as smartphone apps to set and track goals (e.g., losing weight, quitting smoking) may help people manage these conditions. However, prior research suggests that some mhealth users with a chronic condition track health or behaviors without tracking progress on health goals, which theoretically grounded mhealth intervention research suggests could have negative implications for health and behavioral outcomes (e.g., blood glucose management, increased physical activity). Since multimorbidity is increasing with aging of the population and people with multiple conditions may especially benefit from goal setting, additional research is needed to examine how use of mhealth to track health goals varies by number of conditions. Therefore, the aim of this study is to describe use of mhealth to track health goals in a nationally representative sample of U.S. adults ≥ 50 years old with at least one chronic condition by comparing those with one vs. two or more conditions, while controlling for age.

Methods: We analyzed combined data from the 2017 and 2018 National Cancer Institute Health Information National Trends Survey (N=6,789). We created a self-reported morbidity count (1, 2+) for diabetes, hypertension, cardiovascular disease, lung disease, and cancer (excluding non-melanoma skin cancer). Respondents ≥ 50 years old with at least one condition that reported use of smartphones, tablets, and/or other devices (e.g., Fitbits, glucometers) to track health or behaviors (n=291) were categorized into two groups: (1) “goal trackers” (n=149) use apps to track progress on health goals and (2) “non-goal trackers” (n=142) do not use apps to track progress on health goals. Age in years was measured as a continuous variable (M=56.69, SD=16.45, Range=18-101). We used weighted logistic regression to analyze associations between number of conditions and use of mhealth to track health goals, controlling for age.

Results: U.S. adults ≥ 50 years old report having one (34.17%) or two or more (61.82%) of the five chronic conditions. Goal trackers (56.25%) make up more than half of adults ≥ 50 years old with at least one chronic condition. Compared to adults ≥ 50 years old with one condition, those with two or more conditions have more than two times the odds of being non-goal trackers than goal trackers, controlling for age (OR=2.44, 95% CI=1.08, 5.53, p=.032).

Conclusion: Findings revealed that multimorbidity is associated with not using mhealth to track progress on health goals among adults ≥ 50 years old who use mhealth to track health or behaviors. Future studies could consider gathering the perspectives of older age mhealth users, particularly those with multiple conditions, to identify ways to facilitate and increase use of mhealth technologies to track progress on health goals.

USABILITY AND ACCEPTABILITY OF A REAL-TIME MOBILE INTERVENTION TO REDUCE SEDENTARY BEHAVIOR BEFORE AND AFTER CANCER SURGERY

Carissa A. Low, PhD¹, Michaela Danko, BS, BA¹, Krina C. Durica, M.A.¹, Raghu Mulukutla, n/a², Yiyi Ren, n/a², Elynn B. Youm, BA³, David L. Bartlett, MD¹, Dana H. Bovbjerg, PhD¹, Anind K. Dey, PhD⁴, John M. Jakicic, PhD¹

¹University of Pittsburgh, Pittsburgh, PA; ²Carnegie Mellon University, Pittsburgh, PA; ³Vitalant - HCWP, Pittsburgh, PA; ⁴University of Washington, Seattle, WA

Background: Sedentary behavior (SB) is common after cancer surgery and may negatively affect recovery and quality of life, but postoperative symptoms (e.g., pain) can be a significant barrier to patients achieving recommended physical activity levels. We conducted a single-arm pilot trial evaluating the usability and acceptability of a real-time mobile intervention that detects prolonged sedentary behavior in the perioperative period and delivers prompts to walk that are tailored to daily self-reported symptom burden.

Methods: Patients (N = 15; M = 49.3 years old, range 25-65; 71% female) scheduled for abdominal cancer surgery consented to the study, which involved using a Fitbit smartwatch with a companion smartphone app across the perioperative period (from a minimum of 2 weeks before surgery [M=26 days preop] through 30 days post-discharge; M=66 total days using the intervention, M = 10 day in-patient stay). Participants received prompts to walk after any SB that exceeded a prespecified threshold, which varied from day to day based on patient-reported symptom severity. Participants also completed weekly semi-structured interviews to collect information on usability, acceptability, and experience using the app, and smartphone and smartwatch logs were examined to assess participant study compliance.

Results: Of eligible patients approached, 79% agreed to participate. Attrition was low (n = 1, 7%) and due to poor health and prolonged hospitalization. Participants rated (0-100) the smartphone and smartwatch apps as very easy (M = 93.7 and 94.1, respectively) and pleasant to use (M = 94.1 and 93.8, respectively). Overall satisfaction with the whole system was 90.6, and the mean System Usability Scale score was 83.8. Overall compliance with symptom reporting was 53%, decreasing significantly from before surgery (73% of all days) to inpatient recovery (32%) and post-discharge (41%). Overall Fitbit compliance was 76% but also declined from before surgery (96%) to inpatient (60%) and post-discharge (63%). Post-discharge Fitbit compliance was significantly lower among the seven patients who were readmitted (44%) than in the seven patients not readmitted (80%).

Conclusions: Perioperative cancer patients were willing to use a smartwatch- and smartphone-based real-time intervention to reduce SB, and they rated the apps as very easy and pleasant to use. Compliance with the intervention declined significantly after surgery, especially among patients who were readmitted. The effects of the intervention on postoperative activity patterns, recovery, and quality of life will be evaluated in an ongoing randomized trial.

HOW KROGER'S OPT-UP(R) NUTRITION SCORING TOOL TAKES A BIG BITE OUT OF IMPROVING GROCERY CHOICES

Samuel Kramer, MS, RD, CSSGB, LD, CISSN¹, Allison Baker, MS, RD, LDN, CSSYB²

¹The Kroger company, Cincinnati, OH; ²The Kroger Company, Cincinnati, OH

Introduction: Eating “healthy” has become a dynamically complex challenge. Customers desire autonomy, but also seek purchasing guidance with the inundation of conflicting information available. Kroger's proprietary nutrition scoring tool, Opt-Up, has revolutionized grocery shopping behavior by objectively rating foods on a scale of 0-100 by factoring nutrient density. These categories can be further broken down into green, yellow, and red food categories. Green indicates an Opt-Up score between 71 – 100; yellow 36 – 70; red 1– 35. To generate this singular food score, positive points are given for protein, fruits, nuts, vegetables, and fiber. Negative points are distributed for saturated fat, sugars, sodium, and Calories. Customers can continuously improve their basket and overall score (recommended is 600 on a scale of 0-1000). Most importantly, shoppers have access to Nutrition Information, “Better For You” purchases, and various personalized dietary tags (i.e. Paleo, vegan, Gluten-Free, Keto-Friendly, etc). In turn, Kroger can utilize these data to personalize needs in order to increase customer loyalty, assortment quality and price satisfaction.

Methods: All User participants (n = 19,824) were stratified into three groups: Heavy Users (n = 3,752) (1+ average visits/week), High Health (n = 4,575) (high value on health), and Low Health (n = 3,595) (lower value on health). A control group was implemented that did not utilize the app. Data was analyzed using a 14-week utilization period.

Results: On average, all groups improved their Opt-Up Score better than the control. More specifically, all users increased their score by 13 points with 31% of those households seeing an increase in their score by 30 points, compared to only 26% in the control group. The highest increase was seen in the Heavy Users (22 points compared to the control) and the highest score was in the High Health Group (665 compared to 648 in control). In general, households were shown to increase their purchase of green and yellow products, including produce, while decreasing their purchase of red products (p < 0.05).

Discussion: Utilizing Kroger's Opt-Up nutrition scoring tool has demonstrated to effectively improve customer purchasing behavior towards more nutrient-dense foods. Customers are also shifting away from foods that are lacking in beneficial nutrients. Users are empowered to make their own choices, track their progress simply, and gain insightful knowledge by making cost-effective feasible changes to their diet choices. Perhaps the Opt-Up tool provides people with a greater internal locus of control and therefore can determine their own outcomes of health and desire to purchase nutrient-dense foods. Furthermore, Opt-Up facilitates progress by providing intrinsic motivation to achieve greater health and/or provide for the family and extrinsic motivation to achieve a higher overall score.

RESPONSE PATTERNS AND PRELIMINARY EFFECTS OF A CARE-GIVER TEXT MESSAGE INTERVENTION TARGETING SUGARY BEVERAGES IN RURAL SCHOOLS

Maryam Yuhas, PhD, RD¹, Annie Loyd, MPH, RDN, CHES¹, Brittany A. McCormick, MPH², Kathleen J. Porter, PhD, RD¹, Lee M. Ritterband, PhD³, Philip Chow, PhD¹, Deborah F. Tate, PhD⁴, Jamie Zoellner, PhD, RD¹

¹University of Virginia, Christiansburg, VA; ²University of Virginia, Forest, VA; ³University of Virginia School of Medicine, Charlottesville, VA; ⁴University of North Carolina, Chapel Hill, NC

Relative to national estimates, adolescents in rural Southwest Virginia region are consuming four times more sugar-sweetened beverages (SSB). Kids SIPsmarter is a middle school-based intervention addressing this major public health issue. As part of a multilevel approach, caregivers are engaged through a 6-month interactive text messaging program, that parallels their child's school-based curriculum. While using text message strategies to reach and engage caregivers are promising, understanding response parameters can provide insight to further improve user engagement. Therefore, the objective of this study was to use year one results from two middle schools to explore the response patterns and preliminary effects of the intervention. Caregivers received educational and personalized strategy messages twice a week and assessment messages that measured daily SSB frequency among the caregiver and child every five weeks. The text messaging software used responses to categorize SSB consumer types (i.e., parent/child, consumer/non-consumer), provide feedback, and allow for an SSB reduction strategy selection. The five assessment points were used to examine response rates, impact of reminders, time to response, changes in SSB intake patterns and frequency, and changes in strategy selection. Of 264 eligible caregivers, 94 (36%) enrolled in the intervention. Average response rate was 84%. Of the responders, 59% replied on the first attempt. Subsequent reminders increased responses by 13%, 9%, and 7% respectively. Around 94% of responses were received within 24 hours. At baseline, 60% of caregivers fell into both (caregiver and child) SSB consumers category and 13% were both non-consumers. By the final assessment, both consumers dropped to 32% and both non-consumers increased to 42%. From baseline to final assessment, frequency of SSB per day significantly decreased among caregivers (-0.3, SE=0.06)($p < 0.001$) and children (-0.2, SE=0.05)($p < 0.001$). Of the available strategy options, "tasty alternatives" was the top selected, followed by "breaking the habit", and "home/shopping tips". This study helps understand how rural caregivers respond to periodic assessment messages and provides guidance for future cohorts. Approximating the time to response and the impact of reminders has helped optimize the use and timing of text based assessments and reminders. Future research should examine a combination of both subjective and objective criteria to obtain better insight into text message engagement in rural communities.

