Background: Black Women Living with HIV (BWLWH) bear the disproportionate burden of HIV as well as lower rates of antiretroviral therapy (ART) adherence and viral suppression compared to other racial/ethnic groups. This is linked to health disparities, structural inequities and psychosocial factors faced by BWLWH, which affect both access to and retention in care. However, the relationships between substance use, social support, and HIV-related health outcomes (i.e. viral suppression, ART adherence) have not been adequately explored among BWLWH. The present study seeks to add to existing literature by assessing how perceived social support (PSS) moderates the relationship between substance use and HIV viral load as well as medication adherence.

Methods: 119 BWLWH in the Southeastern United States completed self-report measures on PSS (the Multidimensional Scale of Perceived Social Support), substance use disorder (SUD), alcohol use disorder (AUD) via the Mini-International Neuropsychiatric Inventory and adherence. The Wisepill, an electronic monitoring device, also measured adherence in the past two weeks. HIV viral load was assessed via blood specimen.

Results: Linear regressions were conducted to examine the effects of PSS on adherence and viral load log. Higher PSS from friends ($\beta = -.263$, $p = .008$) and significant others ($\beta = -.219$, $p = .025$) predicted lower viral load. Furthermore, there were three trends, as PSS from family predicted lower viral load ($\beta = -.191$, $p = .061$) and both PSS from friends ($\beta = .162$, $p = .089$) and PSS from significant others ($\beta = .170$, $p = .070$) predicted self-report adherence in the past week. PSS did not predict SUD or AUD in the past 12 months. However, moderational analyses indicated that SUD predicted lower Wisepill adherence in the past week ($\beta = -.273$, $p = .035$) and past two weeks ($\beta = -.273$, $p = .033$) only for women low in PSS from friends. SUD also predicted lower Wisepill adherence in the past two weeks only for women who were low in PSS generally ($\beta = -.294$, $p = .024$). Interestingly, for women who were high in general PSS, SUD predicted higher Wisepill adherence in the past four weeks only ($\beta = .360$, $p = .006$).

Conclusion: Our findings indicate that adherence and viral load may be more easily bolstered by understanding the role of various forms of social support and SUDs among BWLWH. Social support interventions for BWLWH with SUDs may improve medication adherence, the corollary of which is viral suppression.

DEVELOPING AND PRETESTING A PREP PEER NAVIGATION INTERVENTION FOR YOUNG ADULT LATINO MEN WHO HAVE SEX WITH MEN

Rosa A. Cobian Aguilar, B.A., B.S.¹, Aaron J. Blashill, Ph.D.¹, Claudia M. Carrizosa, MD, MPH², Isaiah J. Jones, n/a³, David Rivera, n/a¹, Nicholas Lucido, n/a⁴, Kelsey A. Nogg, M.A.⁵, Kalina M. Pre-Exposure Prophylaxis (PrEP) is an effective medication taken daily to prevent HIV infection, especially when used with condoms. Latino men who have sex with men (MSM) are at high risk for new HIV diagnoses and are less likely to take PrEP compared with non-Hispanic White MSM. Latino MSM also face numerous personal, interpersonal, and logistical barriers to obtaining PrEP. Patient navigation is a barrier-focused intervention model focused on assisting individuals in obtaining recommended healthcare in a timely manner. This study describes an iterative process of developing a peer patient navigation (PN) intervention to assist young adult Latino MSM access PrEP. In collaboration with a Participatory Planning Group and using Social Cognitive Theory, the project team developed both English and Spanish-language patient-focused materials along with a flexible manual for the peer navigator. Intervention development included the following steps: 1) developing initial program concepts (e.g., key phrases, visuals to portray main ideas) for comprehension and attractiveness; 2) developing draft PN modules for participants facing a particular barrier; and 3) producing finalized materials with the assistance of a graphic design team. Four rounds of pretesting interviews with 18 young adult Latino MSM (mean age: 24.4 years, 50% Spanish speaking) were conducted to modify intervention materials, starting with initial program concepts and moving into intervention execution. Data from audio-recorded pretesting interviews were summarized and used to modify the intervention, which was then reviewed by additional interview participants. This iterative process continued until participants expressed positive feedback about modules and materials and expressed understanding of the content. The final produced PN intervention includes an introductory module, five educational modules (HIV prevention, PrEP introduction, PrEP efficacy, PrEP side effects, and PrEP adherence), and a module focused on decision support. Patient education is facilitated using infographics, palm cards, and a decision support tool. The educational modules are designed to be delivered as needed in tandem with personalized strategies to improve access and decrease barriers to PrEP initiation and adherence. Future research will examine feasibility of delivering the PrEP PN intervention in a randomized controlled trial.

A MIXED-METHODS EXPLORATION OF FAITH, SPIRITUALITY, AND HEALTH PROGRAM INTEREST AMONG OLDER AFRICAN AMERICANS WITH HIV

Allysha Maragh-Bass, PhD, MPH¹, Danetta E. Hendricks Sloan, PhD, MSW, MA², Amy Knowlton, ScD, MPH²

¹FHI 360, Durham, NC; ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD

Background: African Americans and persons living with HIV (PLWH) are living into older age with more complex care needs than non-PLWH. Evidence is needed to inform programs to promote quality of life and advance care planning (ACP) health literacy in caregiving relationships of the populations. We explored faith/spirituality-related correlates of interest in participating in a potential program on ACP and stress management among African American PLWH and their main caregivers.

Methods: Data were from the AFFIRM Care study. Participants were recruited from an HIV clinic and completed surveys, interviews, and focus groups. Quantitative analyses included logistic regression. Qualitative data were coded using grounded theory.

Results: Nearly half of participants had less than a high school education (47.9%), and roughly 90% of participants had heard of at least one ACP-related topic although most had only heard of advance directives (86.6%; N=315). Qualitative themes related to quality of life emphasized faith/spirituality, specifically: (1) Coping with life challenges; (2) Motivation to improve health for loved ones; and (3) Support programs for people living with HIV (N=39). Regarding interest in future quality of life programs, roughly half of participants expressed great interest (53.0%). Statistically-significant positive correlates included: satisfaction with religion/spirituality ($p < .05$), pain intensity ($p < .01$), and less comfort accepting care from social network members ($p < .10$; N=288). Negative correlates included greater HIV-related stigma ($p < .10$), and preference for initiating discussions of ACP with healthcare providers prior to major illness (as compared to other disease stages) ($p < .05$).

Conclusions: Results suggest the importance of addressing faith/spirituality in programs to promote ACP health literacy and engagement and quality of life among African Americans PLWH and their main caregivers. Prioritizing skill-building and grounding in community- and faith-based settings with input from faith leaders may reduce inequities in quality of life and improve ACP outcomes among African Americans with HIV.

FOCUS ON SINGLE TABLET REGIMEN AND LIPID PROFILE AMONG YOUTH LIVING WITH HIV IN MULTIDISCIPLINARY ADOLESCENT HIV CARE SETTINGS

Sitaji Gurung, MD MPH¹, Kit Simpson, DrPH, MPH², H. Jonathon Rendina, PhD, MPH³, Christian Grov, PhD, MPH⁴, Terry T. Huang, PhD, MPH, MBA⁴, Stephen S. Jones, BA Mathematics⁵, Tyra Dark, PhD, MA⁶, Sylvie Naar, n/a⁷

¹CUNY Graduate School of Public Health & Health Policy/PRIDE Hunter College, Flushing, NY; ²Medical University of South Carolina, Charleston, SC; ³Hunter College and The Graduate Center, CUNY, New York, NY; ⁴CUNY Graduate School of Public Health and Health Policy, New York, NY; ⁵RFcuny - Hunter College - PRIDE Health Consortium, NEW YORK, NY; ⁶Florida State University College of Medicine, Tallahassee, FL; ⁷Florida State University, Tallahassee, FL

Background: HIV itself and antiretroviral therapy (ART) are known to contribute to the elevated risk of cardiovascular disease (CVD), including lipid abnormalities. Although early treatment with ART might reduce the negative effect of HIV on overall cardiovascular risk, many HIV medications have intrinsic toxicity profiles. Single tablet regimens (STRs) have become an integral part of HIV management. STR has the potential for improved adherence due to a lower pill burden, especially among youth living with HIV (YLH). The current study examined whether detectable VL and STR contribute to lipid abnormalities among YLH aged 14–26y.

Methods: We analyzed a subsample of 398 de-identified electronic health records of YLH extracted from multidisciplinary adolescent HIV clinics for the *Adolescent Medicine Trials Network* 154 Cascade Monitoring Protocol. We conducted bivariate and multivariable logistic regression analyses to examine differences in lipid abnormalities by VL and STR status.

Results: Our sample included a higher proportion of black (305, 76.8%) and males (69.6%) with mean age of 21y. Nearly half (44.4%) of YLH had a detectable VL and a majority of YLH were currently on ART. Nearly half (40.7%) of YLH did not meet the ideal range of HDL and 28.5% were in the clinically high range of LDL cholesterol. Similarly, 15.1% of YLH had high total cholesterol and 15.4% had high triglycerides. Among those who were currently prescribed STR, we observed a significantly lower proportion of YLH with high total cholesterol compared to those who were not on STR (14.2% vs. 33.3%; $p < 0.05$). Among those with detectable VL, we observed a significantly higher proportion of YLH with low HDL compared to those without detectable VL (50.9% vs. 33.3%; $p < 0.001$). After adjusting for demographic and clinical covariates, treatment with STR significantly decreased the odds of having high total cholesterol (CI 0.03, 0.59; $p < 0.01$) and low HDL (CI 0.03, 0.88; $p < 0.05$) compared to those not on STR. On the other hand, having a detectable VL significantly increased the odds of having low HDL compared to those without detectable VL (CI 1.24, 3.47; $p < 0.01$).

Conclusions: Detectable VL significantly increased the odds of having low HDL, while the use of STR is associated with a more favorable lipid profile. Our findings suggest the adoption of STR may be an important strategy to lower VL and protect YLH against metabolic dysfunction associated with HIV.

CIGARETTE SMOKING AND METABOLIC SYNDROME IN YOUTH LIVING WITH HIV: FINDINGS FROM ELECTRONIC HEALTH RECORDS IN THE UNITED STATES

Sitaji Gurung, MD MPH¹, Kit Simpson, DrPH, MPH², Terry T. Huang, PhD, MPH, MBA³, H. Jonathon Rendina, PhD, MPH⁴, Christian Grov, PhD, MPH⁵, Richard Zhao, BA⁵, Demetria Cain, PHD MPH⁶, Tyra Dark, PhD, MA⁷, Sylvie Naar, n/a⁸

¹CUNY Graduate School of Public Health & Health Policy/PRIDE Hunter College, Flushing, NY; ²Medical University of South Carolina, Charleston, SC; ³CUNY Graduate School of Public Health and Health Policy, New York, NY; ⁴Hunter College and The Graduate Center, CUNY, New York, NY; ⁵PRIDE Health Research Consortium, Jamaica, NY; ⁶PRIDE Health Research Consortium/Hunter College, New York, NY; ⁷Florida State University College of Medicine, Tallahassee, FL; ⁸Florida State University, Tallahassee, FL

Background: Detectable viral load (VL) has been found to be associated with cardiovascular disease (CVD) and smoking among HIV-positive population. A recent study reported 20.4% of youth living with HIV (YLH) smoking cigarette daily or almost daily, and observed significance of cigarette smoking with higher mean log 10 VL. Metabolic changes leading to the development of atherosclerosis can start early in life, but are often undiagnosed in their early stages. Metabolic syndrome is a growing concern that may surpass smoking as one of the leading risk factors of CVD. We examined the association of smoking and metabolic syndrome with VL in YLH aged 14–26y.

Methods: The data for this study were drawn from the *Adolescent Medicine Trials Network* 154 Cascade Monitoring Protocol. De-identified electronic health records of YLH who received care in 2016 were extracted from multidisciplinary adolescent HIV clinics across the United States. This study utilized a subsample of 398 YLH. Multivariable linear regression was used to examine whether smoking and components of metabolic syndrome are related to a greater likelihood of high VL.

Results: Our sample included a higher proportion of blacks (76.8%) and males (69.6%) with mean age of 21y. Overall, 44.4% had a detectable VL, 26.9% were cigarette smokers based on ICD-10 diagnoses of tobacco dependence, and 27.6% met the criteria for metabolic syndrome. In bivariate analyses, having a detectable VL compared to those without detectable VL significantly increased the odds of being a smoker ($p < 0.05$) and were more likely to have low HDL cholesterol ($p < 0.001$). Subsequent analyses controlled for demographic and clinical covariates demonstrated that being a smoker was associated with a log 10 increase in VL copies/mL by 0.36 (CI 1.08, 1.92; $p < 0.05$) and having two components of metabolic syndrome was associated with a log 10 increase in VL copies/mL by 0.45 (CI 1.20, 2.03; $p < 0.01$).

Conclusions: Smoking and the presence of two components of metabolic syndrome were associated with VL non-suppression, highlighting the importance of smoking cessation in viral suppression and in reducing the overall burden of CVD risk in YLH. Our findings of greater prevalence of metabolic syndrome suggests routine monitoring of metabolic risks in YLH.

INTERPERSONAL AND COMMUNITY INFLUENCES ON PREP INITIATION AND ADHERENCE AMONG YOUNG ADULT LATINO MEN WHO HAVE SEX WITH MEN

Nicholas Lucido, n/a¹, Kristen J. Wells, PhD, MPH², Janna R. Gordon, M.S.³, Claudia M. Carrizosa, MD, MPH⁴, Christian B. Ramers, MD, MPH, AAHIVS⁵, Kalina M. Lamb, MA⁶, Kelsey A. Nogg, M.A.⁷, Rosa A. Cobian Aguilar, B.A., B.S.², John P. Brady, MS⁸, Isaiah J. Jones, n/a⁹, David Rivera, n/a², Martin Fuentes, B.A. Political Science/International Affairs¹⁰, Aaron J. Blashill, Ph.D.²

¹San Diego State University, Crockett, CA; ²San Diego State University, San Diego, CA; ³SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; ⁴SDSU Research Foundation, San Diego, CA; ⁵Family Health Centers of San Diego, San Diego, CA; ⁶Oregon State University, Corvallis, OR; ⁷University of Colorado Denver, Denver, CO; ⁸SDSU/UC San Diego JDP in Clinical Psychology, La Jolla, CA; ⁹San Diego State University, El Cajon, CA; ¹⁰Family Health Centers of San Diego, San Diego, CA

Introduction: Men who have sex with men (MSM) are the largest at-risk population for new HIV diagnoses, and HIV diagnoses are increasing among young Latino MSM. Pre-Exposure Prophylaxis (PrEP) is an effective medication taken daily to prevent HIV, especially when used with condoms. However, Latino MSM are less likely to take PrEP compared with non-Hispanic White MSM. The purpose of this study was to identify interpersonal- and community-level barriers and facilitators to PrEP initiation and adherence among young Latino MSM.

Methods: Using purposeful sampling, 27 Latino men, ages 18-29 years, participated in semi-structured in-depth interviews assessing barriers and facilitators to PrEP initiation and adherence and completed self-report demographic surveys. Interviews were audio recorded and transcribed verbatim. Content analysis was used to identify both *a priori* and emerging themes. Two coders independently coded each transcript, then resolved discrepancies via consensus.

Results and Discussion: Community and interpersonal influences, PrEP stigma, and sexual orientation discrimination all contribute to PrEP initiation and adherence among Latino MSM. Participants described a complex interaction between the LGBTQ and Latino communities' perspectives on PrEP. Most mentioned the LGBTQ community as being supportive and described learning about PrEP from their community, LGBTQ social media, and support groups for MSM using PrEP. Participants also mentioned PrEP stigma within the Latino and LGBTQ communities and values placed on masculinity/*machismo*, within the Latino community, as barriers to PrEP uptake and adherence. Stigma and sexual orientation discrimination were both emerging themes as participants indicated LGBTQ and Latino communities, family, friends, and the healthcare system as sources of stigma and discrimination. Participants feared their healthcare provider would make it difficult to obtain a PrEP prescription, due to PrEP stigma and sexual orientation discrimination.

Conclusions: Although PrEP can significantly reduce HIV infections among at-risk populations, Latino MSM continue to access PrEP less than non-Hispanic White and Black MSM populations. Interactions between interpersonal- and community-level factors influence PrEP initiation and adherence among Latino MSM. Identified facilitators and barriers should be targeted by interventions to reduce HIV risk and increase PrEP initiation and adherence among Latino MSM.

EFFECTIVE TRAINING AND QUALITY ASSURANCE STRATEGIES ASSOCIATED WITH HIGH-FIDELITY EBI IMPLEMENTATION IN PRACTICE SETTINGS

M. Margaret Dolcini, PhD¹, Melissa Davey-Rothwell, PhD², Ryan R. Singh, MPH¹, Joseph Catania, Ph.D.¹, Alice A. Gandelman, MPH³, Vasudha Narayanan, MA, MBS, MS⁴, Justin H. Harris, Honors Bachelor of Science, Honors Bachelor of Arts⁵, Virginia Mckay, PhD, MA⁶

¹Oregon State University, Corvallis, OR; ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ³California Prevention Training Center, Vallejo, CA; ⁴Acumen LLC, Berkeley, CA; ⁵Western University of Health Sciences, Lebanon, OR; ⁶Washington University in St. Louis, St. Louis, MO

Background: High quality implementation of evidence-based interventions (EBIs) is important for program effectiveness and is influenced by training and quality assurance (QA). However, gaps in the literature contribute to a lack of guidance on training and supervision in practice settings, particularly when significant program adaptations occur.

Purpose: We examined training and QA in relation to program fidelity among organizations delivering a widely disseminated HIV counseling and testing EBI in which significant adaptations occurred due to new testing technology.

Methods: Using a maximum variation case study approach, we examined training and QA in organizations delivering the program with high and low fidelity (Agencies: 3 = high fidelity; 3 = low fidelity (total number of personnel interviewed = 25; clients interviewed = 194).

Results: We identified themes that distinguished high- and low-fidelity agencies. For example, high-fidelity agencies more often employed a team approach to training; demonstrated use of effective QA strategies; leveraged training and QA to identify and adjust for fit problems, including challenges related to adaptations; and understood the distinctions between the primary EBI and other testing programs. The associations between QA and fidelity were strong and straightforward, whereas the relationship between training and fidelity was more complex.

Conclusions: The implementation of behavioral interventions in public settings requires high quality training and QA approaches that can address program fit and program adaptations. The study findings reinforced the value of using effective QA strategies. Future work should address methods of increasing program fit through training and QA, identify a set of QA strategies that maximize program fidelity and is feasible to implement, and identify low-cost supplemental training options.

BARRIERS AND FACILITATORS TO LATINO MEN WHO HAVE SEX WITH MEN ENGAGING IN HIV-PREVENTION AND BEHAVIORAL HEALTH SERVICES

Audrey Harkness, Ph.D.¹, Rosana Smith-Alvarez, B.A.², Daniel Mayo, Bachelor of Science (B.S.)¹, Steven A. Safren, Ph.D.³

¹University of Miami, Miami, FL; ²University of Miami, Key Biscayne, FL; ³University of Miami, Coral Gables, FL

Background: Latino gay, bisexual, and other men who have sex with men (MSM) experience disproportionate rates of new HIV infections across the U.S. In Miami, the U.S. city with the highest rate of HIV infections in the U.S., Latino MSM also lead in HIV incidence, while uptake of HIV-prevention (e.g., pre-exposure prophylaxis [PrEP]) and behavioral health services is lacking. The current study characterizes barriers and facilitators to Latino MSM engaging in HIV-prevention and behavioral health services.

Method: Participants include 26 Latino MSM (61.5% U.S. born) and 10 key informants who work in HIV-prevention and/or behavioral health services with Latino MSM in the Miami, FL area. Latino MSM were recruited from a pool of participants who were eligible for our HIV-prevention and behavioral health clinical trials and participated (“engagers;” n = 15) or did not participate (“non-engagers;” n = 11). We conducted semi-structured interviews in English, Spanish, or both regarding Latino MSM’s barriers and facilitators to engaging in HIV-prevention (regular HIV testing, PrEP) and behavioral health services. Interviews were recorded and transcribed for thematic analysis in NVivo 12. The first author reviewed 10 transcripts to develop an initial codebook, with iterative revisions to the codebook as new codes emerged from the data.

Results: The qualitative analysis identified 115 codes grouped into 10 categories that reflect Latino MSM’s barriers and facilitators to engaging in HIV-prevention and behavioral health services. The categories include: (1) degree of perceived need or relative importance, (2) anticipated emotional responses to engaging in services, (3) anticipated consequences of engaging in services, (4) degree of knowledge or awareness of health and related services, (5) views on the medical system and services, (6) influence of peers/social network, (7) influence of providers/staff/organizations, (8) cultural factors, (9) structural factors, and (10) relevance of public health/outreach messaging. Specific codes within each category will be further discussed in the presentation.

Conclusions: Findings highlight key factors that may need to be addressed by developing new implementation strategies to scale up and disseminate needed HIV-prevention and behavioral health services to Latino MSM. The findings also highlight the multilevel nature of these barriers and facilitators, implicating the need for coordinated individual, interpersonal, and structural/community level implementation strategies to achieve full engagement in needed services among Latino MSM.

FREQUENCY OF AND REASONS FOR INTEGRATED PRIMARY CARE CONSULTATIONS IN TWO AMBULATORY CLINICS IN AN UNDERSERVED COMMUNITY

Jennifer Battles, MS¹, Michael Vriesman, n/a², Alyssa M. Vela, PhD³, Jennifer Carty McIntosh, PhD⁴, Andrew R. Champine, PsyD LP⁵

¹Eastern Michigan University, Ypsilanti, MI; ²Eastern Michigan University, Belleville, MI; ³McLaren Flint, Fenton, MI; ⁴McLaren Flint - Family Medicine, Flint, MI; ⁵McLaren Health Care, Bay City, MI

Introduction: Integrated primary care (IPC) is a method for expanding behavioral health services within primary care clinics. Behavioral health consultants (BHC) are capable of addressing a wide range of behavioral and mental health concerns in IPC. However, with significant variation in conceptualization and implementation of IPC across clinics, little is known regarding the utilization of IPC to address a variety of concerns. Further, it is unclear if there are operational variations between primary care settings, such as internal medicine (IM) and family medicine (FM).

Methods: Twelve months of IPC data were reviewed from two independent, co-located ambulatory clinics in Flint, Michigan. Primary care physicians (PCP) at these clinics typically treat underserved, low-SES patients with diverse backgrounds. IPC referrals were reviewed to determine the frequency and reasons for referrals, as well as to identify any differences between IM and FM clinics. Referrals were coded as mental health (e.g., depression), behavioral health (e.g., chronic pain), or combined mental and behavioral health (e.g., substance use).

Results: There were a total of 254 referrals, with 201 referrals in FM and 53 in IM. Mental health referrals were most common in both FM (73%) and IM (60%). In FM, depression (33%), anxiety (16%), adjustment disorder (11%) and bipolar disorder (10%) were the most frequent reason for referral. FM made referrals for behavioral health reasons (17%) such as diabetes (6%), smoking cessation (6%), and weight loss (5%). In IM, depression (42%), anxiety (21%), diabetes (9%), bipolar disorder (8%), sleep hygiene (8%), weight loss (6%), chronic pain (6%), and differential diagnosis (6%) were the most common reasons for referrals. IM made referrals for behavioral health (19%) or combined mental and behavioral health concerns (19%) more frequently than FM.

Conclusions: With a longer history of integration, IPC was more frequently utilized in FM, with an emphasis on referrals for mental health. While IM physicians made less frequent referrals, their reasons for referrals were more varied, including more behavioral health concerns compared to FM. These results provide direction for future IPC development, with attention to goals to increase utilization for behavioral health concerns. Differences between FM and IM clinics, plans to address these areas of need, and implications for IPC in the broader community will be reviewed.

HEALTH CHARACTERISTICS & ENGAGEMENT OUTCOMES OF COMPLEX PATIENTS IN THE UNIVERSITY OF UTAH HEALTH INTENSIVE OUTPATIENT CLINIC

Brittany L. Sisco-Taylor, PhD¹, Angela Fagerlin, PhD¹, Rebecca K. Delaney, PhD¹, Peter Weir, MD, MPH¹, Bernadette Kiraly, MD¹, Elissa M. Ozanne, PhD¹¹University of Utah, Salt Lake City, UT

Background: Intensive Outpatient Care Programs, like the UofU Health Intensive Outpatient Clinic (IOC), expand primary care services for high-risk, high-need patients through interdisciplinary, team-based, and personalized care that addresses patients' medical, behavioral health, and social needs. Recent literature suggests that to be successful, these clinics must improve patients' engagement. To improve the effectiveness of these programs, it is important to characterize the heterogeneity in patients' health and social needs, and to evaluate the clinic's impacts on patient engagement outcomes.

Aim: To characterize the health status of patients seen in the IOC and examine whether their engagement outcomes improved over 6 months of care.

Methods: Patients' health across three domains (i.e., chronic illness, behavioral health, and pain) was summarized with electronic health record data, using ICD-9/10 diagnosis codes and associated Clinical Classifications Software (CCS) categories from any visits after the IOC intervention began (January 2017–August 2019). Patients' multi-morbidity at their first IOC visit was partially summarized using 12 CCS categories corresponding to some of the most prevalent conditions: chronic illness (5 CCS codes; e.g., diabetes mellitus, diseases of the heart); behavioral health (3 CCS codes: mood/anxiety/substance-related disorders); and pain (4 CCS codes: e.g., musculoskeletal/joint disorders). Engagement was indexed by online surveys (Modified Picker Survey (communication), Patient Trust Scale, and Self-Efficacy Scale), completed by a subset of patients who received the IOC intervention for at least 6 months. Paired *t*-tests evaluated pre-post improvements in engagement from baseline to 6-month follow-up.

Findings: Of 121 patients ages 20 to 72 (65% female; 79% white; 9% Hispanic/Latinx; 82% insured through Medicaid; *Mage* = 47 years(*SD*=11.8)) seen in the IOC, 75% had a chronic illness, 81% had a behavioral health diagnosis, and 77% experienced pain. The most prevalent chronic illnesses were hypertension (75%), GERD (67%), asthma (48%), and type 2 diabetes (39%). The most prevalent behavioral health diagnoses were major depression (81%), nicotine dependence (48%), anxiety (40%), PTSD (34%), and alcohol and drug dependence (21%). The most prevalent pain diagnoses were chronic pain (77%), low back pain (52%), and headache (45%). IOC survey participants (*n* = 39; demographics similar to full sample), had significant improvements in their communication with care team, trust in care team, and self-efficacy for disease management ($t_{(38)}=5.45, p<.001$, $t_{(36)}=2.40, p=.022$, and $t_{(38)}=2.41, p=.021$; respectively).

Conclusion: The IOC serves diverse subpopulations of high-need patients and has led to improvements in patients' engagement with their healthcare.

6:15 PM-7:30 PM

BARRIERS TO HPV VACCINE SERIES COMPLETION IN AN INSURED POPULATION

Aruna Kamineni, PhD, MPH¹, Paula R. Blasi, MPH¹, Gabrielle Gundersen, MPH¹, Malia Oliver, BA¹, John Dunn, MD, MPH², Denise Galloway, PhD³, Margaret Madeleine, PhD, MPH³¹Kaiser Permanente Washington Health Research Institute, Seattle, WA; ²Kaiser Permanente Washington, Seattle, WA; ³Fred Hutchinson Cancer Research Center, Seattle, WA

Human papillomavirus (HPV) is the most common sexually transmitted infection in the United States. Infection with certain types of HPV can lead to cervical cancer as well as other cancers in both men and women. HPV vaccines are safe and efficacious for preventing certain types of HPV infection. However, individuals must receive either 2 doses (for ages 9-14) or 3 doses (for ages 15 and older) for complete immunization. The requirement for multiple doses may limit the effectiveness of the HPV vaccine for cancer prevention. To better understand barriers to completing the multiple-dose HPV vaccine series, we conducted a pilot study among members of an integrated health care system (Kaiser Permanente Washington) who had clinical documentation of only one dose of HPV vaccine. We surveyed parents or legal guardians of 11-17-year-old girls (*n*=10) and boys (*n*=18), as well as 18-31-year-old women (*n*=20) and men (*n*=9), about their reasons for not completing the HPV vaccine series. Most participants (70.2%) were non-Hispanic white, and most (77.2%) reported the highest level of education attained by an immediate family member as a bachelor's degree or higher. Among parents of children, commonly reported barriers to HPV vaccine series completion included a lack of awareness about the need for additional doses or a lack of clinician recommendation for additional doses (28.6%), as well as the inconvenience of returning for additional doses (17.9%). Concerns about the HPV vaccine or vaccines in general were more common among parents of girls (30.0%) compared with parents of boys (16.7%). Among adult participants, barriers to HPV vaccine series completion included the inconvenience of returning for additional doses (31.0%), a lack of awareness or a lack of clinician recommendation for additional doses (10.3%) and forgetting (10.3%). Our findings suggest opportunities for clinicians and health care systems to play a greater role in promoting HPV vaccine series completion. For example, clinicians could counsel patients about the cancer-prevention benefits of HPV vaccination and the need for multiple doses, while addressing parents' psychological barriers by listening to and addressing their concerns about the vaccine. Health care systems could provide cues to action through electronic health record prompts for clinicians and reminder letters, emails, phone calls, or text messages for patients. Finally, health care systems could address the inconvenience of obtaining multiple doses by offering HPV vaccination in school-based health centers, pharmacies, and mobile immunization clinics, while also encouraging opportunistic vaccinations. Future research could explore the effectiveness of these and other health promotion strategies to facilitate completion of the HPV vaccine series.

LONG-TERM EFFECTIVENESS OF IMPROVING ACCESS TO PSYCHOLOGICAL THERAPIES (IAPT) IN NORWAY: A RANDOMIZED CONTROLLED TRIAL

Solbjørg M.M. Sæther, PhD¹, Marit Knapstad, PhD¹, Otto R.F. Smith, PhD¹¹Norwegian Institute of Public Health, Bergen, Hordaland, Norway

Background: Prompt Mental Health Care (PMHC, the Norwegian adaption of the English program Improving Access to Psychological Therapies, IAPT) has been found successful in the short-term in alleviating symptoms of anxiety and depression, and in improving functional status, health-related quality of life and mental wellbeing, also when compared to treatment as usual (TAU). However, long-term outcomes of any IAPT-like treatment model compared to TAU have yet to be investigated.

Objectives: To investigate the effectiveness of PMHC treatment compared to TAU 12 months after PMHC entry.

Method: Randomized controlled trial with parallel assignment in two PMHC sites (Sandnes and Kristiansand) from November 2015 to March 2018. In total, 681 adults (aged ≥18 years) considered for admission to PMHC due to anxiety and/or mild to moderate depression (Patient Health Questionnaire (PHQ-9)/Generalized Anxiety Disorder scale (GAD-7) scores above cut-off) were randomly assigned (70:30 ratio: n=463 to PMHC, n=218 to TAU) using simple randomization within each site with no further constraints. Main outcomes were recovery rates and changes in symptoms of depression and anxiety from baseline to 12 months follow-up. Secondary outcomes functional status, health-related quality of life, mental wellbeing and work participation.

Results: 12 months after baseline, the reliable recovery rate was 59.4% in PMHC and 36.6% in TAU, yielding a between-group effect size of 0.51 (95%CI: 0.26 to 0.77, $p < 0.001$). Differences in change of symptoms gave between group effect sizes of -0.67 (95%CI: -0.99 to -0.36, $p < 0.001$) for depression and -0.71 (95%CI: -1.15 to -0.27, $p < 0.001$) for anxiety, both in favor of PMHC. PMHC was also at 12 months more effective than TAU in improving functional status (between-group effect size: -0.42 (95%CI: -0.72 to -0.12)), health related quality of life; (-0.55 (95%CI: -0.96 to -0.15)) and mental wellbeing (0.61 (95%CI: 0.61 to 0.93)). Based on the current data, there was no evidence for an effect of PMHC on work participation.

Conclusions: Effects achieved during treatment with PMHC, in symptom alleviation, as well as functional status, health-related quality of life and mental wellbeing, were maintained also after end of care. At 12 months follow-up, PMHC was still substantially more effective than TAU on all these measures. Future studies with more statistical power should provide more precise estimates of the effect of PMHC on work participation.

MENTAL HEALTH SELF-STIGMA AND PERCEIVED LEVELS OF SOCIAL SUPPORT ON MENTAL HEALTH OUTCOMES AMONG PACIFIC ISLANDERS

Cindy J. Garcia, n/a¹, James R. Pike, MBA², Patty Kwan, PhD, MPH³, Genesis Lutu, n/a⁴, Lolofi Soakai, n/a⁵, Paula Palmer, PhD⁶, Sherine El-Toukhy, PhD, MA⁷, Melanie Sabado-Liwag, PhD, MPH⁸

¹California State University of Los Angeles, Los Angeles, CA; ²University of North Carolina, Los Angeles, CA; ³California State University of Northridge, Los Angeles, CA; ⁴Claremont Graduate University, Los Angeles, CA; ⁵Motivating Action Leadership Opportunity, Los Angeles, CA; ⁶Claremont Graduate University, Claremont, CA; ⁷National Institutes of Health, Bethesda, MD; ⁸California State University, Los Angeles, Los Angeles, CA

Background: In the United States, Pacific Islanders (PIs) endure heavy mental health burden yet report low use of mental health services. Research on Pacific Islanders mental health is scarce, especially in regards to self-stigma and social support.

Aim: The aim of the current study was to investigate how perceived levels of social support and levels of self-stigma moderate mental health outcomes (depression, anxiety, and stress) among PIs.

Methods: PIs with no previous mental illness diagnosis, between the ages of 18 and 35 and resided in California (N=213), were electronically surveyed about their mental health, perceptions about mental health, and perceived levels of social support. Mental health outcomes were assessed using the Depression, Anxiety, and Stress Scale (DASS-21). Perceived levels of social support were assessed using the Multidimensional Scale of Perceived Social Support (MSPSS). Levels of self-stigma were assessed using the Self-Stigma of Mental Illness Scale (SSMIS). A series of ordinary least square regression models were tested to examine the effect of mental health self-stigma and perceived social support (friends, family, significant other) on depression, anxiety, and stress.

Results: Over a quarter of the sample was classified as reporting above normal levels of depression (25.3%), stress (26.8%), and anxiety (34.3%). Unlike family support with a protective effect, perceived social support from friends was associated with higher level of depression and amplified through an interaction with mental health self-stigma ($ps < .05$). Similar findings were found with higher levels of anxiety and stress.

Conclusion: These results suggest that the interaction between mental health self-stigma and social support from friends may negatively affect multiple aspects of mental health more so than other forms of social support. Future interventions to reduce self-stigma may improve mental wellness among young adult PIs.

PERCEIVED SOCIAL SUPPORT MEDIATES THE ASSOCIATION BETWEEN CUMULATIVE HEALTH RISK AND HEALTH OUTCOMES AMONG HOMELESS ADULTS

Sajeevika S. Daundasekara, PhD¹, Daphne C. Hernandez, PhD, MEd, FAAHB¹, Adam Alexander, Ph.D.², Diane Santa Maria, DrPH, MSN, RN, PHNA-BC, FSAHM,FAAN³, Lorraine R. Reitzel, PhD, FAAHB⁴, Darla E. Kendzor, PhD⁵, Michael S. Businelle, PhD⁵

¹University of Houston, Houston, TX; ²Oklahoma Tobacco Research Center, Oklahoma City, OK; ³Cizik School of Nursing, Houston, TX; ⁴University of Houston, HOUSTON, TX; ⁵University of Oklahoma Health Sciences Center, Oklahoma City, OK

Introduction: Individuals experiencing homelessness are at greater risk of exposure and vulnerability to health risk factors leading to diminished physical and mental health. However, evidence is lacking on the mediating role of social support in the association between health risk factors and negative health outcomes among homeless adults. We examined the potential mediating role of social support on the association between cumulative health risk and poor health outcomes among adults experiencing homelessness.

Method: Adults experiencing homelessness were recruited from six homeless shelters in Oklahoma City (n=567). Participant's health outcomes measured included, depression assessed using the eight-item Patient Health Questionnaire, post-traumatic stress disorder (PTSD) assessed using the four-item Primary Care Post-Traumatic Stress Disorder screener and self-rated overall health status on a five point Likert type scale (1=Excellent to 5=poor). Urban life stress (Urban Life Stress Scale), perceived stress (Perceived Stress Scale) and distress intolerance (Distress Tolerance Scale) were used as latent construct of the cumulative health risk (CHR) with higher values representing greater risk. The total score from the interpersonal support evaluation list (ISEL-12) was used to measure the perceived availability of social support. Covariate adjusted mediation models were conducted to evaluate the indirect effects of cumulative health risk on health outcomes through perceived social support.

Results: Majority of the sample were males (63%), white/non-minority (57%), not married (88%) and unemployed (88%). Thirty-one percent of the adults experiencing homelessness had depressive symptoms, 32% screened positive for PTSD symptoms and 37% rated their health as poor/fair. According to the bootstrapped 95% confidence intervals, the indirect effect of CHR on depression through perceived social support (b=0.160, 95% CI =0.059, 0.155) and CHR on poor health through perceived social support (b=0.052, 95% CI =0.006, 0.103) was significant. The indirect effect of CHR on PTSD through perceived social support was not significant (b=0.045, 95% CI =-0.003, 0.093).

Conclusions: Social support partially mediates the association of cumulative health risk on depression and poor health. Providing social support in the form of appraisal, belonging, and tangible support could provide better results for reducing depression symptoms and improve health status among homeless adults.

CLINICAL TRIAL OF REMOTELY ADMINISTERED, MOBILE-BASED ATTENTION MODIFICATION FOR POSTTRAUMATIC STRESS SYMPTOMS

Paige Tripp, BA¹, Andrea Niles, Ph.D¹, Joshua Woolley, M.D, PhD¹, Ana Pesquita, PhD², Thomas C. Neylan, MD¹, Aoife O'Donovan, PhD¹

¹University of California, San Francisco, San Francisco, CA; ²University of Birmingham, San Francisco, CA

Although behavioral therapies are effective for posttraumatic stress disorder (PTSD), patient access is limited. Attention bias modification (ABM), a cognitive training intervention that aims to reduce attention bias for threat, can be broadly disseminated using technology. We remotely tested an ABM mobile app for PTSD symptoms (PTSS). Participants with clinically significant PTSS (PTSD Checklist > 33; N=689; M age = 32; 80% female) were randomly assigned to personalized ABM, non-personalized ABM, or placebo training. ABM was a 12-day modified dot-probe paradigm with threatening and neutral words. Primary outcomes of PTSS and anxiety were collected at baseline, post-training, and 5-week follow-up. Mechanisms, assessed during treatment, were attention bias and self-reported threat sensitivity. Data collection was completed in 10 months with 75% of participants that completed day one on the app completing at least 10 out of 12 total training sessions. No group differences emerged on outcomes or attention bias. Non-Personalized ABM showed greater reduction in self-reported threat sensitivity during training compared to Placebo (p=.044). This study is the largest mobile-based trial of ABM to date. Data highlight high feasibility and acceptability of a remotely conducted PTSD intervention. However, our specific form of ABM was not efficacious in reducing PTSD severity.

IMPLEMENTING A DBT GROUP INTERVENTION IN A PRIMARY CARE SETTING: A FEASIBILITY AND ACCEPTABILITY STUDY

Denise Guarino, PsyM¹, Laura M. Lesnewich, n/a², Lynn Clemow, PhD³, Christopher D. Hughes, M.S.⁴, Shireen L. Rizvi, PhD, ABPP⁵¹Montefiore Medical Center, Bronx, NY; ²Rutgers University-New Brunswick, Highland Park, NJ; ³Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; ⁴Warren Alpert Medical School of Brown University, Providence, RI; ⁵Rutgers University, Piscataway, NJ

People in the United States are more likely to seek mental health treatment from primary care providers than mental health specialists. Incorporating effective transdiagnostic interventions in integrated behavioral health settings that can address a variety of psychological problems across clinical severities can reduce burden on primary care providers and increase the accessibility of evidence-based treatments. Dialectical Behavior Therapy (DBT) is a comprehensive treatment originally developed to treat borderline personality disorder and suicidality whose behavioral skills teachings have been adapted to meet the needs of various clinical populations. DBT skills-only interventions have been delivered effectively in diverse settings within transdiagnostic populations but have not been researched directly in primary care settings. This year-long pilot study aimed to test the feasibility and acceptability of a modified DBT skills-only group intervention in a primary care setting. The DBT skills groups were open enrollment, rolling admissions, and ran continuously for 50 weeks. Participants were 35 adult patients of a primary care medical practice struggling with a variety of mental health challenges; all participants received the active intervention. Results showed that the intervention was feasible and acceptable, with high ratings of enjoyment, skill helpfulness, and skills practice across weekly and post-treatment measures. Both quantitative and qualitative measures indicated mindfulness skills were the most helpful and frequently used skills by participants. Paired t-tests showed clinically significant reductions in participant somatization, $t(33) = 2.99$, $p = .005$, depression, $t(33) = 2.83$, $p = .008$, rumination, $t(33) = 3.13$, $p = .004$, and emotion dysregulation, $t(33) = 2.34$, $p = .025$, and significant increases in participant skills use, $t(32) = -3.65$, $p = .001$, in the intent-to-treat sample ($N=35$) with small-to-medium effect sizes. Medium-to-large effect sizes were found in the subset of the sample that received an adequate dose of the intervention ($N=16$). Hierarchical linear models demonstrated a statistically significant effect of time on decreases in weekly somatization, $t(210.5) = -5.04$, $p < .0001$, depression, $t(209.1) = -7.25$, $p < .0001$, and anxiety, $t(157.8) = -4.45$, $p < .0001$, symptoms. These preliminary data support the clinical utility of using a subset of DBT skills as a transdiagnostic group intervention in primary care settings.

PATTERNS AND CORRELATES OF DEPRESSION AND ANXIETY AMONG LATINA IMMIGRANT WOMEN

Daron Ryan, MPH¹, Stephanie Tornberg-Belanger, MS, MPH¹, Georgina Perez, MSW¹, Serena Maurer, PhD¹, Deepa Rao, PhD¹, KC Gary Chan, PhD¹, India J. Ornelas, PhD¹¹University of Washington, Seattle, WA

Background: Latina immigrant women in the United States are at increased risk of adverse mental health outcomes due to economic, political, cultural and social stressors related to migration and resettlement. However, few studies have described correlates of depression and anxiety symptoms among Latina immigrant women.

Methods: Our study used data collected as part of the Amigas Latinas Motivando el Alma (ALMA) study, which is evaluating a community-based intervention to reduce stress, depression, and anxiety symptoms among Latina immigrant women ($N = 109$). Interviewers administer baseline surveys that assess demographics, depression symptoms (PHQ-9), anxiety symptoms (GAD-7), immigration-related stressors, self-compassion, and resilience. We used descriptive statistics, chi-square statistics and t-tests to describe correlates of depression and anxiety in the sample.

Results: Participants had a mean age of 41 years, 85% were from Mexico, and had lived in the United States 15 years on average. At baseline, 24% of participants reported moderate to severe depressive symptoms (overall mean PHQ-9 total score of 7.1) and 29% of participants reported moderate to severe anxiety symptoms (overall mean GAD-7 total score of 7.0). Higher scores of depressive symptoms were associated with having smaller social networks ($p=0.05$), increased social isolation ($p=0.00$), increased perceived stress ($p=0.00$), and higher levels of immigration-related stress ($p=0.01$). Higher scores of anxiety symptoms were associated with having smaller social networks ($p=0.03$), increased social isolation ($p=0.00$), increased perceived stress ($p=0.00$), and immigration-related stress ($p=0.00$). Depression and anxiety symptoms were also negatively associated with scores of self-compassion ($p=0.00$) and resilience ($p=0.01$).

Conclusions: Findings suggest that Latina immigrant women experience multiple types of stressors and that these are associated with increased symptoms of depression and anxiety. Findings also suggest that resilience and self-compassion may be related to lower levels of depression and anxiety. More research is needed to further assess the relationship between stress and poor mental health among Latina immigrants, such as types of stressors and severity. Latina immigrants may benefit from interventions that reduce social isolation and promote self-compassion, resilience, and stress-reduction.

SELF-COMPASSION AS A MECHANISM THROUGH WHICH ATTACHMENT INFLUENCES MENTAL HEALTH AND QUALITY OF LIFE

Kyla Brophy, MSc¹, Adina Coroiu, PhD², Annett Korner, PhD³¹McGill University Department of Educational and Counselling Psychology, Montreal, PQ, Canada; ²Harvard TH Chan School of Public Health, Boston, MA; ³McGill University, Montreal, PQ, Canada

Background: Self-compassion can be defined as exercising kindness towards oneself when faced with personal suffering. The ability to be self-compassionate may be shaped by early attachment experiences and has been linked to lower levels of psychopathology and enhanced well-being. This study examined whether two distinct features of self-compassion (self-warmth and self-coldness) mediate the relationship between: 1) attachment anxiety and depression; 2) attachment avoidance and depression; 3) attachment anxiety and quality of life; 4) attachment avoidance and quality of life.

Methods: Participants ($N = 2,253$; 53.4% female, $M_{age} = 50$ years) from a German general population sample completed the Self-Compassion Scale (SCS), Adult Attachment Scale (AAS), Beck Depression Inventory-Fast Screen (BDI-FS), and European Organization for Research and Treatment of Cancer Quality of Life Questionnaire (EORTC QLQ-C30). Parallel mediation using PROCESS for SPSS examined whether insecure attachment (anxiety and avoidance) predicted increased symptoms of depression and decreased quality of life through self-warmth and self-coldness in four separate models.

Results: **MODEL 1:** Attachment anxiety had a significant indirect effect on depressive symptoms via self-warmth (std. $\beta = .01$, 95% CI [.01, .02]) and self-coldness (std. $\beta = .17$, 95% CI [.15, .20]). The total effect of attachment anxiety on depressive symptoms was reduced from $\beta = .29$ to $\beta = .11$ ($p < .001$) when self-warmth and self-coldness were added to the model. **MODEL 2:** Attachment avoidance had a significant indirect effect on depressive symptoms via self-warmth (std. $\beta = .02$, 95% CI [.01, .03]) and self-coldness (std. $\beta = .15$, 95% CI [.13, .17]). The total effect decreased from $\beta = .28$ to $\beta = .11$ ($p < .001$) when mediators were added to the model. **MODEL 3:** Attachment anxiety had a significant indirect effect via self-coldness (std. $\beta = -.11$, 95% CI [-.13, -.09]), but not self-warmth ($\beta = -.01$, 95% CI [-.01, .00]). The total effect decreased from $\beta = -.18$ to $\beta = -.07$ ($p > .001$). **MODEL 4:** Attachment avoidance had a significant indirect effect via self-coldness (std. $\beta = -.09$, 95% CI [-.11, -.07]), but not via self-warmth (std. $\beta = -.01$, CI [-.01, .00]). The total effect decreased from $\beta = -.21$ to $\beta = -.12$ ($p < .001$).

Discussion and Conclusions: Most research testing the relationship between attachment, self-compassion, psychopathology, and quality of life has used a Self-Compassion Scale total score, but did not consider the possibly differing contributions of the sub-dimensions of this construct. The indirect effects via self-warmth appear to be of negligible magnitude or non-significant, speaking against self-warmth as a mediator. Our findings suggest that self-coldness may be particularly relevant as a treatment target when addressing relational struggles, with both theoretical and clinical implications for psychotherapy and future research.

CHRONIC STRESS, EARLY LIFE ADVERSITY AND DEPRESSIVE SYMPTOMS: THE MODERATING ROLE OF POSITIVE SOCIAL RELATIONSHIPS

Chantal Paquin, Ph.D.¹, Linda Booij, PhD², Jean-Philippe Gouin, PhD²¹Concordia University, Lachine, PQ, Canada; ²Concordia University, Montreal, PQ, Canada

Introduction: Chronic stress is associated with risk for elevated depressive symptoms in adulthood. Exposure to early life adversity (ELA) may compound this risk. However, positive social relationships may buffer the impact of chronic stress and ELA on depressive symptoms. The goal of this study was to test whether positive social relationship may buffer the associations between chronic stress, ELA, and depressive symptoms. **Methodology:** This cross-sectional study included 168 partnered middle-aged mothers of either an adolescent with an autism spectrum disorder or intellectual disability, the chronic caregiving group ($n = 94$), or with a typically-developing adolescent, the comparison group ($n = 74$). ELA was assessed using the Childhood Trauma Questionnaire. Depressive symptoms was assessed using the Center for Epidemiologic Studies Depression. Participants also completed a daily diary to assess daily feelings of joy experienced across several social relationships (their child, partner, family, friends and coworkers) for 6 consecutive days. An averaged measure of the daily relationship joy was computed from the diary data. A moderation analysis tested the three-way interaction among chronic stress, ELA, and relationship joy when predicting current depressive symptoms.

Results: The three-way interaction was statistically significant ($F(1, 160) = 9.70$, $p < .01$, $R^2 = .047$). Participants with the highest depressive symptoms where chronically stressed mothers who reported greater ELA exposure and lower daily relationship joy, while participants with the lowest depressive symptoms were mothers of typically developing adolescents who reported low ELA and higher daily relationship joy. Simple slopes analysis indicated that daily relationship joy attenuated the association between ELA and depressive symptoms of mothers under chronic parenting stress ($F(1, 160) = 9.21$, $p < .01$) but not for mothers raising a typically-developing adolescent ($F(1, 160) = 1.72$, $p < .19$). The results remained significant after controlling for socioeconomic status and marital satisfaction.

Conclusion: Positive emotions elicited by social interactions moderated the associations among chronic stress, ELA and depressive symptoms. Although longitudinal studies are needed to disentangle the directionality of these associations, these findings suggest a potential mechanism underlying the stress buffering effects of social support.

EFFECTS OF RESISTANCE TRAINING ON DEPRESSION AND CARDIOVASCULAR DISEASE RISK IN BLACK MEN

Joseph T. Ciccolo, PhD¹, Mark E. Louie, EdD, n/a², Nicholas SantaBarbara, PhD³, Alex Ajayi, PhD⁴, Shira Dunsiger, PhD⁵, Michael P. Carey, PhD⁶, Andrew M. Busch, PhD⁷

¹Teachers College, Columbia University, NEW YORK, NY; ²Rutgers University, The State University of New Jersey, Fair Lawn, NJ; ³UCLA, Marina Del Rey, CA; ⁴Augsburg University, Minneapolis, MN; ⁵The Miriam Hospital and Brown University, Portsmouth, RI; ⁶The Miriam Hospital and Brown Univ, Providence, RI; ⁷Hennepin Healthcare/University of Minnesota, Saint Paul, MN

Background: Depression is underrecognized and undertreated in Black men. Depression also contributes to cardiovascular disease (CVD), and Black men have the highest rate of mortality from CVD. Resistance training (RT; i.e., weight lifting) can have beneficial effects on depression and CVD.

Method: Fifty Black men with clinical symptoms of depression were randomized into 12 weeks of RT or an attention-control group. Behavioral Activation techniques were used to support adherence to the RT. Both groups met twice/week during the intervention, and follow-up assessments were done at end-of-treatment (EOT) and 3 months later. Depression was assessed with the interview-administered Quick Inventory of Depression Symptomology (QIDS). CVD risk variables included body composition, blood pressure, cholesterol, and high-sensitivity C-reactive protein (HS-CRP). As this was a pilot trial, we focus on effect sizes rather than statistical significance.

Results: Using a series of longitudinal mixed effects models with subject specific intercepts, associations between condition and primary (QIDS) and secondary (CVD risk variables) outcomes were examined. Models adjusted standard errors for clustering of repeated responses within participant. The analysis was restricted to those with at least one follow-up assessment (n=38). There were medium sized effects indicating lower mean QIDS scores for the RT group at EOT ($b=-1.89$, 95% CI: -4.26-.04, $f^2=.14$) and 3-month follow-up ($b=-1.90$, 95% CI: -5.61-0.81, $f^2=.15$). Mean reductions in QIDS score from baseline to EOT was 6.24 points (SD=4.33) for the RT group vs. 3.24 (SD=3.80) for control. At the 3-month follow-up, mean reductions were 4.38 (SD=6.19) for RT participants vs. 1.75 (SD=4.27) for the control. There was a medium sized effect indicating lower body fat in RT vs. control at the EOT ($b=-.71$, 95% CI: -2.37-.95), but not at the 3-month follow-up. There was no indication of differences between groups in blood pressure, cholesterol, or HS-CRP.

Conclusion: The high disease burden of depression and CVD, along with the persistent barriers to care facing Black men warrant the development of novel interventions for depression for these men. The results of this study suggest that RT is feasible and may be effective for reducing depression and CVD risk in this population. A future, fully powered study is needed.

This study was funded by the National Institute of Nursing Research (NINR) R21 NR016112.

This abstract is sponsored by the CVD SIG.

IMPACT OF AN ADULT ADHD TOOLKIT UTILIZED IN A PRACTICE SETTING

Cory B. Lutgen, BS¹, Elisabeth Callen, PhD, GStat¹, Natalia Loskutova, MD, PhD¹

¹American Academy of Family Physicians National Research Network (AAFP NRN), Leawood, KS

Introduction: Approximately 5% of the US adult population has Adult ADHD, which has negative impacts on quality of life. The diagnostic features of ADHD in adults and management strategies differ from pediatric ADHD. Healthcare professionals report a need to increase their knowledge of the disorder and confidence in diagnosis and management of ADHD in adults through education, tools and resources. To address this need, the American Academy of Family Physicians National Research Network (AAFP NRN) collaborated with a panel of experts to create a web-based Adult ADHD Toolkit composed of information, content, and tools to aid in the diagnosis, management and treatment of adults with ADHD.

Objectives: To assess the impact of utilizing an Adult ADHD Toolkit in a practice setting.

Methods: Primary and behavioral healthcare professionals from AAFP NRN practices (n=6) used the Adult ADHD Toolkit for 17 weeks. Data on Toolkit use, usefulness, implementation, impact, and changes in ADHD-related knowledge, confidence and practice were collected via pre-post and weekly surveys and end of study interviews. Mixed method approach was used to analyze data. Time series and regression analyses were used to track the change in use/implementation of the Adult ADHD Toolkit as well as the knowledge change between pre, mid, and post surveys.

Results: The access to and use of the Adult ADHD Toolkit had a positive longitudinal impact on provider competence and confidence related to Adult ADHD. An observable change in knowledge occurred in the content areas related to nature of ADHD, ADHD diagnosis in adults, treatment and management of ADHD in adults, and patient safety, including use of stimulants in adults. Provider reports on usability, usefulness and ease of implementation of Toolkit and perceived impact on the diagnosis, treatment, and management of adults with ADHD are favorable.

Conclusions: Adoption of the Adult ADHD Toolkit into routine care of adults with ADHD provides critical information to providers, educators, patients, and learners to expand their knowledge about Adult ADHD and provide informed care to Adult ADHD patients.

IMPACT OF ONLINE AND OFFLINE NETWORK AND SUPPORT ON DEPRESSIVE SYMPTOMS AMONG A NETWORK OF ONLINE GAMERS

Tyler Prochnow, MEd¹, Meg Patterson, PhD, MPH², Logan Hartnell, MA³, M. Renee Umstattd Meyer, PhD, MCHES, FAAHB¹¹Baylor University, Waco, TX; ²Texas A&M University, College Station, TX; ³Adler University, Chicago, IL

Introduction: As video game use increases, public health professionals have been concerned with gaming's effects on mental health, citing greater risk for depressive symptoms and reduced real life social involvement. While the fifth edition of the Diagnostic and Statistical Manual of Mental Disorders lists Internet Gaming Disorder as a condition for further study, recent studies have uncovered possible cognitive and social benefits to online gaming. Many games provide a chat function for players to extend real life relationships and make new online friendships; however, little is known about the development of online gaming friendships. One way to investigate the impact of social connection is through social network analysis.

Methods: An online gaming site was used as a bounded network, with a clear member list, to perform whole network analysis. Members of this site were asked to report demographics such as age, race, education, marital status, and employment. Depressive symptoms were measured using the Patient Health Questionnaire (PHQ-9). Social support was measured and divided into "in-real-life" (IRL) support and online support. Members were also asked to report members of their IRL network and members of the online community with whom they spoke to about important life matters. Multi-level modeling was used to parse out variance described by demographics, IRL measures, and online measures. Linear network autocorrelation modeling was used to determine the impact network connections had on depressive symptoms while controlling for the dependent nature of network analysis.

Results: The model including IRL network measures accounted for 31% of the variance exhibited in PHQ-9 scores. Within this model, IRL support had an inverse relationship with PHQ-9 scores ($\beta = -0.46$). The model including online network measures significantly explained 50% of the variance ($R^2 = .50$, $F(9,27) = 2.98$, $p = .01$), with more online connections significantly predicting PHQ-9 scores ($\beta = 0.46$). A significant network autocorrelation model included IRL support ($\beta = -2.66$), IRL connections ($\beta = 1.81$), online support ($\beta = 2.40$), and network effects ($\beta = 0.06$). A significant network effect coefficient means the depressive symptoms present within a gamer's network were significantly associated with the depressive symptoms of the gamer.

Conclusions: Both online and IRL network and social support measures accounted for significant variance in PHQ-9 scores in this network. Members with more depressive symptoms may be seeking help through online channels. In this sample, the support felt from online and IRL sources had inverse associations with depressive symptom scores which may imply differences in use and utility of these types of support.

EMOTIONAL EATING ASSESSED RETROSPECTIVELY VS. PROSPECTIVELY: DISTINCT IMPLICATIONS FOR WEIGHT LOSS

Christina Chwyl, B.A.¹, Stephanie Manasse, Ph.D.¹, Ross Crosby, Ph.D.², Evan M. Forman, PhD¹¹Drexel University, Philadelphia, PA; ²Sanford Health, Fargo, ND

Emotional eating (eating in response to negative emotions) has been proposed as a key driver of overeating leading to difficulties with weight maintenance and has been shown to predict weight loss outcomes. Typically, it is assessed via retrospective self-report measures. Yet, emotional eating is an inherently temporal construct, with elevated negative emotions proposed to predict subsequent eating. Little is known about the accuracy of retrospective emotional eating measures. We aimed to assess this by examining the degree to which a common retrospective emotional eating measure corresponded to momentary emotional eating assessed prospectively. We examined the predictive validity of these measures by examining whether they predicted percent weight loss post-intervention. As part of a behavioral weight loss intervention, participants ($N = 188$; $BMI_{Avg} = 36.91$) reported their retrospective emotional eating at baseline. For the first two weeks of the program, participants completed ecological momentary assessment (EMA) surveys assessing their emotions and dietary adherence. Using linear mixed models that controlled for average emotion levels, we examined how momentary emotions at one time point affected participants' likelihood of lapsing from their diet at the next time point. In particular, we examined momentary anxiety/stress, sadness, loneliness, and the average of these emotions. Then, we created person-specific indices of momentary emotional eating from the standardized residual values. We found a significant, small positive association between retrospective and momentary emotional eating due to loneliness ($r = .23$, $p = .002$), but not due to other emotions ($r_s < .13$). Next, we examined how emotional eating affected percent weight loss post-intervention. Emotional eating assessed retrospectively had near-zero associations with weight loss ($\beta_s < .08$). On the other hand, eating following momentary sadness predicted *less* weight loss ($\beta = -.15$, $p = .04$), and eating following momentary loneliness predicted *more* weight loss ($\beta = .26$, $p < .001$). All other associations were near zero ($\beta_s < .10$). Our results indicate that retrospective and momentary emotional eating have some, but minimal, concordance with one another. Future work would benefit from examining what constructs these measures truly assess, and why self-reported dietary lapses following different emotions (e.g. loneliness vs. sadness) have different effects on weight loss outcomes.

ENGAGEMENT IN THE TEMPORAL INFLUENCES ON MOVEMENT AND EXERCISE (TIME) STUDY PILOT

Shirlene D. Wang, BA¹, Stephen S. Intille, PhD², Aditya Ponnada, B.Des², Genevieve F. Dunton, PhD, MPH¹¹University of Southern California, Los Angeles, CA; ²Northeastern University, Boston, MA

The attainment of recommended levels of physical activity and sleep and limiting sedentary time deteriorates in emerging adulthood. While interventions promoting these behaviors are typically successful, information is lacking on the different mechanisms explaining why people adopt versus maintain positive health behaviors. The Temporal Influences on Movement and Exercise (TIME) Study will use real-time mobile and wearable technologies to collect intensive longitudinal data (ILD) to identify time-varying factors that predict within-subject variation in behavioral “episodes” (e.g., ≥ 10 min of physical activity, ≥ 120 min sedentary time, ≥ 7 hr sleep) and “lapses” (i.e., not attaining recommended levels for ≥ 7 days) during the adoption and maintenance phases.

TIME is a prospective within-subject case-cross-over observational study across a 12-month period with emerging adults (ages 18–24, $N=250$). Using ecological momentary assessment (EMA), self reports of reflective factors (e.g., intentions, planning, goal-setting) will be collected while reactive variables (e.g., locations, social contexts, phone/app use) and behaviors (i.e., physical activity, sedentary behavior, sleep) will be continuously and passively collected using built-in sensors of smartphones and smartwatches. With long-term ILD studies, sustaining participant engagement in real-time assessment procedures can be challenging given the potential for burden and disinterest. To track and monitor participant engagement in the TIME study, a variety of measures are being collected passively (e.g. device notification state, EMA completion time, device use), through self report (e.g. daily stress, travel), at baseline (e.g. occupation, personality), at study completion (e.g., perceived burden, system usability, perception of interruption), and by study staff (e.g., reasons for participant contact, length of contact). Microinteraction-EMA single-question assessments delivered on the smartwatch are also being used as a viable alternative to obtain high-temporal-density data with low burden when full EMA is not used. Based on pilot study data being used to refine the study design, descriptive statistics on a subset of possibly predictive engagement metrics will be presented. Barriers to engagement identified in the pilot study via quantitative data analysis and qualitative feedback ($n=30$) and how we adjusted procedures with the intent of overcoming barriers to engagement in the main trial will be addressed.

FEASIBILITY AND ACCEPTABILITY OF BLOOD SPOT COLLECTION AMONG UROLOGICAL CANCER SURVIVORS AND THEIR PARTNERS

Karly M. Murphy, PhD¹, Nat Sufrin, MS², David Victorson, PhD³¹Northwestern University, Chicago, IL; ²City University of New York, New York, NY; ³Northwestern University Feinberg School of Medicine, Chicago, IL

Measuring biomarkers alongside patient reported outcomes (PROs) can elucidate pathways by which behavioral and psychosocial factors affect health. Biomarkers have traditionally been collected via venipuncture, a relatively invasive procedure that must be performed by a phlebotomist and requires prompt lab access. In comparison, blood spot collection on filter paper from a finger prick is a non-invasive, safe, and effective alternative. In the present study, we examined the feasibility and acceptability of longitudinal blood spot collection.

The present study is a secondary analysis of data collected from urologic cancer survivors and their partners. Blood spots and PROs were collected by a research assistant at baseline, 8 weeks, and 6 months. Participants also completed acceptability survey regarding blood spot collection at 6 months. We hypothesized that $>90\%$ of participants would provide usable blood spots at baseline, and that there would be no difference between PRO and blood spot collection rates. In addition, we expected that the majority of participants would not find the procedure difficult, experience only slight or no discomfort, and be willing to undergo a similar procedure in future studies. Finally, we explored the concurrent associations between reported level of discomfort and PROs of anxiety, depression, and positive affect.

The majority of participants ($N=119$) were cancer survivors (65.5%), married (80.7%), Caucasian (87.4%), and male (59.5%). At baseline, 95.8% of participants provided usable blood spots. Paired samples t-tests indicated no significant differences between collection rates of PROs and blood spots (Baseline: $t(118)=-1.42, p=0.158$; 8 weeks: $t(118)=-1.00, p=0.319$; 6 months: $t(118)=0.82, p=0.417$). The majority of survey respondents found the procedure not difficult at all (71.2%). In addition, most participants indicated that collection and resulted in no (42.5%) or slight (41.1%) discomfort, and 94.5% of respondents indicated that they would be willing to undergo a similar procedure in future studies. Logistic regression revealed marginally significant concurrent associations between level of discomfort and depression ($\beta=0.06, p=0.056$) and positive affect ($\beta=-0.07, p=0.052$), indicating that affective symptoms may be associated with increased discomfort. Overall, these findings support the feasibility and acceptability of blood spot collection via finger prick to obtain biomarkers for psychosocial and behavioral research.

FEASIBILITY OF USING FOOD IMAGES AND CROWDSOURCING TO CAPTURE REAL-TIME EATING BEHAVIORS

Katharine Harrington, MPH¹, Lauren Giurini, n/a², Linda Van Horn, PhD¹, Kiarri N. Kershaw, PhD¹, Shannon Zenk, PhD³¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Lake Forest College, Lake Forest, IL; ³University of Illinois at Chicago, Chicago, IL

Background: Using mobile devices to assess health behaviors in real time (e.g., ecological momentary assessments, EMA) is increasingly popular, but documenting eating behaviors remains a challenge. Most EMA studies use checklists, but these are rarely comprehensive and self-assessment may influence eating behaviors.

Objective: To examine the feasibility of using smartphone-captured images to document real-time eating behaviors.

Methods: Participants (n=48) took pictures of their meals and snacks for one week using a commercially available smartphone application as part of an EMA study. Prior to this data collection, participants completed the Block Fat/Sugar/Fruit/Vegetable Screener to assess their usual eating behaviors. After data collection, participants were surveyed about their experiences. The study team uploaded images to Amazon's Mechanical Turk (mTurk), a crowdsourcing distributed human intelligence platform. mTurk workers were instructed to assign a count of fruits, vegetables, salty snacks, or sweet snacks to the images. Two workers assessed each image, and their responses were compared. When answers were discordant, a study team member assigned the final count. T-tests compared image-derived weekly food counts to the participant-reported number of days per week food items are usually eaten.

Results: Most participants (88%) remembered to take pictures of their meals and snacks at least half of the time or better. Few reported difficulties uploading pictures (18% agree or strongly agree). Only 4.2% reported substantial behavior change from taking pictures of their food. mTurk worker coding of food items were highly concordant: 85.4% for fruits, 67.9% vegetables, 83.2% salty snacks, and 81.4% sweet snacks. There were no significant differences between mTurk counts and self-reported weekly intake for any food categories (fruit [mean from image and screener, respectively=3.58, 3.59; p=0.9880], vegetables [mean=9.96, 10.62; p=0.5419], salty snacks [mean=4.17, 3.79; p=0.5632], and sweet snacks [mean=3.77, 4.54; p=0.3674]).

Conclusions: The feasibility of using participant-captured images and mTurk crowdsourcing technology to measure eating behaviors was studied. The method was generally well-accepted and executed by participants, and the images were accurately assessed by mTurk workers. This method offers a potential time-efficient and cost-effective strategy for capturing eating behaviors in real time.

RECRUITMENT OF HEAD AND NECK CANCER PATIENTS IN SMOKING RESEARCH IN RURAL APPALACHIA: CONSIDERATIONS AND CHALLENGES

Stephen Owen, B.S.¹, Jennifer Vaughn, MD, MSPH², Jeff Stein, PhD², Warren K. Bickel, Ph.D.³¹Virginia Tech Carilion School of Medicine, Roanoke, VA; ²Fralin Biomedical Research Institute at VTC, Roanoke, VA; ³Fralin Biomedical Research Institute at VTC, ROANOKE, VA

The advancement of patient-centered cancer care requires clinical research. Unfortunately, clinical research can be inhibited by recruitment and enrollment issues. These challenges are particularly evident while studying head and neck cancer patients with a history of cigarette smoking in rural Southwest Virginia, a region featuring a predominantly white population marked by low education and income and a high rate of smoking (25%-30% of the general population). This population is challenging to enroll in clinical research due to poor access to healthcare, low socioeconomic status, lack of familiarity with research, and discomfort discussing smoking status. Sharing these challenges may be of particular benefit to the research community given the potential to provide a platform where common challenges may be discussed and resolved. Here, we highlight challenges associated with recruitment of head and neck cancer patients who are current or former cigarette smokers in an ongoing observational research study examining predictors of smoking cessation. We do so in order to identify common recruitment-related issues with the intent of developing solutions to overcome these issues. Various recruitment modalities are being employed in an effort to enroll 100 patients who were treated for head and neck cancer with curative intent in the past 5 years and were smokers at the time of diagnosis. Over 24 months, a total of 100 patients were identified as eligible and invited to participate. However, only 36 have enrolled, despite \$20-100 compensation, study visits being brief (~30 minutes) and scheduled to coincide with regularly scheduled clinical appointments. Of the patients enrolled, only five patients (13.89%) have stopped smoking follow diagnosis of head and neck cancer, compared to successful smoking cessation in 50-60% of head and neck cancer patients in prior literature outside of rural Virginia. Overall, average age of first cigarette use is 13.6 (±4.8). Patients report low income (>90% make less than \$29,000/year), limited education (< 17% have a college education), and are predominantly male (65%) and white (>90%). Challenges associated with recruiting head and neck cancer patients with a history of tobacco use from rural Southwest Virginia limits what is known about smoking cessation in this population. Ongoing recruitment efforts and solutions for mitigating these challenges will be discussed.

DOES ASSESSMENT ALTER RESPONSES? AN EXAMINATION OF REACTIVITY IN AN ECOLOGICAL MOMENTARY ASSESSMENT OF BODY COMPARISONS

Rachel I. MacIntyre, M.S.¹, Kristin E. Heron, Ph.D.², Charlotte A. Dawson, B.A.¹, Danielle Arigo, Ph.D. in Clinical Psychology³, Kelly Filipkowski, PhD⁴¹Virginia Consortium Program in Clinical Psychology, Norfolk, VA; ²Old Dominion University, Norfolk, VA; ³Rowan University, Glassboro, NJ; ⁴Misericordia University, Dallas, PA

Body comparisons, or comparing one's body to that of another, are common among women, and can shape how they feel about their bodies. Previous research has used ecological momentary assessment (EMA) to capture body comparisons as they occur in daily life; however, the act of completing EMA could also potentially alter the natural occurrence of these comparisons and associated phenomena. The present study examined the reactivity of assessing body comparisons by comparing the results of related constructs (e.g., body dissatisfaction, mood) on days participants received body comparison EMA items to days they did not receive these items. Undergraduate women ($N = 75$, ages 18–25) completed surveys four times daily for 11 days via a smartphone survey app. The surveys during the first four days included items assessing body dissatisfaction, mood, and daily activities. The surveys during the last seven days included the same items in addition to items assessing body comparisons (although all surveys were balanced to ensure similar length). Pre- and post-EMA measures of trait-level body dissatisfaction, appearance comparison tendency, disordered eating, and depression were also collected. Multilevel analyses revealed that assessments of body dissatisfaction and mood did not significantly change when participants received body comparison items ($ps > .05$). However, during the days they did receive body comparison items, they reported fewer occasions of watching tv ($p = .022$), internet use ($p = .006$), and social media use ($p = .031$). Paired sample t-tests showed participants' trait-level body dissatisfaction, appearance comparison tendency, and disordered eating were significantly lower at the post-EMA assessment than at the pre-EMA assessment ($ps < .01$). No significant difference in depression symptoms between pre and post were found ($p = .550$). Although assessing body comparisons did not alter participants' reports of constructs that are commonly studied with these comparisons (i.e., momentary body dissatisfaction and mood), findings suggest some media use measures were potentially reactive to completing social comparison EMA items. Participants either engaged in media content less when reporting on their body comparisons or they experienced response fatigue and reported these behaviors less often. Given that similar results were not found for other measures and the surveys were balanced making it no less burdensome to deny a behavior, the former of the two is more likely. This reactivity to completing body comparison EMA items highlights the need for researchers to provide greater consideration to reactivity in social comparison EMA designs to prevent biased results. The reductions found in trait-level measures also suggest there may be utility in using EMA in body dissatisfaction interventions.

PSYCHOMETRIC VALIDATION OF CHINESE VERSION OF THE FIVE FACET MINDFULNESS QUESTIONNAIRE IN CHINESE COLORECTAL CANCER PATIENTS

Ted C.T. Fong, PhD¹, Adrian H.Y. Wan, PhD, M.S.W., M.A. (Trauma Psychology), PCPsych, MA (Asian Studies)², Venus Wong, PhD¹, Rainbow T.H. Ho, PhD, REAT, BC-DMT, AThR, RSMT/E, CGP, CMA²¹Centre on Behavioral Health, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong

Introduction: Mindfulness has emerged as an important correlate of well-being in various clinical populations including cancer patients. The Five Facet Mindfulness Questionnaire (FFMQ) is a widely used 39-item instrument to assess five facets of mindfulness. The present study evaluates the psychometric properties of its 20-item short version (FFMQ-SF) in the Chinese context.

Research Design: This study was based on a clinical sample of 127 Chinese colorectal cancer patients. Factorial validity was assessed using exploratory factor analysis and Bayesian structural equation modeling with zero-mean small variance informative priors on cross-loadings and residual covariances. Convergent validity was examined by regressing physical and mental health measures on the FFMQ-SF facets.

Results: The five-factor structure with approximate zero cross-loadings provided an acceptable fit (PP limits = -3.3 to 114.3, PPP = 0.038, PPPP = 0.701) to the data with satisfactory reliability ($\alpha = 0.69$ to 0.85). Out of the five facets, acting with awareness consistently predicted lower levels of perceived stress, negative affect, anxiety, depression and illness symptoms ($\beta = -0.35$ to -0.41 , $p < .05$) and better quality of life ($\beta = 0.27$ to 0.31 , $p < .05$). Interestingly, this facet was not significantly associated ($r = 0.03$ to 0.17 , $p > 0.05$) with the other facets.

Conclusions: The present findings provide support to the factorial validity and reliability of the FFMQ-SF as a precise assessment of different facets of mindfulness. Further studies are needed to elucidate the convergent validity of the FFMQ-SF in other contexts.

Acknowledgments: This work was supported by the General Research Fund of the Hong Kong Research Grants Council (GRF/HKU 17611615). We would like to express our thanks to Joshua Yau and other colleagues of the Centre on Behavioral Health for their help in study coordination and the participants for joining this study.

EXPERIENCE SAMPLING METHODOLOGY: A VALID APPROACH FOR ASSESSING SOCIAL CONTEXT AND YOUTH PA

Celina H. Shirazipour, PhD¹, Julie Bowker, PhD², Rocco Paluch, MA³, James Roemmich, PhD⁴, Nenette Caceres, MS⁵, Sarah-Jeanne Salvy, PhD⁵

¹Research Center for Health Equity, Cedars Sinai Medical Center, West Hollywood, CA; ²University of Buffalo, Department of Psychology, Buffalo, NY; ³University of Buffalo, Department of Pediatrics, Buffalo, NY; ⁴United States Department of Agriculture (USDA) - Agriculture Research Service (ARS), Grand Forks, ND; ⁵Research Center for Health Equity, Cedars-Sinai Medical Center, West Hollywood, CA

Social factors have been identified as key predictors of youth physical activity (PA), and an important avenue for research aiming to promote PA. Research is needed to determine appropriate methods for measuring ecologically valid relationships between the social context of PA and PA behavior. The objective of this study was to validate experience sampling methodology (ESM) as an appropriate method for measuring PA and PA social context, particularly assessing the influence of social context on youth PA. Young adolescents (12-14 yo) wore accelerometers while simultaneously completing seven days of ESM. Across the nine participants, this approach resulted in 550 data points for assessing the social context, as well as validating ESM through estimates of metabolic equivalent (MET). Both methodologies yielded similar conclusions with regard to the influence of social context on youth PA. Youth were more physically active in the presence of peers and friends than when alone or when in the presence of family members. Accelerometry and ESM also yielded similar conclusions for MET. However, the difference in METs between the two methods became greater ($\beta = 0.96$, $p < .0001$) as the MET values increased. Specifically, for higher intensity activities, METs estimated from ESM were greater than METs estimated from accelerometry. ESM produces similar conclusions as accelerometry when assessing the social context of youth PA. Specifically, findings provided further support for the importance of peers and friends for youth PA. However, differences exist between ESM and accelerometry when assessing higher intensity activities.

SLEEP HEALTH AND PERFORMANCE PROGRAMMING FOR AIR FORCE ROTC

Jordan M. Ellis, MA¹, Caley Kropp, MS, MA¹, Ashley M. Griffith, MA², Reid Hlavka, M.A.³, David Sager, M.A.⁴, Jessica Ford, PhD⁴, Matthew C. Whited, Ph.D, Licensed Psychologist⁴

¹East Carolina University, San Antonio, TX; ²East Carolina University, GREENVILLE, NC; ³East Carolina University, Winterville, NC; ⁴East Carolina University, Greenville, NC

Introduction: Sleep disturbance is the number one non-injury related medical concern reported by service members post-deployment, and military populations report poor sleep duration in general compared to civilians. Poor sleep quality has been observed in college student populations, and sleep disturbance is a significant risk factor for many physical and mental health conditions. Air Force ROTC cadets function as both college students and trainees for future military leadership positions. The responsibilities associated with these roles and campus environment may be risk factors for poor sleep, and place AFROTC cadets at risk for suboptimal performance when entering the operational Air Force and future health conditions. A sleep health and performance briefing for the Performance Improvement and Leadership for Officers in Training (PILOT) Program was developed to inform AFROTC cadets about the importance of healthy sleep and the effects of poor sleep, assess the sleep quality of AFROTC cadets, and to provide evidence-based and culturally sensitive strategies for improving sleep health.

Methods: Forty-six AFROTC cadets engaged in a 1-hour briefing focused on sleep health and performance. Sleep knowledge was assessed pre- and post-briefing. The Pittsburgh Sleep Quality Index (PSQI) was administered prior to the briefing and at one-month follow-up ($n = 13$). Satisfaction and applicability were also assessed.

Results: Prior to the briefing, cadets reported sleeping an average of 6.79 hours per night, with only 51% sleeping 7 or more hours and 13% sleeping < 6 hours per night. The PSQI composite score indicated that 81% of cadets experience poor sleep quality, though only 38% perceived poor sleep quality. Ratings of sleep quality and sleep time did not change significantly at one-month follow-up. However, cadets demonstrated improved knowledge about sleep health in performance and 80.4% reported being highly satisfied with the educational briefing.

Discussion: Overall, AFROTC cadets reported poor sleep quality and behaviors that are comparable to other college student samples. The PILOT program briefing resulted in increased sleep health knowledge amongst AFROTC cadets; however, sleep behavior did not appear to improve following this brief educational intervention. Additional follow-up, assessing other metrics such as readiness to change sleep, and including interventions such as self-monitoring should be tested in future iterations.

WHOLE HEALTH FOR WOMEN VETERANS WITH MENTAL HEALTH CONDITIONS: A NEEDS ASSESSMENT OF PATIENT PREFERENCES FOR WELLNESS SERVICES

Katherine Hall, PhD¹, Nivedita Chaudhry, MD², Elizabeth E. Van Voorhees, Ph.D.³, Michelle Pebole, n/a⁴, Karen M. Goldstein, MD, MSPH¹, Jillian Thompson, MT-BC⁵, Ryan P. Parker, M.Div, BCC-PTSD, ACPE¹

¹Durham VA Health Care System, Durham, NC; ²Durham VA Health Center, Raleigh, NC; ³Durham Veterans Affairs Health Care System, Durham, NC; ⁴University of Illinois at Urbana-Champaign, Champaign, IL; ⁵Dept of Veterans Affairs: Durham VA Health Care System, Cary, NC

The Veterans Health Administration (VHA) is undergoing a transformational shift, from disease-focused care to a Whole Health System that emphasizes physical, mental, emotional, and spiritual health and well-being among all Veterans. Wellness services for women Veterans vary widely across the VHA system, without consensus on the need for, or organization of, specialized services for women Veterans with mental health conditions. Understanding needs and priorities of women Veterans is essential to guide the implementation of patient-centered behavioral health services. A multi-disciplinary work group comprising exercise and health promotion experts, chaplaincy services, and clinicians from behavioral health, women's health primary care, and rehabilitation initiated a quality improvement project to assess patient needs and preferences for whole health services. A survey was distributed to a convenience sample of women Veterans using the Women's Health-Mental Health Clinic at the Durham VA Medical Center. We asked patients to rank their priorities for wellness across a wide range of services, and to indicate their preference for the location (e.g., VA facilities, community, home-based) and format (e.g., women-only, mixed gender groups) that these programs be delivered. 107 women Veterans 18-65+ years old (65.3% African American; 5.9% LatinX) completed the survey. Over 50% of patients ranked relationships, physical activity, sleep/nightmares, pain management, anger, or spiritual/moral pain as top wellness priorities. Patient preferences for where and how wellness services be delivered differed by wellness domain. On average, patients ranked main VA facility (55%), community-based non-VA facilities (39%), and community-based VA facilities (33%) as preferred locations for whole health services; fewer patients endorsed home-based programs with: video stream (19%), apps or website (12%), or telephone counseling (6%). Relative to group format, 4% of patients endorsed mixed-gender groups; 44% indicated no preference and 52% indicated preference for women-only groups. In this sample of women Veterans with mental health conditions, schedule conflicts, travel difficulties, and psychological barriers were most commonly reported barriers to participating in these programs. The results from this quality improvement project highlight considerations for tailoring the content and (trauma-informed) delivery of Whole Health services for women Veterans with mental health conditions.