TAILORED IVR & SMS INTERVENTION TO SUPPORT MEDICATION ADHERENCE. A FEASIBILITY RANDOMISED CONTROLLED TRIAL.

Katerina Kassavou, PhD¹

¹The University of Cambridge, Cambridge, England, UK

Objectives: The aim of this trial was to assess the feasibility and potential efficacy of the Medication Adherence for Patient Support (MAPS) intervention to improve treatment adherence in patients with hypertension, or comorbidities of hypertension, type 2 diabetes and/or cholesterol, compared to usual care.

Setting: UK primary care setting (5.7% uptake to invitation).

Participants: Patients presumed to be non-adherent to prescribed medications were eligible for inclusion. In total 140 patients (46% female, 64.3% between 50-79 years old) were randomly allocated to intervention (n=84) or control group (n=56), of whom 133 completed the intervention and 119 completed the study follow up measurements.

Intervention: MAPS was a highly tailored interactive voice response and text messaging intervention delivered to patients' phones for a duration of three months, after a baseline consultation with a health care facilitator.

Primary and secondary outcome: The primary outcome was change at three months follow up in blinded practice records of repeat prescription and unblinded patient report of days of adherence. Secondary outcome included changes in systolic blood pressure, glucose levels, and quality of life at three months follow up. We also examined treatment fidelity and engagement.

Results: medication adherence was significantly improved at the intervention group compared to the control group ($t=2.27$, $p=0.025$). Systolic blood pressure was 0.56 mmHg (95%CI -7.423 to 6.301) and HbA1c was 4.5 mmol/mol (95%CI -13.099 to 4.710) lower at the intervention group compared to the control group. Intervention drop out was 2.5%; whereas treatment fidelity was 97% and treatment engagement 47%.

Conclusions: MAPS is a low-burden and potentially very low-cost addition to usual care that can increase access to advice and support treatment adherence with fidelity of message receipt; and shows promise as a nonpharmacologic treatment option for primary care programs. Future research is needed to evaluate the intervention effectiveness and cost-effectiveness.

CHANGING DRIVER BEHAVIOR DURING FLOODS: TESTING A NOVEL E-HEALTH INTERVENTION USING IMPLEMENTATION IMAGERY

Kyra Hamilton, PhD¹, Jacob J. Keech, BPsych(Hons), PhD Candidate², Amy E. Peden, PhD³, Martin S. Hagger, PhD⁴¹Griffith University, Mt Gravatt, Queensland, Australia; ²Griffith University, Mt Gravatt, Brisbane, Queensland, Australia; ³University of New South Wales, Kensington, Sydney, New South Wales, Australia; ⁴University of California, Merced, Merced, CA

Objective: Drowning is the third leading cause of injury-related death. Activities such as driving through floodwater are commonly reported behaviors that precede drowning. In Australia, more than half of flood-related drowning deaths are the result of driving through floodwaters. Drawing upon our previous research, the current pre-registered study aimed to develop and evaluate a theory-based behavioral intervention employing a novel implementation imagery technique to promote safer intentions and beliefs regarding driving through floodwaters.

Methods: The study adopted a randomized controlled trial design. Participants were Australian residents holding a driver's license ($N = 460$) and quotas were used to recruit a sample with similar demographic characteristics to proportions of flood-related transport deaths in the Australian population. The study was registered on the ANZCTR clinical trials registry prior to data collection (ACTRN12618001212246). A rigorous lab-based pilot process involving qualitative interviews was undertaken prior to the trial. The control (publicly available information about the risks of driving through floodwater) and intervention (control stimuli + implementation imagery exercises) condition stimuli were delivered online using videos. Measures were taken pre-intervention, immediately post-intervention, and at a one-month follow-up. Data were analyzed using mixed design ANOVAs and Johnson-Neyman moderation analyses using the Process Macro.

Results: The intervention reduced intentions and subjective norms regarding driving through floodwater, and improved action planning regarding avoiding driving through floodwater. The control condition also improved on intentions and subjective norms post-intervention, but effects were only retained at the follow-up for the intervention group. Further analyses indicated that the intervention showed effects on post-intervention perceived behavioral control, perceived severity, anticipated regret, and barrier self-efficacy in individuals who had a modest level of intention or willingness to drive through floodwater at baseline.

Conclusions: The implementation imagery intervention is a promising approach for creating changes, at least in the short term, in some psychological constructs that are associated with driving through floodwater. Further research is needed to evaluate this intervention in "real-world" settings and to examine effects on actual behavior among drivers with at least some level of intention to drive through floodwater.

EXTENDING SYSTEMS THINKING TO TOOLS: AN EVALUATION FRAMEWORK SUPPORTING DIABETES AND HEART DISEASE PREVENTION AND MANAGEMENT

Jennifer Mandelbaum, MPH¹, Kristian G. Myers, MPH, CHES², Tramaine McMullen, MPH³, Courtney L. Brightharp, MPH³, Kelly Kavanaugh, MPH, CHES³¹University of South Carolina, Columbia, SC; ²S.C. Dept. of Health & Environmental Control, Columbia, SC; ³S.C. Dept. of Health and Environmental Control, Columbia, SC

Background: Systems thinking is a concept that acknowledges public health approaches as dynamic and interconnected, governed by feedback, actions, and reactions of stakeholders. Despite its promise, a major challenge remains in operationalizing the concept of systems thinking into tools critical for implementation and evaluation. This work aims to illustrate the value of systems thinking in the development of a multilevel evaluation tool. This tool was developed for a statewide approach targeting diabetes and heart disease prevention and management in underserved counties in South Carolina.

Methods: South Carolina adopted a developmental evaluation framework to support systems thinking and improve the state's efforts with implementing and evaluating two complex and complementary five-year cooperative agreements. To demonstrate a systems thinking approach, an evaluation tool was created to acknowledge the contribution of state-, partner-, and health system-level roles in the implementation of chronic disease prevention and management activities. South Carolina hypothesizes that this systems thinking evaluation tool will enhance their ability to demonstrate results based on the stage of implementation and support sustainability of program activities.

Results: Systems thinking was applied to develop an evaluation tool with questions addressing approach, efficiency, effectiveness, sustainability, and impact of program activities. Indicators were developed to capture barriers, facilitators, and interdependent activities at various levels that address medication therapy management, lifestyle change programs, and adoption of electronic health record modifications to support evidence-based quality measurement. Data from this tool will be used to evaluate progress and monitor continuous quality improvement opportunities.

Conclusion: Addressing the complex nature of chronic disease prevention and management requires a systems thinking approach. This evaluation tool realistically demonstrates how to apply systems thinking in public health practice. Future steps include creating a conceptual model that captures and maps key interrelationships that influence health outcomes. This conceptual model may be used to effectively communicate how systems thinking is being applied to increase partner engagement and buy-in, therefore aiding in the elimination of siloed thinking and supporting sustainability.

INTEGRATING WEIGHT GAIN PREVENTION WITHIN PRIMARY CARE: A QUALITATIVE EVALUATION OF THE IMPLEMENTATION OF BALANCE/EQUILIBRIO

Miriam Berger, MPH¹, Cayla Treadway, B.A.², Dori Steinberg, PhD, RD¹, Sandy Askew, MPH³, Tia A. Willis, MPH¹, Gary Bennett, PhD¹¹Duke University, Durham, NC; ²Duke University, DURHAM, NC; ³Duke University, Ocoee, FL

Background: For patients with obesity struggling to lose weight, clinical guidelines recommend halting further weight gain, yet implementation of such interventions is lacking within primary care. To address this gap, we tested a bilingual weight gain prevention intervention, Balance/Equilibrio, using a randomized controlled effectiveness trial within Piedmont Health Services (PHS), a network of Federally Qualified Health Centers (FQHCs) in central North Carolina. Obtaining perspectives of diverse healthcare professionals can provide nuanced insight the implementation of such a trial and its pragmatic design.

Objective: The current qualitative study explores the barriers of and facilitators to the implementation of Balance from the perspectives of health system staff.

Methods: Participant recruitment was conducted through purposive sampling of health system employees from a variety of backgrounds. Two researchers conducted in-person/phone semi-structured qualitative interviews (n=18), which were digitally-recorded and professionally-transcribed verbatim. Interviews were double-coded for emergent themes by two independent researchers using NVivo 12 and reviewed by a third researcher; discrepancies in coding were discussed until consensus was reached. Responses were compared within and across participants to determine emergent themes.

Results: Mean participant age was 36.9 (± 9.7) years. The majority identified as female (89%) and non-Latino white (66%); 39% provided direct medical care to patients; and 44% had been PHS employees for ≥7 years.

Respondents discussed myriad challenges in implementing a digital obesity treatment within an overburdened FQHC system. Several providers spoke of treating patients with complex comorbidities during short outpatient appointments, interfering with patient referral to Balance. Staff turnover also reduced awareness of Balance; 33% of respondents knew little about the trial.