TBI AND CHRONIC MULTISYMPTOM ILLNESS AMONG GULF WAR VETERANS: A CALL FOR BETTER IDENTIFICATION

Nicole L. Sullivan, PhD¹, Naomi S. Kane, PhD², Fiona S. Graff, PsyD³, David R. Litke, Ph.D.⁴, Karen S. Quigley, Ph.D.⁵, Wilfred Pigeon, PhD⁶, Drew Helmer, M.D.¹, Joseph F. Rath, PhD⁷, Lisa M. McAndrew, PhD⁸

¹Veterans Administration New Jersey Health Care System, East Orange, NJ; ²VA New Jersey Health Care System, Department of Veteran Affairs, East Orange, NJ; ³VA NJ Healthcare System, East Orange, NJ; ⁴VA NJHCS, East Orange, NJ; ⁵Northeastern University, Boston, MA; ⁶Veteran Affairs, Canadaigua, NY; ⁷Rusk Rehabilitation at NYU Langone Health, New York, NY; ⁸War Related Illness and Injury Study Center, Veterans Affairs New Jersey Healthcare System, East Orange, NJ

Background: Traumatic Brain Injury (TBI) was once considered rare among veterans who served in the 1990-1991 Gulf War. However, recent research suggests high rates of service-related TBI among this cohort, with estimates from 12.2%-68.6%. While the Department of Veterans Affairs mandated TBI screenings for all returning veterans in 2007, those who sustained a TBI during the first Gulf War may remain under-identified and undiagnosed. Documentation of TBI is important given recent findings showing a relationship between TBI and chronic multisymptom illness (CMI). CMI is a constellation of disabling, medically unexplained physical symptoms common among Gulf War veterans. The current study aimed to 1) compare rates of self-reported TBI with documented TBI-related diagnoses, and 2) assess the relationship between TBI and CMI symptoms among Gulf War veterans.

Methods: 268 Gulf War veterans with CMI participated in an RCT comparing Problem-Solving Treatment to Health Education. The current study analyzed self-report data from the baseline assessment and a review of TBI-related diagnoses through VA medical records. The analysis included only those participants who were enrolled in VA medical care (N=216). Participants completed the Brief Traumatic Brain Injury Screen and the Kansas Symptom Questionnaire to assess self-reported history of TBI and severity of CMI symptoms. T-tests examined the relationship between TBI and severity of CMI symptoms.

Results: 74.2% of participants screened positive for a history of TBI. However, only 10.6% had a TBI-related diagnosis documented in their VA medical record. Results showed that participants with a self-reported history of TBI had significantly more severe CMI symptoms compared to those in the non-TBI group ($t(211) = 4.20, p < .001$), with a mean difference of 10.28 points (95% CI: 5.46, 15.10) on the Kansas Symptom Questionnaire (range 0-70).

Conclusion: These results confirm previously reported high rates of TBI among Gulf War veterans, and highlight the gap between self-reported history of TBI and TBI-related documentation within VA medical records. This gap is concerning given the finding that history of TBI is related to severity of CMI. Taken together, these findings suggest the need for greater identification of TBI among Gulf War veterans and call for further research on the relationship between TBI and the longitudinal progression of CMI symptoms. Limitations include the study's cross-sectional design.

DOES A FORMATION OF PHYSICAL ACTIVITY PLANS DECREASE THE TIME SPENT ON SEDENTARY BEHAVIOR? PRELIMINARY FINDINGS

Zofia Szczuka, MA¹, Ewa Kulis, MA², MAGDALENA KRUK, MA³, Monika Boberska, MA², Anna Banik, PhD¹, Karolina Horodyska, PhD¹, Aleksandra Luszczynska, PhD⁴

¹SWPS University of Social Sciences and Humanities, Wrocław, Dolnośląskie, Poland; ²SWPS University of Social Sciences and Humanities, Warsaw, Mazowieckie, Poland; ³SWPS University of Social Sciences and Humanities, WROCLAW, Dolnośląskie, Poland; ⁴Wrocław Faculty of Psychology, SWPS University in Wrocław, Wrocław, Śląskie, Poland

Background: Individual planning is an effective self-regulation strategy for supporting people in their efforts to translate goal intentions into behavior change. Dyadic and collaborative planning extends individual action planning and refer to target individuals forming plans together with a partner. Physical activity and sedentary behavior are interlinked, i.e., time spent on physical activity may replace time spent on alternative behaviors, such as sedentary behavior. Additionally, planning to avoid a given behavior (e.g., sitting to watch a movie) is less effective strategy than planning to engage in alternative behaviors (e.g., engaging in physical activity). The main aim of the study was to evaluate whether forming individual, dyadic, and collaborative physical activity plans may reduce the time spent on sedentary behavior.

Methods: Study sample consisted of 297 patient-partner dyads ($N = 594$, aged 18-90 years old). Participants were randomly assigned to one of four conditions: Active control (education only, no planning) or three experimental groups (individual planning, dyadic planning or collaborative planning). All dyads participated in a physical activity and sedentary behavior education session, delivered after the baseline measurement. The time spent on sedentary behavior, measured by International Physical Activity Questionnaire, was the main outcome (self-reported at the baseline [Time 1, T1] and at a 10-week follow-up [Time 2, T2]).

Findings: Preliminary analyses showed a significant effect of time: The level of sedentary behavior decreased between T1 and T2; the decrease was observed consistently, across the four experimental conditions. There was no significant time x group interaction, indicating a lack of significant effects of experimental conditions. Sensitivity analysis conducted with age, gender, and the role in the dyad (patient/partner) as covariates showed a similar pattern of findings. Age formed a significant interaction with time, with a larger reduction of sedentary time found in older participants.

Discussion: Results showed a lack of effects of forming physical activity plans on sedentary behavior. The effect of time may result from education regarding physical activity and sedentary behavior, delivered after T1 measurement to all participants. Further studies may need to clarify if other types of planning (e.g., planning to engage in active breaks) may be useful to reduce sedentary behavior.

CROWDSOURCING BEHAVIORAL AND SOCIAL SCIENCE RESEARCH ACCOMPLISHMENTS THAT HAVE IMPROVED PUBLIC HEALTH

Farheen Akbar, MPH¹

¹National Institutes of Health, Rockville, MD

The Office of Behavioral and Social Sciences Research (OBSSR) at the National Institutes of Health (NIH) launched a crowdsourcing effort to generate an extensive and diverse list of behavioral and social sciences research accomplishments that have led to improved health. The behavioral and social sciences research community submitted their ideas on what they considered to be impactful accomplishments in the field and interacted and voted on others' ideas. These accomplishments were not limited to NIH funded research and submitters were encouraged to share a broad array of ideas. Approximately 200 submissions were posted to the crowdsourcing platform which were vetted by an expert panel of social and behavioral scientists at the NIH. We would like to share some examples that rose to the top from this crowdsourcing effort with the SBM community. We would like to raise awareness of this effort as OBSSR plans to regularly crowd-source the social and behavioral science research community going forward in order to keep the list of behavioral and social sciences research accomplishments current. A poster session will also allow us to learn from conversations with the SBM attendees and modify future efforts to include their feedback.

COUNTING AND RECEIVING GOAL-SETTING INSTRUCTIONS: EFFECTIVENESS IN IMPROVING VEGETABLE INTAKE AMONG COLLEGE STUDENTS

Trishnee Bhurosy, PhD¹, Susan E. Middlestadt, PhD², Hsien-Chang Lin, PhD², Krisha Thiagarajah, PhD, RDN², Alyce D. Fly, PhD³

¹Rutgers Cancer Institute of New Jersey, Somerset, NJ; ²Indiana University School of Public Health-Bloomington, Bloomington, IN; ³Indiana University, Bloomington, IN

Background: Given the role of diet in affecting health, it is essential to identify effective approaches such as self-monitoring and goal setting to help individuals improve their eating behaviors. Previous dietary interventions among college students used self-monitoring and goal setting minimally, most of them did not employ an experimental design and were not mobile. Mobile interventions to improve eating behaviors are easily accessible, convenient to use and can reach a wider range of individuals.

Objective: To assess whether a mobile intervention that consisted of self-monitoring (i.e., daily counting of red/orange vegetables consumed that day) followed by goal setting (i.e., instructions to set a goal to eat more the next day) improved red/orange vegetable intake among undergraduate students.

Methods: This study used a two-group pre-posttest experimental design (N=165). Participants were undergraduates living in dorms at a large Midwestern university. After completing a background survey, participants uploaded photos of meals from their smartphones and provided descriptions of the meals to an online platform for three days [Monday, Tuesday, Wednesday]. In addition, those in the intervention group (N=85) were asked to use a checklist to count the number of times they ate red/orange vegetables and to set a goal to eat them one more time, the next day. The dependent variable was a measure of eating behavior—the average of two raters' estimate of red/orange vegetable intake on that day based on review of uploaded photos and descriptions. The unit of the behavior variable was frequency (number of times/day). Generalized Estimating Equations (GEE) with robust variance estimation assessed the group by time interaction on red/orange vegetable intake.

Results: GEE analysis yielded statistically significant group by time interactions for Tuesday (time 2) ($\beta=0.77$, $p<0.01$) and for Wednesday (time 3) ($\beta=0.55$, $p<0.01$). For the intervention group, mean frequency intake increased from 0.93 times per day on Monday to 1.56 on Tuesday and 1.32 on Wednesday; whereas for the control group, mean intake was 0.97, 0.82 and 0.79.

Conclusions: Those in the intervention group, who used the checklist to count their vegetable consumption and set a goal to eat one more the next day, improved their vegetable intake. This novel mobile photo method for counting followed by goal setting, is a potential strategy for behavior change among undergraduate students during their formative years. Further research is needed on whether counting followed by goal setting in mobile interventions is effective in sustaining long-term behavior change among undergraduates.

DOES A TAILORED WEIGHT MANAGEMENT INTERVENTION PROGRAM IN THE WORKPLACE WORK?

Shu-Fang Shih, Ph.D., M.S., M.B.A.¹, Lien-Hsin Wang, MEd.²

¹University of Michigan, Ann Arbor, MI; ²Ho Tai Development Co., Ltd, Taipei, Taipei, Taiwan (Republic of China)

Background: Research has confirmed that workplace health promotion has both economic and non-economic benefits for enterprises. Obesity is a severe health threat and affects work efficiency and overall corporate productivity. The prevalence rate of overweight and obesity in Taiwan reached 43% in 2016, the highest among Asia countries. Presently, weight management programs in Taiwan and other countries are mostly group-oriented, and they have failed to achieve the expected outcomes for those who have poor adherence and those who have low intention to overcome barriers. Research suggested that a tailored and individualized health promotion program in the workplace may be effective for behavioral changes and health outcomes.

Methods: This research employs a quasi-experimental design to assess the effectiveness of a weight management program in the workplace. Subjects in the experimental group participated in a program with dynamic tailoring for a period of eight weeks. Drawing on the trans-theoretical model, the program used motivational interviews, self-management, goal setting, and social support to help participants build a positive belief, adopt a healthful lifestyle, and achieve their goals. The control group received general health information routinely provided by the company. The participants were followed up and their BMI, body fat, and waistline were measured in one and five weeks after program implementation. Other measurements such as dietary behavior, physical activity, self-efficacy towards healthy diet and exercise, stages of changes on weight management behavior, weight control belief were measured in one week after the program implementation.

Findings: Results showed significant improvement in the experimental group's dietary behavior, self-efficacy, stages of behavioral changes, weight control belief, BMI, body fat, and waistline before and after the workplace intervention. In one week after the program implementation, we only observed significant difference in dietary behavior, stages of behavioral changes, weight control belief, and BMI. Five weeks later, significant difference between the experimental and control groups was observed on BMI, body fat, and waistline.

Implications for D&I Research: This research suggests individualized, tailored-made intervention in the workplace is effective for weight management. The intervention may work better than generic health promotion strategies targeting in improving high-risk groups in workplaces.

EXPLORING THE ASSOCIATION BETWEEN SOCIAL SUPPORT AND WEIGHT LOSS AMONG LATINA AND NON-HISPANIC WHITE BREAST CANCER SURVIVORS

Emily Janio, MPH, CPH¹, Julie Kircher, MA², Michael A. Hoyt, Ph.D.², Dara Sorkin, PhD²¹UC Irvine, Irvine, CA; ²University of California, Irvine, Irvine, CA

Background: Breast cancer survivors are at high risk for weight gain. Relative to non-Hispanic whites (NHW), Latinas have a higher rate of obesity. Furthermore, among survivors, obesity can be exacerbated by and contribute to high levels of symptom burden. This in turn is linked to an increased risk of morbidity and mortality. While it is imperative to develop interventions that assist breast cancer survivors in managing their weight, it is also vital to understand the factors that impact survivors' ability to maintain health-promoting behaviors. Such factors may include social influences. These influences, such as social support and persuasion, may be positive. Other interactions may be negative and include sabotage and pressure. The study of the influence of these factors on health has produced mixed findings, and further research is warranted.

Methods: Forty-eight female breast cancer survivors (24 Latinas and 24 NHW) were enrolled in *Mi Salud, Mi Vida*, a 12-week mobile-health weight loss intervention. The control group received a self-monitoring app, while the intervention group received an app containing both self-monitoring and personalized feedback for self-discovery. At baseline and 12 weeks, participants completed surveys pertaining to the types of social influence they were currently experiencing.

Results: The mean age was 52 years and the average time since cancer diagnosis was 8 years. At time 1, Latinas experienced significantly greater persuasion ($p = .007$), pressure ($p < .001$), and encouragement for healthy eating ($p = .02$), and a greater trend towards discouragement from healthy eating ($p = .06$) than did NHW. At time 2, Latinas experienced greater persuasion ($p = .04$) than did NHW. Linear regression showed that among whites, increased social support was associated with decreased BMI ($b = -.65$; $p = .002$), even when the intervention was controlled for ($b = -.64$; $p = .003$). Among Latinas, a trend between undermining and greater BMI was seen ($b = .27$; $p = .08$), however, this association was explained by the intervention.

Discussion: Findings suggest that among NHW, social support may promote weight loss. While Latinas experienced greater amounts of social influence at each time point, this was not associated with weight change. A limitation of this pilot study was sample size, however, its findings suggest that future interventions may benefit from leveraging social influences.

DEVICE-MEASURED WEIGHT LOSS AND TRACKING OF PHYSICAL ACTIVITY, WEIGHT, AND FOOD INTAKE AMONG OVERWEIGHT AND OBESE INDIVIDUALS

Michael C. Robertson, MPH¹, Yue Liao, MPH, PhD², Thuan Le, MPH³, Leticia A. Gatus, DrPH, MPH⁴, Karen Basen-Engquist, PhD³¹University of Texas MD Anderson, Houston, TX; ²The University of Texas MD Anderson Cancer Center, Houston, TX; ³University of Texas MD Anderson Cancer Center, Houston, TX; ⁴MD Anderson Cancer Center, Houston, TX

Self-monitoring of health-related behaviors is a strategy emphasized by numerous behavior change theories. Self-monitoring physical activity, weight fluctuations, and eating behaviors are widely prescribed and are generally associated with weight loss. However, the majority of existing studies have analyzed self-reported data, and there is little research concerning how these self-monitoring behaviors may interact with one another to influence weight loss among overweight and obese individuals.

We conducted secondary data analysis on data from two waves (2018 and 2019) of a 6 month weight loss intervention for overweight and obese school district employees. Participants received a Fitbit wireless physical tracker and a Wi-Fi-enabled weight scale, and were encouraged to self-monitor their physical activity, weight, and food intake in the Fitbit mobile app. We conducted non-parametric missing data imputation and multiple linear regression ($N=189$) to evaluate the associations of device-measured weight loss with the percentage of days over the study period that participants 1) wore the physical activity device, 2) used the wireless scale, and 3) logged at least 800 calories of food. All analyses adjusted for age, race/ethnicity, gender, education, and marital status.

On average, participants wore the Fitbit device 68.8% of days ($sd=23.9$), weighed themselves 40.2% of days ($sd=22.8$), and logged food 18.9% of days ($sd=21.5$) over the 6 month intervention. Weighing ($p < .001$) and food logging frequency ($p=.002$) were associated with weight loss, but Fitbit wear was not. There was an interaction such that food logging was associated with increased weight loss among participants who weighed themselves less frequently ($p=.004$). There was no interaction between Fitbit wear and weighing or food logging frequency. Fitbit wear was associated with weight loss among older individuals, and weight gain among younger individuals ($p=.020$). There was no evidence of moderation of self-monitoring behaviors by age, gender, education, or marital status.

Results support the primacy of consistent self-monitoring of weight for weight loss. Food logging may be particularly helpful for individuals who are less likely to adhere to consistent self-monitoring of weight. Physical activity trackers may be more readily adopted, but their use is less clearly linked to weight loss. Weight loss interventions may be best served by prioritizing consistent self-monitoring of weight.

CLINICALLY SIGNIFICANT WEIGHT LOSS & DECREASED BLOOD PRESSURE & HBA1C FOUND IN INTENSIVE BEHAVIORAL WEIGHT MANAGEMENT PROGRAM

Stephanie Wilhoit-Reeves, MDiv, MSW, LCSW¹, Laurel Sisler, MSW, LCSW, LCAS², Shannon Aymes, MD¹, Alexandria Forte, MSW³, Adam O. Goldstein, MD, MPH²

¹UNC Weight Management Program/UNC Family Medicine, Chapel Hill, NC; ²UNC Tobacco Treatment and Weight Management Programs/UNC Family Medicine, Chapel Hill, NC; ³UNC School of Social Work, Chapel Hill, NC

Background: The UNC Weight Management Program (WMP) is an evidence-based, financially sustainable program embedded in an academic primary care setting at The University of North Carolina at Chapel Hill Family Medicine Center (FMC). Patients with overweight and obesity are eligible to participate in WMP, primarily run by an interdisciplinary team of clinical social workers and preventive medicine residents. Based on The US Preventive Services Task Force and Medicare guidelines, WMP offers 26 Intensive Behavioral Therapy sessions per year through group and individual counseling based on the guiding principles: 1) sustainable change over rapid weight loss; 2) 5-10% weight loss; 3) setting goals and taking positive health actions; and 4) self-care.

Methods: A retrospective evaluation of WMP participants' health data was conducted. Eligible participants completed at least 4 visits and had a baseline weight, blood pressure, and hemoglobin A1c (HbA1c) recorded in the Electronic Health Record prior to their first visit. Paired t-tests were used to assess changes in weight, HbA1c and systolic and diastolic blood pressures from baseline.

Results: WMP served 673 patients over 3895 visits from September 2015 to June 2019 (47.3% white, 43.5% black, 92% non-hispanic/latino and 77.9% female). Of the patients served, 186 participants met eligibility criteria. Participants saw an average weight decrease of (9.7 lbs, $P < 0.001$) at 18 months compared to baseline, a 0.196 point absolute decrease (6.66 to 6.46, $P = 0.004$) in HbA1c at 24 months from baseline, and decreases in average systolic and diastolic blood pressure (mean difference 2.78 mm Hg, $P = 0.002$ and 1.94, $P = 0.03$, respectively) at 18 months from baseline. One third of participants ($n = 60$) achieved clinically significant weight loss of 5% or more at 18 months.

Conclusions: WMP is an intensive behavior and lifestyle change weight management program augmenting primary care providers' ability to effectively treat obesity. Participation in an evidence-based behavioral program for weight management appears to be associated with significant decreases in weight, blood pressure and blood sugar (hemoglobin A1c).

CULTURAL TAILORING OF FAMILIAS SALUDABLES: A LATINX FAMILY-BASED, BEHAVIORAL CHILDHOOD OBESITY PREVENTION CURRICULUM

Diana Aguirre, MPH, CHES¹, Mara Bird, PhD²

¹CSULB Center for Latino Community Health, Evaluati, Long Beach, CA; ²Center for Latino Community Health, Evaluation and Leadership Training, Long Beach, CA

Problem Statement: Childhood obesity continues to be an epidemic in the United States, with Latinx children disproportionately affected (Holub et al., 2013). Providing culturally and linguistically appropriate, family-based, behavioral obesity prevention programs helps to create rapport with Latinx families and could increase effectiveness (Peña et al., 2012). The *Familias Saludables* curriculum was adapted for cultural, linguistic, and age-appropriateness (middle childhood) to serve as a family-centered childhood obesity prevention treatment program.

Methods: The *Familias Saludables* curriculum adapted three curricula: the evidence-based KidShape 2.0 weight management program (base curriculum), the Sports, Play, and Active Recreation for Kids (SPARK) After School Physical Activity curriculum, and the *Sanos y Fuertes*: Healthy and Strong intervention.

Results: The curriculum content was delivered simultaneously in both languages by bilingual staff, unless participants preferred English only. Children perceived the information to be for parents if delivered in Spanish. Spanish-delivery cued parents to encourage their child(ren) to participate actively. The parent coaching component (adults only) was primarily delivered in Spanish. The SPARKS physical activity curriculum (kids only) was primarily implemented in English. Family health education, worksheets, and supplemental handouts were provided both in English and Spanish (double-sided). Images, foods, recipes, and examples provided were tailored to be culturally, linguistically, and age appropriate for our Latinx families with children 5-12 years old who live in urban environments.

Conclusion/Implications: Cultural and linguistic competence is important to address the needs and adequately serve the multicultural, multiracial, and multilingual needs of the diverse population of the United States. Tailoring of behavioral intervention curricula using an asset-based lens helps to facilitate lifestyle change because it increases relevancy to families' lives, common environmental contexts, and food preferences. A family-based approach also allows for discussion of health practices that support both heritage and current day cultural milieu.

COPING DIFFERENTIALLY MODERATES THE ASSOCIATIONS BETWEEN WEIGHT STIGMA, DEPRESSIVE SYMPTOMS, AND QUALITY OF LIFE

Alyssa K. Choi, B.A.¹, Brooke C. Cullen, A.A.², A. J. Tomiyama, Ph.D.²¹San Diego State University, San Diego, CA; ²University of California, Los Angeles, Los Angeles, CA

Background: Weight stigma is stressful, negatively impacting psychological and physical health. However, little research has examined strategies to help individuals who are targets of weight stigma combat its consequences. The well-established coping literature shows that approach-oriented coping has been linked to favorable health outcomes, whereas avoidance-oriented coping has been linked to poorer health outcomes. Given this, the current study tested coping as moderators of the associations between weight stigma and its known outcomes. The overarching goal of this pilot study was to provide proof of concept and choose measures for an upcoming longitudinal study of weight stigma and coping. We hypothesized that individuals who report higher approach-oriented coping and lower avoidance-oriented coping would evidence lower perceived stress, fewer depressive symptoms, and higher quality of life in relation to weight stigma.

Method: In 214 participants (87.4% female; mean BMI = 23.95) reporting experiences with weight stigma, moderation models tested the interactions between anticipated, experienced, and internalized weight stigma, three measures of emotion regulation and coping (COPE, Brief CRI, ERQ), and four health outcomes (perceived stress, depressive symptoms, psychological quality of life, and physical quality of life), controlling for BMI and gender. Given the large number of tests, we interpreted results only when a significant moderator emerged for the same measure of weight stigma and at least two health outcomes.

Results: Approach-oriented coping significantly moderated the associations between internalized weight stigma and physical and psychological quality of life [$\Delta R^2_s > .01$, $F(1, 208) > 5.15$, $ps < .024$], and disengagement coping significantly moderated the associations between internalized weight stigma and depressive symptoms and physical quality of life [$\Delta R^2_s > .01$, $F(1, 208) > 4.09$, $ps < .045$].

Conclusion: Approach-oriented and disengagement coping significantly moderated the associations between internalized weight stigma and mental and quality of life outcomes. If longitudinal and experimental studies support the present findings, intervening on coping strategies may promote better outcomes in individuals who are targets of weight stigma.

PERCEPTIONS OF THIN AND PLUS SIZED MODELS AND ASSOCIATED FACTORS

Julia Caroline Miller, MA¹, Robert A. Carels, PhD, MBA, ABPP¹¹East Carolina University, Greenville, NC

Background: Traditionally, clothing retailers in the United States showcase their clothing using models with a thin physique. Recently, some retailers have begun to incorporate more diversity among the models in terms of body size. Little research has been done to examine this change and understand how newly included “plus” sized models are perceived.

Purpose: The current study aims to examine whether models that are considered plus size are perceived differently than conventional, thin models, and if so, to examine potential factors that contribute to a difference in perception, such as weight bias.

Methods: The study included 331 undergraduate students at a mid-sized south-eastern university ($M_{age} = 18.58$, $SD_{age} = 1.51$, $M_{BMI} = 23.9$, $SD_{BMI} = 4.65$, 60.1% female, 69.5% white, 15.5% black, 81.1% Freshman). Data was collected through an online survey platform. Students first viewed randomized images of either thin or plus sized models and answered questions about each image (i.e. Does the model look attractive in this dress?) Students then completed measures that assessed weight stigma, internalized weight bias, and body appreciation, as well as a self-esteem and mood before and after viewing the images.

Results: A t-test revealed that thin models ($M = 173.42$, $SD = 42.85$) were rated as significantly more favorably than plus sized models ($M = 162.6$, $SD = 46.17$, $t(330) = 2.8$, $p < .01$). Ratings of thin sized models were positively associated with pressure from peers to be thin ($r = .12$, $p < .05$) and inversely with weight bias ($r = -.15$, $p < .01$). This appeared to be sex specific, as more favorable perceptions of the thin model was inversely associated with weight bias for male participants ($r = -.28$, $p < .01$), but was overall not correlated for female participants when controlling for males. Ratings of plus sized models were inversely associated with a need to look athletic ($r = .16$, $p < .01$) and with weight bias ($r = -.33$, $p < .001$). A multiple regression analysis found that ratings of plus sized models was predicted by both weight bias and a need to look athletic ($F(2, 313) = 21.11$, $p < .001$), with an R^2 of .113. No associations were found with ratings of either types of models with internalized weight bias, body appreciation, and self-reported BMI.

Conclusions: Models appeared to be viewed differently based on their weight, with thin sized models rated more positively. It's likely that factors such as weight bias, pressure to be thin, and a need to look athletic influenced ratings of each type of model. Interestingly, higher weight bias was associated with lower ratings of both plus and thin sized models, though the effect was stronger for plus models. While the inclusion of more body diversity among models is certainly a positive step, it is clear that more needs to be done in terms of reducing widespread weight bias.

THE ASSOCIATION BETWEEN HUSBAND'S WEIGHT BIAS, WEIGHT COMMENTS AND HIS AND HIS WIFE'S PSYCHOLOGICAL AND RELATIONSHIP OUTCOMES

Julia Caroline Miller, MA¹, Robert A. Carels, PhD, MBA, ABPP¹, Reid Hlavka, MA¹, Jennifer Selensky, MA¹, Abigail Shonrock, BA¹¹East Carolina University, Greenville, NC

Background: Previous research found that wife internalized weight bias (IWB) and other weight related concerns, paired with husbands' weight related comments/criticisms, were found to be strongly associated with psychological distress and negative relationship outcomes among wives (Carels et al., 2019).

Purpose: The purpose of the current follow-up study is to examine how husband weight bias, IWB and weight related concerns/suggestions directed toward his wife impact his and his wife's psychological distress and negative relationship outcomes, and whether wife's or husband's BMI played a role in the observed relationships. The study further examined correspondence between husband and wife reported data (i.e. reported frequency of weight criticisms).

Methods: The study included 209 husbands ($M_{age} = 49.0$, $SD_{age} = 14.4$) and 209 wives ($M_{age} = 48.9$, $SD_{age} = 14.3$) who were married and in a heterosexual relationship. Data was collected through an online survey platform that aimed to collect a nationally representative U.S. sample (including age, race, and country region). Wives and husbands completed measures that assessed IWB, weight stigma, weight concerns/criticisms directed toward the wife, mate value, relationship satisfaction, sexual intimacy, self-esteem, and depressive symptoms.

Results: Husband and wife data were found to have consistent correspondence across variables. Notably, husband and wives reported similar rates of husband criticisms, suggestions, or concerned comments about wife's weight and similar reporting of husband's ideal mate and whether wives met their husband's ideal mate. Husband IWB was positively correlated with his own reported weight bias and his reported weight related comments towards his wife. Husband's own reported weight related comments, weight bias, and IWB was associated with his own and wife reported psychological distress and negative relationship outcomes. Interestingly, wife BMI was only correlated with husband weight related comments and husband's reported marital satisfaction. Further, regression interaction models indicated that wife BMI did not consistently interact with weight bias to predict husband and wife outcome variables.

Conclusions: The current study expanded previous research on the impact of IWB and weight bias and other weight related concerns/suggestions and their impact on psychological distress and negative relationship outcomes among husbands and wives, and an exploration of how BMI may interact in these relationships.

A QUASI-EXPERIMENTAL TEST OF A PROCESS- VS. OUTCOME-FOCUSED WEIGHT-LOSS PROGRAM

Celina R. Furman, n/a¹, Alexander J. Rothman, Ph.D.¹¹University of Minnesota, Minneapolis, MN

Research suggests that focusing on the process of losing weight (e.g., dieting, exercise) may be more beneficial for long-term goal pursuit than focusing on weight-loss itself. This study used a quasi-experimental design to test if a weight-loss program with a process (vs. outcome) focus would improve weight-loss outcomes and subjective experiences with weight loss. Individuals ($N = 448$) participating in process or outcome weight-loss programs at four gyms were assessed at three time points: baseline, end of program (8 weeks), and 2-months following (16 weeks). Participants had their weight measured at baseline and 8 weeks, and completed surveys assessing their use of weight-loss strategies, satisfaction with weight loss, enjoyment of the program, and the difficulty of the program requirements. At 16 weeks, participants self-reported their weight, continued use of weight-loss strategies, and their satisfaction with their diet, physical activity, health, and weight. The gyms provided attendance data during the program and 2-months after, from which we were able to derive an objective measure of participation in workouts.

On average, participants lost 3.19% of their starting weight over 16 weeks. Contrary to expectations, there were no differences across programs in weight loss at 8 or 16 weeks, and those who participated in the process (vs. outcome) program were not more satisfied with their weight loss. Participants in the process and outcome programs found their programs to be equally enjoyable, but those participating in the outcome (vs. process) program reported greater intentions to continue the use of weight-loss strategies, and those participating in the process (vs. outcome) program found the program requirements to be more difficult ($ps < .05$). Yet, more participants in the process program (62.3%) completed the program requirements (e.g., minimum number of workouts) than participants in the outcome program (20.3%), and participants in the process (vs. outcome) program used more weight-loss strategies (e.g., increasing healthy food intake, reducing sedentary behavior), and completed more workouts at 8 and 16 weeks ($ps < .05$). In sum, findings indicate that participation in each program had similar outcomes, but the process focused program may have unique behavioral benefits, such as maintaining engagement with the behavioral demands of weight-loss (e.g., dieting, exercise). This idea should be systematically tested in future research.

MENTAL HEALTH DIAGNOSTIC PATTERNS IN A NATIONAL SAMPLE OF BEHAVIORAL WEIGHT LOSS PROGRAM ATTENDEES

Jacqueline F. Hayes, PhD¹, Katherine J. Hoggatt, PhD², Jessica Y. Breland, PhD³¹The Miriam Hospital/Brown University, Providence, RI; ²San Francisco VA Health Care System, San Francisco, CA; ³VA Palo Alto Health Care System, Menlo Park, CA

Individuals with obesity experience higher rates of mental health disorders (both single disorders and multiple co-occurring mental health disorders) than individuals of normal weight. However, while mental health disorders are associated with a greater number of treatment barriers and may negatively impact weight loss treatment outcomes, little is known about the mental health burden of individuals using behavioral weight loss programs. The current study identifies common mental health diagnoses and diagnostic patterns among participants of MOVE!, the Veterans Health Administration's (VHA) behavioral weight loss program. We used national VHA administrative data from fiscal year 2014 to identify veteran VHA primary care patients who participated in at least one MOVE! session in the previous year (95,798 men and 15,032 women). Using latent class analysis, we stratified by gender and identified different classes of veterans based on their patterns of mental health diagnoses. We also assessed the role of age on class formation and membership. Common classes included one characterized by the absence of mental health disorders, a class characterized by depressive disorders, a class characterized by multiple co-occurring mental health disorders, and a class not characterized by any particular diagnoses, but with a significant comorbidity burden. Unique classes were also found in men in different age groups, including a class characterized by PTSD and depressive disorders in both younger and older men and a class characterized by depressive disorders and substance use as well as a class characterized by severe mental illness among middle-aged men. With the exception of older men, the majority of patients belonged to a class characterized by at least one psychiatric disorder. Additionally, younger patients of both genders were more likely to fall into class characterized by psychological disorders than were older patients. It may be warranted to tailor MOVE! programming to include treatment factors that focus on overcoming barriers to weight loss program engagement and adherence that are associated with mental health disorders and/or consider addressing both obesity and mental health diagnosis in MOVE! contexts. A holistic approach may be particularly important for younger patients who have a higher comorbidity burden and longer care horizons.

ANYTHING YOU CAN DO I CAN DO BETTER: SOCIAL COMPARISON AND WEIGHT LOSS IN A LIFESTYLE INTERVENTION PROGRAM

Chelsea Larsen, MPH¹, Jean Harvey, PhD, RDN², Rebecca Krukowski, PhD³, Courtney Monroe, PhD, EP-C¹, Shelly Naud, PhD², Delia West, PhD¹¹University of South Carolina, Columbia, SC; ²University of Vermont, Burlington, VT; ³University of Tennessee Health Science Center, College of Medicine, Memphis, TN

Background: Social comparison is the process of comparing oneself to others in general, as well as to individuals perceived as better off (upward comparison) or worse off (downward comparison), to evaluate one's self-worth or success. Social comparison can increase motivation to engage in behavior change efforts or can result in negative self-evaluation and consequent amotivation. The impact of social comparison among individuals engaged in an online group-based behavioral weight control intervention has not been examined. Therefore, the purpose of this study was to examine whether general social comparison, upward comparison or downward comparison is associated with weight loss outcomes.

Methods: Participants were enrolled in a two site (VT and SC) 6-month online lifestyle intervention program with counselor-facilitated weekly chats. Participants completed the Iowa-Netherlands Comparison Orientation Scale (INCOM) at baseline. The INCOM is a 23-item survey assessing an individual's tendency to make social comparisons and includes 3 subscales: general comparison, upward comparison, and downward comparison. Responses, which range from 1 (strongly disagree) to 5 (strongly agree), are summed for all participants for each subscale. Higher scores indicate a greater tendency to engage in that type of comparison. Weight was objectively measured at baseline and 6 months.

Results: Participants (n=418) had overweight/obesity (M BMI= 35.6 kg/m²), mostly identified as white (72%) and female (91%) and lost an average of 6.3±5.9% at 6 months. INCOM scores were as follows: general comparison 34.6±8.1; upward 16.7±4.9; and downward 14.6±5.1. None of the subscale scores were correlated with 6-month weight loss. However, significantly higher scores were noted among participants who identified as white compared with minority participants on all three scales, indicating greater likelihood to engage in all type of social comparison. Similarly, those with overweight compared with those with obesity were more likely to engage in social comparisons. There were no significant differences in scores between men and women, or among those who dropped out (N=58) compared to those retained.

Conclusion: The tendency to compare oneself with others does not appear to influence weight losses achieved in a behavioral program, either positively or negatively, suggesting that social comparison may not be a relevant psychosocial variable for understanding lifestyle program outcomes.

FACTORS ASSOCIATED WITH OPTIMAL WEIGHT MANAGEMENT AMONG AFRICAN AMERICAN AND WHITE ADULTS INITIALLY SUCCESSFUL AT WEIGHT LOSS

Amber W. Kinsey, PhD¹, Janice Phillips, BS², Marissa A. Gowey, PhD³, Catherine D. Jones, MSPH⁴, Jamy Ard, MD⁵, Gareth Dutton, PhD³

¹University of Alabama at Birmingham, Birmingham, AL; ²University of Alabama at Birmingham, Birmingham, AL; ³University of Alabama at Birmingham, Birmingham, AL; ⁴Department of Physical Therapy / University of Alabama at Birmingham, Birmingham, AL; ⁵Wake Forest School of Medicine, Winston Salem, NC

Background: Providing ongoing treatment through extended care programs improves weight loss maintenance (WLM), but the effectiveness of these programs for African Americans (AA) are mixed.

Objective: To use the nominal group technique to generate and prioritize factors associated with WLM as experienced by AA and White adults to identify unique factors impacting long-term weight management among AAs.

Methods: AA and White adults who were former participants of structured, behavioral obesity treatment programs implemented at the academic health center (Look AHEAD, ImWeL and Live Well) and achieved $\geq 5\%$ weight loss during that time were classified as Maintainers (continued $> 5\%$ weight reduction for ≥ 1 year) or Regainers ($\leq 5\%$ weight reduction) based on current weight. The average time between participants' completion of initial treatment and the study visit confirming maintainer or regainer status was 1.6 ± 0.5 , 1.7 ± 0.1 , and 11.3 ± 0.8 years for ImWeL, Live Well, and Look AHEAD trials, respectively. Race-stratified nominal groups were conducted to generate WLM facilitators and barriers. These factors were individually prioritized via an online ranking activity.

Results: Participants (N=104; 81.7% women; 48.1% AA) included 46 Maintainers (22 AA, 24 White) and 58 Regainers (28 AA, 30 White). All groups identified common factors associated with WLM, including daily weighing, self-monitoring, regular physical activity, and mindful eating. However, the perceived importance of these factors differed between Maintainers and Regainers and between AA and White adults. Physical activity was the most important facilitator and barrier endorsed by AA Maintainers and Regainers. Daily self-weighing (facilitator) and lack of motivation for, and engagement in physical activity (barrier) were the most important factors for White Regainers. External accountability (facilitator) and losing discipline for weight control behaviors (barrier) were the most important factors for White Maintainers. In contrast to other groups, AA Maintainers' responses indicated that they were more likely to hold themselves accountable, not likely to rely on support from others, and were accepting of minor weight regain.

Discussion: Findings demonstrate the importance of considering participant preferences and experiences in the development of lifestyle interventions for WLM, particularly for AA. Strategies targeting physical activity maintenance and autonomy-supportive approaches may improve WLM in AA.

VALIDATION OF A PORTABLE BIOELECTRICAL IMPEDANCE ANALYSIS DEVICE AGAINST A GOLD STANDARD CRITERION IN CHILDREN

Ethan T. Hunt, MPH¹, Lauren E. von Klingraeff, MPH¹, Alexis Oliveira, n/a¹, Keith Brazendale, PhD², Rodrick Dugger, MPH³, Michael Beets, M.Ed, MPH, PhD¹, R. G. Weaver, Ph.D.¹, Bridget Armstrong, PhD¹, Sarah Burkart, MPH, PhD¹

¹University of South Carolina, Columbia, SC; ²University of Central Florida, Orlando, FL; ³University of South Carolina Arnold School of Public Health, Columbia, SC

Background: Tanita Corporation recently released the DC-430U bioelectrical impedance analysis (BIA) scale. This BIA scale includes a novel proprietary child-specific equation for estimating body composition. The purpose of this study was to validate the new Tanita DC-430U portable BIA unit against a criterion dual-energy X-ray absorptiometry (DEXA) Lunar Prodigy in a sample of healthy children.