Despite these challenges, support for Balance was a common theme among the majority of respondents. Many described key trial strengths as the bilingual Spanish format and its pragmatic, adaptable research design. Several respondents felt that interventions like Balance could provide a reimbursable approach to manage weight-related conditions when considering Medicaid transformation into value-based care. Respondents praised Balance as a successful research collaboration that served the community by integrating within the healthcare system.

Conclusion: This qualitative study demonstrated that a pragmatic weight gain prevention treatment within FQHCs was well-received by health system leaders, although staff turnover created a barrier to awareness among some. Researchers considering obesity treatment interventions within community-based settings may want to consider a sustainable and integrated approach that is mission-driven.

USING A COMMUNITY-BASED PARTICIPATORY APPROACH TO IMPROVING FOOD AND PHYSICAL ACTIVITY ACCESS IN RURAL WV

Sam Zizzi, n/a¹, Karly Casanave, n/a¹, Kerry Gabbert, n/a¹, Emily C. Murphy, PhD¹¹West Virginia University, Morgantown, WV

The Be Wild, Be Wonderful, Be Healthy project is a five-year CDC funded project that aims to increase access to physical activity and healthy eating in rural West Virginia. The two counties chosen by the CDC have high rates of adult obesity (>40%) and low access to healthy food. The project is grounded in a community-based participatory approach, with university Extension agents as the key players in each county to help the research team build relationships with key informants and community members. The primary interventions focus on policy, systems, or environmental changes identified by community members and funded through contracts of approximately \$5,000. In year one, the research team conducted in-person meetings in each county along with 20 key informant interviews and a focus group. Then, 18 projects were funded to initiate changes in communities. Participants in the interviews and focus group included community members involved with food banks, senior centers, family nutrition programs, the Extension service, faith-based organizations, schools, and local government. Data from these interviews, the contract applications, and a community partner tracking form were analyzed to provide a summary of reach and effectiveness in year one for this study. Qualitative analysis of key informant interviews followed an interpretive phenomenological approach (Smith, Jarman, Osborn, 1999). Higher order themes identified during interview coding included community assets, opportunities, and barriers. Respondents highlighted people, places, and organizations as key assets in promoting physical activity and healthy eating. The primary barriers for physical activity were related to access or safety (e.g., few locations, lack of transportation, unsuitable built or natural environment). The barriers to healthy eating that respondents identified included limited access to fresh and affordable fruits and vegetables. The range of funded projects included efforts to build new trails, improve existing trails, and increase access to youth sports in the communities. For healthy food, partners focused on increased access or quality at food pantries, a senior center, low income housing and for backpack programs at schools. US Census and WV Department of Education data were used to generate denominators for population reach estimates for the implemented projects in each county. Based on these data, the combined intervention is estimated to have reached 9300 residents, or 34% of the total population. Additional components of the intervention that have yet to be evaluated include social media communications (@BeHealthyWV). Year 2 efforts will focus on expanding reach and sustaining successful projects by providing additional funding and linking partners together to form functional coalitions.

IMPLEMENTATION PROCESSES OF THE HEALTHY EATING HEALTHY AGING PROGRAM IN COMMUNITY-BASED ORGANIZATIONS

Judy Leong, BSN¹, SONIA BISHOP, BS², Sou Hyun Jang, Ph.D.¹, Eun Jeong Lee, Ph.D.³, Emily V. Brown, MPH², Wendy E. Barrington, PhD, MPH⁴, Linda K. Ko, PhD²

¹University of Washington, Seattle, WA; ²Fred Hutchinson Cancer Research Center, Seattle, WA; ³Asian American Resource and Information Network, Wood Ridge, NJ; ⁴University of Washington School of Nursing, Seattle, WA

Background: Heart disease is the second leading cause of death among older Asian Americans and Pacific Islanders (AAPIs). A community-academic partnership implemented an evidence-based heart health intervention focused on promoting healthy eating and healthy aging through community-based organizations (CBOs) serving older AAPIs. CBOs are critical settings for community health education. However, there is inadequate research examining how evidence-based intervention (EBI) are implemented in CBOs. This project examined processes that facilitated implementation of Healthy Eating Healthy Aging (HEHA) among CBOs serving older AAPIs.

Methods: We recruited 13 CBOs that implemented the HEHA program, where all the respondents were CEOs or senior managers. HEHA was delivered across nine U.S. states in seven Asian languages via ethno-linguistic-specific community health education for older AAPIs (n=3001). We developed a semi-structured interview guide using the Consolidated Framework for Implementation Research (CFIR) to capture how HEHA played into the five domains of CFIR: intervention characteristics, outer setting, inner setting, characteristics of the individuals, and process. We coded the transcripts and identified emerging constructs under the CFIR domains.

Results: Participants' mean age (standard deviation) was 56.67 (15.95) years; all of them identified as AAPIs. More than half were female (58%) and most had a graduate school degree (83%). Four CFIR domains emerged from the interviews: intervention characteristics, outer setting, inner setting, and implementation process. Under intervention characteristics, two constructs emerged as facilitating implementation of the HEHA program: 1) the CBOs' beliefs in the strength of HEHA to promote healthy eating, and 2) HEHA's adaptability to different AAPI subgroups. Under outer setting, CBOs described the communities' needs for healthy eating programs and that the HEHA program met those needs. Three constructs emerged under inner setting: 1) the CBOs' structural characteristics and social standing in the community, 2) the CBOs' culture, and 3) the CBOs' perception of HEHA program content as being manageable. Finally, under implementation process, the CBOs provided an evaluation of HEHA and suggested future improvements.

Conclusion: Through the interviews, we were able to identify constructs within the domains of CFIR that facilitated implementation of HEHA. CBOs are key settings for community health education, particularly among immigrant populations. Understanding processes that lead to successful implementation of EBIs in CBOs are critical for accelerating the dissemination and implementation of best practices.

CONTACT-BASED EDUCATION IS AS EFFECTIVE AS A DIDACTIC LECTURE IN REDUCING OPIOID USE DISORDER RELATED STIGMA IN MEDICAL STUDENTS

Sophia Mort, BS¹, Elizabeth A. Beverly, PhD²

¹Ohio University, Athens, OH; ²Ohio University Heritage College of Osteopathic Medicine, Athens, OH

Introduction: The opioid crisis has created challenges for the medical community, including an increased patient load with substance use disorders and concerns regarding physician burnout. Current recommendations to address chronic pain and opioid-related stigma in the medical curriculum point to contact-based education as a promising tool to tackle these issues. Contact-based education has effectively been used to reduce mental illness-related stigma, and research is needed to investigate the application of this educational method in the context of substance abuse. To assess the effectiveness of contact-based education in changing medical students' future professional plans and stigmatic opioid-related attitudes, we implemented two curricular interventions (a contact-based panel and a didactic lecture) at an osteopathic medical school.

Methods: Medical students were randomized to a curricular intervention and completed pre- and post-surveys to measure opioid-related stigma and professional plans. One group of participants attended a lecture on opioids and medication assisted treatment (MAT) developed by a clinical psychiatrist; a second group interacted with a 5-member panel of experts in the opioid-field. Both interventions lasted 60-minutes. We conducted Fisher's exact tests, paired t-tests, and repeated-measures ANOVA to examine changes in pre-post scores.

Results: A total of 109 students participated in the study (age=24.2±2.6 years, 64.2% female, 79.8% white, 56.0% second-year students). The number of participants differed per group due to drop-out: lecture=52, contact-based=57. Baseline responses were similar across groups. Following the session, participants in both interventions rated drug abuse (mean increase=21.1%, t(108)=7.08, p<0.001) and diversion (mean increase=7.6%, t(108)=2.90, p=0.005) as significantly more problematic. Importantly, participants from both interventions expressed increased confidence in caring for patients with opioid use disorder (percent increase=45.6%, p<0.001), and increased interest in pursuing MAT training (percent increase=21.5%, p=0.042). Both curricular interventions were equally effective at reducing opioid-related stigma. The lecture and panel resulted in an average 3.6-point (t(51)=4.01, p<0.001) and 3.4-point (t(56)=3.89, p<0.001) decrease on the stigma scale, respectively.

Conclusion: Exposure to opioid-specific education with a focus on MAT, either through contact-based education or a didactic lecture, improves medical students' opioid-related attitudes and reduces opioid use disorder stigma. This is an encouraging finding as it opens up possibilities for medical programs to address stigma using multiple educational methods depending on the program's resources and current curricular design.

HEALTHCARE PROVIDER TRAINING ON LGBTQIA+ HEALTH: AN INTRODUCTORY MODULE

Brenda Cassidy, DNP, RN, CPNP-PC¹, Betty J. Braxter, BSN, MS, PhD², Andrea F. Fischl, PhD, MPH²

¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh, Pittsburgh, PA

Background: Stigmatization and discrimination associated within the LGBTQIA+ community result in a cascade of health inequities. The Institute of Medicine and Healthy People 2020 highlight reduction of barriers to care related to associated stigma and lack of training for health care providers (HCP) to address the unique health issues in LGBTQIA+ persons.

Purpose: This project aimed to promote cultural competence among nursing students through development of a learning module on best practices in LGBTQIA+ health.

Methods: An exploratory qualitative design utilized focus group methodology to obtain a variety of views from stakeholders. Convenience sample was recruited from the school of nursing and LGBTQIA+ collaborative partnerships to obtain qualitative data from both populations. Focus groups were comprised of nursing students and faculty, members of the LGBTQIA+ community and HCPs who care for LGBTQIA+ individuals. Groups were conducted at the University School of Nursing. Snowball sampling was utilized to recruit nursing students and faculty; purposive sampling recruited providers who care for LGBTQIA+ individuals and participants from University Affinity Groups: Queer Professionals, Student Rainbow Alliance, Pride Health. Participants provided feedback on learning module after development.