Methods: Participants were eligible to participate if they were elementary aged (5-12 yrs.) and had no medical conditions that would prevent them from completing a DEXA scan. Following an overnight fast, participants had their % body fat estimated by both BIA and DEXA. Single absolute ICC and Spearman rank-order correlation were calculated to assess the strength of association between the two methods. A Bland-Altman plot was constructed to assess agreement between the BIA and DEXA % body fat estimates. A difference of 10% between the BIA and DEXA was deemed acceptable.

Results: A total of (N=50) participants (mean age = 9.1 yrs., ± 2.2 yrs., 56% Female) participated in the study. Mean % body fat was higher in DEXA when compared to BIA (28.5 ± 6.5 vs. 20.6 ± 9.0 , $P < .05$). ICCs examining the association between BIA and DEXA for % body fat was weak-to-moderate 0.48 (96% CI = 0.17, 0.68). A moderate-to-strong Spearman rank-order association of 0.78 was calculated. Absolute mean difference between BIA and DEXA was 8.5%. The Bland Altman also indicated that BIA consistently underestimated % body fat when compared to the DEXA across differing levels of % body fat estimates. 84% (n=42) of participants examined fell within pre-determined LOA.

Conclusions: Consistent with past BIA validation literature, BIA underestimated % body fat when compared to DEXA. However, this particular BIA device appears to underestimate body composition at greater magnitude than past studies. The moderate to strong Spearman rank-order correlation indicates that the Tanita DC-430U may be an appropriate tool when examining relative changes in body composition in children. However, this device consistently underestimates body composition by approximately 8% in children when compared to DEXA.

AN ANALYSIS OF WEIGHT STIGMATIZATION IN HEALTH CARE SETTINGS

Shefali T. Patel, B.S.¹, Mary A. Gerend, Ph.D.²¹Florida State University College of Medicine, Lakeland, FL; ²Florida State University College of Medicine, Tallahassee, FL

Introduction: Weight stigmatization involves the stereotypes, prejudice, and discrimination imposed on individuals because of their higher body weight. Exposure to weight stigma leads to detrimental effects on health. As the prevalence of obesity increases, it is imperative that weight stigma be addressed. One of the most concerning areas in which weight stigma exists is health care. This study sought to 1) assess the nature of people's lived experience with weight-based discrimination in health care settings and 2) to determine what strategies patients use to cope with such stigmatization.

Methods: Adult men (n = 9) and women (n = 23) with a body mass index of 30 or greater (i.e., classified as "obese") and previous experiences with weight discrimination took part in the qualitative study. Participants answered questions about their experiences with weight stigmatization in health care settings and associated coping strategies using a semi-structured interview format. Interviews were recorded, transcribed, and coded for recurrent themes and patterns in the responses.

Results: Most participants reported at least some experience with weight discrimination in health care settings. The vast majority of responses centered on providers making diagnoses solely based on weight without taking into account other factors or symptoms. In some cases, serious medical conditions, such as hypothyroidism and uterine fibroids, were left undiagnosed in favor of weight-based conditions. Many participants reported rude or offensive comments made by physicians and medical staff in regards to their weight. Participants regularly encountered stigmatizing physical or environmental barriers in clinics and hospitals such as lack of high-capacity scales or properly-sized blood pressure cuffs. Participants utilized a wide variety of coping strategies to deal with weight discrimination. The most frequently used coping mechanisms were seeking social support and binge eating or turning to food for comfort.

Conclusion: Findings from the present study have important implications for interventions aimed at reducing weight stigma in health care settings. The results of this study warrant further examination of how physicians can provide more patient centered-care to obese patients and minimize weight-based discrimination during patient-provider interactions. It may also be useful to integrate opportunities for medical students to learn about and reduce the negative effects of weight stigma.

RECRUITMENT STRATEGIES FOR MEN OF COLOR

Roxana Farias, MPH¹, Michaela Kiernan, PhD², Susan D. Brown, PhD³¹Stanford Prevention Research Center, Palo Alto, CA; ²Stanford University School of Medicine, Stanford, CA; ³Kaiser Permanente Northern California, Oakland, CA

Racial and ethnic minorities in the US suffer disproportionately from obesity and other comorbidities, yet remain underrepresented in health research. For a 3-year randomized behavioral weight-management trial, we wanted to recruit a sample of individuals who were overweight/obese and had elevated blood pressure or taking blood pressure medication but who also reflected the diverse racial/ethnic backgrounds living in the urban counties surrounding our research center—specifically 55% individuals of color and 50% men. Of special interest was to recruit ~25% men of color.

Direct mail is an appealing recruitment strategy for reaching large target populations of interest such as individuals from underrepresented racial/ethnic backgrounds living across widespread geographical areas. In prior experimental research by our team and others, direct mail letters with a targeted statement about health disparities for subgroups of color generated greater interest in trial participation among women of color than generic letters. Here, we describe our strategies for recruiting men of color.

Via a third-party commercial direct marketing firm, we identified potential men and women of color who lived in zip codes with a high prevalence of individuals of color within ~1 hour from the research center. Direct mail letters included a targeted statement about health disparities for mortality for subgroups of color as well as 10 recommended elements found to increase response rates in prior research (e.g., trial's purpose, benefits to recipients). Additional recruitment strategies regardless of race and ethnicity included local and regional newspaper advertisements, radio spots, and others.

Of randomized participants (n=321), men of color comprised 25.5% (n=82) of the sample, with women of color 23.1% (n= 74), White men 19.6% (n=63), and White women 31.8% (n=102). Direct mail was the most effective strategy among men of color (78.0%, n=64/82) than women of color (50.0%, n=37/74), White men (17.5%, n=11/63), or White women (17.6%, n=18/102). In contrast, newspapers advertisements were much less effective for recruiting men of color (9.8%, n=8/82) than women of color (20.3%, n=15/74), White men (47.6%, n=30/63), or White women (41.2%, n=42/102).

We would not have reached recruitment goals for men of color by solely relying on newspaper advertisements and other non-targeted strategies. Direct mail with targeted statements about health disparities appears advantageous.

RURALITY, BARRIERS TO HEALTHY DIET AND EXERCISE, AND CORRESPONDING HEALTH BEHAVIORS AMONG OVERWEIGHT APPALACHIAN ADULTS

Xiaochen Zhang, MPH¹, Ryan Baltic, MPH¹, Gregory Young, MS¹, Electra D. Paskett, PhD¹¹The Ohio State University, Columbus, OH

Purpose: Barriers to healthy eating and exercise among Appalachian adults may vary by rurality, which could lead to differences in these health behaviors. We sought to determine if there were differences in barriers to healthy eating and exercise by Rural-Urban Continuum Code (RUCC) and to examine the relationship between barriers and corresponding health behaviors.

Methods: Data were from a group-randomized trial that compared a 1-year faith-based weight loss intervention to an active control group among overweight Appalachian adults. Participants from the weight loss group who provided complete data on barriers were included in the analysis. The number of individual-level and social-environmental barriers to healthy eating and exercise were summed. RUCC for each participating church's county of residence was used to define rurality. Baseline and 12-month data on exercise and fruit/vegetable intake were self-reported using standard questionnaires. Mixed effect models were used to examine the association between number of barriers and corresponding health behaviors.

Results: Among the 402 included participants, most were female, white, and married or living with a partner. The number of individual-level barriers to healthy eating differed across rural-urban classification: Appalachian adults from churches in metropolitan counties reported encountering the most barriers (1.38 ± 0.87), followed by those from churches in nonmetropolitan counties not adjacent to a metro area (1.18 ± 0.83), and those from churches in nonmetropolitan counties adjacent to a metro area had the fewest barriers (1.02 ± 0.75). The number of social-environmental barriers to healthy eating and to exercise did not differ across rural-urban classification. Although no association was observed in social-environmental barriers to healthy eating, each increase in the number of individual barriers was associated with 0.355 (95%CI: -0.587, -0.124) decrease in daily fruit/vegetable servings. Each increase in the number of barriers to exercise was associated with 48% lower odds of regular exercise (OR=0.52, 95%CI: 0.40, 0.68) and 24% lower odds of higher level of physical activity (OR=0.76, 95%CI: 0.58, 0.99).

Conclusion: Individual barriers to healthy eating varied by degree of rurality. Barriers to healthy eating and exercise were associated with lower odds of corresponding healthy behaviors. Strategies are needed to address these barriers to improve health behaviors among Appalachian adults.

COMPARING REACH AND RETENTION STRATEGIES ACROSS COHORTS OF A CHILDHOOD OBESITY TREATMENT TRIAL IN A MEDICALLY UNDERSERVED AREA

Maryam Yuhas, PhD, RD¹, Jamie Zoellner, PhD, RD¹, Wen You, PhD¹, Jennie Hill, PhD², Donna-Jean P. Brock, M.S.¹, Bryan Price, B.S.¹, Paul Estabrooks, PhD²¹University of Virginia, Christiansburg, VA; ²University of Nebraska Medical Center, Omaha, NE

Collaborative systems-based approaches can help address challenges to implementing childhood obesity treatment programs in small towns and rural regions. However, it is unclear how best to recruit and retain families within these programs. This case study describes collaboratively-developed strategies to address reach and retention for a comparative effectiveness trial of two childhood obesity treatment interventions in a rural, medically-underserved region. Strategies were enacted by healthcare, community, and parent partners. Adaptations to recruitment and retention strategies were tracked across 3 cohorts of program families. Reach and retention strategies used in Cohort 1 (C1) included a population health management approach (e.g., medical record identification of eligible children, pediatrician endorsed recruitment letter to the family, follow-up recruitment call), community distribution of recruitment materials, and Parent Advisory Team (PAT) representation at intervention classes. C2 included addition of another clinical recruitment partner, revisions in recruitment materials, distribution of recruitment materials in schools, instructor training in social support strategies for retention, and additional social support from the PAT. C3 added another recruitment clinical partner and program site, expanded eligibility to include younger children, revised recruitment materials again, and added an informational video played in recruitment partner waiting rooms. Physician referral was consistently the most effective enrollment strategy; however, enrollment rates declined across cohorts (44/271, 17% C1; 45/627, 7% C2; 50/830, 6% C3). Of the 1735 eligible families, about 1/3 declined participation and half were not able to be contacted by phone. Of the 192 families scheduled for baseline assessment, 63 (33%) did not attend. Additionally, of 48 potential self-referred families, 29 (60%) did not attend an eligibility screening appointment. Families that did enroll in the study were largely representative of the region's race/ethnicity and household income (63% minority, 42% earning < \$25,000/year). Retention appears more responsive to the adaptations between cohorts, with 6-month retention rates for C1 and C2 at 66% and 85%, respectively (C3 is on-going). Successful recruitment and retention strategies will be presented, along with barriers and lessons learned when recruiting and retaining families into childhood obesity treatment interventions.

QUALITATIVE COMPARATIVE ANALYSIS OF FACTORS THAT EXPLAIN SUCCESS IN A RURAL CHILDHOOD OBESITY TREATMENT PROGRAM

Caitlin Golden, MPH¹, Jennie Hill, PhD², Kate A. Heelan, PhD³, Todd Barteet, PhD³, Bryce M. Abbey, PhD³, Paul Estabrooks, PhD²¹University of Nebraska Medical Center, Lincoln, NE; ²University of Nebraska Medical Center, Omaha, NE; ³University of Nebraska Kearney, Kearney, NE

Qualitative comparative analysis of factors that explain success in a rural childhood obesity treatment program

The purpose of this study was to explore the variation in outcomes of Building Healthy Families (BHF), an adapted evidence- and family-based childhood obesity program, to identify the context under which the program is most effective in supporting child weight status changes and to understand the conditions or combination of conditions that are necessary and sufficient for successful child weight loss. A necessary condition is one that must be present for the desired outcome to occur but its presence doesn't guarantee the outcome. A sufficient condition is one that, if present, guarantees the outcome will occur. Conventional statistical models may not capture the nuances of these conditions, particularly in smaller sample sizes. Thus, a qualitative comparative analysis (QCA) technique was used to determine (1) program conditions (e.g., group size, normative outcomes) (2) child characteristics (e.g., age, attendance, self-regulation scores), and (3) parent characteristics (e.g., mom/dad/both, parent change in weight) contributed to child weight status improvement. A truth table using a crisp set analysis that includes dichotomizing these conditions and characteristics was used to determine the necessary and sufficient conditions for large magnitude child BMI z-score changes. Of the 75 BHF child participants over nine cohorts with baseline and three-month data (end of program), participants who ranked as the 10 most successful (BMI z-score changes ranging from -0.47 to -0.97) and as the 10 least successful (BMI z-score changes ranging from -0.02 to 0.11) were included in the analysis. Necessary conditions for successful childhood weight loss included high child attendance and self-regulation, at least one high attending adult, parents with high self-regulation scores, and a mother who lost weight during the program. The only distinguishing condition (i.e., sufficient and in addition to the necessary conditions) found in the analysis for all highly successful children was whether or not the mother achieved clinically meaningful weight loss (i.e., $\geq 5\%$). This suggests that family-based childhood obesity program implementers should continue to focus on encouraging high attendance and self-regulation strategies, but could potentially improve program outcomes by using goals for mothers' achievement of clinically meaningful weight loss to increase the likelihood of child success.

GREATER BODY APPRECIATION PREDICTS LESS EATING PATHOLOGY IN YOUNG ADULTS WITH OVERWEIGHT AND OBESITY

Heather Eisele, Ph.D.¹, Sylvia Herbozo, Ph.D.², Gabrielle Bolivar, M.A.³, Dean Lim, M.A.⁴¹University of Illinois- Chicago, Chicago, IL; ²University of Illinois at Chicago, Chicago, IL; ³Loma Linda University, Riverside, CA; ⁴Loma Linda University, Loma Linda, CA

Body appreciation, characterized as respect for, acceptance of, and holding favorable opinions of one's body, has been associated with increased intuitive eating, decreased weight loss strategies, and decreased disordered eating behaviors. Studies have also found negative relationships between body appreciation and BMI, suggesting that individuals who are of higher weight may be less accepting of their bodies. However, to our knowledge, no research has assessed the relationship between body appreciation and eating pathology specifically for individuals with overweight/obesity, and only one study has utilized a racially/ethnically diverse sample. The current study examined the relationship between body appreciation and eating pathology in racially/ethnically diverse young adults with overweight/obesity. Participants were 130 young adults (89.3% racial/ethnic minority; 71.5% female) aged 18 to 30 ($M = 20.88$, $SD = 3.11$) with a body mass index (BMI) of 25 or greater ($M = 30.30$, $SD = 4.86$). Of the sample, 81 (62.3%) were overweight and 49 (37.7%) were obese. Participants completed a demographics form, the Body Appreciation Scale-2 (BAS-2), and the Eating Disorder Examination-Questionnaire (EDE-Q). On average, participants had moderate levels of body appreciation ($M = 3.18$, $SD = 0.94$; range 1-5) and global eating pathology ($M = 3.17$, $SD = 1.37$, range 0-6) with lower scores on the restraint ($M = 2.66$, $SD = 1.52$) and eating concern ($M = 2.24$, $SD = 1.23$) subscales of the EDE-Q. Linear regression analyses indicated that higher body appreciation was associated with lower global eating pathology ($b = -0.60$, $p < .001$), eating restraint ($b = -0.45$, $p = .001$), and eating concern ($b = -0.46$, $p < .001$). Results extend past research on the potential benefits of body appreciation for eating pathology to individuals with overweight/obesity and suggest that body appreciation may also be beneficial for individuals from diverse racial/ethnic backgrounds. Future research should continue to investigate the relationship of body appreciation and eating pathology for individuals of varying BMIs and racial/ethnic backgrounds, including its potential role as a protective factor in eating pathology.

Learning Objectives:

- Describe the levels of body appreciation and eating pathology in racially/ethnically diverse young adults with overweight/obesity
- Describe relationships between body appreciation and eating pathology in this sample

APPLYING A STRUCTURED WEIGHT LOSS STUDY TO AN OPEN ENROLLMENT, PRIMARY CARE, DEPARTMENT OF DEFENSE MEDICAL TREATMENT SETTING

Marc Patience, Licensed Psychologist, Ph.D.¹, Ann S. Hryshko-Mullen, Ph.D., ABPP-CHP, CBSM¹, Gerald W. Talcott, Ph.D., ABPP², John Blue Star, Licensed Psychologist, Ph.D.¹

¹USAF, San Antonio, TX; ²University of Virginia, San Antonio, TX

Introduction: With an estimated 66% percent of DoD service members overweight or obese (Meadows, et al., 2018), the need for evidence-based treatment delivery remains high. Investigators have previously reported a successful adaptation of the “Look Ahead/Fit Blue” behavioral weight loss program for DoD service members (Krukowski, 2018). This program incorporates self-monitoring behaviors (activity, diet, and weighing oneself) as well as diet and physical activity education. The present study seeks to translate “Fit Blue” into an open enrollment Military Treatment Facility (MTF).

Methods: From JAN 2016 to JUN 2019, 13 rounds of 12 week groups based on “Fit Blue” were offered. 90-min. sessions emphasized Motivational Interviewing and goal check-ins, with educational components transcribed from “Fit Blue.” Participants were invited weekly to report on weight and self-management behaviors including the number of days in a week they weighed in and tracked calories, minutes engaged in moderate physical activity, and if personally identified goal were met. Group members were referred by providers across the MTF. At the end of each round of treatment, members were invited to additional rounds.

Results: 77 participants (83%) returned for at least a second session. Of these, 74% were female, 26% were active duty, 16% retired from active duty, 55% were family members of active duty or retired service members, and 4% were of unknown military affiliation. 62% of participants attended 6 sessions or more. Average percent weight loss across participants was 3.6%. Percentage weight change ranged from -12% (gained 32lbs) to 25% (lost 55 lbs.). A median 1.6% (3 lbs.) weight loss per 12-session iteration attended was observed. Average weight loss by quartile in ascending order of success was -2.2% (gained 4.8 lbs.), 1.3% (lost 2.6 lbs.), 3.5% (lost 8.1 lbs.), and 12.1% (lost 27 lbs.). Increases in behaviors of interest were observed across quartiles including median number of sessions attended (5, 4, 8, 13), average days per week they tracked calorie intake (2.5, 3.5, 3.9, 5.2), and average days per week they weighed in (4.2, 4.6, 4.9, 5.4).

Conclusion: This study demonstrates that the Fit Blue model can be adapted to a standard medical treatment setting within the DoD. The majority of members opted for multiple sessions and averaged a weight loss of 2-5%, likely resulting in clinically significant health benefits (NIH, 2013). Participants that lost the most weight were more adherent to daily weighing, calorie tracking, and were likely to attend more sessions and more than one group iteration. Participants represented in the highest percent weight loss quartile engaged in the most active minutes as well as highest percentage of weeks engaged in any form of moderate activity. Future efforts should seek to increase referrals, decrease attrition, and increase adherence to self-reported health behaviors.

INFLUENCE OF WEIGHT SELF-PERCEPTION, WEIGHT STATUS, AND WEIGHT MISPERCEPTION ON THE PURSUIT OF WEIGHT LOSS AMONG YOUNG ADULTS

Maddison M. Bean, MS, RDN¹, Kari-Lyn K. Sakuma, PhD, MPH², Nina Taylor, MPH³

¹Oregon State University, Philomath, OR; ²Oregon State University, Corvallis, OR; ³Oregon State University, New York City, NY

Background: Weight loss behavior is salient during young adulthood and can contribute to negative physical and psychological health outcomes. Weight self-perception and weight status do not always align, leaving gaps in how we understand who engages in weight loss behavior. The purpose of this study was to assess the associations between weight loss behavior and weight self-perception, weight status (by BMI), and weight misperception among a nationally representative sample of U.S. young adults.

Methods: Data were analyzed from Wave III (2001-2002) of the National Longitudinal Study of Adolescent to Adult Health. Participants were 18-26 years old. Adjusted logistic regression models were fit to examine associations between weight loss behavior and weight self-perception, BMI, and weight misperception.

Results: Weight loss behavior was significantly greater among young adults who thought they were “overweight” compared to “the right weight” (OR=7.28, 95% CI: 5.57, 9.51) and among those with a BMI indicative of “overweight/obese” compared to “healthy weight” (OR=1.60, 95% CI: 1.27, 2.02) after controlling for sex, age, income, race, and ethnicity. Females were significantly more likely to pursue weight loss than males (OR=2.33, 95% CI: 1.87, 2.90). A significant interaction was seen between sex and BMI. Therefore, data were stratified by sex, showing that weight loss behavior was significantly influenced by weight self-perception and BMI for males, but only by weight self-perception for females.

Discussion: Although BMI is a standard metric used to determine weight status and for health recommendations, weight self-perception appears to be a more robust factor in influencing weight loss behavior among both young men and women. Failing to discuss weight self-perception during healthcare interactions may be problematic, especially for young women. Those at increased risk for engaging in potentially harmful weight loss behaviors may be missed during this critical time of solidifying eating habits and beliefs if only BMI is assessed.

CHANGES IN PAIN ANXIETY DURING INTENSIVE PEDIATRIC PAIN REHABILITATION PREDICT PAIN, ACTIVITY, AND DEPRESSION AT FOLLOW-UP

Karen Weiss, Ph.D.¹, Michele Tsai Owens, Ph.D.¹, Yeon Joo Ko, B.S.², Varun Awasthi, B.S.², Kristen Daniels, MLIS², Sabina Havkins, PT³, Sandy Lehman, RN³, Tonya M. Palermo, PhD⁴

¹University of WA/Seattle Children's Hospital, Seattle, WA; ²Seattle Children's Research Institute, Seattle, WA; ³Seattle Children's Hospital, Seattle, WA; ⁴University of Washington School of Medicine; Seattle Children's Research Institute, Seattle, WA

Intensive interdisciplinary pain rehabilitation programs (IIPRP) are typically recommended for youth with debilitating chronic pain conditions who do not respond to outpatient multi-modal treatment. A growing body of research on IIPRP demonstrates improvements in functioning, pain, and distress with recent studies indicating long term maintenance of gains. Some studies have documented improvements in physical functioning, but little is known about how these changes contribute to longer term outcomes of pain, activity engagement, and mood. In addition, existing conceptual models (fear-avoidance model of chronic pain, self-efficacy model) suggest pain-related anxiety and self-efficacy may be important mechanisms related to behavior health change. For this preliminary study, we aimed to test whether improvements in physical functioning (measured via objective measures of gait speed and core and upper body strength), self-efficacy, and pain-related anxiety during an IIPRP would predict activity limitations, pain, and depressive symptoms at 3-month follow-up. Twenty-five participants (10-18 years old) completed measures prior to, upon completion, and 3-months post participation in an IIPRP where they participated in physical and occupational therapy, pain psychology, and medical services for 1-3 weeks. Measures included the 6-Minute Walk Test; 100-Foot Walk; Sit-Up and Push-Up subtests of the Bruininks-Oseretsky Test of Motor Proficiency, 2nd edition (BOT-2); Self-Efficacy Scale; Numerical Pain Rating Scale; Pain Catastrophizing Scale for Children; PROMIS depression SF and Fear of Pain Questionnaire – Child Report. Preliminary results indicate improvements in physical functioning did not predict pain, activity limitations, or depressive symptoms at follow-up ($R^2 < .065$, $p > .18$). Changes in pain catastrophizing predicted significantly fewer activity limitations ($R^2 = .402$, $\beta = .634$, $F(1,23) = 15.46$, $p < .001$) less pain ($R^2 = .235$, $\beta = .484$, $F(1,23) = 7.05$, $p < .01$) and fewer depressive symptoms ($R^2 = .339$, $\beta = .582$, $F(1,23) = 11.78$, $p < .01$) at follow-up. Changes in fear of pain predicted lower pain intensity at follow-up ($R^2 = .151$, $\beta = .388$, $F(1,23) = 4.08$, $p < 0.05$). Study results suggest improvements in self-efficacy of managing one's own pain and pain-related anxiety predicted outcomes at follow-up whereas changes in physical functioning did not. Results are preliminary as recruitment for this study is ongoing and the current sample size is limited. Our long-term goal is to investigate mechanisms of change within IIPRP to guide tailoring treatment to maximize efficacy.

ANGER MEDIATES THE LINK BETWEEN TRAIT FORGIVINGNESS AND PAIN OUTCOMES AMONG INDIVIDUALS WITH CHRONIC LOW BACK PAIN (CLBP)

Terence M. Penn, M.A.¹, Demario S. Overstreet, M.S.¹, Edwin N. Aroke, Ph.D., CRNA², Deanna D. Rumble, PhD¹, Leann Long, PhD³, Matthew C. Morris, PhD⁴, Burel R. Goodin, PhD¹

¹The University of Alabama at Birmingham (UAB), Department of Psychology, Birmingham, AL; ²The University of Alabama at Birmingham (UAB), School of Nursing, Birmingham, AL; ³The University of Alabama at Birmingham (UAB), Department of Biostatistics, Birmingham, AL; ⁴University of Mississippi Medical Center, Department of Psychiatry and Human Behavior, Jackson, MS

Chronic low back pain (CLBP) is among the most prevalent and painful conditions worldwide. Growing evidence suggests that anger is a major issue among individuals suffering from chronic back pain. Further, anger and resentment have been shown to complicate the course of chronic pain. One factor that may ameliorate the influence of anger on chronic pain is forgiveness, broadly defined as a cognitive process of decreasing negative, resentment-based thoughts, emotions, and motivations. Previous findings suggest that higher levels of forgiveness for a specific interpersonal transgression is associated with lower levels of pain and anger. Moreover, partial correlation analyses suggest a potential interplay between forgiveness, anger, and pain outcomes; though, little research has examined this relationship through formal mediation analyses. The purpose of this study was to examine whether anger mediates the relationship between trait forgiveness (i.e., tendency to forgive interpersonal transgressions over time) and self-reported pain outcomes among individuals with CLBP. CLBP participants ($N = 91$) completed the Brief Pain Inventory – Short Form, PROMIS Item Bank v1.1 – Anger, Trait Forgivingness Scale, and demographic items. In a cross-sectional, regression-based model adjusted for age, sex, and income level, findings revealed that anger significantly mediated the association between trait forgiveness and CLBP outcomes including pain severity [Indirect Effect = -0.03 , 95% CI: -0.05 to -0.004] and pain interference of daily functioning [Indirect Effect = -0.04 , 95% CI: -0.08 to -0.007]. Specifically, a greater level of trait forgiveness is associated with less anger ($p < 0.01$), which in turn is associated with less pain severity ($p = 0.003$) and less pain interference ($p < 0.001$). Our findings suggest that less anger may be a key factor through which forgiveness influences pain outcomes. These findings further highlight the potential of forgiveness-based interventions for ameliorating anger and thereby improving pain outcomes among chronic pain patients.

CHANGES IN SEDENTARY BEHAVIOR PREDICT CHANGES IN SYMPTOMS IN PATIENTS WITH CHRONIC LOW BACK PAIN.

Laura D. Ellingson, PhD¹, Jeni Lansing, MS², Maria Perez, MS², Kathryn J. DeShaw, PhD³, Jacob D. Meyer, PhD², Greg Welk, PhD²¹Western Oregon University, Monmouth, OR; ²Iowa State University, Ames, IA; ³Loras College, Dubuque, IA

Chronic back pain is common, disabling, and difficult to manage. Behavioral treatments are recommended, but finding behavioral targets that are feasible and result in meaningful symptom improvement is a challenge for the field. The purpose of the present work was to examine behavioral predictors of symptom improvement in patients with chronic low back pain who participated in a physical activity intervention. Fifty-six adults with chronic low back pain completed a physical activity intervention wherein they were randomized to receive a Fitbit activity monitor alone or in conjunction with health coaching, or were assigned to a wait-list control condition for three months. Regardless of group assignment, all participants were encouraged to move more and sit less. Active and sedentary behaviors were assessed pre and post-intervention using ActiGraph and activPAL monitors, respectively, and pain symptoms were examined using the total score from the short form of the McGill Pain Questionnaire (MPQ). A regression analysis was conducted with group, baseline pain symptoms, changes in sedentary time and changes in moderate and vigorous physical activity (MVPA) as predictors and change in pain symptoms as the dependent variable. Results demonstrated that the full model was significant ($R^2=0.50$, $p=0.01$). Change in sedentary time was a significant predictor of changes in pain ($\beta=0.30$, $p=0.03$), while change in MVPA was not ($\beta=0.02$, $p=0.87$). Group and baseline pain symptoms were also non-significant predictors in the model (group: $\beta=0.26$, $p=0.07$; baseline pain: $\beta=-0.24$, $p=0.08$). Results suggest that reducing sedentary behavior may be a feasible and meaningful target for improving pain symptoms in adults with chronic low back pain. Future research that explicitly targets this behavior and explores psychobiological mechanisms connecting sedentary behavior and pain could help optimize behavioral interventions to improve chronic low back pain.

OUTCOMES OF INTERDISCIPLINARY PAIN MANAGEMENT FOR CHRONIC OPIOID USERS IN SAFETY NET PRIMARY CARE

Samantha N. Mladen, M.S.¹, Mark Ryan, MD², Kristen O'Loughlin, MA¹, Emily K. Donovan, B.A.¹, Bruce Rybarczyk, PhD¹¹Virginia Commonwealth University, Richmond, VA; ²Virginia Commonwealth University School of Medicine, Richmond, VA

Background: The use of integrated interdisciplinary programs for the treatment of chronic non-malignant pain is rising along with recognition of the nature of chronic pain. However, despite primary care physicians being the first point of contact for patients with chronic pain, there are limited studies on chronic pain management in primary care settings operating with limited resources, or those working with medically underserved patient populations.

Method: Participants were patients ($n=27$) with long-term opioid-intensive management of chronic pain actively receiving care from an interdisciplinary pain management team within a safety net primary care clinic. Participants ranged in age from 33 to 76 ($M=54$, $SD=11$); were 56% African American/Black, 7% Latinx, and 37% White; and 67% female. Participants received interdisciplinary care from their primary care physician (PCP) and a behavioral health clinician. Outcome measurements were obtained approximately every two months from patients and assessed various aspects of pain-related functioning. Additionally, patients' Morphine Daily Equivalents (MDE), engagement with members of the interdisciplinary team, and exposure to specific behavioral interventions were assessed through chart review.

Results: Behavioral interventions received by patients and longitudinal assessment of their pain outcomes will be presented, including assessment of interactions and mechanisms. Data from over one year of follow-up will be presented, representing visits approximately every two months. At baseline, MDE ranged from 20 to 720 ($M=238$, $SD=187$) with high pain interference scores out of 10 ($M=7$, $SD=2$). On the Opioid Risk Tool, 22% were in the high-risk range, 19% moderate risk, and 59% low risk. Patient self-efficacy was also low (22% severe, 30% moderate, 33% mild, 11% minimal impairment) and pain catastrophizing was high (37% severe, 30% moderate, 33% mild). Preliminary data indicate a diversity of patient pain profiles, but general trends suggest patient interest in decreasing medication usage, improving perceived self-efficacy, and increasing engagement in non-medical management of pain.

Discussion: This project seeks to provide alternative pain management strategies for individuals using opioids for chronic pain management. Preliminary results offer hope for the effective management of chronic pain without sole reliance on opioid use. Continued complex measurement of patient experiences will allow for longitudinal assessment of trends, mechanisms, and interactions, in a sample with concerning baseline pain functioning scores. Additionally, "lessons learned" will be offered for providers considering implementing similar care in their own clinics.

EFFECT OF PAIN VARIABILITY ON DAY-TO-DAY CHANGES IN FIBROMYALGIA SYMPTOMS

Danielle M. Wesolowicz, MS¹, Michael E. Robinson, PhD¹, Roland Staud, MD¹¹University of Florida, Gainesville, FL

Introduction: Fluctuating pain levels have been noted in Fibromyalgia (FM); however, few studies have examined the effects of pain variability on symptom course. Studies on FM symptoms have found variations in fatigue, mood, and perceptions of pain unpleasantness can change in the experience of pain over time. Further, past research indicates while some FM patients find fluctuating pain levels distressing, others display resiliency (e.g., effective coping, maintaining positive mood; together, this suggests the experience of fluctuating pain may change the experience of FM symptoms for some individuals. The goal of this study was to examine the effect of pain variability on associations between pain, mood, and fatigue in a sample of FM patients.

Methods: 69 individuals (97% female) diagnosed with FM were asked to call a secure automated phone line each morning for 180 days. Participants then provided ratings of their current experience of the following symptoms using a 0-100 scale (100 most intense) as follows: pain intensity, pain unpleasantness, fatigue, depressed mood and anxious mood.

Results: Multilevel modeling was used to examine the effect of pain unpleasantness, fatigue, and mood on pain intensity. Participants' total amount of pain variability was quantified as their intraindividual standard deviation (ISD) of pain intensity across 180 days (greater ISDs represent greater pain variability). Participants displayed significant within- and between-subject variability in pain intensity. Across all 180 days, higher pain unpleasantness ($b=.823$, $p<.001$) and fatigue ($b=.178$, $p=.001$) predicted higher pain intensity. Greater within-person fluctuations in pain unpleasantness ($b=.001$, $p<.001$), fatigue ($b=.003$, $p=.006$), depression ($b=.005$, $p<.005$), and anxiety ($b=.004$, $p<.001$) all predicted higher pain intensity. While total amount of pain variability (ISD) was not a significant predictor of pain, pain variability moderated the effects of fluctuating pain unpleasantness ($b=.010$, $p=.016$) and fatigue ($b=-.005$, $p=.030$) on pain intensity. There were no significant effects for average depression or average anxiety, nor no significant interactions between pain variability and fluctuating depression or anxiety on pain intensity.

Discussion: Findings suggest affective dimensions of pain and fatigue play an important role in predicting the course of pain over time, and fluctuations in pain unpleasantness, fatigue, and mood predict pain course. Further, for individuals showing greater pain variability over time, fluctuating pain unpleasantness has a stronger effect in predicting pain intensity, while fluctuating fatigue has a weaker effect in predicting pain intensity. Findings suggest that for FM patients with more variable patterns of pain, affective dimensions of pain may be a better predictor of pain intensity than other FM symptoms like fatigue.

EXAMINING THE UTILITY OF THE PEDIATRIC PAIN SCREENING TOOL TO RAPIDLY IDENTIFY RISK AMONG YOUTH WITH ACUTE MUSCULOSKELETAL PAIN

Hayley Turner, BA¹, Christina Rusu, n/a¹, Anna Wilson, PhD¹, Amy Holley, PhD¹¹Oregon Health and Science University, Portland, OR

Objective: The Pediatric Pain Screening Tool (PPST) is a 9-item screening measure used to identify risk for poor outcomes in youth with chronic pain. The current study examines the utility of the PPST in assessing pain and psychosocial risk in youth seeking treatment for acute musculoskeletal (MSK) pain. We hypothesized youth identified as high risk would have higher pain intensity, pain-related fear, pain catastrophizing, pain-related disability, and sleep disturbances than those in lower risk groups.

Methods: Participants were 110 youth (ages 10-18, $M=13.98$ years, 51.8% female, 53.2% Caucasian) with acute MSK pain participating in a longitudinal study examining risk for development of chronic pain. Youth were recruited from emergency departments ($n=58$) or outpatient clinics ($n=52$). Participants completed the PPST and measures assessing pain, pain-related fear, pain catastrophizing, disability, and sleep disturbances. Using pre-established cut-offs, PPST scores categorized youth into low, medium, and high risk groups. Associations among risk group, demographic and clinical factors were examined. ANOVA and chi-square were used to examine associations between PPST risk groups and self-report measures.

Results: Youth reported moderate pain intensity ($M=4.20$, $SD=2.19$; 0–10 NRS) with 49.6% experiencing pain >4 days per week. Acute pain locations were arm (16.4%), leg (64.5%), and back/neck (19.1%) pain. PPST scores classified 25.5% of youth as high risk, 21.8% medium risk, and 52.7% low risk. PPST risk groups did not significantly differ by child age, sex, race, pain location, fracture status, or BMI. One-way ANOVAs revealed differences in pain intensity, disability, pain-related fear, and pain catastrophizing (p values $<.01$) by PPST risk group. Post hoc analyses revealed the high risk group had significantly greater pain intensity, pain-related disability, pain-related fear, and pain catastrophizing than both the low and medium risk groups (p values $<.05$). Chi-square revealed differences in pain frequency by PPST risk group ($p=.02$). Risk group was not associated with sleep disturbances.

Conclusions: Results suggest the PPST can rapidly screen youth with acute MSK pain to assess level of psychosocial and pain risk. PPST risk may be used to inform treatment recommendations. Future research with longitudinal data will examine if youth identified as higher risk have poorer outcomes, including increased likelihood of transitioning to chronic pain.

RESILIENCE MECHANISMS: A POTENTIAL PROTECTIVE FACTOR FOR ACUTE PAIN EXPERIENCE AND PAIN CATASTROPHIZING

Madisen Frederick, BA¹, Caitlin A. Kienzler, BS²¹University of Colorado Denver, Castle Rock, CO; ²University of Colorado Denver, Denver, CO

Introduction: Recent research has suggested that resilience may serve as a protective factor against chronic pain by decreasing chronic pain experiences and other pain-related factors. However, research has not explored the relationship between resilience and two major pain-related factors: pain catastrophizing and acute pain experiences. Moreover, the overall framework of resilience, its definition, and how it's measured present discrepancies within the literature. Utilizing the Brief Resilience Scale (BRS), we hope to validate the conceptualization of resilience as mechanistic in the context of pain, supporting the Outcome/Process-Oriented framework currently presented in the literature. The current study hypothesizes: (a) individuals with greater resilience mechanisms will report lower scores in pain catastrophizing compared with individuals low in resilience mechanisms (b) individuals with greater resilience mechanisms will report lower subjective pain ratings during an acute pain experience compared with individuals low in resilience mechanisms (c) resilience mechanisms will act as a mediator between the relationship of acute pain ratings, pain catastrophizing, and objective measures.

Method: As part of a larger study, the current study will conduct an acute pain cold-water task, utilizing the BRS and the Pain Catastrophizing Scale (PCS) as measurements to determine its influence on both acute pain experience and pain catastrophizing.

Data Analysis Plan: An ANOVA will determine significant differences between BRS and PCS scores and the demographic variables in the event we need to control for these variables. We then plan to conduct a single correlational matrix to determine significance among the relationships between: resilience mechanism, acute pain ratings, pain catastrophizing, and objective pain measures. If we find significance in these relationships, a Preacher & Hayes (2004) mediation analysis will be used to determine possible mediation effects of resilience mechanisms between these relationships.

Discussion: This study serves importance in the context of pain, for the Outcome/Process-Oriented framework of resilience suggests resilience mechanisms to be modifiable. Attempting to better understand these mechanisms and their effects are salient to further improve current forms of strength-based interventions via adequately incorporating resilience mechanisms as a potential protective factor for pain management and overall health outcomes.

IMPLICIT PAIN-RELATED FEAR: SOMETHING OR NOTHING? THE RELATION BETWEEN IMPLICIT RESPONDING, MOVEMENT AND DISABILITY.

Eric S. Kruger, PhD, DPT, MS¹, Kevin E. Vowles, PhD²¹The University of New Mexico, Albuquerque, NM; ²Queen's University Belfast, Belfast, Northern Ireland, UK

Chronic low back pain (CLBP) is a common condition that can lead to emotional distress and physical disability. Fear of pain, a phobic-like response to pain, can contribute to significant avoidance behavior and is associated with disrupted physical and emotional functioning. While questionnaires remain the standard for measurement of pain-related fear, recent work has explored the use of implicit assessment methods. This work suggests that those with CLBP are more likely to implicitly interpret, that is, rapidly and reflexively, back movements and postures as threatening. Despite these recent positive findings, many questions remain about the clinical utility of implicit biases of pain-related fear. Two questions we investigated were if implicit pain-related fear correlated with already established explicit instruments (e.g., Tampa Scale of Kinesiophobia) and if implicit pain-related fear predicted self-reported functioning and physical movement. We used the Implicit Relational Assessment Procedure (IRAP), to assess convergent, predictive and unique predictive validity of implicit pain-related fear. Seventy-four participants with CLBP were recruited and completed the pain-related fear IRAP, along with self-report measures of pain-related fear, distress, and disability, as well as three physical tasks involving the low back (repeated forward bending, loaded forward reach and timed up and go). Both explicit and implicit biases were demonstrated, suggesting the presence of pain-related fear, however, implicit pain-related fear failed to demonstrate convergent validity with previously established instruments, predictive validity of physical functioning, and performance during physical tasks. On the contrary, explicit pain-related fear predicted physical functioning and physical performance. Therefore, implicit pain-related fear, while present in patients with CLBP, may not provide additional utility above and beyond explicit measures of pain-related fear. Further, given the time and technology needed to conduct an implicit assessment and the lack of internal consistency and relatively poor predictive performance of implicit methods, it is recommended that clinical assessment of pain-related fear be based on questionnaire-based instruments.

ADVERSE CHILDHOOD EXPERIENCES AND EXPERIMENTAL PAIN SENSITIVITY AMONG COMBAT VETERANS.

Jeffrey Hernandez, B.S.¹, Niloofar Afari, PhD², Andrew Listvinsky, n/a¹, Herbert Matthew, PhD³¹Veterans Medical research foundation, San Diego, CA; ²VA Center of Excellence for Stress and Mental Health and Department of Psychiatry UC San Diego, San Diego, CA; ³VA San Diego Healthcare System, San Diego, CA

Childhood adversity has been identified as a risk factor for several chronic pain conditions. It is possible dysregulated pain processing plays a role in this relationship; however, we are unaware of any study that has examined this among combat veterans, whom are at a higher risk for chronic pain than civilian samples. The purpose of the present study was to examine the preliminary association between self-report of childhood adversity and indicators of pain processing as measured by quantitative sensory testing (QST) among combat Veterans of Iraq and Afghanistan (N = 19). Childhood adversity was measured by the Adverse Childhood Experiences (ACE) scale, a widely-used questionnaire that assesses household dysfunction, physical, emotional and sexual childhood abuse, as well as physical and emotional neglect. QST assessment included static measures of pain processing including thermal pain threshold and tolerance, pressure pain threshold, and dynamic measures including temporal summation and conditioned pain modulation (CPM). The association between total ACE scores and QST measures was examined using Pearson's *r*. Participants were primarily male (*n* = 15, 79%) with a mean age of 33.2 (SD = 6.7) and average pain rating of 4/10 (SD = 2.8) over the previous month. ACE scores were unrelated to thermal pain threshold and tolerances and pressure pain thresholds. However, higher ACE scores were associated with higher thermal pain intensity ratings at threshold (*r* = .47, *p* = .04). Additionally, higher ACE scores were associated with lower CPM (*r* = -.49, *p* = 0.03). These preliminary findings suggest childhood adversity may be associated with deficient pain inhibition among combat veterans. Future research utilizing a larger sample is needed to verify study results and better examine the association between childhood adversity and experimental pain sensitivity.

SEX DIFFERENCES IN TREATMENT RESPONSE TO PSYCHOSOCIAL INTERVENTIONS FOR CHRONIC PAIN

Matthew Herbert, PhD¹, Jillian Clark, PhD¹, Niloofar Afari, PhD², Julie Wetherell, PhD³¹VA San Diego Healthcare System, San Diego, CA; ²VA Center of Excellence for Stress and Mental Health and Department of Psychiatry UC San Diego, San Diego, CA; ³UCSD, San Diego, CA

Although sex differences in clinical and experimental pain have been widely studied, few investigations have examined sex differences in response to psychosocial interventions for chronic pain. The purpose of the present study was to 1) examine sex differences in treatment response at posttreatment and 6-month follow-up following an 8-week acceptance and commitment therapy (ACT) or cognitive behavioral therapy (CBT) intervention, and 2) explore sex by modality interactions in treatment response. Participants were 114 adults with chronic pain randomized to receive ACT (men: *n* = 27; women: *n* = 30) or CBT (men: *n* = 29; women: *n* = 28). The primary outcome was pain interference as measured by the Brief Pain Inventory (BPI). Binary logistic regression was used to determine sex differences in treatment response assessed in two different ways: minimal clinically significant change (1-unit decrease on BPI) and moderate clinically significant change (30% or greater improvement on BPI). There were no sex differences in pain interference at baseline. A total of 41 (36%) and 43 (38%) participants achieved minimal clinically significant change, and a total of 30 (26%) and 31 (27%) achieved moderate clinically significant change at posttreatment and 6-month follow-up, respectively. There were no sex differences in minimal clinically significant change at either assessment time point. However, women were more likely to achieve 30% or greater reduction in pain interference at posttreatment (OR = 3.35, *P* = .04) and 6-month follow-up (OR = 2.02, *P* = .01). In exploratory analyses, the sex by modality interaction approached significance for moderate clinically significant change at posttreatment (OR = .17, *P* = .06). Inspection of simple slopes revealed that women receiving CBT were significantly more likely to be treatment responders than men (OR = 8.85, *P* = .02); no sex differences were found in the ACT group. Taken together, our results suggest women may experience greater reductions in pain interference following psychosocial interventions for chronic pain compared to men; however, this depended on the criteria used. Furthermore, women may respond particularly well to CBT immediately after treatment compared to men.

INTERPRETATION BIAS FOR AMBIGUOUS SITUATIONS: ITS PSYCHOMETRIC PROPERTIES AND ASSOCIATION WITH EYE MOVEMENTS

Frederick Chan, BSocSc¹, Keisuke Takano, PhD², Hin Suen, BSocSc¹, Tom Barry, PhD¹¹The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²Ludwig-Maximilians-University Munich, Munich, Bayern, Germany

Theories propose that negative interpretation bias may account for the maintenance of health anxiety and chronic pain. This tendency to appraise ambiguous situations negatively has also been suggested to be associated with selective attention towards or away from potential threats. Previous studies used reaction time paradigms with ambiguous word and face stimuli to measure interpretation bias. However, these tasks lack contextual information which may explain the mixed findings in the literature. Unlike previous measures, the Interpretation Bias Task (IBT) asks responders to rate the probability of benign and negative resolutions for real-world situations where it is unclear what will happen. Yet this novel task has not been validated, nor has its association with attentional processing been examined.

In study 1, we conducted exploratory (EFA) and confirmatory factor analyses (CFA) for the IBT in a sample of young adults ($n = 237$). Several items were removed due to unsatisfactory factor loadings and inappropriate wordings. The model with remaining items showed satisfactory fit. Moreover, self-reported health anxiety symptoms were correlated with interpretation bias for bodily threat and illness-related situations, but not that for social or achievement-related situations, indicating the domain specificity of IBT. The results in study 1 were then confirmed in a CFA in study 2 with a larger sample with similar backgrounds ($n = 1103$). In study 3, undergraduate students with and without chronic pain ($n = 63$) completed the IBT and an eye-tracking task in which they free-viewed faces that were labelled as doctors, patients, or healthy people. IBT scores were calculated based on study 1 and 2. A data-driven machine-learning approach (EMHMM) was adopted to analyse eye movements. Results showed that the chronic pain group interpreted ambiguous situations as more indicative of bodily threat and illness. More interestingly, those with more negative interpretations for illness-related situations tended to avoid looking at the eye region of doctors' and patients' faces, suggesting a relation between negative interpretation bias and avoidance of health-related threats.

The IBT is a reliable and valid measure of interpretation bias. This study suggests interpretation bias may be one mechanism explaining the course and severity of health anxiety and chronic pain, indicating a potential novel intervention target.

6:15 PM-7:30 PM

INTERPRETATION AND ATTENTIONAL PROCESSING FOR AMBIGUOUS INFORMATION IN CHRONIC PAIN: A DATA-DRIVEN MACHINE-LEARNING STUDY

Frederick Chan, BSocSc¹, Hin Suen, BSocSc¹, Tom Barry, PhD¹¹The University of Hong Kong, Hong Kong, N/A, Hong Kong

Theories propose that the tendency to interpret ambiguous sensations as indicative of pain, and to selectively attend towards or away from pain-related cues, might underlie the chronicity of pain. However, eye-tracking studies in this context have yielded mixed results. One reason for this is that these studies use arbitrary criteria to quantify eye movements within predefined time windows and regions of interest, which neither capture the dynamic nature of attention nor takes individual differences into account. A data-driven machine-learning method (EMHMM) to analysing eye movements in the presence of pain-related stimuli could therefore offer new insights.

Sixty-three young adults and 63 old adults, half of whom had chronic pain and half did not, completed an interpretation bias task which measured the extent to which they appraised ambiguous sensations as indicative of pain, and an eye-tracking task in which they free-viewed neutral and injury scene images. Subjects' personalised viewing patterns were visualised by EMHMM and were then clustered into an explorative group and a focused group.

Results showed that old adults interpreted ambiguous sensations as more indicative of pain and were also more explorative when looking at neutral images compared to young adults. Also, the association between interpretation bias and being explorative for neutral images was only significant in old adults. One explanation is that when looking at neutral scenes where injury is not present (ambiguous situations), people with greater interpretation bias might perceive them as more negative and thus use a more explorative strategy to detect potential threat in the environment. Further, people with chronic pain had greater interpretation bias than the pain-free group, but there was no difference in eye movements between the two groups.

Numerous studies have investigated cognitive biases in chronic pain, but this study is the first to adopt a data-driven machine-learning method for eye movement analyses and to include a sample of elderly. Our findings show that interpretation bias is greater in older adults and in those with chronic pain, and it might influence how people attend to ambiguous visual information. This study partially supports the models that suggest biased interpretation and attention interact with each other and together account for the maintenance of chronic pain. These two forms of cognitive biases may be novel intervention targets for chronic pain patients.

DIFFERENTIAL IMPACTS OF DEPRESSION AND ANXIETY ON ACUTE PAIN AMONG INDIVIDUALS WITH COMORBID PAIN AND OPIOID USE DISORDER

Amy Wachholtz, PhD, MDiv, MS¹¹University of Colorado Denver, Denver, CO

Comorbid pain and opioid use disorder is a significant problem that requires better treatment. Further, this comorbidity often co-occurs with additional mental health comorbidities such as depression or anxiety which may alter how individuals respond to both pain and MAT treatment. The goal of the present study was to examine the impact of depression and anxiety on co-morbid opioid addiction and chronic pain with regards to acute pain tolerance, sensitivity, and perception.

Method: 120 participants with chronic pain and Opioid Use Disorder (OUD) were included (62% male); 60 on an opioid agonist (Medication Assisted Therapy: MAT) for OUD; 60 were not currently on an opioid agonist. Participants completed an acute pain task (cold pressor) in conjunction with a mood assessment (HADS) to assess multiple aspects of pain (tolerance, sensitivity, perception) and mood. Participants placed their non-dominant hand in 2°C water and reported first pain experience (Sensitivity, in seconds), to remove the hand when it was “too painful to bear” (Tolerance, in seconds), and rate the level of pain they experienced (Severity, 0-100 scale).

Results: Within the OUD population on active MAT, patients were more likely to experience elevated anxiety ($F(1,117)=7.33, p<.01$) and depression ($F(1,117)=6.45, p<.01$) compared to the non-MAT group. Depressed individuals on MAT, were more likely to report the stimuli as more severely painful ($F(1,58)=3.76, p<.05$) while Anxious MAT individuals reported greater sensitivity to pain ($F(1,58)=3.95, p<.05$). Both anxious and depressed MAT patients showed less tolerance for pain ($p<.05$'s), compared to non-depresses/anxious individuals in the MAT group, and the non-MAT group.

Discussion: Depressed mood and anxiety differentially affects the pain experience for patients with chronic pain and OUD. Empirical treatment approaches to differentially treat pain sensitivity vs severity vs tolerance will be discussed. Assessment and understanding of these differences are likely to open pathways to more targeted psychotherapy treatment options for individual patients which will allow us to move beyond sole reliance on opioids for pain treatment.

EXAMINING HEART RATE ERROR ACROSS DIFFERENT EXERCISE TYPES AND INTENSITIES IN FREE-LIVING CONDITIONS

Megan Heintzelman, BS¹, Matthew Saponaro, MS², Greg Dominick, PhD²¹University of Delaware, Belcamp, MD; ²University of Delaware, Newark, DE

Background: Wrist-worn Fitbit devices consistently underestimate heart rate (HR) compared to criterion measures (e.g. Polar HR monitor). However, this systematic bias appears to be compounded by additional sources of HR error derived from variations in activity type and intensity, particularly within free-living conditions. This study examined the variability and magnitude of Fitbit HR errors based on activity type, activity intensity, and when activity type and intensity are combined.

Methods: Participants (N=18) were healthy adults who concurrently wore a Fitbit Charge HR (wrist) and Polar H7 (chest) for 7 continuous days while recording any purposeful exercise bouts lasting ≥ 20 minutes. Reported exercise types included walking, running, and using an elliptical. Percent heart rate reserve (%HRR) was used to classify relative intensity as light, moderate, and vigorous (%HRR= 30-39, 40-59, ≥ 60 , respectively). Minute-level HR data were used to calculate mean HR differences, mean absolute percent error (MAPE), and effect sizes (Cohen's d) for type, intensity, and type-and-intensity.

Results: When all exercise bouts were combined, overall mean HR difference between Polar and Fitbit was 5.16 bpm, agreement between devices was high ($r=0.910$) and error was low (MAPE=4.1%). Results were similar when each type and intensity level were examined. However, combining type-and-intensity produced the greatest mean HR differences for vigorous walking (HRdiff=12.01 bpm, MAPE=0.88, $r = 0.562$) and light running (HRdiff=6.84 bpm, MAPE=0.075, $r=0.198$).

Conclusion: HR differences and associated error was greater when activity type and intensity were combined. These results suggest that individual differences in fitness may contribute to the HR errors observed. Future research should examine Fitbit HR error based on %HRR rather than mean HR as those with higher fitness would elicit a lower HR response compared to those with lower fitness.

GENDER DIFFERENCES IN A RANDOMIZED CONTROL TRIAL TO INCREASE PHYSICAL ACTIVITY AMONG MEXICAN-AMERICAN MIDDLE SCHOOL STUDENTS

Katherine Arlinghaus, MS, RD, LD¹, Matthew Kilburn, n/a¹, Angelica Cortave, n/a¹, Elizabeth Gamez, n/a², Laura Gonzalez, n/a², Craig A. Johnston, PhD¹¹University of Houston, Houston, TX; ²Rice University, Houston, TX

Background: Moderate-vigorous physical activity (MVPA) declines during adolescence, with greater declines among females than males. Physical education class (PE) is an opportunity to increase MVPA, but it is unclear if this occurs in traditional PE classes in which various sports and games are taught and played. The purpose of this randomized control trial was to examine MVPA over time in a circuit-based physical activity program compared to PE class as usual among all students and by gender.

Methods: Mexican American middle school students (N=196) were recruited from a charter school district in Houston, Texas, and randomized to receive either circuit-based PE or PE as usual (i.e. learning and playing different sports games) for a school year. Students in the circuit-based PE class were taught to regulate their exertion/intensity by monitoring their heart rate during physical activity. MVPA was assessed using accelerometry (Actigraph AG, model GT1M) at baseline and at the end of the academic year. Evenson cut points were used to categorize physical activity as MVPA. A repeated measures ANOVA was conducted to examine changes in MVPA over the academic year, overall and stratified by gender.

Results: Participants were 12.06 ± 0.61 years old and 53% were female. Overall those in circuit-based PE increased their MVPA significantly more than those in PE as usual ($F=5.78$, $p=0.02$). Males in both conditions increased MPVA and there was no significant difference between conditions ($F=1.40$, $p=0.24$). There was a significant difference between conditions among females ($F=5.06$, $p=0.03$). Females in the circuit-based condition increased MVPA, whereas MPVA decreased among those in the PE as usual condition.

Conclusions: Circuit-based PE may be an important strategy to increase MVPA, particularly among females. This study illustrates the importance of the type of PE programming needed to facilitate MVPA and has policy implications for PE curriculum requirements. Further research is needed to understand gender differences in MVPA to better tailor physical activity opportunities.

EFFECTS OF EXERCISE DOSE AND INTENSITY ON BODY MASS, FITNESS, AND SOCIAL FUNCTIONING AMONG OLDER ADULTS

Charleen J. Gust, BA¹, Laurel P. Gibson, BA¹, Angela Bryan, PhD², Gregory Giordano, MS¹¹University of Colorado Boulder, Boulder, CO; ²University of Colorado Boulder, BOULDER, CO

As a result of scientific and medical advances, there has been a dramatic social transformation in longevity, with an increasing number of individuals living longer than ever before. This rise in life expectancy necessitates research on lifestyle choices and health-promoting behaviors that reduce the risk of age-related disease and improve quality of life and functioning. Regular exercise, which can reduce or even reverse several of the physical, emotional, and social issues characteristic of aging, is one such health behavior and was targeted in the current intervention. Specific aims of this trial include: (1) to explore baseline associations between exercise participation and demographic (e.g., gender), health (e.g., body mass index), fitness (e.g., VO_2 max), and social (e.g., social support) outcomes; and (2) to determine whether changes in several of these outcomes depend on exercise dosage. Sedentary adults aged 60 and over were randomly assigned to either low-intensity continuous training (LICT) or moderate-intensity continuous training + interval training (MICT+IT) as part of a 16-week, supervised exercise paradigm. Tests of baseline associations showed significant negative correlations between age and baseline loneliness ($r = -.188$, $p = .02$) and perceived isolation ($r = -.174$, $p = .03$) and a significant correlation between gender and baseline social disconnectedness ($r = .160$, $p = .04$), with men reporting more social disconnection than women. Preliminary regression analyses were utilized to evaluate changes in outcomes of interest from baseline to follow-up. There was a linear effect of time on body mass index (BMI) [$F(1, 153) = 12.117$, $p = .001$]; on average, BMI decreased by 0.138 kg/m^2 during the intervention, and this decrease did not significantly differ by condition [$F(1, 153) = 2.244$, $p = .136$]. There was also a linear effect of time on VO_2 peak [$F(1, 153) = 4.376$, $p = .038$], with an average increase of 0.012 L/min from baseline to follow-up. This effect was qualified by a significant linear timeXcondition interaction [$F(1, 153) = 18.679$, $p < 0.001$]; relative to participants assigned to the LICT condition, those assigned to the MICT+IT condition showed greater improvements in VO_2 peak. Additional analyses will test a preliminary mediational model to examine associations between changes in BMI, fitness, and social function. Implications for future intervention development will be discussed.

DESIGNING A MULTIPLE TECHNOLOGY-BASED PHYSICAL ACTIVITY INTERVENTION FOR LATINA ADOLESCENTS: FORMATIVE RESEARCH FINDINGS

Britta Larsen, PhD¹, Emily D. Greenstadt, MA, MPH², Job G. Godino, PhD³, Bess H. Marcus, Ph.D.⁴, Michelle Zive, PhD, MS, RD⁵

¹University of California, San Diego, San Diego, CA; ²UCSD Health, La Jolla, CA; ³University of California San Diego, San Diego, CA; ⁴Brown University, Sharon, MA; ⁵UC San Diego-Center for Community Health, La Jolla, CA

Background: Only 3% of adolescent girls meet national physical activity guidelines, with Latina adolescents reporting especially low activity. To address this disparity, we are developing an individually-tailored, theory-based intervention to increase moderate-to-vigorous physical activity (MVPA) in Latina adolescents, using multiple channels, including social media platforms (Instagram) and SMS messages. Given the scarcity of interventions for Latina teens and the rapid evolution of technology use in adolescents, we conducted focus groups to inform the most effective and acceptable use of technology channels for this intervention.

Methods: Nine focus groups, each ranging from two to eight Latina teens (n=50), were held to better understand preferences for content, volume, and timing of Instagram posts and SMS messages that promote physical activity and behavioral processes of change. Participants viewed a slideshow of 16 sample Instagram posts and 12 sample text messages. They were asked how often they would like to receive information via each channel, if they found the content appealing, helpful, and/or motivating, and, if not, to offer suggestions to improve the content. Participants recorded their feedback on a provided notepad.

Results: Overall, participants expressed a preference for generalized content on Instagram, and for personalized text messages based on their goals and activity. Written feedback on the sample Instagram posts elicited emergent themes including preferences for brightly colored images, limited and succinct text, concrete tips and applicable information, incorporation of cultural themes and Spanish phrases, images of relatable and ethnically diverse models engaging in physical activity, images promoting social support, and videos demonstrating specific exercises. Regarding SMS messages, participants preferred personalized messages and reminders based on their goals and unique wearable tracker data at a rate of no more than one message per day. They favored casually worded, positively framed messages, and were averse to language they perceived as “negative”, “annoying”, or “nagging.”

Conclusion: Latina teens were generally receptive and enthusiastic towards Instagram and SMS messages as physical activity intervention channels, and expressed consistent preferences for how to utilize each channel. Appropriate use of these technology channels has potential for high reach, low cost interventions in this high-risk population.

EFFECTIVENESS OF ADAPTING AND IMPLEMENTING THE COMMUNITY GUIDE APPROACHES TO PROMOTE PHYSICAL ACTIVITY IN A MICROPOLITAN CITY

Barbara I. Baquero, PhD, MPH¹, Daniel Sewell, PhD, MS², Nicole Novak, MPD, MSc², Rebecca S. Bucklin, MPH², Adriana Maldonado, MA², Natoshia Askelson, PhD, MPH³, Jason Daniel-Ulloa, PhD, MPH⁴, Rima Afifi, PhD, MPH², Heidi Haines, MS², Garrett Ross, AA⁵, Brian Dunn, MBA⁶, Edith A. Parker, DrPH, MPH²

¹University of Washington, Seattle, WA; ²University of Iowa, Iowa City, IA; ³University of Iowa, CPHB N412, IA; ⁴University of Washington Bothell, Bothell, WA; ⁵Ottumwa Family YMCA, Ottumwa, IA; ⁶Sieda Community Action, Ottumwa, IA

Strong evidence supports the promotion of physical activity (PA) in community settings, yet few studies have tested how effective this evidence is to promote PA among residents of micropolitan rural (mid-size classification) communities.

We engaged in a Community-Based Participatory Research (CBPR) intervention to promote PA among residents of a micropolitan community in the Midwestern US. In partnership with community stakeholders, we adapted informational, environmental, behavioral and social support recommendations from the Community Guide to the context, need, and resources of the community. Lay Health Advisors were recruited and trained to implement the two-year intervention. We report the 2-year findings.

We used a hybrid type I study to evaluate the community-wide intervention impact. We had a random recruited cohort of residents who completed an interview assessing demographics and wore an accelerometer for the following 7 days at baseline, 12-, and 24-months. In addition, we randomly selected respondents for two (2013 and 2018) cross-sectional community-wide surveys to measure PA with the Global Physical Activity Questionnaire (GPAQ). Using the cohort data, we estimated the intervention's impact on the temporal change in PA by first computing the centered log ratio compositional slope for MVPA and sedentary behavior and then performing MANCOVA regression. Using the cross-sectional community surveys, we estimated the population level PA change using calibrated GPAQ in a stratified analysis using census data.

The cohort consisted of 120 participants with a mean (sd) age of 47 (14), 67% of which were female, 60% had some college education or more, and on average participants had MVPA of 76 min/day. There was a significant global change in PA ($p = 0.029$). Overall, there was a decrease in sedentary behavior and an increase in light activity. On average, we observed a reduction of 45 minutes of sedentary behavior and increase of 35 minutes of light activity per day among cohort participants. At the community-level we found a significant increase of MVPA overtime ($p = 0.011$). The trend of MVPA of the population increased between 2013 and 2018.

Using CBPR principles allowed for effective contextualization of the intervention to community resources and needs. Adapting and implementing evidence-based approaches for promoting PA in a micropolitan context was effective at increasing PA and decreasing sedentary behavior among residents.

EFFECTS OF EXERCISE INTERVENTION DELIVERY METHODS ON MODERATE TO VIGOROUS PHYSICAL ACTIVITY AMONG PROSTATE CANCER SURVIVORS

Heather J. Leach, PhD¹, Nicole Culos-Reed, PhD², George A. Tomlinson, PhD³, Sara Durbano, BSc⁴, Amna Iqbal, BSc⁴, Jessica M. Danyluk, MKin, CSEP-CEP⁵, Shabbir Alibhai, MSc, MD⁴

¹Colorado State University, Fort Collins, CO; ²University of Calgary, Calgary, AB, Canada; ³The BRU and University Health Network, Toronto, ON, Canada; ⁴University Health Network, Toronto, ON, Canada; ⁵Health and Wellness Lab, Faculty of Kinesiology, University of Calgary, Calgary, AB, Canada

Purpose: Prostate cancer (PC) is commonly treated with androgen deprivation therapy (ADT), which leads to fatigue, loss of muscle mass, and reduced quality of life (QOL). Physical activity (PA) is an effective intervention to counter these side effects, contingent upon increasing and sustaining PA. Supervised exercise programs demonstrate consistent benefits and increased PA; however, few studies have directly compared other delivery methods. This study examined changes in moderate to vigorous PA (MVPA) following a supervised 1:1, supervised group-based (SGB), or a home-based smartphone-(HBS) assisted exercise intervention in PC survivors on ADT.

Methods: Participants were men with PC on ADT, stratified by length of ADT use and site. All participants were instructed to complete 4–5 days/week of aerobic, resistance and flexibility exercise for 6-months. Those in the 1:1 supervised and SGB interventions received 3 face-to-face sessions per week with a qualified exercise professional. MVPA was assessed at baseline and 6-months (post-intervention), using an Actigraph GT3X accelerometer, and the Godin Leisure-Time Exercise Questionnaire (GLTEQ). Accelerometer data were extracted in 60-second epochs, and MVPA was defined as >1952 activity counts per minute. Accelerometer MVPA was expressed as weekly minutes, and number of continuous bouts ≥10 minutes per day. For the GLTEQ, weekly MVPA minutes were calculated as total strenuous x 2 + total moderate. Means ± standard deviations and frequencies (%) were calculated; change in MVPA was compared between groups using the Wilcoxon rank sum test.

Results: At baseline ($N=53$), participants were 70.1 ± 7.5 years old, mostly white (71.7%), on ADT for ≥3 months (67.9%), and diagnosed with clinical stage T1-2 (50.1%) or T3 (34.0%) PC. Accelerometer MVPA decreased by 9.8 ± 88.1 (1:1), 10.6 ± 42.7 (SGB) and 38.0 ± 195.4 (HBS) minutes per week ($p=0.63$). MVPA bouts increased by 0.2 ± 2.7 (1:1), 0.4 ± 1.8 (SGB), and 0.3 ± 7.6 (HBS) ($p=0.86$). Self-reported MVPA increased by 80.0 ± 116.5 (1:1), 62.8 ± 192.4 (SGB), and 5.8 ± 238.3 (HBS) minutes per week ($p=0.59$).

Conclusion: No differences in MVPA change were found between intervention groups, suggesting PC survivors may benefit from multiple exercise delivery modalities.

DO PHYSICAL ACTIVITY BEHAVIORS DIFFERENTIALLY INFLUENCE COGNITIVE FUNCTION IN YOUNGER VERSUS OLDER BREAST CANCER SURVIVORS?

Lindsey L. Hanson, MS¹, Joan Severson, MS², Arthur F. Kramer, PhD³, Edward McAuley, PhD⁴, Diane K. Ehlers, PhD¹

¹University of Nebraska Medical Center, Omaha, NE; ²Digital Artefacts, Iowa City, IA; ³Northeastern University, Boston, MA; ⁴University of Illinois, Urbana, IL

Evidence suggests younger breast cancer survivors (BCS) experience greater psychological burden compared to older BCS. It is unknown if these differences extend to cognitive function (CF) or how lifestyle behaviors (e.g., moderate-to-vigorous physical activity [MVPA]) influence CF in younger vs older BCS. This study: 1) examined differences in CF between BCS < 60 and 60+ years-old across a 6-month period; and 2) determined if MVPA differentially influenced CF by age group. BCS ($n=249$) completed questionnaires and cognitive tasks assessing CF and MVPA (Godin Leisure-Time Exercise Questionnaire). CF was operationalized as subjective memory impairment (SMI; Frequency of Forgetting Scale) and cognitive performance (Flanker, Mazes, Task-Switch, Trails B). A subsample ($n=204$) also wore an accelerometer. We used analysis of covariance to examine differences in CF by age (< 60 vs 60+) and test between-subjects effects of baseline MVPA and age*MVPA interaction on CF across time in the full and accelerometer samples. Models were adjusted for employment, menopause, diagnosis stage, chemotherapy, time since diagnosis, comorbidities, and depressive symptoms. BCS < 60 years-old reported more MVPA ($p=.002$) and greater memory impairment compared to BCS 60+ years-old ($p=.01$). Younger BCS performed faster on Mazes, Task-Switch, and Trails B (all $p < .05$). Neither self-reported nor objectively-estimated MVPA were associated with SMI (all $p > .21$). However, self-reported ($p=.02$) and objective-estimated MVPA ($p=.08$) were associated with faster Task-Switch performance. No age*MVPA interactions were observed in either sample. Among covariates, receipt of chemotherapy, depressive symptoms, number of comorbidities, time since diagnosis, menopausal status at diagnosis, and employment status differed by age group. Additionally, chemotherapy and depressive symptoms emerged as predictive of age differences in SMI. Although often equally operationalized as CF, our data suggest SMI and cognitive performance are distinct constructs with distinct etiologies. Greater SMI among younger BCS were reflective of chemotherapy receipt and depressive symptoms, while reduced cognitive performance in older BCS was related to reporting more comorbidities. Research to dissect the age- versus cancer-related components of observed effects is warranted. Further, evidence-based approaches (other than MVPA) to decreasing depression may be beneficial for improving SMI, particularly in younger BCS. Findings also suggest that engagement in MVPA may elicit selective objective cognitive benefits among BCS of any age.

EXERCISE BELIEFS AND PHYSICAL ACTIVITY: USING NETWORK ANALYSIS TO MAP ASSOCIATIONS AMONG BELIEFS

Sarah Volz, n/a¹, Alexander J. Rothman, Ph.D.¹, Austin S. Baldwin, PhD², Michael Chmielewski, Ph.D.²¹University of Minnesota, Minneapolis, MN; ²Southern Methodist University, Dallas, TX

Research on how beliefs about exercise relate to exercise engagement has focused on how endorsement of exercise beliefs differ across levels of exercise. Additional insight may be gleaned by examining whether there are also differences in the nature and strength of the relations between exercise beliefs. Network analysis provides a way to describe the conditionally independent relations between a set of variables for a given group of individuals. Thus, this approach can provide information on how the unique relations between psychologically relevant variables may vary as a function of behavior.

The present study examines differences in relations between beliefs about exercise for individuals who vary in their level of moderate-to-vigorous physical activity (MVPA). Leveraging data from a prior study (Chmielewski, Sala, Tang, & Baldwin, 2016), we conducted a network analysis to examine the interrelations between a set of exercise beliefs (e.g., self-efficacy, social norms, intrinsic motivations) across those with 0 min/week of MVPA (N = 216), 1-165 min/week of MVPA (N = 198), and 285+ min/week of MVPA (N = 194). Comparisons of overall network strength and structure using the Network Comparison Test (van Borkulo, Epskamp, & Millner, 2016) suggest that the networks were quite similar across groups. The global network strength for individuals with no MVPA was marginally stronger than for individuals with low MVPA ($S = 1.92$, $p = .056$), but individuals with high MVPA did not differ in strength from the other two groups, $ps > .3$. The three groups did not differ in their overall structure, indicating that similar beliefs were connected in all three networks, $ps > .16$. The present findings suggest that the associations between this set of evaluative beliefs about exercise are relatively consistent across levels of exercise, with potentially overall weaker connections for those with low MVPA relative to those with no MVPA. Moving forward, it will be important to replicate these findings with larger samples, as well as to compare groups with more narrowly defined patterns of exercise behavior.

PARENT- AND TEACHER-REPORTED BEHAVIOR AS PREDICTORS OF PRESCHOOL CHILDREN'S PHYSICAL ACTIVITY

Sarah Burkart, MPH, PhD¹, Christine W. St. Laurent, MPH, PhD², Lisa Keller, PhD², R. Glenn Weaver, PhD¹, Michael Beets, M.Ed, MPH, PhD¹, Sofiya Alhassan, PhD²¹University of South Carolina, Columbia, SC; ²University of Massachusetts Amherst, Amherst, MA

Background: Children's hyperactive and inattentive behavior can be indicative of ADHD development. In school-age children, national survey data indicated that children with ADHD engage in less moderate-to-vigorous physical activity (MVPA) than typically developing peers, but these trends conflict with other studies. Data in preschoolers is sparse within the literature and has shown that hyperactive and inattentive children had higher levels of MVPA. Previous studies have relied on parent report to describe children's hyperactive and inattentive behaviors, which is an inherent limitation as parents are not with their children during the preschool day. Therefore, the purpose of this study was to identify relationships between preschoolers' parent (PR) and teacher-reported (TR) behavior and PA.

Methods: Baseline data from children ($n=58$, $age=4.0\pm0.8$ years, 52% male) enrolled in two preschool centers were utilized for this cross-sectional analysis. Children's hyperactivity and inattention was assessed via PR and TR subscales using the Behavior Assessment System for Children, Third Edition. PA was assessed with Actigraph GT3X+ accelerometers for seven consecutive days. Linear regression models were conducted with PA intensities as outcome variables and children's behavior variables as predictors with a second set of models adjusted for age and sex.

Results: A one unit increase in hyperactivity t-score was associated with a 1.4 minute reduction in sedentary min/day (95% CI=-2.64, -0.23) and a 0.9 minute increase in MVPA (95%CI=0.38, 1.37) while a one unit increase in inattention was associated with 0.7 minute increase in MVPA (95%CI=0.06, 1.33). All associations remained significant following adjustment for age and sex. No associations were observed between PR behavior and total day PA. There was a weak positive association between PR and TR inattention ($r=0.39$, 95%CI=0.13, 0.60), but no relationship between PR and TR hyperactivity.

Discussion: In this sample, greater TR hyperactivity and inattention were associated with less sedentary time and greater MVPA during the preschool day. Interestingly, there were no associations between PR and total day PA. This suggests that parents and teachers observe and report children's behavior differently, which may be problematic for studies utilizing a single assessment. Future studies should utilize multiple measures to accurately depict these relationships in children.

FACILITATION OR DETERIORATION: THE EFFECT OF HIGH-INTENSITY EXERCISE ON EXECUTIVE FUNCTION

Liang Hu, Ph.D.¹¹Zhejiang University, Hangzhou, Zhejiang, China

Backgrounds: Research evidence has shown that acute exercise facilitates executive function (EF). However, some studies suggest that high-intensity exercise can deteriorate EF, potential due to more cognitive efforts required to maintain the high workload. The effect of acute high-intensity exercise on EFs remains inconclusive. In addition, most previous studies focus on just one component of EF without testing the general effect of acute exercise on the three components of EF.

Purpose: To provide evidence on the effect of high-intensity acute exercise on EF, in comparison with moderate-intensity.

Method: The study adopts a within-subject experimental design. 29 college students (14male, 15female) completed measures of EF for three times, i.e., prior to and following 20-min running at high- (90% Heart Rate Reserve, HRR) and moderate- (40-60% HRR) intensity, respectively. The cognitive tests measure three components of EF, namely the 2-Back (updating), Flanker (inhibition), and More-odd shifting (shifting), which were arranged in a counter-balanced randomized order. A series of gender (male v.s. female) x time (pre- v.s. post-exercise) x intensity (high- v.s. moderate-intensity) multivariate repeated-measure multivariate analysis of variance (MANOVA) were performed to examine whether intensity influence the relationship between exercise and EF.

Results: First, the manipulation check indicated that high-intensity exercise was associated with higher levels of mental effort ($t=-3.72$; $p=.000$), perceived fatigue ($t=-3.51$; $p=.000$) and task difficulty ($t=-3.52$; $p=.000$) as compared with moderate-intensity exercise. The MANOVAs demonstrated no significant interaction effect ($ps > .101$) for intensity x gender and main effects for gender ($ps > .079$), but the main effect of intensity was significant for all RTs on three EF measures ($ps < .028$). Specifically, a significant reduction in RT of 2-back test from baseline to high-intensity condition ($p < .05$) was observed, whereas no difference between baseline and moderate intensity ($p=.43$) was identified. However, for Flanker and More-odds switching test, exercising at both moderate and high-intensity reduced RT from baseline to post-exercise at both high- and moderate-intensity exercise, and there was no difference in RT between the two intensities.

Conclusion: In general, 20-min running at both high- and moderate-intensity induced an improvement in performance of EF. Effect of high-intensity acute exercise is at least comparable with moderate exercise, indicating facilitative rather than detrimental effect on EF. Further studies are needed to test the different combination of intensity and duration on EF and elucidate the mechanisms underlying such difference.

PILOT STUDY TESTING THE EFFICACY OF A NOVEL VIRTUAL REALITY SIMULATION TO EXPERIMENTALLY MANIPULATE ENVIRONMENTAL ELEMENTS

Katrina Oselinsky, BS¹, Dan Graham, PhD¹¹Colorado State University, Fort Collins, CO

Background: Data from observational studies indicates that the presence of certain environmental elements (e.g., lights and trees) are correlated with higher levels of physical activity. Due to the costly and at times, near impossible nature of manipulating environmental elements and randomly assigning people to experience different versions of an environment, few experimental studies have been done.

Purpose: To test the efficacy of a novel virtual reality (VR) program that enables researchers to experimentally manipulate environmental elements in a time and cost-effective manner.

Methods: A VR simulation was developed to mimic the downtown area of Fort Collins, Colorado. Participants were randomly assigned to experience one of two versions of the VR model: the control condition ($n=10$) and the greenery-enhanced version ($n=3$) where participants saw additional street trees, planters, and flowers in the downtown area. Participants were fitted with a VR headset (Samsung Odyssey) and HP backpack computer to enable them to move freely in a large gymnasium. Subjects were given a five-minute period to adjust to the VR experience after which they were allowed to stay in their assigned simulation for up to 30 minutes. Afterwards, the subjects were asked to complete a survey about their experience.

Results: Participants in the greenery-enhanced condition remained in the simulation for 18% longer on average than those in the control condition. 92% of participants reported little to no nausea, dizziness or eyestrain.

Conclusions: The study demonstrates that VR technology can be successfully utilized to experimentally manipulate environmental elements and to understand how these environmental changes impact physical activity-relevant outcomes including perceived safety, attractiveness, and walking behavior itself.

WORK HARD, PLAY HARD: THE RELATIONSHIP BETWEEN PHYSICAL ACTIVITY AND ALCOHOL USE IN COLLEGE STUDENTS

Charlotte A. Gilbert, n/a¹, Cinnamon Stetler, PhD¹¹Furman University, Greenville, SC

Physical activity has been associated with many positive outcomes. However, higher levels of physical activity seem to be associated with higher rates of alcohol use among college students. Few studies have studied the direction of this relationship, and important confounds, such as extraversion and sensation-seeking, remain unaddressed. In addition, studies have shown inconsistent findings concerning the influence of gender in this association. To address these questions, we collected 4 waves of data from each semester of junior and senior year. A total of 1,534 undergraduate students (65% female) from four different universities participated in this study. Participants reported how much mild, moderate, and high physical activity they engaged in in the past week. They also reported how frequently they consumed alcohol (from never to 4 or more times a week). Our results indicated that alcohol use positively predicted future physical activity ($r's = .10 - .11$) and physical activity positively predicted future alcohol use ($r's = .08 - .14$). In addition, these correlations were stronger in males ($r's = .05 - .28$) compared to females ($r's = .04 - .11$). We also examined extraversion and sensation-seeking as confounding variables in this relationship. However, when we controlled for these traits, the relationship between physical activity and alcohol use remained significant. These findings advance theoretical understanding of how these health behaviors are linked and suggest further studies to explore potential causal mechanisms. It is important to better understand this relationship in order to develop targeted interventions to promote healthy behaviors in college students.