Evaluation Plan: Focus groups captured qualitative data; a note taker and panopto recording technology were utilized to record content of focus group discussion. Transcription of each group was verified by faculty for inter-rater reliability of content. Qualitative analysis identified themes from each of the Focus Groups through consensus agreement amongst PI and CIs. Themes were identified across groups and utilized to drive content of the learning module.

Results: Major themes identified across focus groups included: *appropriate terminology, health disparities in LGBTQIA+ individuals, respectful communication about gender identity and sexual orientation*. Themes regarding learning module delivery platform included an emphasis on *interactive strategies and use of testimonials from LGBTQIA+ individuals*. An introductory learning module was developed using interactive strategies based on thematic analysis with assistance from the University Teaching and Learning Center staff. A case was constructed for students to practice learned concepts.

Implications: This innovative strategy utilized content themes driven by nursing students and faculty, LGBTQIA+ individuals and HCP who care for them to inform a learning module that supports culturally competent and gender-affirming care with LGBTQIA+ individuals. The module is currently being piloted with nursing students to assess changes in knowledge and attitudes with consideration for development of a simulation platform to apply learned concepts in a variety of health care settings.

RESEARCH MINISTRY AMBASSADORS TRAINING: COMMUNITY HEALTH SURVEY DATA COLLECTION AND NEW ROLE AS COMMUNITY PATIENT ADVOCATES

Diana Ingram, PhD, MPH¹, Rebecca Johnson, PhD, MSc², Paris Davis, PhD, MBA³, Regina Greer-Smith, MPH, LFACHE⁴

¹Pastors4PCOR, Chicago, IL; ²Northwestern University, Chicago, IL; ³Triedstone Full Gospel Baptist Church, Chicago, IL; ⁴healthcare Research Associates, LLC, Apple Valley, CA

Faith-based communities often support and serve vulnerable and minority populations who experience the poorest health outcomes and adverse impact of health disparities shown by local and national health statistics. One characteristic of urban faith-based communities is centralized accessibility to health-related information and resources that are much needed to improve health outcomes. Pastors4PCOR (P4P), a grassroots faith-based community entity located in Chicago, developed a Research Ministry Ambassador (RMA) program to build the capacity of lay members from faith-based communities to become "research ready" for engagement and collaboration in health-related initiatives with academic health researchers. A values-based initiative, RMAs were educated about equitable partnership, trustworthy and respectful research behaviors and to serve as patient advocates. The P4P research education program introduced faith-based community representatives to patient-centered research, providing tools to navigate and interpret health-related research projects through design, development and implementation, reporting and dissemination of research. P4P-trained and IRB certified RMAs administered a 10-item community health survey (in Illinois and Arkansas) to assess faith-based community perceptions of prevalent health conditions and factors including demographic information. Between 2016-2018, RMAs collected surveys (N=1056) from African-American (98%) residents living in Illinois (Chicago) and Arkansas (Little Rock) representing 25 faith-based community churches. RMAs used survey results to inform leadership discussion and planning to maximize resources in addressing community health concerns. In this session, RMAs share first-hand experience based on their participation and real-life application of skills and knowledge gained. Highlights of their experience includes: RMAs becoming a PCORI Patient Ambassador; joining PPRNs; involvement in P4P RMA group network; presenting at community and academic forums; and opportunities for additional health condition specific training. In sum, building capacity of faith community members to engage meaningfully with research promotes equitable engagement with researchers and brings the "voice" of lay communities to the decision-making table of faith-based leaders, patient-centered researchers and agencies.

PARTICIPANT PSYCHOSOCIAL RESPONSE AFTER RECEIVING CLINICALLY ACTIONABLE GENOMIC INFORMATION FROM A BI-BANK

Alanna Kulchak Rahm, PhD, MS, LGC¹, Anna M. Baker, PhD², Adam Buchanan, MS, MPH, CGC³, Jessica Goehring, MS, LGC¹, Kasia Tolwinski, PhD⁴, Laney Jones, PharmD, MPH¹

¹Geisinger, Danville, PA; ²Bucknell University, Lewisburg, PA; ³Geisinger, Hillsborough, NC; ⁴McGill University, Montreal, PQ, Canada

Background: Several healthcare systems, including Geisinger through their MyCode Community Health Initiative (MyCode), now conduct population-based genomic screening and report actionable results to patients. It is unknown whether patient experience in this context differs from that of indication-based genetic testing and counseling. MyCode participants receive their result from the Genomic Screening and Counseling Program (GSC). The GSC notifies the participant of the result, notifies the primary care provider, gives information about disease risk and recommended management, encourages sharing results with relatives, and offers a visit with genetic counselors.

Methods: Participants in this analysis were 63 individuals who received genetic information from the GSC (N=55) or their family members who underwent cascade testing (N=8). Transcripts from semi-structured qualitative interviews conducted 6 months or more after receiving the result or after cascade testing were analyzed using a two-part coding process to identify psychosocial reactions across interviews, followed by thematic coding within this domain. A priori codes were derived from the literature and interview guides and de novo codes developed after reviewing transcripts. Inter-rater reliability was reached between two coders for each theme.

Results: Participants reported positive, negative, neutral, and conflicting (more than one emotion) responses to receiving genetic information in this context; often noting a change over time. Initial negative responses consisted of fear, guilt, and concern about future health. Concerns for specific gene-related risks and procedures needed, anxiety about communicating to family, and worry about insurance and cost were also reported. Positive responses included feeling “grateful” and that the result was useful for medical care and prevention. Neutral reactions, like not being surprised at the result due to family history, were also reported. Many participants stated receiving the information was “not a big deal” or they were “just not worried,” noting confidence in medical professionals or not experiencing any symptoms. Many participants also noted the result was no different from information they receive from other medical screening.

Conclusion: Overall, MyCode participants appear to have integrated results from genomic screening and noted the importance of the information for medical care and prevention; with any initial negative reactions based on immediate medical impact rather than regret about receiving the information. These results indicate psychosocial response in this context may not be overly negative, that participants adjust to genomic information over time, and that this information is no different from other medical information.

ILLNESS RISK PERCEPTIONS AND HEALTH PROTECTIVE BEHAVIORS PRIOR TO GENETIC SEQUENCING

Courtney L. Scherr, PhD¹, Kerstin M. Kalke, MA¹, Hannah Getachew-Smith, MPH¹, Christin Hoell, MS, CGC¹, Sharon Aufox, MS¹, MAUREEN E. SMITH, n/a¹

¹Northwestern University, Chicago, IL

Background: Health protective behaviors (HPB) are believed to be driven by risk perceptions. However, personal experience with disease (affected vs. unaffected) and beliefs about genetic etiology may impact HPB in negative or positive ways. We explored the impact of risk perception, personal experience, and beliefs about genetic etiology on HPB among a sample of participants enrolled in the Electronic Medical Records and Genomics study at Northwestern.

Methods: Eligible participants (1) saw a Northwestern Medicine physician; (2) were ≥ 18 years; (3) could speak and read English or Spanish; and (4) agreed to have genetic sequencing with results placed in their electronic health record. Participants completed a baseline survey that asked about demographics, risk perception based on the Brief Illness Perception Questionnaire (BIPQ), personal experience with disease, and perceived causes of disease. A hierarchical multiple regression was conducted in SPSS to determine if the addition of personal experience and beliefs about genetic etiology improved the prediction of HPB beyond risk perception alone.

Results: A total of 604 participants completed the survey. The average age was 56, the majority were female ($n = 381$; 63.1%), white ($n = 506$; 83.8%), and non-Hispanic ($n = 575$; 95.2%), and unaffected ($n = 402$; 66.5%). The hierarchical regression model of gender, age, race/ethnicity, education, BIPQ score, personal experience, and belief in a genetic etiology was statistically significant, $R^2 = .152$, $F(7, 413) = 10.587$, $p < .0005$, adj. $R^2 = .138$. The addition of BIPQ score led to a significant increase in the prediction of HPB R^2 of .018, $F(1, 415) = 8.626$, $p = .003$ (Model 2), as did personal experience, $R^2 = .012$, $F(1, 414) = 5.938$, $p = .015$ (Model 3). Belief in a genetic etiology did not significantly increase the prediction of HPB.

Conclusions: Risk perception predicted HPB, but not as expected; those who viewed a disease as more threatening were less likely to engage in HPB. We found support to consider personal experience when examining the relationship between risk perception and HPB. Those affected were less likely to engage in HPB perhaps due to reduce efficacy beliefs, however, additional investigation is needed. Results suggest those who are most concerned and affected by disease may need additional support to promote informed decision making and uptake of HPB. These findings will be examined longitudinally, after the return of genetic test results.