DIFFERENCES IN COGNITIONS AND PHYSICAL ACTIVITY AMONG HIGHER AND LOWER RESILIENCE ADULTS WITH CHRONIC PAIN

Jocelyn E. Blouin, MSc¹, Miranda A. Cary, PhD², Nancy C. Gyurcsik, PhD¹, Danielle R. Brittain, PhD³, Kelly Corrine Hall, MPH, CHES⁴, Lauren S. Davis, n/a⁵

¹University of Saskatchewan, Saskatoon, SK, Canada; ²University of British Columbia Okanagan, Kelowna, BC, Canada; ³Colorado School of Public Health at the University of Northern Colorado, Greeley, CO; ⁴University of Saskatchewan, Couer D'Alene, ID; ⁵Welltok, Denver, CO

Nearly 20% of Canadian adults experience chronic pain persisting 6+ months. Participation in light and moderate-vigorous physical activity is a recommended pain self-management strategy, but participation is low. Resilience, which involves adapting well to adverse events like chronic pain, may help people sustain participation in valued behaviors including physical activity. Based on resilience models, adults with higher resilience may use more adaptive cognitive resilience mechanisms, including pain acceptance and self-regulatory efficacy to overcome pain-related barriers [SRE-pain] and less maladaptive cognitive vulnerabilities, including pain catastrophizing, to be active. To date, very little research has examined resilience in adults with chronic pain. Thus, the study purpose was to examine whether adults living with chronic pain who reported higher versus lower resilience differed in resilience mechanisms, vulnerabilities, and physical activity. Participants ($N = 195$; $M_{age} = 40.03 \pm 12.68$ years) completed online surveys that assessed pain acceptance, SRE-pain, pain catastrophizing, and demographics, including pain intensity, at Time 1. Light and moderate-vigorous physical activity were assessed 2 weeks later at Time 2. Higher ($n = 97$) and lower ($n = 98$) resilience groups were identified and compared using a multivariate analysis of covariance (MANCOVA). The overall MANCOVA, controlling for pain intensity, was significant; Pillai's Trace = .29, $p < .001$, $\eta^2_{partial} = .29$. Follow-up ANCOVAs revealed that higher resilience adults reported significantly higher pain acceptance and SRE-pain, lower pain catastrophizing, and greater moderate-vigorous physical activity compared to lower resilience adults (p 's $< .05$; small to large effect sizes: $\eta^2_{partial}$'s = .03 to .26). Findings provided novel prospective evidence that adults with chronic pain differed in resilience mechanisms, vulnerability, and the higher intensity behavior of moderate-vigorous physical activity. Future research should examine the stability of differences in resilience-related cognitions and whether they help adults to sustain physical activity. A better understanding would provide the foundation for future intervention research promoting resilience mechanisms and reducing vulnerabilities to target improved physical activity engagement among adults to better manage their chronic pain.

EVALUATION OF THE ACCEPTABILITY AND USABILITY OF A WEARABLE ACTIVITY TRACKER AMONG LOW-ACTIVE FEMALE ADOLESCENTS

Vicki R. Voskuil, PhD, RN, CPNP-PC¹, Sarah Stroup, BSN, RN², Madeline Leyden, n/a³

¹Hope College, Holland, MI; ²Spectrum Health, Grand Rapids, MI; ³Hope College, Plymouth, MI

Background: Most adolescents do not meet guidelines for physical activity (PA) and only 20% of girls meet the recommendations by the 9th grade. Although few interventions involving wearable activity trackers have been conducted, there is some evidence that these devices may motivate adolescent girls to become more physically active.

Purpose: The aim of this study was to evaluate the acceptability and usability of the Fitbit Flex 2 among inactive adolescent females.

Methods: This exploratory descriptive study included adolescent females in the 8th and 9th grades ($N = 33$) who were recruited from a high school in the Midwest. Girls were excluded if they were involved in sports ≥ 3 days a week, had a health condition that compromised their PA, or did not read and write English. Participants were given a Fitbit Flex 2 to use for one week and were given access to the Fitbit App by computer or phone. Daily steps, distance in miles, and active minutes were tracked by the research team. Focus groups were conducted to determine participants' perceptions of the tracker device and app. Girls also completed a survey regarding the acceptability and usability of the activity tracker (0-3 Likert scale). SPSS V23.0 was used to analyze quantitative data. Thematic analysis was used to examine qualitative data in ATLAS.ti 8.4.

Results: Mean age of the sample was 14.62 ($SD = .60$) years. Of the participants who reported race ($n = 24$), 58% were non-white. Participants completed a daily average of 7,758.87 ($SD = 1763.69$) steps, 3.66 ($SD = 1.98$) miles, and 21.69 ($SD = 13.71$) minutes of MVPA. Participants liked using the Fitbit (Mean = 2.94, $SD = .25$) and agreed that it was easy to use (Mean = 2.56, $SD = .50$). Of the girls who used the Fitbit App ($n = 28$), all but one liked using it. Girls reported that the Fitbit Flex 2 made them more aware of their PA goals, motivated them to do more steps, and kept them active. Some girls reported issues with usability including difficulty getting the tracker on and off the wrist, lack of a screen on the Fitbit for visualizing PA data, and confusion regarding the green light system. Limitations included a small sample size and missing MVPA data.

Conclusions: Overall, the Fitbit Flex 2 was well received by participants and they recommended including it in interventions to increase PA. A more advanced activity tracker with a screen display and better reliability for capturing MVPA minutes is suggested for future research.

THE IMPACT OF ACTIVE VIDEO GAME PLAY UPON TIME SPENT IN PHYSICAL ACTIVITY AND SCREEN-BASED ACTIVITIES IN SEDENTARY CHILDREN.

Kelsey E. Ufholz, PhD¹, Kyle D. Flack, PhD, RD², James Roemmich, PhD³¹USDA Grand Forks Human Nutrition Research Center, Grand Forks, ND; ²University of Kentucky, Lexington, KY; ³United States Department of Agriculture (USDA) - Agriculture Research Service (ARS), Grand Forks, ND

Background: Few children obtain recommended amounts of daily physical activity, partly due to excess time spent in screen-based sedentary activities. Active video games (AVG) combine screen-based technology with physical motion and can lead to light to moderate physical activity in children. However, evidence suggests providing children with AVGs does not increase moderate to vigorous physical activity (MVPA), possibly because children who play AVGs tend to also engage in sedentary screen-based activities, such as sedentary video games and television, rather than active play. How beginning AVG play influences children's choice of other activities, both active and sedentary, is currently unknown.

Objectives: To examine how exposure to active video games influences children's physical activity, sedentary activity, and time spent in alternative activities

Methods: Sedentary children (N = 49) (ages 8-12; BMI percentile 8-97th) were provided with a video game system, active and sedentary video games. Participants were instructed to play the active video games three times per week and the sedentary video games as they chose for six weeks, followed by a 4-week washout when both game types were played ad libitum. Participants were instructed to wear a physical activity monitor for seven days and fill out a 24-hour recall detailing time spent in school, active play, and screen-based activity on four randomly selected days at baseline, post-treatment (week 6), and post washout (week 10).

Results: MVPA did not change over time ($p = 0.094$). Light activity decreased baseline to 10 weeks ($p = 0.006$) and 6 to 10 weeks ($p = 0.017$), while sedentary behavior increased from baseline to 10 weeks ($p = 0.005$) and 6 to 10 weeks ($p = 0.007$). AVG play increased from baseline to 6 weeks ($p < 0.001$) and decreased from 6 to 10 weeks ($p < 0.001$), while sedentary video game play decreased from baseline to 6 weeks ($p = 0.001$) and baseline to 10 weeks ($p = 0.0001$). Changes over time were not observed in active play ($p = 0.191$), social activities ($p = 0.592$), other hobbies ($p = 0.398$), or television ($p = 0.319$). Computer/phone use showed an almost significant decrease from baseline to 6 weeks ($p = 0.053$). AVG play also did not vary based upon the season ($p = 0.525$) or school year ($p = 0.733$).

Conclusion: AVG play did not impact children's involvement in active play or MVPA. AVG does not appear to lead to increased time on screen-based devices, although it may displace light activity.

FEASIBILITY OF A BRIEF, VIDEO-CHAT INTERVENTION FOR PROMOTING LIFESTYLE PHYSICAL ACTIVITY SELF-EFFICACY AMONG WORKING ADULTS

Tiffany Bullard, B.S.¹, Sean P. Mullen, PhD¹¹University of Illinois at Urbana-Champaign, Urbana, IL

Engagement in lifestyle physical activity (LPA) can complement other forms of structured physical activity (PA) and provides more choices in one's pursuit to meet public health guidelines. We hypothesized that mobile health interventions providing motivational support may promote LPA via self-efficacy-enhancement. To test this hypothesis, participants were randomized to receive three, brief (10-minute) Social Cognitive Theory (SCT)-guided Google Duo-powered video-chat sessions targeting LPA or time-matched video-chats emphasizing work-life balance, each conducted in the first three weeks of a six-week study. A 2 (group) x 2 (time) repeated measures ANOVA was conducted to examine change in self-efficacy for LPA among (N=72) low-active, working adults between ages of 25-64 ($M=46.57 \pm 9.24$; 73.60% women; 100% work 35+ hours/week). Self-efficacy was assessed prior to the first video chat and at the end of the third chat, and covariates assessed at baseline included age, gender, education, self-efficacy and PA (7-day average Fitbit Charge 3-derived steps). There was high compliance (98.61%) with video chat completion and one dropout (missing data was minimal and assumed random at week 1 and 3 [1.39%, 4.17%, respectively] and plausible values were estimated and imputed via established procedures). Overall, 82.60% of participants reported that they enjoyed participating in the study, 84.10% would recommend this program to a friend/family member, and 73.9% believed the video chats were helpful for increasing their PA levels (irrespective of group). As hypothesized, there was a statistically significant group x time interaction involving self-efficacy for LPA, $F(df=1, 62)=4.029$, $p=0.049$, partial $\eta^2=0.061$ (moderate effect). After completion of the video chat-phase, participants in the LPA-targeted intervention groups' self-efficacy > control group ($M_s = 83.24 \pm 2.73$ vs. 76.16 ± 2.77). Similarly, a second RM-ANOVA was conducted for self-efficacy to regulate work-life (SRWL) and although no such interaction was found ($p > 0.05$), both the intervention and control group showed improvements in SRWL from week 1 ($M_s = 71.60 \pm 20.45$ vs. 67.88 ± 14.15) to week 3 ($M_s = 77.31 \pm 23.25$ vs. 77.53 ± 14.40); as hypothesized, change was more pronounced among control group. These data support our hypothesis that SCT-guided video interactions with low-active, full-time working adults may promote confidence for engaging in LPA. Additional data on feasibility outcomes will be presented and implications will be discussed.

PERCEIVED PHYSICAL ACTIVITY COMPETENCE SPATIAL AUTO-CORRELATION AMONG ADOLESCENT FRIENDSHIP NETWORKS AT A SUMMER CARE PROGRAM

Tyler Prochnow, MEd¹, Christina N. Bridges Hamilton, MPH¹, Meg Patterson, PhD, MPH², Haley Delgado, B.S.³, M. Renee Umstattd Meyer, PhD, MCHES, FAAHB¹

¹Baylor University, Waco, TX; ²Texas A&M University, College Station, TX; ³Baylor University, Hewitt, TX

Introduction: Adolescent physical activity (PA) is considered vital for healthy psychological, social, and physical development. Adolescents who report feeling they are more competent in PA are more likely to achieve recommended amounts of PA. However, most adolescents do not achieve these recommended amounts with a notable decline as they get older. While schools provide a structured environment for PA, some children, particularly in low-income families, depend on summer programs for supervision and structured care during summer months. This study aims to investigate adolescents' perceived PA competence at a summer care program and the possible role of friendship networks have in an adolescent's competence levels.

Methods: Adolescents at a summer care program (age 8-12) completed researcher-administered surveys at the start (time 1) and end (time 2) of summer. Perceived skill competence was measured by asking adolescents to rate how good they felt they were at PA in certain settings: at school, outside, on the playground, at the summer care program, and at home. Adolescents were also asked to provide names of up to five peers whom they hung around with, talked to, and did things with the most while at the program. Analysis of variance (ANOVA) was used to determine potential differences in mean perceived skill competence responses based on setting. Linear network autocorrelation models were used to determine network effects or clustering of perceived skill competence within the program.

Results: At time 1, ANOVAs revealed that adolescents (n=100; μ age=9.9 years; 47% male; 62% Black) reported significantly higher perceived skill competence while at the summer care program than in any other setting. However, there were no significant differences among perceived skill competence scores based on setting for adolescents surveyed at time 2 (n=77; μ age=9.8 years; 51% male; 60% Black). There was a significant network effect for average perceived skill competence scores at time 1, indicating adolescent perceived skill competence scores were associated with those of their friends. This association was not significant at time 2.

Conclusions: It is possible this summer care program facilitated opportunities for adolescents who may have differing perceived skill competence to interact with each other and become friends. These opportunities may also encourage adolescents of all competence levels to be more physically active together during the summer months.

COGNITIVE FUNCTIONING AND EXPLICIT PHYSICAL ACTIVITY ATTITUDES AND SELF-REGULATION ASSOCIATED WITH THE ACTIVITY CHOICE INDEX

John F. Adamek, M.S.¹, Adam P. Taggart, MSc², Tiffany Bullard, B.S.², Jason D. Cohen, Ph.D.³, Arthur F. Kramer, Ph.D.⁴, Edward McAuley, Ph.D.⁵, Sean P. Mullen, Ph.D.²

¹University of Illinois at Urbana-Champaign, Champaign, IL; ²University of Illinois at Urbana-Champaign, Urbana, IL; ³Washington University in St. Louis, St. Louis, MO; ⁴Northeastern University, Boston, MA; ⁵University of Illinois, Urbana, IL

Physical activity (PA) assessments typically fail to account for transient moments in one's daily life and the extent to which effortful decisions (vs. non-conscious motives) account for one's choosing of active over sedentary behavior (e.g., walking instead of taking transportation). The *Activity Choice Index* (ACI; "During the past 7 days, how often have you engaged in ... choosing to park further away from destination, 1 = Never, 5 = Always") is a relatively new 6-item questionnaire designed for this purpose. To date, the ACI has been validated in Portuguese samples and little is known about the extent to which choices are associated with executive functioning (EF) and explicit (physical activity self-beliefs) vs. implicit motives. The purpose of this study was to validate the ACI in a U.S. sample of middle-aged adults and to test theorized mechanisms underlying the activity choices targeted by the ACI. Data from this study were derived from 133 middle-aged adults ($M_{age} = 53.82$; 79% women; BMI = 32.06) who were randomized to either a cognitive-motor training or attention control video-watching intervention, each involving a 20-hr supervised program. Participants completed baseline (M0) and post-intervention testing at Month 1 (M1). At M0 and M1, participants wore a Fitbit for 7 days (3-day average was computed), and completed the *Godin Leisure-Time Exercise Questionnaire* (GLTEQ), *Physical Activity Self-Regulation Questionnaire* (PASRQ), measures of PA-related self-efficacy, explicit and implicit attitudes, and a battery of cognitive assessments (e.g., dual task [DT] performance). No group differences in ACI (only assessed at M1 follow-up) were observed, so subsequent analyses used the collapsed sample. Bivariate correlations were low but statistically significant ($p < .05$) between ACI and baseline and M1 Fitbit steps (r 's = .28, .25) and GLTEQ (r 's = .24, .21). Baseline and M1 PASRQ (r 's = .46, .40), exercise self-efficacy (r 's = .21, .27) and self-schema (r 's = .19, .19) were positively associated with ACI. Interestingly, implicit attitudes were not associated with ACI (r 's = -.03, -.10, $p > .05$) and negative correlations were found with specific ACI items "park further away" and "standing over sitting" (r 's = -.21, -.30). DT correlated only with the "park further away" item at M1 ($r = .22$). The pattern of findings suggests that components of EF and conscious PA self-regulation may have a key role in enacting daily, effortful decisions to be physically active. This study adds to the scientific evidence supporting the ACI's construct validity and provides novel relations with cognitive performance. Together, these findings offer support for the theorized role of EF and self-regulation in conscious activity choices.

SUBJECTIVE ACTIVATION ASSOCIATED WITH LOWER BLOOD PRESSURE AFTER EXERCISE USING VIDEOGAMES, BUT NOT STANDARD EXERCISE

Roman Palitsky, MA, MDiv¹, Shira Dunsiger, PhD², Eva R. Serber, Ph.D.³, Joseph T. Ciccolo, PhD⁴, Beth C. Bock, PhD⁵¹Brown University, University of Arizona, Providence, RI; ²The Miriam Hospital and Brown University, Portsmouth, RI; ³Medical University of South Carolina, Charleston, SC; ⁴Teachers College, Columbia University, NEW YORK, NY; ⁵Brown University, Miriam Hospital, Providence, RI

Aerobic exercise has salutary effects on resting blood pressure, and choice in the mode of exercise may potentiate this benefit. Differences in modes of exercise may yield different subjective states during exercise, with implications for effects on health-related outcomes including cardiovascular biomarkers. Subjective experiences of activation may facilitate the regulation of autonomic arousal and, correspondingly, blood pressure. Thus, individuals who experience greater subjective arousal during exercise may have greater opportunity to entrain autonomic regulation. This study examined data from a trial comparing exercise video games (EVG) and standard exercise (SE) protocols. We anticipated that pre-post exercise increases in subjective activation would be associated with greater reductions in resting heart rate (RHR), systolic and diastolic blood pressure (sBP and dBP). Data were analyzed from 171 healthy adults randomized to SE ($n=85$) vs. EVG ($n=86$) conditions. Both conditions involved supervised exercise sessions thrice weekly for 12 weeks. Activation was assessed via the Felt Arousal Scale (FAS), a single-item Likert scale of subjective activation (1 = low arousal, 6 = high arousal), administered before and after exercising, once weekly. RHR, sBP, and dBP were recorded at baseline and at 12 weeks. Number and duration of exercise sessions was not significantly different between conditions. Participants in the EVG condition had greater increases in pre-to-post session FAS scores over the course of the intervention period. Adjusting for condition, increases in pre-to-post session FAS scores were not associated with differences in RHR by end of treatment ($p=.35$). However, increased FAS scores were associated with reduced sBP ($b=-3.35$, $SE=2.24$, $p=.03$) and reduced dBP ($b=-2.31$, $SE=1.27$, $p=.04$) at end of treatment. Moderation analyses revealed an effect of increased FAS scores on BP in the EVG condition (sBP $b=-7.29$, $p=.02$; dBP $b=-5.09$, $SE=1.77$, $p=.01$), but not the SE condition (sBP: $p=.57$; dBP: $p=.51$). These findings provide evidence that subjective activation during exercise may play a role in downstream effects on blood pressure, independent of the effects of minutes and intensity of exercise. Other emotive factors such as enjoyment may contribute to the influence of arousal, and should be examined in further research.

EFFECTS OF PROPORTIONAL COMPETITION WITH GROUPS

Monica C. Martinez, B.S. in Psychology¹, Triton Ong, B.S., M.A.², Jesse Dallery, Ph.D.³¹Drexel University, Philadelphia, PA; ²Behavioral Health and Technology Research Clinic, Gainesville, FL; ³University of Florida, Gainesville, FL

Group contingencies and competitive arrangements have been studied as tools to increase physical activity. Proportional competition, in which a prize is split based on relative performance rather than "winner take all", is especially understudied. This study aims to examine how variations of proportional competition affect physical activity. Specifically: 1) describe physical activity observed within conditions, 2) evaluate differences in physical activity between conditions, and 3) examine individual and group trends in daily physical activity.

Eight participants were instructed to wear a Fitbit Zip™ for five Using a within-subjects reversal design, we compared four conditions: baseline (no competition), independent proportional competition (all participants against each other), between-group competition (participants cooperate within teams and against other teams), and within-group competition (participants compete within and across teams).

Baseline steps were low ($M=4,821$, $SD=4,577$), slightly higher in between-group ($M=6,983$, $SD=4,757$), higher in within-group ($M=11,712$, $SD=5,622$), and highest in independent proportional competition ($M=12,598$, $SD=6,660$). The differences between conditions were statistically significant ($F(5,234)=14.004$, $p<.001$). Tukey post-hoc revealed that step counts in both within and independent conditions were significantly higher than between ($\Delta M=4728.95$, $p=.001$; $\Delta M=5615.80$, $p<.001$) and baseline conditions ($\Delta M=6890.20$, $p<.001$; $\Delta M=7777.05$, $p<.001$), and that there were no significant differences between the within and independent proportional competition condition means ($p=.973$) as well as the between-group and baseline means ($p=.430$). Individual time series graphs show that daily step counts generally followed group trends, and those who did not follow trends remained stable throughout the study.

These results show that if an intervention relies on a competition among different groups, a within-group competition set-up would most likely produce the best results. However, independent proportional competition yielded the highest number of steps and was most preferred by the participants on average, showing that proportional competition alone or in groups can be effective for increasing activity level. Future research should evaluate if similar results can be seen in different populations (e.g. sedentary adults, children) or used for different health behaviors (e.g. caloric intake, weight loss).

PROMOTING WELL-BEING AMONG LATINOS: CAN A PHYSICAL ACTIVITY INTERVENTION MOVE THE NEEDLE?

Patricia Rodriguez Espinosa, Ph.D., M.P.H.¹, Ines Campero, BA², Michele L. Patel, PhD³, Dulce Garcia, N/A⁴, Sandra J. Winter, PhD, MHA⁵, Catherine A. Heaney, PhD, MPH⁶, Abby C. King, PhD⁷

¹Stanford School of Medicine, Palo Alto, CA; ²Stanford University School of Medicine, Palo Alto, CA; ³Stanford University School of Medicine, Menlo Park, CA; ⁴Stanford Prevention Research Center, Palo Alto, CA; ⁵Senior Coastsiders, Half Moon Bay, CA; ⁶Stanford University, Stanford, CA; ⁷Stanford University School of Medicine, Stanford, CA

Latinos are currently the largest racial/ethnic minority population in the US. Few studies have examined well-being among Latinos and the evidence appears mixed. Physical activity (PA) provides known health and well-being benefits; however, less than 30% of Latinos report engaging in PA daily. This research examines whether a PA intervention leads to changes in overall well-being and its constituent sub-domains. Data are derived from the On the Move Trial (N=350 Latinos, mean age=51 years, 73% women), which tested the effectiveness of a linguistically and culturally targeted interactive PA intervention across communication modalities (human phone contacts vs. computer-driven text-messaging). Participants completed a novel, psychometrically validated measure of well-being, the Stanford Well for Life Scale (SWLS). The SWLS assesses nine well-being domains, including physical health, stress and resilience, financial stability, spirituality/religiosity, purpose and meaning, sense of self, experience of emotions (both positive and negative), social connectedness, and exploration/creativity. An overall well-being score was also calculated. A series of multiple regression models were employed to evaluate between-arm differences. Compared to the text-advising arm, the phone-based human advising arm showed baseline to 6-month improvements in overall well-being ($\beta=.17$, $p < .05$), along with improvements in the following domains: stress and resilience ($\beta=.28$, $p < .05$), experience of emotions ($\beta=.24$, $p < .01$), and purpose and meaning ($\beta=.19$, $p < .05$). As expected, no changes were detected for domains not hypothesized to be impacted by PA, such as finances, exploration/creativity, or religiosity/spirituality. Preliminary evaluation of 12-month data indicate improvements in overall well-being are stable and may potentially increase in magnitude ($\beta=.29$, $p < .01$). The findings suggest that programs employing some form of real-time person-to-person contact, including by phone, appear promising for improving well-being relative to computer-driven forms of mobile contact like text-messaging. This has implications for the development and implementation of technology interventions. As the US becomes increasingly diverse, optimizing health and well-being for racial/ethnic populations is a crucial next step for public health and health equity research.

“I PLAN SO I CAN:” INCREASES IN EXERCISE BEHAVIOR OVER TIME ARE PRECEDED BY EXERCISE PLANNING AND SELF-EFFICACY

Erika A. Waters, PhD, MPH¹, Nicole Ackermann, MPH², Julia Maki, PhD³, Linda Cameron, Ph.D.⁴, Ying Liu, MD, PhD², Chelsey R. Carter, MA⁵, Graham A. Colditz, n/a⁶, Deborah J. Bowen, Professor⁷, Hank Dart, MS²

¹Washington University in St Louis, St Louis, MO; ²Washington University School of Medicine, St. Louis, MO; ³Washington University in St. Louis, St Louis, MO; ⁴University of California, Merced, Merced, CA; ⁵Washington University in St. Louis, St. Louis, MO; ⁶Washington UNiversity School of Medicine, St Louis, MO; ⁷University of Washington, Seattle, WA

Purpose: Self-regulation interventions that include mental imagery can increase exercise behavior months later. We examine two unanswered questions: what is the trajectory of behavior change over time that is associated with such interventions; and what health cognitions precede such changes?

Methods: 500 adults age 30-64, with < 150 minutes of exercise in the last week and few comorbidities, were randomized to one of six experimental conditions in a 3 (risk display format: text vs. table vs. risk ladder) x 2 (mental imagery topic: exercise vs. sleep hygiene [active control]) factorial design. After receiving personalized risk estimates, participants listened to an audiorecording that used mental imagery to guide them in developing goals related to exercising or sleep hygiene behaviors and in making plans for achieving the goals. Participants received text message reminders to complete the mental imagery for 3 weeks post-intervention, 4 weekly surveys by text to assess behavior and imagery and goal-related constructs, and a mailed survey 90 days post-baseline. To limit participant burden, the text message surveys included only items related to the participant's assigned mental imagery topic. This precluded measuring exercise behavior among participants in the sleep condition, and vice versa. Therefore, these analyses include only participants who engaged in exercise-related mental imagery (n=229). Repeated measures data were analyzed using a correlated errors model with a compound symmetry covariance structure. Minutes of exercise in the last week was the outcome. Predictors for exercise at each timepoint were imagery and goal-related variables from the previous timepoint: image clarity, planning, positive affect, and self-efficacy. Several covariates were included.

Results: 83% of participants answered all 4 text surveys. Exercise increased from baseline to 90-day followup (from 52.5 to 115.2 mins/week, $p < .001$). The largest increases were between baseline and week 1 (from 52.5 to 99.4 mins, $p < .001$) and between week 1 and week 2 (from 99.4 to 114.0 mins, $p < .001$). Exercise decreased slightly from week 4 to 90 day followup (119.4 to 115.2 mins) but remained higher than baseline ($p < .001$). Planning and self-efficacy at one timepoint were positively associated with exercise behavior at the next timepoint ($b=12.1$ and $b=8.9$ mins/week, respectively, $p < 0.05$), but image clarity and positive affect were not ($p > 0.05$). The benefits of planning and self-efficacy did not change over time ($p > .05$ for their interaction terms with time).

Conclusions: Using audiorecordings and text messages to administer mental imagery-based self-regulation interventions is feasible and can encourage exercise behavior over a 90-day time period. Using text messaging for survey administration is also feasible, despite space constraints imposed by the text messaging format.

6:15 PM-7:30 PM

CHANGES IN PSYCHOSOCIAL OUTCOMES IN COMMUNITY-DWELLING OLDER ADULTS FOLLOWING A “STAND UP AND MOVE MORE” INTERVENTION

Neda E. Almassi, B.S.¹, Brianna N. Leitzelar, M.S., M.A.¹, Kevin M. Crombie, M.S.¹, Kelli F. Koltyn, Ph.D.¹¹University of Wisconsin - Madison, Department of Kinesiology, Madison, WI

Background: Older adults spend most of their waking hours sedentary, increasing risk for functional decline, chronic disease, and premature mortality. Emerging research suggests that sedentary behavior interventions can reduce sedentary time but little is known about effects of such interventions on psychosocial variables, which may be important in sustaining sedentary behavior reductions over time.

Objective: To examine the effect of a “Stand Up and Move More” workshop on habit strength, self-regulation (SR), self-efficacy (SE), and outcome expectations (OE) in those who participated in the sedentary intervention (SUMM) compared to waitlist controls (WLC). It was hypothesized that only the SUMM group would show improvements in habit, OE, SE, & SR over time.

Methods: Community-dwelling older adults ($N = 56, 74 \pm 7.2$ years) were randomized to either a SUMM group ($n = 31$) or a waitlist control group (WLC $n = 25$). SUMM met for 4 weekly sessions & a refresher session at 8 weeks. Accelerometers measuring sedentary time & questionnaires assessing habit, SR, SE, and OE were administered at baseline, post-workshop (week 4), & follow-up (week 12). Data were analyzed with 2x3 repeated-measures ANOVAs & Pearson's correlation coefficients.

Results: There were significant group by time interactions ($p < 0.05$) for habit strength, SR, and OE. SUMM decreased sitting habit and increased habit of standing up post-workshop & maintained at follow-up, whereas WLC had no change. Though SR composite score increased across the 12 weeks, it was higher in the SUMM group post-workshop, compared to WLC. OE also improved in the SUMM group compared to no change in WLC. SE for standing up an additional 10-12 times/day did not change across the 12-weeks but changes in SE negatively correlated with total sedentary min/day ($r = -0.31, p < 0.05$) such that greater increases in SE were associated with greater decreases in sedentary min/day post-workshop.

Conclusions: A 4-week SUMM workshop effectively promoted more frequent use of SR strategies and improved habit such that subjects were more likely to take standing breaks and less likely to sit. Results also suggest that the workshop increased expectations of positive outcomes as a function of standing more. Future interventions should consider examining habit, OE, SE, and SR to better understand the psychosocial factors underlying sedentary behavior change.

A CROSS-SECTIONAL EXAMINATION OF PHYSICAL ACTIVITY, SEDENTARY TIME, AND SLEEP BETWEEN PARENTS AND NON-PARENTS USING NHANES

Danae Dinkel, PhD¹, Kelsey Lu, MS², Jemima John, PhD³, Kailey Snyder, PhD⁴, Meredith Lucas, BA, BSN, RN⁵, Lisette T. Jacobson, Ph.D., MPA, M.A.⁵¹University of Nebraska at Omaha, Omaha, NE; ²KU Med Center - Wichita, Wichita, KS; ³MD Anderson Cancer Center, Houston, TX; ⁴Creighton University, Omaha, NE; ⁵University of Kansas School of Medicine-Wichita, Wichita, KS

Background: Physical activity (PA) is widely accepted as a health-enhancing behavior. Unfortunately, the majority of U.S. adults do not meet aerobic PA recommendations. Parents in particular are at increased risk of physical inactivity due to barriers related to caregiving, lack of time, competing responsibilities, and limited social support. Few studies have examined parental status and gender-related differences in PA and associated health behaviors, especially from a nationally representative sample. These potential differences will inform key areas for future intervention, program delivery, and policy development. Therefore, the purpose of this study was to examine PA and related health behaviors of parents and non-parents and to determine whether these differences varied by gender.

Methods: Cross-sectional data from five cycles of the National Health and Nutrition Examination Survey (2007-2008, 2009-2010, 2011-2012, 2013-2014, and 2015-2016) were used for analysis. The Global Physical Activity Questionnaire was used to assess subjects' physical activity and sedentary time. Health-related variables explored included body mass index (BMI), waist circumference, amount of sleep, hours worked, and sedentary time.

Results: Overall, non-parents ($n=4324$) reported more recreational moderate-to-vigorous PA ($p < 0.001$), more sleep ($p = .05$) a lower BMI ($p < 0.001$) and waist circumference ($p = .0007$) compared to parents ($n=5217$). However, parents reported fewer hours of sedentary time each week in comparison to non-parents ($p < .0001$). While there were statistically significant differences in BMI across parental status, we found no significant between-group differences for BMI across gender for parents ($p < .521$) and non-parents ($p < 0.870$). Further, when comparing non-parents and parents by gender, the primary difference in findings was that while female non-parents reported more sleep than female parents ($p < .0002$), there was no significant difference between the sleep of male non-parents and male parents ($p = .626$).

Conclusion: Non-parents, especially males, reported higher levels of PA, sleep and other positive health outcomes while parents reported less sedentary time. Thus, future interventions should: 1) Explore potential underlying mechanisms behind these disparate behavioral outcomes; and 2) Focus on the development and implementation of PA engagement and sleep improvement strategies especially for female parents that can be integrated into parents' daily routines.

WHAT MOTIVATES CHILDREN AND ADOLESCENTS TO BE PHYSICALLY ACTIVE? PERSPECTIVES FROM A GERMAN SPORTS SCIENCE ACADEMY

Zinnowitz 2019 AG1, n/a¹, Carina Mnich, BA¹, Claudio Nigg, PhD¹¹Karlsruhe Institute of Technology, Karlsruhe, Baden-Württemberg, Germany

Background: Physical inactivity in childhood and adolescence is a global phenomenon that is also present in Germany, with only 26% of youth meeting the WHO physical activity (PA) guidelines. Thus, we investigated which motivational aspects play a role in youth's PA behavior.

Method: Participants were current or former scholarship students of the German national academic foundation promoting the top German academic students across disciplines who participated in the summer 2019 Sports Science Academy. An online questionnaire based on a consensus of 15 motivational factors included individual (e.g. curiosity, fun), social (peers and family), and environmental (e.g. facilities, geographics) aspects. Items were rated on a scale from 0 ("not motivating at all") to 3 ("highly motivating") separately for children (6-12 years) and adolescents (12-17 years).

Results: Participants (n=79 [86% participation rate]; 50.6% female, mean age=28.24 years [SD=9.23], BMI=22.20 kg/m² [SD=1.89], PA=7.07 hours/week [SD=3.96]) completed the survey. The five most important motivational aspects for children as rated by the participants were: Fun (m=2.81 [SD=.49]), family role model of active lifestyle (m=2.47 [SD=.74]), curiosity (m=2.28 [SD=.69]), accessible facilities (m=2.19 [SD=.71]) and imitation of peers (m=2.09 [SD=.71]). The three lowest ratings were marketing (m=1.07 [SD=.72]), physical appearance (m=1.00 [SD=.82]), and health (m=.52 [SD=.70]). The five most important factors for adolescents as rated by the participants were: Judgement by peer group (m=2.55 [SD=.60]), group belonging (m=2.45 [SD=.71]), physical appearance (m=2.39 [SD=.79]), social media (m=2.27 [SD=.90]), and fun (m=2.25 [SD=.58]). The lowest ratings were geographic factors (m=1.35 [SD=.66]), curiosity (m=1.33 [SD=.69]), and health (m=1.25 [SD=.84]).

Discussion: This sample rated the PA motivations different for children and adolescents. In childhood, motivation was thought to include individual, family, and environmental aspects. In adolescence, peer/social influences seem to be the most salient, while adolescents' own interests are less important. For both children and adolescents, health was deemed as least motivating. This should be used to tailor developmentally appropriate interventions to promote youth PA.

RECRUITMENT OF PARTICIPANTS FOR PHYSICAL ACTIVITY INTERVENTIONS: SHOULD WE USE WALK SCORES?

Bernardine M. Pinto, Ph.D.¹, Shira Dunsiger, PhD², Madison M. Kindred, Ph.D.³, Kimberly C. Rawlinson, MPH¹¹University of South Carolina, Columbia, SC; ²The Miriam Hospital and Brown University, Portsmouth, RI; ³Augusta University, Augusta, GA

Considerable time and effort are expended in recruiting and screening individuals to participate in physical activity intervention trials. One approach to developing targeted recruitment is to assess the objective walkability of potential participants' residential neighborhoods (that is, the ease of pedestrian mobility reflected in a Walk Score). We have completed recruitment of sedentary breast cancer survivors into a randomized controlled trial. A total of 874 participants contacted the study staff: 279 (32%) screened eligible, 441 (50%) screened ineligible, 114 (13%) were non-responsive and 40 (5%) were not interested. Walk Score data were determined using Walk Score® (<https://www.walkscore.com/>) for the sample of 808 participants who provided home addresses at screening. Walk Scores range from 0-100, with a score < 50 indicating car dependence and a score > 70 indicating high walkability. Participants were 57.4 years of age on average (SD=12.23), the majority (85%) were Non-Hispanic and reported their race as White (64%). The sample's mean Walk Score was 18.27 (sd=21.18, range: 0-97). Using analysis of variance, we examined the association between average neighborhood walkability and screening result. As a subsequent step, using spearman rank correlations, we examined associations between age and Walk Score separately by screening result. Results indicate a significant difference in mean Walk Score by screening result ($F=3.20$, $p=.02$). Posthoc comparisons using a Sidak adjustment suggest significant differences in mean walkability with eligible participants having significantly lower Walk Scores compared to ineligible participants (mean difference=-5.0, SE=1.65, $p=.01$). Finally, among eligible participants, there was a significant negative correlation between age and Walk Scores suggesting older participants lived in areas that did not facilitate walking ($\rho=-.13$, $p=.03$). There were no other significant associations between age and walkability among ineligible, non-responsive or not interested participants. These data suggest that recruitment efforts could be directed towards residential neighborhoods that have low Walk Scores, if the goal is to recruit sedentary individuals. Additionally, intervention trials for older breast cancer survivors may invest recruitment efforts in neighborhoods with low walkability. Assisting these individuals to find locations that facilitate physical activity may be essential to developing effective interventions.

QUALITY OF LIFE BURDEN IN CUTANEOUS T-CELL LYMPHOMA

Trisha Bhat, BA¹, Christina Herbosa, BA¹, Yevgeniy R. Semenov, MD, MA², Amy Musiek, MD³, Donna B. Jeffe, PhD³

¹Washington University School of Medicine in St. Louis, St. Louis, MO; ²Massachusetts General Hospital, Boston, MA; ³Washington University School of Medicine, St. Louis, MO

Cutaneous T cell lymphoma (CTCL) is both an oncologic diagnosis and an inflammatory disease, and patients therefore carry the emotional burden of a cancer diagnosis as well as the physical and psychological burden of CTCL symptoms and treatment. Quality of life (QoL) in patients with CTCL therefore remains an important outcome measure. As a first step in evaluating QoL in this patient population, CTCL patients were recruited from general dermatology and multidisciplinary CTCL clinics between July 2017 and August 2019 (n=119; mean age 65 [38-90]; 54 [45%] women; 97 [82%] white; 82 [69%] married; 25 [21%] advanced stage [IIB-IV]). QoL was measured at study enrollment using the eight subscales of the RAND SF-36 (with higher scores indicating better QoL) and the Skindex-29 Emotions, Symptoms, Functioning, and overall summary scores (5-point scale), with higher scores indicating more negative impact of one's skin condition on QoL over the past four weeks. Separate multiple linear regression models for each QoL measure included comorbidities, sex, marital status, CTCL stage (early [IA-IIA] vs. advanced [IIB-IV]), and the severity of itching over the past two weeks using the 10-point Itch Visual Analog Scale (VAS); the Skindex-29 overall measure was also included in each SF-36 subscale model. Advanced stage was associated with impairment of QoL in four of eight SF-36 domains and all Skindex-29 summary measures. Greater number of comorbidities and QoL impairment on the Skindex-29 overall score were both associated with all eight SF-36 subscales, but greater number of comorbidities was not associated with any Skindex-29 summary scores. Conversely, more severe itching on the VAS-Itch was associated with greater QoL impairment on all Skindex-29 summary scores but not on any SF-36 subscales (all $p < .05$). Pruritus is highly prevalent in patients with CTCL and has been previously demonstrated to have a significant impact on QoL, questioning the sensitivity of the SF-36 in evaluating QoL in patients with CTCL. Receiver operating characteristics curves confirmed these findings, demonstrating that the SF-36 subscales less sensitive in distinguishing patients with advanced-stage CTCL from patients with early-stage CTCL compared to the Skindex-29 measures, with areas under the curve (AUCs) ranging from 0.797-0.833 for Skindex-29 summary measures and from 0.352-0.483 for SF-36 subscales (< 0.5 , performing worse than random chance). We are currently interviewing patients to identify the issues determining QoL in this patient population in order to develop a more sensitive measure that addresses these concerns.