GENETIC DIAGNOSIS VIA POPULATION GENOMIC SCREENING PROVIDES VALUABLE INFORMATION TO ADULTS WITH NEUROPSYCHIATRIC DISORDERS

Karen E. Wain, MS, LGC¹, Karahlyn Holdren, BS¹, Lauren Kasparson, MA¹, Emily Palen, MS, LGC¹, Autumn Swan, MS¹, Kasia Tolwinski, PhD², David H. Ledbetter, PhD, FACMG, DABMGG³, Christa L. Martin, PhD, FACMG, DABMGG¹

¹Geisinger, Lewisburg, PA; ²McGill University, Montreal, PQ, Canada; ³Geisinger, Danville, PA

Neuropsychiatric disorders (NPD), such as autism, intellectual disability, epilepsy, schizophrenia, and bipolar disorder, share underlying genomic etiologies and can present with marked intrafamilial variability. Pathogenic chromosomal copy number variants (CNVs) are frequently identified in children with NPD and are often subsequently found in relatives with varying NPD. However, clinical genetic testing is rarely offered to adults with NPD, despite medically-relevant care implications. Through Geisinger's MyCode Community Health Initiative, genetic counselors (GC) disclosed clinically-confirmed pathogenic CNVs identified by population-based exome sequencing to 141 adults with NPD documented in the medical record. Participant responses were initially assessed with an exploratory approach, using thematic analysis by dual coders of audio-recorded disclosure session transcripts (n=14) and post-session GC written notes (n=38). Identified themes informed the development of a post-session GC checklist for subsequent structured data collection. Key themes translated to the checklist include: overall reaction to results, statements of personal utility, disclosure of additional undocumented NPD, previous causal attributions for NPD, and clinical follow-up. Checklist data are available for 59 participants. Generally, reactions were either positive (n=42, 72%) or neutral (n=14, 24%). Statements of personal utility were made by most participants (n=50, 85%), including that the genetic information was valuable (n=45, 76%), helped "make sense" of personal (n=41, 69%) or family (n=21, 36%) NPD history, relieved guilt (n=14, 24%), and validated personal experiences (n=6, 10%). Forty-four individuals (75%) shared undocumented NPD history, including significant family history (n=32, 54%), learning disabilities (n=15, 25%), social problems (n=8, 14%), and psychiatric illness (n=4, 7%). Attributing NPD to social or environmental causes, such as parental divorce or moving in childhood, was common (n=29, 49%). Clinical follow-up was indicated for 26 (44%), including GC support to current medical providers (n=12, 20%) and referral to another medical provider (n=11, 19%) or mental health services (n=7, 12%). These results indicate that receiving a genetic etiology has a positive impact for adults with NPD. Additional research is ongoing to further explore clinical utility, intrafamilial communications and beliefs, and healthcare system infrastructure needs to more broadly support disclosure of NPD results from population genomic screening.

EXPLORING HEALTHCARE EMPLOYEES' PERCEPTIONS OF HEALTH LITERACY TO INCREASE HEALTH LITERACY AMONG UNDERSERVED POPULATIONS

Sherrie Wallington, PhD¹, Carol Cummings, PhD², Mary L. Greaney, PhD³, Sankeerth Rampa, PhD², Faith D. Lees, MS⁴

¹The George Washington School of Nursing, Washington, DC, DC; ²Rhode Island College, Providence, RI; ³University of Rhode Island, Kingston, RI; ⁴Rhode Island Geriatric Education Center, Kingston, RI

Background: Improving poor health outcomes require removing barriers to health literacy. Providing health literacy training to healthcare employees caring for individuals with limited health literacy can aid in health literacy promotion. This qualitative study explored healthcare providers' and staff's perceptions of health literacy, health literacy skills of their patients, barriers health literacy patients encounter, and strategies to increase health literacy among underserved populations.

Methods: Focus groups were held at federally qualified health centers in Rhode Island. All 37 participants provided informed consent and completed a demographic survey. A trained moderator using a semi-structured interview guide led the groups. All transcripts were audio-recorded, transcribed, and coded; codes were reviewed to identify emergent themes.

Results: Focus group participants included doctors, nurses, and staff. Each focus group lasted approximately one hour. Results indicated that staff/providers were concerned about patients' health literacy and use of unreliable health information sources and ability to determine if sources were valid/reliable. All participants felt it important to address patients' limited health literacy and have procedures to assess their social determinants of health. Various teaching methods to address health literacy, including drawing pictures, having family members attend appointments, educational programs, and teach-back methods were emphasized.

Conclusion: This study is an important first step toward exploring health literacy perceptions among staff/providers and patients, and identifying factors that promote and impede health literacy in healthcare settings. Larger, more robust studies should explore the links between social determinants of health literacy, poor health care access, and poor health outcomes.

THE ASSOCIATION BETWEEN FAMILY HEALTH HISTORY AND COMMUNAL COPING IN FAMILIES OF DIFFERENT RACIAL BACK- GROUND

Shana Lanzetta, MA¹, Jielu Lin, PhD¹, Laura Koehly, PhD², Melanie Myers, PhD³¹Northern Arizona University, Flagstaff, AZ; ²National Human Genome Research Institute, Bethesda, MD; ³Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Type 2 diabetes is a complex disease resulted from the joint effect of genetic, socio-environmental and lifestyle risk factors that are clustered in families. Response to shared familial risk of diabetes is a family process, where individuals communicate about risk and establish routines to facilitate one another's health habits and compliance with therapeutics. This process is likely affected by one's perception of risk based on his/her knowledge about family health history (FHH). Capitalizing on network data collected from multi-informant families of different racial backgrounds in the greater Cincinnati area (28 white and 17 black/African American households; 127 participants), we investigate how the density of diabetes diagnosis in one's FHH affects communication about shared risk for type 2 diabetes and encouragement to maintain or adopt a healthy lifestyle (exercising regularly, eating a healthy diet and maintaining a healthy weight). Results suggest a higher concentration of diabetes diagnosis in one's FH is associated with a higher number of risk communication ties in all families. There is a racial difference in the effect of FHH density on encouragement ties. Specifically, more diabetes diagnosis in FHH are associated with an increased number of encouragement ties in families of black/African heritage, whereas in white families there is no such association, due to the fact that encouragement ties are saturated in these families. The findings highlight the need and promise of using FHH to motivate co-encouragement to maintain/adopt a healthier lifestyle in families of black/African heritage.

MEDIATION ANALYSES: APPLICATION OF THE THEORY OF PLANNED BEHAVIOR CONSTRUCTS ON SUGAR-SWEETENED BEVERAGE CONSUMPTION

Petrona Gregorio-Pascual, MA¹, Heike I. M. Mahler, PhD²¹San Diego State University/ UC San Diego, Fallbrook, CA; ²California State University San Marcos, San Marcos, CA

We sought to determine whether any obtained effects of three interventions, based on the Theory of Planned Behavior (TPB), on sugar sweetened beverage (SSB) consumption would be mediated by corresponding effects of the interventions on the three primary TPB cognitions (i.e., attitudes, subjective norms, perceived behavioral control [PBC]). Undergraduates (N = 430) were randomly assigned to condition in a 2 (SSB risks information vs control) x 2 (SSB consumption norms information vs no information) x 2 (SSB reduction planning task vs control) factorial design. Immediately following the interventions, participants' SSB reduction attitudes, subjective norms, and PBC were assessed. SSB consumption intentions and behavior were assessed at an unannounced 2-week follow-up. In any instance where one of the three interventions (i.e., risks, norms, planning task) affected both the dependent variable (i.e., intentions or behavior) and one of the proposed mediators (i.e., attitudes, subjective norms, or PBC) a mediation analysis was conducted using Hayes' bootstrapping (with 5000 resamples) procedure. The results indicated that each of the three interventions produced significantly greater intentions to reduce SSB consumption than did its respective control condition ($p < .03$), and the condition that included all three interventions resulted in the greatest SSB reduction intentions ($p = .04$). Moreover, the effect of the social norms information intervention on SSB reduction intentions was mediated by its effects on all three of the TPB cognitions (for attitudes towards SSB reduction, for subjective norms, and for PBC), whereas the effect of the planning task on participants' intentions was mediated by its effects on their attitudes towards SSB reduction, and their perceived subjective norms. There was no evidence that the greater SSB reduction intentions produced by the SSB risks intervention was mediated by any of the TPB cognitions. Also, although the planning task resulted in lower reported SSB consumption ($p < .05$), there was no evidence that this effect was mediated by corresponding changes in any of the TPB cognitions. The literature would benefit from more efforts to experimentally manipulate all three primary TPB cognitions in a variety of health contexts. It is also important that such efforts attempt to examine the mechanisms through which the interventions produce beneficial effects on intentions and behavior.

HUMOR CAN MAKE YOUNG PEOPLE LISTEN TO EMBARRASSING MESSAGES: TRUTH® TAKES ON SMOKING-RELATED REPRODUCTIVE HEALTH ISSUES

Jessica M. Rath, PhD, MPH, CHES¹, Erin J. Miller Lo, MPH¹, Alexis A. Barton, PhD, MS¹, Siobhan N. Perks, MPH¹, Donna Vallone, PhD, MPH¹, Elizabeth C. Hair, PhD¹

¹Truth Initiative, Washington, DC

Never an organization to shy away from sensitive subjects related to tobacco use, truth has taken on a subject that receives little attention in the public health community: smoking-related erectile dysfunction and menstrual cycle disturbance. Among young people, these problems are typically considered to be the plague of the lifelong smoker and are not something they believe they have to think about.

At the forefront of this issue, in 2019 truth launched a set of advertisements intended to communicate the uncomfortable but critical health message: smoking can cause damage to people's reproductive systems—even in young people. These advertisements were aimed at youth and young adults aged 15 to 24, and reveal that cigarette smoking can bring on unwanted, yet preventable, reproductive issues in an approachable and surprising way.

"Twinkle Twinkle" tackled the message that smoking can cause erectile dysfunction, even in men as young as 20. In the pre-market testing of this advertisement, researchers found that, among the intended audience of young people aged 18 to 24, 89% of the sample agreed that the intended message of "smoking is harmful" was clearly communicated. More than three-quarters of the sample (78%) agreed that it captured their attention, and a majority agreed that the ad was believable (67%) and relevant for their generation (69%).

The campaign also launched "Unflow," a message that humorously communicated the disruptive effects of smoking on menstrual periods. In pre-market testing, researchers found that, among the intended audience of young people aged 15 to 24, 82% of the sample agreed that the intended message of "smoking is harmful" was clearly communicated. A majority of the sample (70%) agreed that the message captured their attention, and like "Twinkle Twinkle," most agreed that it was believable (69%) and relevant for their generation (71%).

While a menstruation message may not directly appeal to males, and an erectile dysfunction message may not directly appeal to females, the overall messages resonated with both genders. The success of the campaign during in-market testing further indicates that truth's willingness to push the envelope and discuss reproductive health is a sound strategy to reach young people.