CHANGES IN PHYSICAL AND MENTAL HEALTH-RELATED QUALITY OF LIFE AFTER QUITTING SMOKING IN INDIVIDUALS WITH MOBILITY IMPAIRMENTS

Romano Endrighi, Ph.D.¹, Yihong Zhao, Ph.D.¹, Deepak Kumar, PT, PhD¹, Rosemary B. Hughes, PhD², Belinda Borrelli, PhD³

¹Boston University, Boston, MA; ²University of Montana, MISSOULA, MT; ³Boston University, Henry M Goldman School of Dental Medicine, Boston, MA

Health-related quality of life (HR-QoL) predicts morbidity and mortality. People with mobility impairments (MIs; use assistive devices to ambulate) smoke at twice the rate of the general population, and smoking is associated with poor HR-QoL. However, it is unknown whether quitting improves HR-QoL in smokers with chronic MIs. We hypothesized that quitting smoking would be associated with better physical and mental HR-QoL, particularly in non-depressed smokers. We also explored the role of MI severity as a moderator. This is a secondary analysis of a smoking cessation induction trial (n=241, 56% female, M age=55.3 yrs, 36% Black). Participants had chronic MIs and did not have to be motivated to quit to enroll. We categorized participants according to smoking status: 'Smokers' (smoking at 4- and 6-months), 'Abstainers' (quit at 4- and 6-months), 'Relapsers' (quit at 4- but relapsed at 6-months), and 'Late Quitters' (smoking at 4- but quit at 6-months). We administered the Medical Outcomes Study ShortForm Health Survey (SF-12) at baseline, 4- and 6-months and computed physical (PCS) and mental (MCS) summary scores. We assessed depression with the Patient Health Questionnaire (depressed=scores ≥ 10), and MI severity by the presence of skilled home care. Data were analyzed as intention-to-treat (missing=smoking) with linear mixed models.

Prospective analysis showed that the effect of smoking status on the PCS score was moderated by depression ($F(3,250)=9.4, p < .001$), after controlling for age, MI severity, treatment group, and time. Among the non-depressed, 'Abstainers' (vs. 'Smokers') improved their PCS score over time ($M \text{ diff.}=16.7, t(250)=3.9, p_{\text{adj}} < .001$). 'Late Quitters' also improved their PCS score vs. 'Smokers' ($M \text{ diff.}=21.5, t(250)=4.1, p_{\text{adj}} < .001$) and vs. 'Relapsers' ($M \text{ diff.}=16.1, t(249)=2.4, p_{\text{adj}}=.03$). Such group differences were not observed among those with depression. We found a significant smoking status by time interaction effect on the MCS score ($F(6,294)=3.5, p=.002$), after controlling for age, depression, MI severity, and treatment group. 'Abstainers' (vs. 'Smokers') improved their MCS score at 4-months ($M \text{ diff.}=13.2, t(225)=3.0, p_{\text{adj}}=.02$) and 6-months ($M \text{ diff.}=20.2, t(225)=4.7, p_{\text{adj}}=.001$). 'Relapsers' (vs. 'Smokers') also improved their MCS score at 4-months ($M \text{ diff.}=13.6, t(223)=2.7, p_{\text{adj}}=.02$) but effects were not sustained at 6-months. 'Late Quitters' (vs. 'Smokers') improved their MCS score though not significantly ($M \text{ diff.}=11.9, t(226)=2.3, p_{\text{adj}}=.07$).

Among smokers with chronic MIs, quitting smoking is associated with marked improvements in physical HR-QoL regardless of MI severity; however, this effect is not observed among those with depression. For mental HR-QoL, marked improvements are observed regardless of depression or MI severity, and the positive effects of quitting are apparent even among late quitters who had been abstinent for two months.

RELATIONSHIP FUNCTIONING AS PREDICTOR OF CONDOMLESS SEX AMONG A SAMPLE OF SEXUAL MINORITY ADOLESCENT MALES

Trey V. Dellucci, MS¹, Sarah Feldstein Ewing, PhD², Travis Lovejoy, PhD, MPH³, Gabriel Robles, PhD⁴, Demetria Cain, PhD MPH⁵, Ruben H. Jimenez, n/a⁶, Sylvie Naar, n/a⁷, Tyrel J. Starks, PhD⁸

¹The Graduate Center at CUNY, New York, NY; ²Oregon Health and Science University, Portland, OR; ³Oregon Health & Science University, Portland, OR; ⁴Hunter College, New York, NY, NY; ⁵PRIDE Health Research Consortium/Hunter College, New York, NY; ⁶Hunter College's PRIDE Health Research Consortium, New York, NY; ⁷Florida State University, Tallahassee, FL; ⁸Hunter College, New York, NY

Background: In 2017, youth (aged 13 to 24) made up to 21% of the new HIV diagnoses in the United States and 87% of those occurred in male youth. Nearly 50% of sexual minority adolescent males (SMAM) do not routinely use condoms. Main relationship partners account for a substantial proportion (as many as 79%) of new HIV infections among sexual minority men. For partnered sexual minority men, positive relationship functioning (e.g. high satisfaction) may be associated with instances of condomless sex (CS), though no studies to date have examined this association in SMAM.

Methods: Adolescents aged 15 and 19 were recruited nationally via online social media advertisements and geo-networking applications, and completed a brief telephone interview as part of ATN156. Analyses utilized data from 85 SMAM who reported being sexually active and who were in a current relationship. Participants were on average 18.03 years old (SD = 1.04), majority Latinx (42.9%) or White (32.4%), and identified as gay (77.5%) or bisexual (22.5%). Two independent logistic regression analyses were conducted to examine the association between relationship functioning and CS in the past 90-days among 1) all sexually active SMAM and 2) sexually active SMAM with a history of CS ($n = 70$). All analyses controlled for age, sexual identity, geographic region, and race and ethnicity.

Results: Relationship functioning was only associated condom use among those with a previous history of CS. Greater relationship satisfaction was associated with a lower likelihood of CS (OR = 0.56, 95%CI: 0.32, 0.98). Neither perceptions of seriousness or commitment to their relationship were associated with condomless sex.

Discussion: Consistent with the adult literature, the findings from the current study support that relationship functioning, specifically relationship satisfaction, is associated with sexual health risk among SMAM. This finding has important clinical and/or policy implications. Specifically, relationship skills training should be included in sexual health education programing as relationship functioning is inherently related to HIV prevention.

TESTING THE GENERALIZABILITY OF THE DRUG USE AND CONDOMLESS ANAL SEX LINK AMONG SEXUAL MINORITY MEN

Kory Kyre, BA Psychology¹, Stephen S. Jones, BA Mathematics², Gabriel Robles, PhD³, Demetria Cain, PhD MPH⁴, Ruben H. Jimenez, n/a⁵, Brett M. Millar, PhD⁶, Patrick Sullivan, PhD, DVM⁷, Tyrel J. Starks, PhD⁶

¹PRIDE Health Research Consortium, New York, NY; ²RFcuny - Hunter College - PRIDE Health Consortium, NEW YORK, NY; ³Hunter College, New York, NY, NY; ⁴PRIDE Health Research Consortium/Hunter College, New York, NY; ⁵Hunter College's PRIDE Health Research Consortium, New York, NY; ⁶Hunter College, New York, NY; ⁷Emory University, Atlanta, GA

Background: The link between drug use – particularly “club drugs” (cocaine, methamphetamine, GHB, LSD, ecstasy, and ketamine) – and sexual HIV risk behavior is well-documented among sexual minority men (SMM). Less consideration has been given to marijuana. In addition, few studies have tested whether this association differs among single SMM vs. those in relationships. For many partnered SMM, sexual agreements place limits on sexual behavior with outside partners and expectations about HIV prevention, and monogamous SMM are less likely to use club drugs. Accordingly, we tested whether these factors may diminish the strength of associations between drug use and condomless anal sex (CAS) with casual partners.

Methods: Between 11/2017 and 9/2019, 60,108 cis-gender SMM were recruited through a mobile dating app ($M_{age} = 36.2$ years) and completed an online survey. The majority were White (55.1%), in a relationship (84.3%), identified as gay (85.4%), and HIV-negative (79.6%; of whom 22.5% were on PrEP). Participants provided demographic data and indicated whether they used marijuana and 6 club drugs (in the previous 90 days) as well as the number of times they had CAS with a casual partner. Partnered SMM indicated their sexual agreement. A hurdle model was calculated to predict the odds of any CAS and CAS frequency among those who reported it. Models included interaction terms between relationship status and drug use and controlled for race and ethnicity, age, HIV status, and PrEP uptake.

Results: Club drug use (OR = 2.64, $p < .001$) was positively associated with the odds of CAS among single and non-monogamous men, but not monogamous men. Marijuana use (OR = 1.43, $p < .001$) was positively associated with the odds of CAS among single and monogamous men, but not non-monogamous men. Club drug use (Rate Ratio = 2.10, $p < .01$) was positively associated with CAS frequency among single and non-monogamous men who had at least some CAS, but not among monogamous men. Marijuana use was not associated with CAS frequency in any group.

Conclusions: These findings highlight the relevance of marijuana use to sexual risk-taking – for at least some groups of SMM. They also suggest that links between drug use and CAS generalize to at least some subgroups of partnered SMM. These findings point to the utility of incorporating a focus on marijuana use in intervention development and epidemiological research focused on sexual health and also of developing drug use interventions to reduce HIV transmission risk among partnered (as well as single) SMM.

Learning Objectives: Participants will be able to describe the links between marijuana and HIV risk behavior, and between club drugs and HIV risk behavior in a large sample of SMM.

Participants will be able to delineate between these drug-sex associations depending on relationship status and sexual agreement among SMM.

6:15 PM-7:30 PM

MEAN LEVEL AND VARIABILITY OF POSITIVE AFFECT AND SLEEP QUANTITY AMONG MOTHERS.

Wei-Lin Wang, Ph.D.¹, Genevieve F. Dunton, PhD, MPH¹, Donald Hedeker, PhD²¹University of Southern California, Los Angeles, CA; ²University of Chicago, Chicago, IL

Background: There is growing interest in the contribution of emotional factors to sleep health. However, much of the research in this area focuses on how trait and/or mean levels of affect influence sleep quantity. The extent to which within-person variation in affect relates to sleep quality and quantity is understudied due to methodological limitations such as lack of real-time data capture measures and statistical models incapable of testing within-subject variability as a predictor. Mothers represent a particularly vulnerable population for experiencing affective volatility given the demands of parenting, and therefore the association between affect and sleep health is an important question to understand in mothers. This study used intensive repeated Ecological Momentary Assessment (EMA) data to examine the associations between mean level of and variability in positive affect (PA) and sleep quantity in mothers.

Methods: This study examined panel data from mothers (Mean = 41.40; SD = 5.98) with children (ages 8-14 years) in the Mothers' and Their Children's Health (MATCH) study. Mothers were assessed six times across three years (every six months). During each assessment wave, mothers completed 8 days of EMA, reporting up to 8 randomly-promoted times per day on how happy and calm/relaxed they were feeling. Mothers' typical weekday sleep duration was measured through self-report questionnaire at each assessment. Data were divided into two sub-data sets (waves 1-3 and waves 4-6) to run an initial test and replication of the results, respectively. The analytic sample size was about 9,000 observations (level 1: prompts) nested within 152 mothers (level 2: persons) in each sub data set. This study employed a novel two-stage data analysis approach, multilevel mixed-effects location scale modeling, using the statistical program MIXWILD.

Results: Results indicated that mean level of PA (i.e., location effect) was positively associated ($\beta = 0.157$ & 0.187 , p 's < 0.05) with mothers' weekday sleep duration time in both sub-data sets. Variability in PA (i.e., scale effect) was inversely related to weekday sleep duration in the first sub-data set (waves 1-3) ($\beta = -0.238$, $p < 0.01$) and not significantly associated with sleep duration in the second sub-data (waves 4-6) ($\beta = -0.017$, $p = 0.85$), although the effect was in the expected direction.

Conclusions: Mothers with higher mean levels of positive affect may sleep longer on weekdays because positive emotions buffer the effects of stress or support goal-directed behaviors such as getting to sleep on time. However, results indicate that volatility in positive affect may influence sleep duration above and beyond the effects of mean positive affect. Therefore, emotional regulation strategies may be important to target in sleep health interventions for parents.

Background: Efforts to discontinue hypnotic use have mixed results and typically have not addressed placebo effects (e.g., cognitive expectancy for nightly use). We developed a method for reducing cognitive expectancy for hypnotics and created the Masked Taper plus Cognitive behavioral therapy Augmented Program (MTcap). MTcap includes 1) masked (i.e., blinded) hypnotic tapering, which is achieved through encapsulation of the hypnotic, 2) components targeting placebo and psychological effects of withdrawal, and 3) cognitive behavioral therapy for insomnia (CBTI), which is considered first-line therapy for insomnia. Using data from an ongoing clinical trial examining the effects of MTcap, we explored a method of describing expectancy for hypnotic effects, comparing participant predicted to actual hypnotic dose among chronic hypnotic users randomized to MTcap.

Methods: We analyzed daily diary data from participants who completed MTcap between March 2019-September 2019. Data included predicted nightly hypnotic dose as a percentage of baseline dose (5 options in 25% increments where 0% = no dose/placebo to 100% = full dose) and self-reported Sleep Quality (SQ; 0 = poor to 10 = excellent). We defined prediction accuracy as "over" (prediction > actual dose), "under" (prediction < actual), and "accurate" (prediction = actual). Expectancy profile was determined by the percentage of days participants' predictions were over, under, or accurate.

Results: All participants (n=8, mean age = 70 years) completed MTcap, yielding 63-70 days of data per participant. Three distinct expectancy profiles emerged. The "generally accurate" group correctly predicted the dose most days (n = 3; 46%, 46%, 68% of days). The "generally over" group overpredicted the dose most days (n = 4; 86%, 86%, 71%, 67% of days). The "generally neutral" group had a non-dominant pattern (n = 1). All participants successfully discontinued hypnotic use after completing MTcap. Six participants reported improvements in SQ over the course of intervention as hypnotic dose was tapered; accuracy in dose prediction was not associated with change in SQ.

Conclusion: Our approach to categorizing prediction accuracy helped identify expectancy profiles that may be associated with reduced cognitive expectancy and successful discontinuation of hypnotics. Future analyses from the larger trial will refine methods of investigating expectancy patterns and potential relations to changes in sleep and hypnotic use.

INSOMNIA IDENTITY AND PSYCHOSOCIAL HEALTH IN NURSES

Jessica R. Dietch, PhD¹, Danica C. Slavish, PhD², Camilo Ruggero, Ph.D.², Kimberly Kelly, Ph.D.², Brett Messman, B.A.³, Sophie Wardle-Pinkston, M.S.⁴, Daniel J. Taylor, Ph.D.⁵

¹Stanford University/VA Palo Alto Health Care System, Templeton, CA; ²University of North Texas, Denton, TX; ³University of North Texas, Dallas, TX; ⁴University of Arizona, TUCSON, AZ; ⁵University of Arizona, Tucson, AZ

Introduction: Insomnia identity (i.e., the belief or complaint that one has insomnia) can be measured independently of actual sleep disturbances, resulting in four categories of sleepers: complaining poor (CP), non-complaining poor (NP), complaining good (CG), and non-complaining good (NG). Preliminary research has demonstrated insomnia identity is linked with mental health and daytime functioning variables more strongly than actual sleep disturbances. The current study sought to extend these findings in a large sample of nurses.

Method: Participants were 389 nurses (92% female; 78% White, 11% Hispanic/Latinx; mean age = 39.5 ± 11.1) from two local hospitals. Participants completed baseline measures of depression, anxiety, posttraumatic stress disorder (PTSD) symptoms, perceived stress, chronotype, and night-shift work, and then completed 14 days of sleep diaries. Participants were categorized into 4 types of sleepers (CP, NP, CG, NG) using sleep diaries (good v. poor sleepers; i.e., 31 or more minutes of wakefulness during sleep period, at least 3x/week) and self-report measures (insomnia complaint v. no complaint; i.e., poor subjective sleep quality as measured by the Pittsburgh Sleep Quality Index).

Results: NG sleepers were the largest category ($n = 318$) followed by NP ($n = 34$), CG ($n = 25$) and CP ($n = 12$). Significant differences emerged between groups for depression, anxiety, PTSD symptoms, and chronotype. CP had significantly higher depression, anxiety, and PTSD symptoms than NG. CG had significantly higher depression and PTSD symptoms and greater evening chronotype tendency than NG. Sleeper category was not associated with night shift work status.

Discussion: Supporting previous research, results indicated individuals endorsing insomnia identity (i.e., insomnia complaint) demonstrated worse psychosocial health compared to individuals who did not endorse insomnia identity, regardless of actual sleep disturbances (i.e., good or poor sleep). One explanation for this is that concern or worry about sleep may be more harmful to psychosocial health than having poor sleep. Future research should aim to understand the mechanisms of the relationship between sleeper category and psychosocial variables and explore additional outcomes (e.g., physical health). Given that nurses provide the front line of care in hospitals and other medical settings, it is essential to understand modifiable factors that contribute to their psychosocial health and wellbeing.

DOES GENERAL SELF-EFFICACY BUFFER THE EFFECTS OF STRESS ON SLEEP?

Jason Hawes, B.A.¹, Eva M. Livingston, BS², Violet Quann, n/a³, Erin L. Merz, PhD, MPH⁴, Emily Rose San Diego, MA⁵

¹California State University, Dominguez Hills, Pasadena, CA; ²California State University, Dominguez Hills, Long Beach, CA; ³California State University, Dominguez Hills, Los Angeles, CA; ⁴California State University, Dominguez Hills, Carson, CA; ⁵University of Memphis School of Public Health, Cordova, CA

Research strongly supports the link between high stress and poor sleep quality. Ethnic minority populations are typically more vulnerable to higher levels of stress. Furthermore, ethnic minorities enrolled in college report higher levels of stress than non-minority students. General self-efficacy (GSE), defined as the belief in one's ability to perform difficult tasks and cope with adversity, is a psychosocial resource that can be useful in combating stressful situations. There have been few studies on GSE in the context of stress and sleep, and none have focused on minority samples. This study explored whether GSE buffered the effects of stress on sleep in an ethnically diverse sample of young adults enrolled at a 4-year university. Cross-sectional data were collected on 345 participants (68% Latino, 13% Black, 7% Asian, 5% White, 2% Pacific Islander, 5% Multiracial). In a model adjusted for sex and age, greater sleep problems were significantly predicted by higher stress, GSE, and the stress-GSE interaction, $F(5, 338) = 18.08, p < .001, R^2 = .20$. The main effect for stress was statistically significant ($b = .474, p < .001$), but the main effect for GSE was not ($b = .087, p = .312$). The significant interaction term ($b = -.019, p = .012, \Delta R^2 = .01$) was probed at low, medium, and high levels of GSE. All simple slopes were statistically significant ($ps < .001$); the stress-sleep relationship was weakest for those who were high in GSE ($b = .384$), and respectively stronger for those who were average ($b = .474$) or low ($b = .565$) in GSE. These findings suggest that higher GSE may buffer the effects of stress on sleep in this sample of ethnically diverse young adults. Furthermore, this buffering effect may work on a gradient. These findings are of theoretical interest because they advance the body of knowledge on stress and sleep by exploring the role self-efficacy plays in this relationship. An applied benefit of this study is GSE's potential as a modifiable psychosocial resource. Future research should explore approaches for enhancing GSE in this population and evaluate whether changes in this broad construct reflect the buffering pattern observed in the current sample. Potential avenues for this within the university context may include culturally competent curricula, mentorship, and/or other personal development programs aimed at promoting the skills and beliefs associated with GSE.

SLEEP AS A LONGITUDINAL PREDICTOR OF RISK FOR METABOLIC SYNDROME AND VISCERAL FAT ACCUMULATION IN COLLEGE FRESHMEN

Aria R. Ruggiero, MA¹, Jane F. Gaultney, PhD¹, Katerina Lantz, n/a¹, Trudy Moore-Harrison, PhD¹, Hannah Peach, PhD¹¹University of North Carolina at Charlotte, Charlotte, NC

Introduction: While an estimated 50-70 million adults experience chronic sleep loss, college students may be twice as likely as the general population to report negative sleep outcomes. Poor sleep has been linked to a number of deleterious health outcomes, including metabolic syndrome (MS), which elevates one's risk of developing conditions like diabetes, heart disease, and stroke later in life. Mixed results have been found as to whether sleep can predict accumulation of visceral fat, which is biologically active fat that is associated with inflammation and obesity. An increased number of college students are meeting an overweight or obese classification, which gives rise to concerns regarding accumulation of visceral fat and developing risk for MS. Weight gain in college students, especially early on, is often labeled "The Freshman 15". The present study examined multiple longitudinal relationships between sleep and risk for MS, visceral fat, and whether visceral fat mediates the relationship between sleep and MS risk.

Method: Participants consisted of college freshmen recruited for a longitudinal study measuring subjective and objective sleep, metabolic health, and body composition (as measured by a DEXA scanner). Time 1 data (N = 131, M = 18.45 years; 60.1% female; 57.2% white) were collected during participants' fall semester, and time 2 data (N = 33, M = 18.59 years; 72.7% female; 56.8% white) were collected during spring semester.

Results: Lower subjective sleep duration ($b = -.29, p < .05$), lower objective sleep duration ($b = -.20, p < .05$), poorer subjective sleep quality ($b = .17, p < .01$), and poorer objective sleep quality ($b = -.20, p < .05$) at time 1 were significantly associated with greater risk for MS at time 2. These effects were present after controlling for age, gender, socioeconomic status, sleep apnea, depression, and stress. Sleep did not significantly predict visceral fat in a linear fashion; however, a significant curvilinear relationship existed between sleep duration and visceral fat cross-sectionally, such that sleeping less than 6 hours ($b = .25, p < .05$) and more than 6 hours ($b = .15, p < .05$) was associated with more visceral fat. Lastly, sleep outcomes predicting risk for MS via visceral fat were not significant.

Conclusion: Results suggest that sleep has the potential to influence risk for MS among college students, a population typically thought to not be at great risk for MS. This serves as a potential avenue for interventions geared at improving sleep (i.e., improving sleep hygiene practices, CBT-I) in order to establish a preventative strategy against negative metabolic health outcomes. Future research should continue to explore the link between sleep and metabolic health in college students, with an emphasis on increasing longitudinal sample size and further elucidating the link between sleep and visceral fat.

FEASIBILITY OF A NOVEL BEHAVIORAL SLEEP EXTENSION INTERVENTION FOR SHORT SLEEPERS WITH ELEVATED BP/HYPERTENSION

Kelly G. Baron, PhD, MPH¹, Jennifer Duffecy, Ph.D.²¹University of Utah, Salt Lake City, UT; ²University of Illinois-Chicago, Chicago, IL

Short sleep duration contributes to increased cardiometabolic disease risk, including hypertension and heart disease yet few studies have examined behavioral sleep extension interventions. The goal of our study was to evaluate the feasibility and preliminary efficacy of a behavioral sleep extension intervention among individuals with elevated BP/hypertension on sleep, blood pressure and patient reported outcomes.

Methods: Adults aged 30-65 with 24h ambulatory blood pressure (ABP) >120/80 mmHg and average weekday sleep duration < 7 h per night were randomized 2:1 to a 6-week behavioral sleep extension intervention versus a self-management control group. The intervention included a wearable sleep tracker, weekly educational content and brief telephone coaching to enhance adherence. The control group was provided with sleep education and instructed to maintain their current sleep schedule. Data were analyzed using descriptive statistics and non-parametric statistics to evaluate differences in between groups as well as pre-post changes within each group. We also conducted bivariate correlations to evaluate predictors of change in sleep and ABP.

Results: A total of 16 adults were randomized into the study (11 intervention, 5 control group, 8 women, M=45.8 SD=9.8 years.) Results at 6-week follow-up demonstrated greater improvement in the intervention group for sleep duration ($p=.027$), reductions in 24h Systolic BP ($p=.013$) and Diastolic BP ($p=.026$), improvements in self reported sleep disturbance ($p=.003$) and sleep related impairment ($p=.008$). Improvements sleep duration were correlated with increased time spent in bed and sleep efficiency. Participants in the intervention group completed 90% of the coaching sessions and rated the enjoyment of the intervention as 4 of 5 out of 5 and reported in particular the use of the wearable tracker was an important component.

Conclusion: results demonstrate that sleep extension intervention is feasible and the intervention was well-received. Results also demonstrate the potential for this intervention to improve sleep duration, quality and 24-h ABP.

EDUCATIONAL GRADIENT IN DIABETES PREVALENCE AMONG FOREIGN BORN ASIAN AMERICANS: IMPLICATIONS FOR HEALTH INTERVENTIONS

Md Towfiqul Alam, MPH¹, Kunga Denzongpa, MPH², Jovanna Orozco, n/a¹, Sandra Echeverria, PhD, MPH²¹University of North Carolina at Greensboro, Greensboro, NC; ²University of North Carolina Greensboro, Greensboro, NC

Educational Gradient in Diabetes Prevalence among Foreign Born Asian Americans: Implications for Health Interventions

Purpose: Educational gradients in diabetes prevalence are pronounced in the United States (U.S.). However, little research exists examining if this gradient holds in Asian Americans, one of the fastest-growing immigrant groups in the U.S. with varying levels of education. We examined educational gradients in diabetes prevalence among foreign born Asian American adults, who represent 80% of all Asian Americans and tested if associations differed by length of stay in the US.

Methods: We used the 2011-2016 National Health and Nutrition Examination Survey (NHANES), a nationally representative sample of the U.S. population that included foreign-born Asian American adults 20 years of age or older ($n=1,762$). Education was classified as < high school, high school, some college, and college degree or more. Diabetes prevalence was clinically assessed using a glycohemoglobin (HbA1c) cut-off of 6.5%. In multivariate logistic regression models that accounted for the multistage sampling design of the NHANES, we examined if educational gradient and HbA1c level remained associated after adjusting for gender, age, income and body mass index (BMI). We also tested for effect measure modification by years in the U.S. (< 10 years vs. 10+ years).

Results: Diabetes prevalence decreased with increasing education (p for trend < 0.05), reaching 22.0% among those with < high school education compared to 7.8% among college educated individuals. In crude models, compared to college educated individuals, those with < high school education had a higher odds of diabetes (Odds Ratio [OR]: 3.32, 95% Confidence Interval [CI]: 2.37-4.64). This association was significantly attenuated after adjusting for age, gender, and household income. Although results were non-significant, there were reversed patterns of association by length of stay in the U.S.: odds of diabetes was highest for those with low education among those living in the U.S. < 10 years only.

Conclusion: There was a clear education gradient in diabetes prevalence among foreign-born Asian Americans and suggested variability by length of stay. Future research should consider the role of education and nativity status in this population to reduce diabetes risk and improve diabetes management.

EFFECTS OF RESIDENTIAL RELOCATION ON SYSTOLIC BLOOD PRESSURE AND PSYCHOSOCIAL WELLBEING

Charlotte Roddick, MA, The University of British Columbia, 2019¹, Chelsea Christie, MA, Frances Chen, PhD, Stanford University, 2009¹¹The University of British Columbia, Vancouver, BC, Canada

Background: Moving or moving frequently is associated with higher rates of cardiovascular disease (CVD) and mortality. A plausible mechanism by which residential relocation may impact health is through disrupting established social networks. Social relationships have a large influence on long-term health outcomes, but it is not clearly established whether or how social disruption resulting from a relocation influences short-term health. This pilot study examines whether moving to a new city is associated with increased CVD risk, and whether the extent to which movers rebuild their social network after relocating predicts improved CVD risk and psychosocial wellbeing.

Methods: Two participant groups were recruited: healthy adults who had moved to the city of Vancouver, Canada in the previous 6 weeks ("movers", $n = 26$, 13 male, $M = 30.62$ years, $SD = 7.35$) and age-matched healthy adults who had lived in Vancouver for at least 5 years ("non-movers", $n = 20$, 7 male, $M = 31.45$ years, $SD = 7.10$). Data were collected at 2 timepoints: at the beginning of the study (T1) and 3 months later (T2). At each timepoint, measures of participants' social networks, psychosocial wellbeing, and blood pressure were obtained at a lab visit.

Results: Visual inspection of the data revealed that the upper quantile, median value, and lower quantile of systolic blood pressure for the movers were all higher than those of the non-movers. A regression analysis controlling for age, gender, and waist-to-hip ratio indicated a statistical trend for movers to have higher systolic blood pressure at T1 ($M = 107.42$, $SD = 11.39$), compared to non-movers ($M = 102.37$, $SD = 10.03$), $\beta = .25$, $t(40) = 1.73$, $p = .092$. Further regression analyses revealed that among movers, increases in social network size over a 3-month period predicted decreases in systolic blood pressure, $\beta = -.70$, $t(14) = -3.34$, $p = .005$, controlling for covariates. There were also trends for increases in movers' social network size to predict decreased stress, $\beta = -.44$, $t(17) = -2.03$, $p = .058$, and decreased depression, $\beta = -.41$, $t(17) = -1.86$, $p = .081$, at the 3-month follow-up.

Conclusions: This pilot study provides preliminary evidence for increased systolic blood pressure, a marker of CVD risk, among recent movers and suggests that this increased risk is mitigated by the extent to which individuals rebuild their social network in the months following their relocation. The findings indicate that large-scale longitudinal research on the effects of residential relocation and social integration into a new community on physical health is warranted.

EFFECT OF A DIGITAL MINDFULNESS INTERVENTION ON NEGATIVE AND POSITIVE AFFECT: DOES EARLY LIFE ADVERSITY MATTER?

Elena Fromer, BS¹, Joanna Guan, BA¹, Julie Vaccaro, BS¹, Sarah M. Fisher, BA², Jonathan Torres-Espinoza, BS¹, Rachel M. Radin, PhD³, Stefanie E. Mayer, PhD¹, Elissa S. Epel, PhD¹, Aric Prather, PhD¹

¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA; ³Osher Center for Integrative Medicine, San Francisco, CA

Individuals exposed to adverse childhood experiences are more likely to experience poor psychological functioning, including persistent reports of negative affect. Mindfulness meditation interventions can be effective in reducing negative affect and improving positive affect; however, it is unknown whether early life adversity moderates this effect. In the current analysis, we examined this question in a rigorous digital mindfulness RCT among employees at a large public university.

This study included participants with moderate-to-high levels of perceived stress (Perceived Stress Scale score greater than or equal to 15) who denied a regular sitting meditation practice. Participants were randomly assigned to one of two conditions: digital mindfulness meditation (n=508) or waitlist control (n=534). Participants in the intervention group were given access to the online application (HeadspaceTM) and asked to complete 10-minute meditation sessions daily for 8 weeks. We assessed early life adversity (e.g., trauma, abuse, household dysfunction) using the Adverse Childhood Experiences (ACE) Questionnaire, and positive and negative affect with the State Affect Scale at baseline and 8-week post randomization. In this analysis we tested the effects of treatment on changes in negative and positive affect as well as the moderating effect of ACE score.

Analyses revealed, as expected, participants who reported a greater trauma history (i.e., higher ACE score) reported at baseline greater negative affect ($r=0.16$) and lower positive affect ($r=-0.12$). With respect to treatment effects, those randomized to the digital meditation showed greater decreases in negative affect ($p<.0001$) and greater increases in positive affect ($p<.0001$) at follow-up compared to waitlist. However, ACE scores, which ranged from 0 to 10 in this sample, did not moderate either of these effects.

These results from this trial indicate that while randomization to the digital meditation condition resulted in a reduction in negative affect and improvements in positive affect, this did not vary as function of ACE score. This suggests that digital meditation is similarly effective regardless of prior trauma history. This is important as digital mindfulness meditation is easily accessible, and thus a scalable method for improving psychological well-being.

IMPROVING QUALITY OF LIFE AND MENTAL HEALTH OF A LOW INCOME COMMUNITY IN A COLOMBIAN CITY: AN EVIDENCE-BASED INTERVENTION

Wendy E. Vera, n/a¹, Andres Vásquez, n/a¹, Mariantonia Lemos, PhD²

¹Universidad EAFIT, Medellín, Antioquia, Colombia; ²Universidad EAFIT, Medellín, Antioquia, Colombia

Background: La Cruz neighborhood is located in the peripheral area of Medellín City and it mostly consists of national migrants that were forcefully displaced from their original homes. The majority of its inhabitants have low socioeconomic status and earn formal or informal salaries below minimum wage. The neighborhood has a small school and few recreational spaces, among those a small library called “Sueños de Papel”. The purpose of this study was to assess the impact of the creation of the library and an evidence-based intervention (EBI) developed according to the needs this specific community presented.

Method: Stage 1 consisted of measurement taking in order to diagnose and evaluate the needs present in the community. In this stage we evaluated 34 people that had visited the library and 49 that hadn't. Upon this results we proceeded to design promotion and prevention programs, based on different behavior change models (Protection Motivation Theory, Reasoned Action Approach). Stage 2 consisted of the application of these programs during the second semester of 2018 and the first semester of 2019. Subjects treated during these workshops were: prevention of violence towards women, sexual education, social media management, promotion of secure attachment, parenting styles and first aid. On stage 3, during the second semester of 2019 posttest measurements were taken in order to evaluate the workshop and library's impact on the community.

Results: showed a statistically significant increase in the personal development scale (Wilcoxon = 248.50, $p < 0.05$); and non-significant increase in the other scales of Quality of Life. Regarding neighborhood perception, statistically significant changes in safeness (Wilcoxon = 2032.50, $p < 0.05$), social change (Wilcoxon = 1937.50, $p < 0.05$) and total test score (Wilcoxon = 2264.00, $p < 0.01$). Finally, a decrease in depression (Wilcoxon = 986.00, $p < 0.01$) and its prevalence from 28.9% a 9.6%. Anxiety did not present any changes.

Conclusion: The creation of a common space in this type of communities can provide a gathering place for inhabitants and a space that can be used for EBIs, which did not exist previously in the neighborhood. Additionally, given the urgency and characteristics of this type of communities EBIs can be considered a very effective and reliable way to intervene problematic issues within them.

EFFECTS OF AUTONOMY SUPPORT, DIET AND EXERCISE SUPPORT, & ACCOUNTABILITY ON WEIGHT LOSS OUTCOMES IN A TRIAL INVOLVING LAY COACHES

Kayla F. O'Connor, B.S.¹, Amy A. Gorin, Ph.D.², Andrea Grenga, B.A.³, Zeely A. Denmat, B.S.⁴, Tricia M. Leahey, Ph.D.²¹University of Connecticut, Springfield, MA; ²University of Connecticut, Storrs, CT; ³Weight Control and Diabetes Research Center, Cranston, RI; ⁴UConn Weight Management Research Group, Hartford, CT

Social factors, such as Autonomy Support (AS) and Diet and Exercise Social Support (Diet/Exercise SS), are known to facilitate weight loss. AS is defined as providing options, empathy, and information to foster behavior change. Diet/Exercise SS are defined as receipt of help and positive reinforcement from social contacts for healthy eating and activity, respectively. Notably, accountability (feeling responsible to others) has not been explicitly examined for weight loss. The purpose of this study was to determine the relative contributions of AS, Diet/Exercise SS, and Accountability on behavioral weight loss (BWL) outcomes. Further, given that these constructs have never been simultaneously examined within the lay coach literature, we investigated whether individuals assigned lay coaches (vs. not) report higher levels of these social influence factors. Data for this study are from a randomized BWL trial examining the effects of lay coaches. All participants (N=278, 75.9% female, 51.8±5.6 years) received a 12-month group BWL program and were randomized to a peer coach (two individuals actively trying to lose weight and supporting one another), mentor coach (successful weight losers who support individuals just starting to lose weight), or no coach. AS, Diet/Exercise SS, and Accountability for weight management were assessed using valid and reliable measures. Weight was objectively assessed. Collapsing across treatment arms, results showed that improvements in AS, Diet SS, and Accountability from treatment start to 12-month predicted 12-month weight losses ($p < .02$), and the relative contribution of each was similar (variance explained was small and ranged from $R^2=0.04-0.07$). In terms of treatment arm differences, the mentor arm had significantly greater improvements in accountability during treatment (Mentor: +0.5±1.8) compared to the peer and no coach arms (Peer: -0.3±1.9, No Coach: -0.4±2.0, $p = .003$), with peer and no coach not significantly different from one another ($p = 0.31$). Similarly, the mentor arm had the greatest increase in Diet SS during treatment, followed by the peer arm, and then the no coach arm ($p < .03$; Mentor: +1.2±0.9, Peer: +0.9±0.8, No Coach: +0.5±0.9). Results suggest that AS, Diet SS, and accountability are key social factors associated with improved BWL outcomes. The addition of lay coaches to BWL treatment is a promising strategy for increasing perceived support and accountability over time.

RELATIONSHIP BETWEEN SOCIAL NETWORKS AND FEELINGS OF LONELINESS DURING PREGNANCY

Qihan Yu, n/a¹, Sydney Miller, B.S.², Aimee Fata, MPH³, Nenette Caceres, MS³, Sara Mazzoni, MD⁴, Sarah-Jeanne Salvy, PhD³¹Cedars-Sinai Medical Center, Los Angeles, CA; ²University of Southern California, Los Angeles, CA; ³Research Center for Health Equity, Cedars-Sinai Medical Center, West Hollywood, CA; ⁴UAB Department of Obstetrics and Gynecology, Division of Maternal-Fetal Medicine, Birmingham, AL

Objective: Evidence garnered over the last 30 years suggests that both social isolation (objective number of social relationships and frequency of contact) and loneliness (the perception that one's social needs are not being met by the quantity or quality of one's social relationships) are detrimental to one's psychological, emotional and physical health. Most of this research has been conducted in adults and less is known about the influence of social relationships during pregnancy. This longitudinal study examines the relationships between social network size (number of relationships), social network density (interconnections between ties in the network) and feelings of loneliness during pregnancy.

Methods: Pregnant women completed study measures once during their first trimester (dating ultrasound, 20 gestational weeks) and again in their third trimester (28-40 weeks). Study measures included interviews and questionnaires assessing characteristics of their social networks (e.g., size and density) and feelings of loneliness (UCLA Loneliness Scale). A linear regression was used to analyze associations between social network size, density and maternal loneliness at each time point. Models controlled for participant's baseline age, race/ethnicity, insurance type, and relationship status.

Results: A total of 94 pregnant women (mean age=23.77, 70.2% Black, 87.2% public insurance, 83% in a relationship/married) completed both assessment time points. Social network size (number of relationships named) during the first trimester did not predict maternal loneliness during the first (= -0.078, 95%CI -0.094-0.087, $p = 0.938$), or third trimester (= 0.754, 95%CI -0.073-0.161, $p = 0.454$); however, mothers' social network density (interconnections between ties in the network) was inversely related to maternal loneliness during the first trimester (= -2.163, 95%CI -3.929-0.165, $p = 0.033$), but not during the third trimester (= -2.73, 95%CI -2.814-2.140, $p = 0.786$).

Conclusions: Social network density was significantly associated with maternal loneliness only in the first trimester of pregnancy. Size and density of social networks do not predict loneliness in the third trimester. Future studies are needed to understand the relationship between social networks attributes, loneliness and perinatal outcomes.

EXPLORING THE INTERACTIVENESS OF THE SOCIO-ECOLOGICAL MODEL'S LEVELS FOR PHYSICAL ACTIVITY IN GERMAN YOUTHS

Carina Mnich, BA¹, Claudio Nigg, PhD¹, Darko Jekauc, n/a², Hagen Wäsche, n/a¹, Steffen C. Schmidt, n/a³, Alexander Woll, Professor⁴¹Karlsruhe Institute of Technology, Karlsruhe, Baden-Württemberg, Germany; ²Karlsruhe Institute of Technology, Institute for Sports and Sport Science, Karlsruhe, Baden-Württemberg, Germany; ³Karlsruhe Institute of Technology, Karlsruhe, Baden-Württemberg, Germany; ⁴Karlsruher Institut of Technology, Karlsruhe, Baden-Württemberg, Germany**Background:** Socio-ecological models (Sallis et al., 2008) have been commonly used to inform physical activity (PA) interventions, targeting the individual, social, community, environment, and policy level. While each of these levels has been associated with PA, less is known about the interaction between them. Thus, this study investigated 1) to what extend model components predict PA and 2) how the components interact over time.**Methods:** Data was obtained of the German national representative MoMo Cohort Study waves 1 and 2 (T1: 2009-2012; T2: 2015-2017). Participants filled in validated questionnaires assessing PA enjoyment and physical self-concept (individual level), social support and socio-economic status (SES) (social level), PA environment and community size (environment level), and PA T2. A path panel prediction model was set-up in three steps: Model 1: T1 variables predicting PA, Model 2: T1 and T2 variables predicting PA, Model 3: adding cross-lags between T1 and T2 variables (e.g. between community size and social support).**Results:** 1,457 participants were included in the analysis (55.1% female, AgeT1=15.60 [SD=3.50], AgeT2=20.83 [SD=3.64]). Model 1 showed a bad model fit ($\chi^2=146.0$; $df=12$; $p<.01$; CFI=.889; RMSEA=.088; $R^2=15.8$). In Model 2, model fit and explained variance improved by adding T2 variables ($\chi^2=360.4$; $df=54$; $p<.01$; CFI=.948; RMSEA=.062; $R^2=30.3$). Explained variance slightly improved by adding the cross-lags in model 3 ($\chi^2=243.9$; $df=25$; $p<.01$; CFI=.963; RMSEA=.078; $R^2=32.2$). Stability paths were added from T1 to T2 variables. Cross-variable interactions within the model's levels were found for: community size predicting PA environment ($b=.09$), SES predicting social support ($b=.07$), and enjoyment predicting physical self-concept ($b=.12$). Cross-level interactions across the model's levels were found for PA environment ($b=.07$) and social support ($b=.07$) predicting enjoyment, SES ($b=.04$) and social support ($b=-.06$) predicting community size, physical self-concept predicting SES ($b=-.09$), and enjoyment predicting social support ($b=.07$). In all models, significant PA predictors were only found on the individual and social level.**Conclusion:** Adding cross-lags into the prediction models helps to understand the directions of social-ecological inter-level relationships. The findings indicate that the lower levels are more likely to influence the higher levels. Possible explanations include the individual agency and the actor's influence on his/her social and/or physical environment. However, these findings need to be replicated and confirmed, using other samples, behaviors, and variables.