BELIEFS ABOUT CANNABIS USE DURING PREGNANCY IN A HISPANIC-MAJORITY REGION OF CALIFORNIA

Sara Fleszar, n/a¹, Linda Cameron, Ph.D.¹, Paul Brown, PhD², Marisela Yopez, Bachelor of Arts³, Rosa Manzo, Ph.D.¹

¹University of California, Merced, Merced, CA; ²UC Merced, Merced, CA; ³University of California Merced, Ceres, CA

Cannabis use during pregnancy has increased within the past decade, with higher prevalence among lower SES and ethnic minority populations. As more states legalize cannabis, use during pregnancy is expected to rise. Pregnant women commonly report using cannabis to treat nausea, pain, and depression, yet research suggests that cannabis use increases risk of pregnancy complications, low birth weight, and admissions of infants into intensive care units. Understanding common beliefs about safety and health risks of cannabis use during pregnancy is critically important when developing health communications and guidelines aimed at ensuring informed choices of cannabis use during pregnancy. Further, identifying groups with higher prevalence of misperceptions can inform efforts to target health communication campaigns. This survey examined differences between genders, ethnicity groups, and cannabis users versus nonusers in their beliefs about the benefits of cannabis use during pregnancy in reducing nausea, depression, pain, and discomfort and its risks of lowered intelligence, brain damage, and behavioral problems for the child. Community members in the San Joaquin Valley, a Hispanic-majority region of California, who were attending local events completed the survey. Participants ($N = 201$) were on average 40.3 ($Mdn = 38.0$) years old, female (72.9%), Hispanic (63.9%), married (51.3%), had at least 1 child (72.6%), and reported using cannabis in the past 6 months (15.4%). Analyses revealed that more males (18.5%) than females (11.7%) agreed that cannabis use during pregnancy reduces nausea ($p = .016$); fewer Hispanic participants (12.9%) than non-Hispanic participants (15.7%) endorsed this belief ($p = .040$); and more participants who had used cannabis in the past 6 months (38.7%) than those who did not (10.7%) endorsed this belief ($p = .003$). More younger men agreed that cannabis use during pregnancy reduces nausea compared with all other age and gender groups ($p = .003$). Compared with participants who had not used cannabis within the past 6 months, those who had reported higher agreement that cannabis use during pregnancy reduces depression and pain as well as higher disagreement that cannabis use during pregnancy lowers the child's IQ and increases the risks of brain damage and behavioral problems (p 's $< .01$). These findings suggest important targets for health communications targeting misperceptions about cannabis use during pregnancy, and particularly the importance of targeting individuals who have used cannabis recently.

COLLEGE STUDENT FOOD INSECURITY AND ATTITUDES TOWARDS CAMPUS

Lisa S. Miller, PhD¹, Timo Rico, EdD², Jennifer Falbe, ScD, MPH¹, Gwen Chodur, in prog¹, Leslie Kemp, MS¹, Shantille Connolly, MPH, CHES¹

¹University of California, Davis, Davis, CA; ²UC Davis, Davis, CA

Background: College students living with food insecurity have an increased risk of poor sleep quality, disordered eating behaviors, psychological distress, lower GPA, and poor diet quality (El Zein et al., 2019; Hattangadi et al., 2019; Lee et al., 2018; Weaver et al., 2019). Past work has shown that food insecure students tend to have low opinions of their institutions due to inadequate accessibility of food (Ilieva et al., 2019) and financial support (Mesa et al., 2019). However, it is unclear whether attitudes differ between students living with low vs high levels of food insecurity. Less favorable attitudes could be indicative of feelings of marginalization, which in turn may increase students' risk of food insecurity (Woodford & Kulick, 2014) in part due to reduced uptake of programs and services designed to decrease food insecurity.

Methods: Undergraduate students (n=1355) from a public university completed the 2019 American College Health Association's National College Health Assessment II. Questions on campus attitudes ("students' health and well-being is a priority at my college/university" and "the campus climate encourages free and open discussion about health and well-being") on a 5-point scale (1=strongly agree; 5=strongly disagree) and food insecurity ("didn't have money to get more food" and "couldn't afford balanced meals") in the last 30 days (1=often true; 2=sometimes true; 3=never true). For both attitudes and food insecurity, responses were combined to form a single index.

Results: After adjusting for gender, transfer status, BMI, race and ethnicity, and financial hardship, logistic regressions showed that campus attitudes significantly predicted food insecurity, Wald = 17.4, $p < .001$. Students with less favorable views were 1.77 times more likely to be food insecure. All covariates were significant.

Conclusions: Campus attitudes were significantly associated with food insecurity. The causal direction of the relationship is unknown, however, it is likely bidirectional and possibly synergistic. That is, as attitudes become more negative, connectedness to the campus decreases, which in turn diminishes the efficacy of assistance programs and activities to impact food insecurity. Future research is needed to increase our understanding of the potentially complex relationship among campus attitudes, connectedness, and food insecurity on college campuses.

DEPRESSIVE SYMPTOMS MODERATE THE EFFECT OF INTERNALIZED TRANSPHOBIA ON BINGE DRINKING IN TRANSGENDER AND GENDER DIVERSE ADULTS

Madalyn M. Liautaud, B.A.¹, Danielle S. Berke, Ph.D.²

¹The Graduate Center, The City University of New York, Brooklyn, NY; ²Hunter College of The City University of New York, CUNY Graduate Center, New York, NY

Binge drinking (i.e., consumption of ≥ 5 standard alcoholic drinks on one occasion) is an important public health concern in the U.S., as it is strongly associated with alcohol-related injuries and increased risk for onset of alcohol use disorders. Despite consistent evidence for alcohol-related disparities among transgender and gender diverse individuals (TGD; i.e., people who have a gender identity that differs from the sex assigned to them at birth, who do not identify with gender binary constructs [man or woman], or who are expansive or fluid in their gender identities), there is a dearth of research on binge drinking in this population. Moreover, extant work examining TGD alcohol use is largely epidemiological in nature, revealing little about mechanisms that may drive problematic drinking in this population. It is possible that depressive symptoms may play a role, given both the greater incidence of depression among TGD individuals and the robust link between depression and high-risk drinking in the general population. Although internalized transphobia (i.e., internalization of society's negative regard for TGD identity and expression) is a risk factor for both substance use and depression among TGD individuals, no study to date has examined how gender-minority specific psychological distress may interact with depressive symptoms to compound high-risk drinking in this population. This cross-sectional study examined depressive symptoms as a moderator of the relation between internalized transphobia and frequency of past 30-day binge drinking. Fifty-six TGD adults (69.6% female sex assigned at birth; 69.6% White; 50.0% between 25-34 years old) completed self-report measures of depressive symptoms, internalized transphobia, and frequency of past 30-day binge drinking. Internalized transphobia was positively associated with frequency of past 30-day binge drinking ($\beta = .53$, $p < .001$). Depressive symptoms interacted with internalized transphobia to predict frequency of past 30-day binge drinking ($\beta = .01$, $p = .01$), such that the predictive power of internalized transphobia on frequency of past 30-day binge drinking grew proportionately stronger as depressive symptoms increased. These results suggest that internalized transphobia may only confer risk for binge drinking among TGD individuals experiencing depressive symptoms. In clinical practice with TGD adults, integrating psychosocial and structural interventions into standard alcohol-related treatments may be warranted.

SOCIAL SUPPORT AS A PROTECTIVE FACTOR AGAINST DAILY DYSREGULATED EATING AMONG SEXUAL MINORITY WOMEN WITH OVERWEIGHT AND OBESITY

Emily Panza, Ph.D.¹, David W. Pantalone, Ph.D.², Laura D'Adamo, B.A.³, Edward Selby, Ph.D.⁴, Rena Wing, Ph.D.¹¹Alpert Medical School of Brown University, Providence, RI; ²University of Massachusetts Boston, Boston, MA; ³Drexel University Center for Weight, Eating, and Lifestyle Science, Philadelphia, PA; ⁴Rutgers, The State University of New Jersey, Piscataway, NJ

Background: Obesity and dysregulated eating behaviors (i.e., overeating, binge eating) disproportionately affect sexual minority women. Recent research suggests that experiencing stigma based on sexual orientation and weight (i.e., minority stress) may heighten risk for dysregulated eating among sexual minority women, yet little work has examined factors that protect against dysregulated eating in this group. Social support reduces risk for dysregulated eating in the general population and mitigates the negative effects of stigma among sexual minority adults. This secondary analysis assessed the potential protective effects of social support among sexual minority women of higher body weight by testing: (1) whether social support predicted less overeating and binge eating in daily life in this group and (2) whether social support buffered the effects of weight stigma events on daily overeating and binge eating.

Methods: Participants in this ecological momentary assessment (EMA) study were 55 sexual minority women (62% bisexual; 55% white; mean age = 25 ± 9; mean body mass index [BMI] = 32 ± 5). General social support was assessed at baseline (Social Support Behaviors Scale; Vaux, Riedel, & Stewart, 1987). For the following five days, participants used a smartphone to report weight stigma and eating behaviors five times daily at random intervals. Generalized linear models were conducted adjusting for age, race, education, BMI, baseline disordered eating symptoms, and EMA assessment completion rate.

Results: Sexual minority women with greater social support at baseline reported 32% fewer overeating episodes ($b = -0.02$, $SE = 0.01$, $p < .05$) and 61% fewer binge-eating episodes ($b = -0.03$, $SE = 0.01$, $p < .05$) during the EMA period compared to women endorsing lower social support. Even among women who experienced weight stigma during the EMA period, women with high social support reported 58% fewer overeating episodes ($b = -1.33$, $SE = 0.41$, $p < .05$) and 89% fewer binge eating episodes ($b = -2.89$, $SE = 1.11$, $p < .05$) compared to women with low social support.

Conclusion: Social support may benefit sexual minority women of higher body weight by reducing risk for dysregulated eating and buffering against the negative effects of weight stigma. Future research should investigate whether social support interventions improve sexual minority women's outcomes in treatments for obesity and dysregulated eating.

USING COMMUNITY BASED PARTICIPATORY RESEARCH TO DEVELOP A WALKING PROGRAM FOR AMERICAN INDIAN AND ALASKA NATIVE OLDER ADULTS

Maja Pedersen, MS¹, Diane K. King, PhD², Jordan Lewis, PhD², Mattea Hoy, BS¹¹University of Montana, Missoula, MT; ²University of Alaska Anchorage, Anchorage, AK

Background: American Indian and Alaska Native (AIAN) older adults are less physically active than other racial/ethnic groups, putting them at highest risk for leading causes of preventable death and disability including heart disease, stroke, and some cancers. Walking is the preferred physical activity (PA) among AIAN older adults, yet little is known about how evidence-based walking interventions can be culturally-adapted and contextually-aligned to maximize their impact. We report on our use of Community Based Participatory Research (CBPR) principles to involve stakeholders in the design of a research protocol and intervention to increase walking among AIAN older adults, while building local capacity for conducting CBPR research. **Methods:** The research team participated in CBPR activities for one year to develop partnerships across two tribal regions in the Northwestern United States, obtain and document stakeholder input on research process steps, and qualitatively analyze meeting notes and transcripts to identify themes to inform design of a culturally relevant, feasible, sustainable walking program.

Results: An academic-community partnership was formed across two universities, one tribal health department, and one regional tribal association. Partners attended six community-based meetings (~N= 1478 attendees including AIAN older adults, adults, and youth) organized by AIAN entities across two states. Process steps for proceeding with the research project included: (1) establishing a Community Advisory Board (N=10 members, 100% AIAN; 50% ages 55+) to oversee research methods and support community priorities; (2) hiring a community liaison as a research team member to build local capacity; and (3) conducting community partner training on CBPR theory and methods. Themes related to PA promotion identified through community meeting notes and transcripts included preferences for: (1) inter-generational programming; (2) social interaction; (3) land-based activities; and (4) use of trauma-informed approaches.

Conclusions: Stakeholder-driven methods to develop culturally and contextually aligned interventions that encourage walking among rural AIAN older adults are critical to assure acceptability, sustainability and public health impact of PA interventions.

“JUST LIKE WHEN A CAR IS RUNNING OUT OF GAS:” QUALITATIVE ANALYSIS OF STRESS, COPING AND HEALTH IN TAXI AND FOR-HIRE VEHICLE DRIVERS

Devika R. Jutagir, PhD¹, Anuradha Hashemi, MPH¹, Sabrina Pan, BS¹, Anna Fernandez, BA¹, Chanel I. Martinez, BA¹, Nujbat Meraji, n/a¹, Andrew Rasmussen, PhD², Francesca Gany, MD, MS¹

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Fordham University, Bronx, NY

Objective: Tomorrow's health challenges call for improved mental and physical healthcare for the increasing numbers of diverse “gig economy” workers, like taxi/for-hire vehicle (FHV) drivers. Drivers are at risk for illnesses requiring behavioral management like cardiovascular disease, diabetes, obesity, hypertension, and cancer. Guided by the Explanatory Model for Illness and the Common Sense Model of Illness Cognition, we examined drivers' experiences of stress, health, and coping and explored the evolving taxi industry's impact on mental and physical health.

Methods: Concurrent with taxi industry changes in 2013-2018, 50 drivers completed 1-hour semi-structured in-depth interviews. Drivers were recruited from driver-frequented NYC sites (e.g., taxi garages). Eligible drivers were aged 20-85 years, were fluent in English, Arabic, Hindi, Bengali, Punjabi, Urdu, Spanish, French, or Fulani, and drove a NYC taxi/FHV for at least five shifts per week or 40 hours per week. Drivers with less than 2 years of experience driving an NYC taxi or less than 6 months of driving a green cab/Uber car were excluded. An interview guide elicited drivers' experiences and beliefs related to stress, health, and coping. The 7 coders, including a physician, a psychologist, community outreach workers, and research assistants experienced in working with drivers analyzed transcripts in Atlas.ti for themes using a grounded theory approach to develop a formal codebook.

Results: Codes included “stressor,” “psychological reaction,” “coping,” and “physical health.” A “lack of control” theme captured mental and physical health challenges reported by drivers and related to their coping strategies. Specific subthemes related to stress and poor health over which drivers lacked control included “physical environment,” “income,” “passengers,” and “narrowing career alternatives.” Coping strategies related to taking control through “taking responsibility” and “controlling emotions” versus ceding control through “fate/religion,” “letting go,” and “avoiding” stressors out of drivers' control.

Discussion: Drivers reported feeling stressed and being unable to engage in health behaviors due to lacking control over many aspects of their professional lives. Culturally tailored mental and physical health interventions must be designed to accommodate driver work environment and income. Interventions that promote taking control versus letting go as appropriate may decrease driver stress. Policy changes may be required.

THE MODERATING EFFECT OF MINDFULNESS ON THE ASSOCIATION BETWEEN STRESSFUL RACIST EVENTS AND SELF-RATED HEALTH

Caitlin J. Simmons, n/a¹, Andrew D. Case, PhD¹

¹University of North Carolina at Charlotte, Charlotte, NC

There is growing evidence that racial discrimination adversely affects health (Krieger et al., 2011) and that greater amounts of perceived discrimination are associated with poorer self-rated health among Black and African American populations (Cuevas et al., 2013), suggesting the need for interventions to reduce adverse health effects of racial discrimination. Mindfulness has been shown to have positive effects on mental health and has been studied as a buffer for negative mental health effects of discrimination (Shallcross & Spruill, 2018; Watson, Hill, & Case, 2019). However, the effect of mindfulness on self-reported physical health has had mixed results (see review by Alsubaie et al., 2017). This study examined the relationship between the experience of racist events, trait mindfulness, and self-rated health using a cross-sectional analysis of 233 self-identified Black or African American (156 female) students attending a large, urban, predominantly white, southeastern university. Greater mindfulness was found to be associated with a greater likelihood of good self-rated health ($p = .002$). Mindfulness also functioned as a buffer ($b = -.00$; $SE = .001$; $p = .022$); high levels of mindfulness were associated with a reduced association between racism-related stress and self-rated health. In addition, at higher rates of stress appraisal, mindfulness had less of an effect on the probability of reporting good self-rated health. The frequency of racist events experienced had no effect on self-rated health, which indicates that the appraisal of racist events as stressful has greater relevance for health than how often racist events are experienced. These results suggest that interventions focusing on mindfulness in racial minority populations may help mitigate the effects of stressful racist events on health especially when stress appraisal is at low to moderate levels.

SELF-STIGMA, RESILIENCE, SOCIAL CONNECTEDNESS, AND DISTRESS AMONG FILIPINO DOMESTIC WORKERS IN HONG KONG: A MEDIATION MODEL

Nelson C. Y. Yeung, Ph.D.¹, Karon K. Y. Kan, BSc¹¹The Chinese University of Hong Kong, Hong Kong, N/A, Hong Kong

Purpose: Filipino domestic workers (FDW) make up nearly 3% of the total population in Hong Kong. Studies suggested work- and immigrant-related stressors could put those FDW at risk for self-stigmatization and poor mental health. However, little is known about how those workers' individual characteristics (e.g., resilience, self-stigma) are associated with their coping resources and mental health. This study examined how self-stigma and resilience might be associated with distress among FDW in Hong Kong, and proposed the role of social connectedness (loneliness, perceived social support) in explaining such associations.

Methods: FDW living in the 18 major districts in Hong Kong (N=346) were recruited through respondent-driven sampling. Their levels of self-stigma, resilience, loneliness, perceived social support, and distress were measured in a cross-sectional survey.

Results: Correlation results indicated that self-stigma was associated with higher loneliness, less perceived social support, and higher distress ($r_s=0.20, -0.38$, and 0.33 respectively, $p<.01$), whereas resilience was associated with lower loneliness, higher perceived social support, and lower distress ($r_s=-0.16, 0.46$, and -0.19 respectively, $p<.01$). Path analyses results supported the proposed mediation model with a satisfactory model fit ($\chi^2(1)=0.07$, $p=.79$, CFI=1.00, TLI=1.01, RMSEA=0.00). Specifically, the indirect effect from self-stigma on distress via increased loneliness and reduced social support ($\beta=0.11$; 95%CI=0.08, 0.14) and the indirect effect from resilience on distress via reduced loneliness and increased social support ($\beta=-0.11$; 95%CI=-0.15, -0.08) were significant, supporting the mediating role of social connectedness in the associations between self-stigma/resilience and distress. Moreover, the direct effect from self-stigma (but not resilience) on distress also remained significant after considering the mediators ($\beta=0.20$; 95%CI=0.13, 0.26).

Conclusions: Self-stigma and resilience might contribute to mental health among FDW in Hong Kong through changing the perceptions of social connectedness. Our findings implied that interventions targeting at reducing self-stigma, enhancing resilience, training skills for facilitating social connectedness might alleviate distress among those workers. Considering the roles of individual characteristics and psychosocial factors could be a novel approach to address the increasingly important mental health issues among migrant workers.

SOCIAL MEDIA USE AND WELL-BEING IN SEXUAL AND GENDER MINORITY YOUNG ADULTS

Erin A. Vogel, PhD¹, Danielle Ramo, PhD², Judith J. Prochaska, PhD, MPH¹, Meredith Meacham, PhD, MPH³, John F. Layton, BA⁴, Gary Humfleet, PhD³¹Stanford University, Stanford, CA; ²Hopelab, San Francisco, CA; ³UCSF, San Francisco, CA; ⁴University of California, San Francisco, Richmond, CA

Introduction: Social media can provide connection with others and access to social support. The relationships between social media use and facets of well-being among sexual and gender minority (SGM) young adults are not well-studied.

Methods: Participants were SGM young adults (N=302, M age = 21.9, 72.2% assigned female at birth) enrolled in Facebook smoking cessation interventions. Sexual identity was 17.2% gay, 16.9% lesbian, 59.3% bisexual and/or pansexual, and 6.6% other; gender identity was 61.3% cisgender, 14.6% transgender, and 24.2% other. Participants reported on maladaptive Facebook use (e.g., distress when unable to access social media, social media use that interferes with other obligations), hours of social media use per week, perceived social support, internalized SGM stigma, depressive symptoms, and smoking behaviors (i.e., cigarette dependence, number of cigarettes smoked in the past-week). Significant bivariate associations with maladaptive Facebook use were entered in an adjusted multiple linear regression analysis.

Results: Adjusting for demographic covariates, maladaptive Facebook use was significantly associated with greater internalized stigma ($r=.22$, $p<.001$) and depressive symptoms ($r=.19$, $p=.001$) and with less social support ($r=-.14$, $p=.017$). Greater use of social media was significantly associated with greater depressive symptoms ($r=.15$, $p=.01$). Maladaptive Facebook use remained significantly associated with internalized SGM stigma ($\beta=.22$, $p=.001$) when adjusting for other correlates.

Conclusions: Taken together, results suggest that maladaptive Facebook use among SGM young adults is associated with psychological stressors, including internalized stigma, low social support, and depressive symptoms. Social online communities, while accessible, may not provide a simple solution to addressing isolation, experienced stigma, and depression in SGM young adults.

CONCORDANCE OF OBJECTIVE AND SUBJECTIVE MEDICATION ADHERENCE MEASURES IN AN HIV PILOT TRIAL

Eugene M. Dunne, PhD¹, Elena Salmoirago-Blotcher, MD, PhD², Michael P. Carey, PhD³¹Brown University, Providence, RI; ²The Miriam Hospital, Brown University School of Medicine, Providence, RI; ³The Miriam Hospital and Brown Univ, Providence, RI

Objective: Antiretroviral therapy (ART) adherence and viral suppression are critical to the “90-90-90” plan to end the HIV epidemic. That is, 90% of persons living with HIV (PLWH) knowing their status, 90% of PLWH in care and receiving antiretroviral medications, and 90% of PLWH on ART achieving viral suppression. Given the importance of medication adherence, this study examined rates of concordance among three measures: self-reported adherence, staff-directed unannounced pill counts, and laboratory-confirmed viral load.

Methods: Participants were 42 PLWH (M age = 47.5 years; 50% female; 33% black; 26% Hispanic/Latino) enrolled in a pilot trial examining the feasibility and acceptability of a mindfulness intervention to improve medication adherence and reduce risky sexual behavior. Data for the present analyses were collected at the three-month follow-up assessment. Self-reported adherence included three items regarding the past 30 days: number of days participant missed a dose; how often did participant take medication as instructed; and “how good of a job” participants did taking their medication as instructed. Pill counts were conducted by telephone by trained study staff. Participants were provided counting trays and instructed on how to count medication during initial in-person visit. Viral load suppression was defined as HIV-1 RNA fewer than 500 copies/mL. Bivariate correlations evaluated concordance rates among adherence and viral load measures.

Results: Over the previous month, participants reported missing at least one medication dose on two days (SD = 2.9), which is equivalent to a 93% adherence rate. Using a 5-point scale, participants described taking their medication as prescribed as “almost always” (M = 3.9, SD = 1.4) and rated their ability to take medication as prescribed as “very good” (M = 3.9, SD = 1.2). Based on pill counts, participants were adherent to 84% (SD = 21%) of their ART medication doses. HIV viral load data showed that 83% (SD = 38%) of patients were virally suppressed. Self-reported medication adherence (i.e., number of days missed) was significantly and negatively correlated with pill count data ($r = -.62$, $p < .001$) and suppressed viral load ($r = -.44$, $p = .003$). Pill count data and suppressed viral load were also significantly correlated ($r = .45$, $p = .009$).

Conclusion: Estimates of ART adherence differed slightly based on self-report (93%) and telephone-conducted pill counts (84%). Both methods demonstrated moderate concordance with biologically measured viral load. Although self-reported and pill count measures of medication adherence introduce human error, they appear to be good indicators of viral suppression for PLWH. With new methods to monitor medication adherence on the horizon (e.g., “smart” pills), future studies should continue to evaluate concordance between subjective and objective adherence measures to optimize patient health.

DIFFERENT TYPES OF STIGMA AND ART ADHERENCE AMONG PEOPLE LIVING WITH HIV: THE MECHANISTIC ROLES OF ART KNOWLEDGE AND ART SELF-EFFICACY

Chengbo Zeng, MPH¹, Xiaoming Li, PhD¹, Shan Qiao, PhD¹, Xueying Yang, PhD¹, Zhiyong Shen, MD, Yuejiao Zhou, MD¹University of South Carolina, Columbia, SC

Background: Previous studies have demonstrated the negative relationship between HIV-related stigma and antiretroviral therapy (ART) adherence among people living with HIV (PLWH). Yet, there are few studies investigating the mechanisms of how different types of stigma affect ART adherence. Based on the information-motivation behavioral skills (IMB) theory, the current study proposed that different types of stigma could impair ART adherence through their negative influences on ART knowledge and ART self-efficacy. This study aimed to examine the mechanistic roles of ART knowledge and ART self-efficacy on the relationships between different types of stigma and ART adherence.

Method: Data were derived from a baseline survey of a prospective cohort study. Data collection was conducted from November 2017 to February 2018 in Guangxi, China. Six hospitals/clinics in five cities with the largest number of HIV patients were selected, and 1,198 PLWH were recruited. Participants were assessed on their sociodemographic characteristics, ART adherence, different types of stigma (i.e., anticipated, internalized, and enacted stigma), ART knowledge, and ART self-efficacy. Path analysis was used to examine the indirect effects from different types of stigma to ART adherence through ART knowledge and ART self-efficacy.

Results: Among the 1,198 PLWH, 64.4% were male, and mean age was 39.4 years. The indirect paths from anticipated stigma (std.β=-0.018, 95%CI: -0.004~-0.001, $p=0.013$) and internalized stigma (std.β=-0.045, 95%CI: -0.013~-0.004, $p<0.001$) to ART adherence through ART self-efficacy were statistically significant while the indirect path from enacted stigma to ART adherence through ART self-efficacy was marginally significant (std.β=-0.013, 95%CI: -0.013~-0.001, $p=0.056$). All types of stigma could impair ART self-efficacy among PLWH, which in turn could compromise their ART adherence. None of the indirect paths from three stigma to ART adherence via ART knowledge was significant.

Conclusion: The mechanistic roles of ART knowledge and ART self-efficacy are different on the relationships between different types of stigma and ART adherence. To intervene the negative impact of HIV-related stigma on ART adherence among PLWH, multilevel interventions targeting different types of stigma and improving ART self-efficacy and knowledge are needed.

EVALUATING EFFECTIVENESS OF A TAILORED SUBSTANCE USE INTERVENTION FOR PEOPLE WITH HIV: IMPLEMENTATION OF PLUS IN NYC HIV CLINICS

Tyrel J. Starks, PhD¹, Stephen S. Jones, BA Mathematics², Sitaji Gurung, MD MPH³, Christopher M. Ferraris, MSW⁴, Ana Ventuneac, PhD⁵, Jeffrey T. Parsons, PhD⁶, Brett M. Millar, PhD¹, Martha A. Sparks, PhD⁵

¹Hunter College, New York, NY; ²RFcuny - Hunter College - PRIDE Health Consortium, NEW YORK, NY; ³CUNY Graduate School of Public Health & Health Policy/PRIDE Hunter College, Flushing, NY; ⁴HIV Center for Clinical and Behavioral Studies at the New York State Psychiatric Institute and Columbia University, New York, NY; ⁵Icahn School of Medicine at Mount Sinai, New York, NY; ⁶Mindful Designs, Teaneck, NJ

Background: People with HIV (PWH) use alcohol and drugs at rates higher than their HIV negative counterparts. This is particularly problematic because drug use is associated with difficulties with antiretroviral medication adherence. The Positive Living through Understanding and Support (PLUS) intervention previously demonstrated efficacy to reduce heavy drinking among PWH. The goal of the current study was to evaluate the effectiveness of PLUS when delivered by mental health care providers in HIV care clinics.

Methods: The study utilized a quasi-experimental design to evaluate the effectiveness of the PLUS intervention to reduce problematic alcohol and drug use among PWH. The intervention was delivered at a 3-site consortium of outpatient clinics, with follow-up assessments completed at 3-, 6-, 9- and 12-months post-intervention. At Clinic 1 (n = 40) and Clinic 2 (n = 22), participants received the PLUS intervention immediately after baseline, as did 22 participants at Clinic 3. At Clinic 3, an additional 90 were assigned to a wait-list control condition, who received the intervention after their 12-month follow-up. Eligible PWH were 18 years or older, prescribed ART, had a detectable viral load within the past year, and reported problematic drinking or recent drug use. Problematic alcohol and drug use were assessed using the Alcohol Use Disorders Identification Test (AUDIT) and the Drug Abuse Screening Test (DAST-10).

Results: Results indicated that participants in the waitlist control group had stable AUDIT and DAST scores over the 12-month follow-up period. While some over-time trends in intervention groups were significant, their effect was small. As a result, there were no significant between-group difference in AUDIT or DAST scores across follow-up assessment time-points. Where present, small linear slope effects suggested that patients at lower-performing clinics with higher average baseline use benefited somewhat more from PLUS implementation.

Conclusions: The absence of intervention effects observed illustrates the importance of linking the goals of implementation research to clinic needs. New York City has achieved 90-90-90 goals and the 3 clinics involved in this trial had strong patient outcomes prior to implementation. Implementing an evidence based intervention at a high-performing clinic may not yield substantive changes in patient outcomes. Implementation researchers need to thoughtfully identify clinic needs in order to insure that intervention content addresses existing delivery challenges.