Funding: Federal Ministry of Education and Research [01ER1503].

HOW DOES STIGMA INFORM SEXUAL AND GENDER MINORITY HEALTH INTERVENTIONS? A SYSTEMATIC REVIEW

Joseph A. Carter, MA¹, Eric K. Layland, MS², Nicholas Perry, PhD³, Jorge Cienfuegos Szalay, MPH¹, Kimberly M. Nelson, PhD, MPH⁴, Courtney Peasant Bonner, PhD⁵, H. Jonathon Rendina, PhD, MPH⁶¹The Graduate Center, City University of New York (CUNY), New York, NY; ²Pennsylvania State University, University Park, PA; ³Brown University, Warren Alpert Medical School, Providence, RI; ⁴Boston University School of Public Health, Boston, MA; ⁵RTI Global Gender Center, New York, NY; ⁶Hunter College and The Graduate Center, CUNY, New York, NY**Background:** Health disparities among sexual and gender minorities (SGM) are driven in part by societally imposed, and heteronormatively informed experiences of stigma. These health disparities are worse among SGM who hold multiple marginalized identities. To achieve equity in health outcomes, research examining empirical psychological and behavioral interventions that address SGM stigma, particularly from an intersectional perspective, are vital. We conducted a systematic review to explore how existing interventions address stigma, and examine whether stigma affects intervention efficacy.**Methods:** This systematic review encompassed existing psychological and behavioral health interventions among SGM

populations. Eligible studies were peer-reviewed, published in English from 2003 onward, and reported empirical results of a behavioral or psychological intervention that address stigma and were implemented among SGM populations.

Results: We identified 37 interventions, most of which were conducted among sexual minority men ($n=28$). Most interventions were tailored or adapted for the unique needs of SGM ($n=28$). The majority ($n=26$) targeted proximal stigma (e.g., internalized, anticipated). Fewer ($n=20$) addressed distal stigma (e.g., enacted, structural). Eleven studies addressed stigma in the content of the intervention, but did not directly measure or intervene on stigma as an outcome. The most common targeted outcomes were HIV transmission ($n=20$), health among people living with HIV ($n=4$), and mental health ($n=7$). Interventions rarely examined stigma as mediating or moderating intervention effects ($n=5$). Seventeen interventions applied an intersectional framework or targeted additional sources of stigma beyond SGM stigma.**Conclusion:** Interventions are increasingly considering health disparities within the context of stigma. Future research should explore whether stigma affects the efficacy of currently existing psychological and behavioral interventions. Further, interventions may benefit from an intersectional approach to examining SGM stigma. The majority of interventions in our review focused on cisgender sexual minority men, with few considering intersecting sources of stigma related to racial/ethnic or gender minority status. Application of an intersectionality framework will be important for intervention development that effectively targets multiple, intersecting sources of stigma among SGM communities.

FACETS OF SOCIAL SUPPORT AND SEDENTARY BEHAVIORS: PROSPECTIVE FINDINGS IN MOTHER-CHILD DYADS

Monika Boberska, MA¹, Karolina Horodyska, PhD², MAGDALENA KRUK, MA³, Ewa Kulis, MA¹, Zofia Szczuka, MA², Karolina Lobczowska, M.A.², Aleksandra Luszczynska, PhD¹

¹SWPS University of Social Sciences and Humanities, Warsaw, Mazowieckie, Poland; ²SWPS University of Social Sciences and Humanities, Wrocław, Dolnoslaskie, Poland; ³SWPS University of Social Sciences and Humanities, WROCLAW, Dolnoslaskie, Poland

Background: There is an abundance of evidence for the significant associations between facets of social support, social control, and behavior change, especially in eating and physical activity area (Edwardson & Gorley, 2011). However, the majority of research focused on within-individual associations, whereas dyadic effects are less clear. The aim of this study was to investigate prospective associations between received and provided collaborative social control, social support and social support satisfaction and the outcome variables, sedentary behaviors (SB) and the number of active breaks in mother-child dyads.

Method: Data from mother-child dyads ($N = 107$; maternal $M_{age} = 41.1$, child $M_{age} = 11.4$) were collected at the baseline (Time 1; T1) and at the 1-month follow-up (Time 2; T2). Mothers and children reported their SB, the number of active breaks, and social support/control variables. Path analysis was performed to test the hypothesized associations.

Findings: Path analysis indicated that received collaborative social control (reported by children; T1) predicted a higher number of active breaks in children (T2). In turn, received social support (reported by children; T1) predicted a lower number of active breaks among children (T2). Additionally, received collaborative social control and received social support reported by children (T1) predicted on child support satisfaction (T2). There were no dyadic (parent-child) effects.

Discussion: Although within-person effects were found for children, the hypothesized dyadic effects were not confirmed. The positive effect of collaborating social control, accompanied by a negative effect of received support on the number of active breaks, may be explained by the reactance effect.

CROSS-SECTIONAL EXAMINATION OF FOOD INSECURITY WITH BEHAVIORAL AND PSYCHOSOCIAL FACTORS AMONG RESIDENTS OF PUBLIC HOUSING

Lisa M. Quintiliani, PhD¹, Jessica A. Whiteley, PhD², Jessica Zhu, n/a³, Emily Sisson, MA⁴, Jennifer Murillo, BA and Master's candidate⁵, Ramona A. Lara, BA in Law⁶, John Kane, n/a⁷

¹Boston University, Boston, MA; ²UMass Boston, Boston, MA; ³Boston University, Brighton, MA; ⁴Boston University School of Public Health, Boston, MA; ⁵Boston Medical Center, Boston, MA; ⁶Boston Medical Center, Hyde Park, MA; ⁷Boston Housing Authority, Boston, MA

Background: There may be associations between those who experience food insecurity, diet/sleep behaviors, and psychosocial/physical factors, information which could help design effective weight management programs for low-income populations.

Purpose: To examine differences in behavioral, psychosocial, and physical factors between those who were food secure compared to food insecure among public housing residents who were overweight/obese.

Methods: Data were from the baseline survey of a randomized controlled trial of a weight management intervention. Food insecurity, behavioral factors, including diet and sleep, and other psychosocial and physical factors, including perceived stress, sleep, social support, and physical symptoms, were measured via interviewer-administered screeners.

Results: Mean age of the sample ($n=102$) was 46.5 years ($SD=11.9$). The majority were Hispanic (67%), female (88%), with high school degree (62%). Nearly half were food insecure (48%). Compared to the food secure group, food insecurity was not significantly associated with a diet composite score nor intake of sugar sweetened beverages. For psychosocial variables, those who were food insecure had higher ratings of perceived stress (adjusted mean difference 3.39, 95% CI:2.00,4.79) and lower social support (adjusted mean difference -0.70, 95% CI:-1.36,-0.11) compared to those who were food secure. For behavioral and physical variables, those who were food insecure had lower odds of feeling rested often/very often (aOR 0.42, 95% CI:0.18,0.98) and higher odds of reporting negative physical symptoms (aOR 4.92, 95% CI:1.84,13.16).

Conclusions: Among this sample of public housing residents, food insecurity was associated with poor sleep, higher stress, higher experiences of physical symptoms, and lower social support. Intervention planners targeting food insecurity among residents of public housing should consider assessing and addressing multifactorial challenges faced by low income residents, taking into account possible contributing factors such as stress, social support, and sleep difficulties.

EFFECTS OF DIGITAL MINDFULNESS INTERVENTION ON MENTAL HEALTH AND WORK STRESS: PRELIMINARY FINDINGS FROM THE STRESS FREE UC STUDY

Julie Vaccaro, BS¹, Jonathan Torres-Espinoza, BS¹, Sarah M. Fisher, BA², Elena Fromer, BS¹, Joanna Guan, BA¹, Elissa S. Epel, PhD¹, Aric Prather, PhD¹¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA

Introduction: Work-related stress is highly prevalent and contributes to poor mental and physical health. A growing body of evidence supports mindfulness meditation to improve well-being in workplace settings; however, traditional in-person practice cannot be easily scaled. In this study, we tested the effects of an 8-week digital meditation program compared to waitlist control on self-reported mental health and work-related outcomes in a large sample of generally healthy university employees.

Methods and Materials: We enrolled 1,128 participants, all with reported perceived stress scale scores (Cohen et al., 1983) of greater than or equal to 15, and not already regular meditators. Participants were randomized to the intervention, (n=544) or waitlist control (n=584) condition for 8 weeks. The intervention was delivered entirely via a self-guided smartphone application (HeadspaceTM). Those in the meditation group were instructed to listen to 10 minute audio sessions per day. The following measures were collected at baseline and 8-weeks post-randomization to test treatment effects on mental health: Perceived Stress Scale (PSS), Patient Health Questionnaire-9 (PHQ9), Generalized Anxiety Disorder-7 (GAD7); and work-related outcomes: Siegrist Effort-Reward Imbalance Scale, Bergen Burnout Inventory, Utrecht Work Engagement Scale. We used linear mixed models to test intervention effects and tested whether treatment adherence served to moderate any intervention effects.

Results: Groups did not differ at baseline on any of the key measures of interest. Analyses revealed that participants randomized to the digital meditation intervention showed statistically significant improvements in measures of distress (perceived stress, symptoms of depression and anxiety), work related stress (burnout, effort-reward imbalance), and work engagement (all p 's < 0.001) compared to the waitlist control condition. Adherence to the meditation treatment moderated many of the results such that more frequent meditation was associated with greater benefits.

Discussion: Findings from this RCT suggest that a digital mindfulness meditation delivered to a healthy population of university employees has the potential to improve outcomes related to workplace stress and mental wellbeing. Strengths of this intervention were that it was self-guided and scaleable. If sustained over time, these effects may have implications to relieve burnout risk and healthcare costs.

MANAGING CHRONIC MEDICAL PROBLEMS IN THE CONTEXT OF UNIVERSITY LIFE: A LONGITUDINAL QUALITATIVE STUDY

Lucy Finkelstein-Fox, M.S.¹, Rachel Abraham, n/a¹, Allison Ferro, n/a¹, Emily Waddington, B.S.¹, Crystal L. Park, PhD²¹University of Connecticut, Storrs, CT; ²University of Connecticut, Storrs Mansfield, CT

Despite the common conception that college is a time of relative freedom and ease, up to a third of college students report long-standing illness that may limit their participation in academic and extracurricular life (Herts, Wallis, & Maslow, 2014; Stewart-Brown et al., 2000). Navigating university life with a chronic illness is undoubtedly challenging, but little research has characterized the stressful experiences of this unique group, such as the domains in which students experience stress and the variability of stressful experiences over time. Because students with chronic illness report considerable difficulties during college and well into adulthood (Maslow et al., 2011), researchers and clinicians must learn more about the everyday stressful experiences of students during their time on campus in order to promote immediate and long-term adjustment.

The present study assessed the stressful experiences of 144 undergraduate and graduate students with self-reported chronic medical conditions. The average participant was 20.9 years old (range = 18-41). Most were female (83.7%), White (74.8%), non-Hispanic (91.1%), and enrolled as an undergraduate student (81.5%). Students reported diagnoses related to digestive disorders (15.3%), asthma (13.2%), and headache/chronic pain (10.4%), with an additional 23.6% reporting multiple illness types. Participants completed three online surveys, spaced two weeks apart. At all timepoints, participants responded to an open-ended prompt, "In a few words, please describe the most stressful part of your illness(es) over the past 2 weeks." A grounded theory approach (Corbin & Strauss, 1990) was used to develop an initial codebook of stressor types. Coding differences were discussed among a group of three coders and the codebook was iteratively revised.

Qualitative responses illustrate the myriad stressful experiences of students with chronic illness, spanning multiple domains of university life. Fourteen distinct illness-related stressor types were identified, including: 1) symptom/pain flare-up; 2) sleep/fatigue problem; 3) diet/eating; 4) preventative health; 5) medication/equipment management; 6) barriers to receiving treatment from the medical system; 7) rumination/uncertainty about the future; 8) self-esteem; 9) concentration/attention; 10) general mental health concerns; 11) social embarrassment/isolation; 12) academics/productivity; 13) other restricted activities of daily living; and 14) none. However, most responses spanned multiple stressor types (e.g., social embarrassment about eating). Further, the types of experiences identified as most stressful varied substantially across occasions. These findings suggest that students with chronic illness may benefit from programming to enhance social connection, reduce stigma, and address academic concerns, in addition to traditional medical care.

DOES ESTRADIOL POTENTIATE THE ANXIOLYTIC EFFECTS OF OXYTOCIN IN WOMEN AND MEN?

Jessica A. Marino, B.A.¹, Jennifer Hahn-Holbrook, PhD¹, Colin Holbrook, PhD², Ian Nel, BA³, Julianne Holt-Lunstad, PhD⁴¹University of California, Merced, Merced, CA; ²University of California, Merced, Catheys Valley, CA; ³University of South Florida, Tampa, FL; ⁴Brigham Young University, Provo, UT

Background: Anxiety and mood disorders are twice as common in women compared to men, suggesting that fluctuations in reproductive-related hormones, such as estrogen (E2) and oxytocin (OT), may play a role in these sex differences. However, until recent decades, the endocrinology of stress-responses has almost exclusively been assessed in males. Despite this, decades of animal research suggest that there are complex sex differences in the endocrine control of stress physiology. Here, we sought to explore how OT impacts stress in human men and women, and to test whether E2 potentiates the effect of OT in reducing stress.

Methods: Using a randomized double-blind design, 85 healthy adult men and women were randomly assigned to receive intranasal OT or placebo, and then psychological and physiological measures of stress were given in the context of an aggressive encounter with a stranger. Physiological measures included salivary E2, salivary cortisol, blood pressure (BP), heart rate and heart rate variability taken before, during, and after the stressful task. Psychological stress measures included the Positive and Negative Affect Schedule Scales (PANAS), Perceived Stress Scale (PSS), and Aggression Questionnaire (AQ).

Results: Regression models showed significant three-way interactions between E2, participant sex, and OT condition in all of the psychological markers of stress (PSS: $\beta = -4.321$, $p < .001$; PANAS, positive: $\beta = 4.027$, $p < .001$; PANAS, negative: $\beta = -5.126$, $p < .001$; AQ: $\beta = -2.576$, $p < .05$) and several physiological markers of stress (Diastolic BP: $\beta = 2.648$, $p < .05$; Systolic BP: $\beta = 2.221$, $p < .05$). Specifically, women who had higher E2 levels reported less negative affect, more positive affect, and lower perceived stress in the OT condition but not in the placebo condition. Conversely, males with higher levels of E2 reported higher psychological stress when given OT (but not placebo). Physiological markers of stress were less consistently modulated by sex, E2 and OT.

Conclusion: Estradiol potentiates anxiolytic effects of OT in women, but has the opposite effect in men. Our findings add to a growing body of research reporting sex differences in the effects of OT administration in humans, and highlight the need for further research on how interactions between endocrine factors moderate sex-differences in stress responses.

CHANGING STRESS MINDSETS TO IMPROVE HEALTH AND PERFORMANCE WITH A NOVEL IMAGERY INTERVENTION: A RANDOMIZED CONTROLLED TRIAL

Jacob J. Keech, BPsych(Hons), PhD Candidate¹, Martin S. Hagger, PhD², Kyra Hamilton, PhD³¹Griffith University, Mt Gravatt, Brisbane, Queensland, Australia; ²University of California, Merced, Merced, CA; ³Griffith University, Mt Gravatt, Queensland, Australia

Objective: Changing individuals' beliefs about the consequences of experiencing stress, stress mindset, has emerged as a technique for promoting adaptive outcomes under stress. This technique may be particularly valuable given the potential malleability of stress mindset through brief non-clinical interventions. However, there is limited data on the effect of these interventions on the management of "real-world" ecological stressors. The current pre-registered study aimed to evaluate the effectiveness of a novel imagery-based intervention for changing stress mindset, and for improving key stress-related outcomes.

Methods: University students visited a research lab twice over a two-week period ($N = 150$). The intervention was delivered following baseline measures in Session 1, and follow-up measures were taken in Session 2. Measures were perceived distress, psychological wellbeing, positive and negative affect, perceived physical health, proactive coping behavior, perceived somatic symptoms, and academic engagement. Objective academic performance data were also retrieved from university records. The intervention was pilot tested prior to the trial and was delivered using videos that provided information about stress, followed by guided imagery exercises. The control group received only a practice guided imagery exercise not related to stress. Data were analyzed using mixed design ANOVAs.

Results: The intervention had a large effect on stress mindset immediately post-intervention, and at the two-week follow-up, relative to the control group. There were no effects of the intervention on the stress-related outcomes for the pre-registered analyses of the whole sample. Further theory-guided analyses revealed robust effects of the intervention on positive and negative affect, perceived distress, proactive coping behavior, and academic performance at the follow-up in participants who had high levels of perceived distress at the baseline.

Conclusions: Findings reveal that the intervention is a promising approach for changing stress mindset, and that stress mindset can improve wellbeing and performance in those experiencing high levels of perceived distress. Future research should seek to replicate these findings and employ intensive longitudinal designs to examine momentary activation of stress mindset and its relationship with key stress-related outcomes following the intervention.

DIFFERENCES IN CANNABIS WITHDRAWAL SYMPTOMS FOR MEN AND WOMEN OVER 21 DAYS

Margaret F. Bedillion, M.S.¹, Emily B. Ansell, Ph.D.²¹The Pennsylvania State University, State College, PA; ²The Pennsylvania State University, University Park, PA

Background: There is emerging consensus that women are at greater risk for more rapidly developing cannabis use disorders and subsequently seeking treatment. Identifying factors that may contribute to the cannabis telescoping effects is an important avenue for further investigation. Prior research suggests that women have a greater sensitivity to the effects of cannabis and may be at a greater risk for adverse outcomes related to cannabis-related consequences. Sex differences may directly impact cannabis withdrawal symptom expression, regardless of frequency and quantity of use. However, no prior research has examined whether withdrawal symptoms vary between men and women when considering naturalistic use patterns in daily life.

Methods: Two hundred and twenty-six recreational and regular cannabis users were recruited for the study and 216 were included in the present analyses due to attrition. Recreational users reported using cannabis on two or more occasions on average per month for the past 6 months and regular users reported a minimum of three times weekly cannabis use for the past 6 months. The mean age of the participants was 21 years old. The sample was 57% female and 43% male. Participants completed the Cannabis Use Disorders Identification Test (CUDIT), the cannabis use disorder (CUD) module of the SCID at baseline followed by three weeks of momentary reports on cannabis use and withdrawal symptoms as part of a smartphone based ecological momentary assessment (EMA).

Results: Withdrawal symptoms, number of days cannabis was consumed, and number of hits of cannabis consumed were calculated from the EMA reports. A one-way ANOVA was performed to examine sex differences in cannabis use, hazardous use, and withdrawal symptoms. Men and women did not differ in number of days used or hits consumed over the 21 day assessment period, nor did they differ in the number of CUD criteria met. However, men reported higher levels of hazardous cannabis use than women at baseline. In addition, women reported higher levels of withdrawal symptoms over the course of the EMA study. **DISCUSSION:** These results support the hypothesis that women are particularly susceptible to cannabis withdrawal symptoms, even within naturalistic longitudinal reports. This tendency to experience more withdrawal symptoms may account for the telescoping effects previously observed for CUD in women. In addition, it is important to note that women reported significantly lower CUDIT scores than men. This suggests that the experience of withdrawal symptoms may be independent of hazardous use. Future research should examine whether additional factors may better inform models of risky cannabis use in women.

DECREASED DAILY QUALITY OF SLEEP WAS ASSOCIATED WITH INCREASED DAILY CANNABIS CRAVING IN RURAL TEENS THAT REGULARLY USE CANNABIS

Maria Drakulich, B.S.¹, Tori Humiston, M.S.¹, Kylie Hill, n/a¹, Catherine Stanger, Ph.D.², Alan Budney, Ph.D.³, Amy Hughes Lansing, Ph.D.¹¹University of Nevada, Reno, Reno, NV; ²Dartmouth College, Lebanon, NH;³Dartmouth College Geisel School of Medicine, HANOVER, NH

Introduction: Cannabis is the most commonly used illicit drug in the United States, and its rate of use, unlike other substances, has not decreased amongst teenagers. Among adolescents that regularly use cannabis, craving is an important predictor of use patterns and failures to abstain from use. Adolescence is also a developmental period where sleep duration and quality are disrupted. Studies have supported associations between cannabis use and sleep but not examining daily variation in sleep quality and cannabis craving among adolescents that regularly use. It was hypothesized that poorer daily sleep quality would be associated with increased daily cannabis craving among rural adolescents that regularly use cannabis.

Methods: Adolescents aged 15-18 (n=1, 46% female) from rural communities who endorsed regular cannabis use in the last thirty days participated in an ecological momentary and passive sensing assessment for fourteen days, including reports of cannabis craving and cannabis use five times daily (averaged for each day) and reports on the prior night's sleep quality each morning. Correlation and multi-level modeling were used to test between and within person daily associations.

Results: Across the fourteen-day study period, worse average sleep quality was associated with increased cannabis craving ($r = -.70$, $p = .01$) but not percent of days with cannabis use ($r = .26$, $p = .39$). In a multilevel model, intraindividual increases in daily sleep quality ($b = .26$, $SE = .13$, $p = .05$) and between person poorer average sleep quality ($b = -2.94$, $SE = .85$, $p = .01$), but not prior day cannabis use ($b = -.01$, $SE = .38$, $p = .98$) were associated with increased cannabis craving.

Conclusion: Poorer average sleep quality predicts greater daily cannabis craving in rural adolescents who regularly use cannabis, while small daily increases in sleep quality above a person's average may also be associated with increased cannabis craving. Further research is needed to better understand the mechanisms linking daily sleep quality with cannabis craving to inform possible intervention approaches.

SUBSTANCE USE AND EXPERIENCED VIOLENCE AMONG FEMALE SEX WORKERS ON BOTH SIDES OF THE HAITI DOMINICAN REPUBLIC BORDER

K. Ria Hearld, PhD¹, John Waters, MD, MSc, MA (OXON)², Julia M. Hasbun, Licenciatura³, Macarena Martínez, Master in Public Health⁴, Amber Altaf, NA⁵, Henna Budhwani, PhD, MPH¹

¹University of Alabama at Birmingham, Birmingham, AL; ²Caribbean Vulnerable Communities Coalition, Santo Domingo, Distrito Nacional, Dominican Republic; ³CVC, Distrito Nacional, Santo Domingo, Distrito Nacional, Dominican Republic; ⁴UAB, Birmingham, AL; ⁵Princeton University, Hoover, AL

Background: Studies that examine behaviors of populations that live and work on a geographic border are scarce, studies that evaluate the behaviors of those who make a living at the border, such as sex workers and day laborers are even fewer. Border studies are scientifically valuable, as they can highlight the intersections of psychological factors, with sociological ones, along with the influences of public health and medical care. Considering the value of these studies, we explored experiences of violence, abuse, and substance use (a coping mechanism) in Haitian sex workers living and working on the border of the Dominican Republic (DR) and Haiti, two nations that share one island.

Methods: Data for this study was from the 2015 Baseline Study on Sex Workers (N=232). We used bivariate analyses to compare outcomes between sex workers of both sides of the border. Multivariable analyses applied location as a control; we reported associations across three measures of physical violence.

Results: We found significant differences between sex workers in our bivariate and multivariate analyses. Sex workers in the Haiti were less likely to experience violence from regular partners relative to sex workers in the DR (OR=0.37, $p < 0.05$); conversely sex workers in Haiti were more likely to experience violence from co-workers (OR=6.38, $p < 0.001$). When including controls, higher education was protective against certain violence ($p < 0.001$). Alcohol use and physical abuse in childhood were statistically predictive of experiencing violence regardless of work location (OR=6.40, $p < 0.001$; and 2.82, $p < 0.01$; respectively).

Conclusions: We find that sex workers on both sides of the DR-Haiti border are victimized, abused, and may cope through substance use. The DR is upper-middle income; Haiti is considered a low-income nation, and these classifications are often associated with population health. However, we find varying rates of violence and substance use, reflecting the possible influence of local culture. Further qualitative studies deconstructing these negative experiences could inform researchers and public health scholars interested in the intersection of psychological and sociological forces on behaviors of high-risk sex workers.

TESTING PATHWAYS BETWEEN NEIGHBORHOOD ENVIRONMENT AND ALCOHOL USE DISORDER IN MEXICAN AMERICAN YOUNG ADULTS

Christina Tam, PhD, MSW¹, Libo Li, PHD², Deidre Patterson, MPH, MAS³, Katherine J. Karriker-Jaffe, Ph.D.³

¹Alcohol Research Group, Public Health Institute, Emeryville, CA; ²Public Health Institute, Emeryville, CA; ³Alcohol Research Group/Public Health Institute, Emeryville, CA

Background: Hispanics born in the United States (US) have higher rates of alcohol use disorder (AUD) compared to those born in their ancestral country. Neighborhoods play a critical role in heavy drinking, with documented protective enclave effects (benefits of living in an area with many other Hispanic residents). For Mexican Americans (MAs), living in ethnic enclaves or in close proximity to the US-Mexico border may help them maintain their cultural identity and reduce acculturation stress. However, border proximity also can lead to high trauma rates given high violence prevalence in these areas. The current study tests associations of neighborhood factors (proportion MA, border proximity) with acculturative stress, ethnic identity and trauma, and, in turn, relationships with AUD in a sample of MA young adults.

Methods: Respondents were sampled from select areas of Southern California (N=622). They completed the Semi-Structured Assessment for the Genetics of Alcoholism and scales on acculturative stress and ethnic identity. Data were linked with neighborhood data from the American Community Survey. The sample was 23.7 years old on average and nearly 60% were female. About half (47.6%) met diagnostic criteria for lifetime AUD, and 40% reported at least one experience of significant lifetime trauma, with rates of both AUD and trauma higher among men. The average distance to a designated port of entry was 13.6 miles, and the average neighborhood proportion Mexican was 41.8%. Because of gender differences in AUD development, we performed multiple-group path analyses to test for differences in mediated effects.

Results: For women, neighborhood proportion Mexican was negatively associated with AUD ($\beta = -0.009$, $p < .05$) while acculturative stress ($\beta = 0.02$, $p < .01$) and trauma ($\beta = 0.17$, $p < .05$) were positively associated with AUD; border proximity and ethnic identity were not associated with AUD (both $p > .10$). For men, only acculturative stress was associated with higher AUD rates ($\beta = 0.02$, $p < .01$). Neither proportion Mexican nor border proximity were related to any of the hypothesized mediators, and all indirect pathways were not statistically significant (all $p > .10$).

Conclusions: Future research should consider other pathways to AUD in MA young adults. Interventions to reduce acculturative stress are indicated. Gender differences suggest trauma-informed AUD treatment may be beneficial for women. Intervention strategies also may need to reach women who live outside of enclaves to reduce the burden of AUD.

ISOLATION, LONELINESS AND OFF-LABEL DRUG USE AMONG RURAL RESIDENTS: SOCIAL MEDIA- AND MTURK-BASED SURVEYS

Sunny Jung Kim, Ph.D., M.S., M.A.¹, Tracy L. Onega, PhD, MA, MS², Jennifer Alford-Teaster, MA, MPH³, Jenna E. Schiffelbein, MPH, CHES⁴, Anna M. Adachi-Mejia, PhD⁵

¹Virginia Commonwealth University School of Medicine, Richmond, VA; ²Dartmouth College/ Geisel Medical School, Lebanon, NH; ³Dartmouth College, Lebanon, NH; ⁴Dartmouth College Geisel School of Medicine, Lebanon, NH; ⁵Geisel School of Medicine at Dartmouth, Lebanon, NH

Background: The current epidemic of off-label drug use and addiction is worsening in isolated rural communities, in particular, where residents experience loneliness and lack of social support. We examined an array of demographic and behavioral characteristics of rural residents to identify whether the magnitude of psychological deficit states (e.g., lack of social support, loneliness) are greater among rural residents with chronic pain and concurrent off-label drug use, compared to those without these conditions.

Methods: We used crowdsourcing and social media platforms to recruit residents in pre-designated rural states, and assessed demographic characteristics, chronic pain status, and their off-label drug use histories. For psychological deficit states, we measured perceived social support, loneliness, rurality attitudes, and attachment toward their residential community by adopting and modifying previously validated questionnaires. These four psychological constructs were analyzed across subgroups using Analysis of Variance and the inference by eye (IE) technique. We also performed structural equation modeling with maximum likelihood estimations to examine to how these psychological deficit states are related to drug abuse and pain status in rural communities.

Results: The participants had an average age of 38.4 years and were 66.7% female and 95% white. Two dichotomized variables characterizing drug abuse and chronic pain status (chronic pain: [yes | no] × off-label substance use [yes | no]) were cross-tabulated to identify four subgroups (chronic pain patients with off-label drug use history [n = 102], chronic pain patients without off-label drug use history [n = 330], non-pain patients with off-label drug use history [n = 104], and non-pain patients without off-label drug use history [n = 497]). Among the eligible participants (n = 1,033), people with chronic pain were more likely to engage in off-label drugs compared to those without chronic pain (Pearson $\chi^2 = 6.26$, $p = .01$). Off-label drug use tended to predict more negative attitudes toward living in rural areas, less social support, and greater emotional isolation than those without pain and off-label drug use (CFI = .97, RMSEA = .05, SRMR = .03).

Conclusion: As psychological deficit states were contributing factors that were distinctive to those with drug abuse and chronic pain in rural communities, it is critical to consider strategies ameliorating emotional isolation and enhancing social support, where these patients can further internalize their improved psychological states to engage in health promoting behaviors. We also argue that advances in social technologies and their ubiquity may offer opportunities to provide easily accessible, cost-effective, personalized social support and resources to rural patients who are hard to reach due to geographical barriers.

HOSPITALS CAN'T DO IT ALONE: NAVIGATING ADDICTION TREATMENT

Laura Harrison, MPH¹, Linda DeMasi, MBA¹, Kate O'Neill, MSN, RN¹, James Wescott, RN¹, Dana Cortapasso, MBA, RN¹, Nancy Kwon, MD, MPA², Jay Enden, MD, MSHPM, FACP³, Joseph Conigliaro, MD, MPH, FACP¹, Jonathan Morgenstern, PhD⁴, John D'Angelo, MD, FACEP¹, Sandeep Kapoor, MD, MS-HPPL¹

¹Northwell Health, New Hyde Park, NY; ²Northwell Health, Glen Oaks, NY; ³Northwell Health, Bay Shore, NY; ⁴Northwell Health, Great Neck, NY

Background: Hospitals support communities in times of crisis, however the current prevalence of substance use issues have put a strain on traditional clinical settings. Patients who are identified as engaging in high-risk substance use face a systematic absence of comprehensive discharge planning and connection to specialized care navigation. In the U.S. in 2018, only 10.2% of people with a substance use disorder received treatment.

Objective: Develop a specialized external navigation framework for substance use.

Methods: Project Connect (PC) is a collaboration between a large healthcare delivery system and a community-based organization. PC was built on top of our Screening, Brief Intervention, and Referral to Treatment (SBIRT) Program in two large emergency departments (EDs). PC staff were on-boarded as health system volunteers and trained on SBIRT, health system policies, and procedures. SBIRT Health Coaches identified patients who would benefit from external care navigation for substance use and called PC staff to engage with the patient, enrolling 298 patients from April 2018 to August 2019. PC staff completed a baseline intake, and structured engagement at 7/30/60/90/120 days. Support provided for patients and families included referrals to the most appropriate services regardless of affiliation (neutrality), connection to transportation, assistance with insurance, and continued conversations to maintain motivation and hope. We utilized REDCap for shared data collection between the two organizations and IBM SPSS Statistics v. 22 for descriptive statistics and analysis.

Results: 200 (68%) patients were successfully reached by PC staff for a baseline intake and external care navigation. Of those able to be reached, 53% were engaged in treatment for their substance use at baseline, 65% at 30 days, 60% at 60 days, 53% at 90 days, and 71% at 120 days. At 120 days, an additional 15% of patients not in treatment reported abstinence. PC staff assisted patients with navigation between levels of care, including detox, inpatient, outpatient, and sober housing. Out of 298 patients enrolled, 45 (15%) attended at least two different programs, and 154 (52%) attended at least one program. Other services provided include family support, social service applications, primary care referrals, and coordination with the criminal justice system.

Conclusions: Project Connect has served to illustrate the importance of measured approaches in formulating cross-organizational collaborations and has proven to be a successful model for supporting patients with substance use issues beyond the hospital setting. 52% of patients engaged in any treatment well exceeds the national average of 10%. Shared communication pathways have allowed for open conversation and continual process improvement. This model is being disseminated to additional EDs and future studies will evaluate patient experience measures.

SBIRT IMPLEMENTATION: PRE-CHARTING OF SCREENING RESULTS AND RESOURCE INFORMATION TO INCREASE PROVIDER INTERVENTIONS

Ruben Tinajero, M.S.¹, Katherine T. Fortenberry, PhD²¹University of Utah, Kansas City, MO; ²University of Utah, Holladay, UT

According to recent epidemiological research, 19.7 million people aged 12 or older met diagnostic criteria for a substance use disorder, highlighting the need to identify individuals with substance use disorders in order to provide them with interventions.¹ Screening, Brief Intervention, and Referral to Treatment (SBIRT) is an evidence based public health approach for the early identification and treatment of individuals with risky substance use.² This study examined the impact of SBIRT implementation at two family medicine training clinics. SBIRT implementation included provider and staff SBIRT education, as well as including the NIDA-modified ASSIST³ in the pre-visit workflow. Despite incorporating screening results into the electronic medical records (EMR), providers documented interventions for positive screens at only 22.3% of visits. Therefore, the behavioral health team began reviewing screening results and providing an additional notification to medical providers prior to the visit, both by flagging patient charts with positive screens and adding a pre-visit chart note. The pre-visit chart note included screening results, intervention options within the clinic (i.e., consulting behavioral health provider) and community resources. Results for 497 patients (female = 67%) who had screened positive for risky substance use indicated that the percentage of documented provider interventions increased from 22.3% to 43.1%. The percentage of referrals was unchanged (8.3% to 5.6%). Results suggest that screening alone for risky substance may not be adequate to change medical provider behavior; however, adding EMR-based notifications and resource reminders may be a cost-effective means of increasing interventions.

VAPING AMONG ADOLESCENTS IN TREATMENT FOR SUBSTANCE USE DISORDERS

Kelly Young-Wolff, PhD, MPH¹, Sara Adams, MPH², Stacy A. Sterling, DrPH, MSW³, Andy S.L. Tan, PhD, MBBS, MPH, MBA⁴, Lisa Carter-Harris, PhD, APRN, ANP-C, FAAN⁵, Ramzi G. Salloum, PhD⁶, Judith J. Prochaska, PhD, MPH⁷

¹Kaiser Permanente Northern California, Oakland, CA; ²Kaiser Permanente Division of Research, Oakland, CA; ³Kaiser Permanente Northern California, Oakland, CA; ⁴Dana-Farber Cancer Institute and Harvard T.H. Chan School of Public Health, Boston, MA; ⁵Memorial Sloan Kettering Cancer Center, New York, NY; ⁶University of Florida, Gainesville, FL; ⁷Stanford University, Stanford, CA

Significance: Little is known about correlates of vaping behaviors among at-risk adolescents. Of particular interest are adolescents who are in treatment for substance use problems, who may be particularly vulnerable to vaping nicotine and cannabis.

Methods: Data were gathered from all adolescents aged 12-17 with a specialty addiction intake appointment in 3 medical offices of a large, integrated health-care system (2017-2019; N=283; 65% male, mean age=15.5). We used natural language processing to extract data on patients' vaping from intake notes. We used multivariable logistic models to test for associations of vaping with socio-demographics, cigarette smoking, and substance use disorders.

Results: Of the 223 patients screened for vaping (79%), 67% reported ever vaping. A majority reported currently vaping nicotine (52%) or cannabis (53%); 43% vaped nicotine and cannabis; and 38% did not currently vape. Few (4%) were documented current cigarette smokers, yet 20% reported smoking blunts. Common reasons for vaping nicotine included availability (47%), flavors (28%), ability to use in places one cannot use other forms of tobacco (19%), friends' use (15%), less dangerous than smoking (15%), and ability to be discreet (7%). Black patients were less likely than other racial/ethnic groups to vape nicotine (OR=.02 to .04, all ps < .01) or cannabis (OR=.09 to .28, all ps < .05), but more likely to smoke blunts (OR=5.8 to 12.1, all p < .02). Those with an alcohol use disorder had higher odds of current vaping of nicotine (OR=3.05, p=.03), and those with "other" substance use disorder (excludes alcohol and cannabis use disorders) had higher odds of current cannabis vaping (OR=3.05, p=.03). Cigarette smoking, age, and sex were not associated with vaping.

Discussion: Among adolescents in addiction treatment, approximately half reported vaping nicotine and/or cannabis. Black youth had low rates of vaping, but high rates of blunt use. Availability, flavors, social norms, and low risk perceptions were key drivers of use. Research is needed to understand vaping patterns in at-risk adolescents and whether vaping interferes with addiction treatment.

THE INTERSECTION OF GENDER AND SUBSTANCE USE-RELATED STIGMA: A SYSTEMATIC REVIEW OF THE LITERATURE

Stephanie A. Meyers, MA¹, Valerie A. Earnshaw, PhD², Dan Werb, PhD³, Laramie R. Smith, PhD⁴¹University of California, San Diego, San Diego, CA; ²University of Delaware, Newark, DE; ³University of California San Diego, La Jolla, CA; ⁴UC San Diego School of Medicine, La Jolla, CA

Background: Women who use drugs are at a greater risk of drug-related harms, like HIV transmission. Furthermore, substance use-related stigma negatively impacts psychological well-being and serves as a significant barrier to health care service access among people who use drugs (PWUD). Less is known, however, regarding how intersectional identities, like gender, shape experiences of substance use-related stigma and harms. We, therefore, sought to answer the following questions: (1) Do non-substance using men or women stigmatize PWUD more? and (2) Do men or women PWUD experience more substance use stigma?

Methods: Data were drawn from a large systematic review of the peer-reviewed scientific literature on substance use-related stigma conducted in 2017 and guided by the Stigma and Substance Use Process Model. Articles were included in the present analysis if they assessed: (1) both gender-based stigma and substance use-related stigma or (2) the moderating effect of gender on substance use-related stigma.

Results: Of the 35 quantitative articles that met inclusion criteria, most studies were from North America (57.1%), with fewer from Australia (14.3%), Europe (11.4%), Asia (8.6%), and Africa (2.9%). Twenty-four (68.6%) articles evaluated stigma from the perspective of non-substance using individuals and 11 (31.4%) assessed stigma from the perspective of PWUD. Of those evaluating stigma from non-substance using individuals, 41.6% found women endorsed more stigma toward PWUD, 16.7% reported that men endorsed more stigma, and 37.5% found no gender differences in endorsement. Of the articles evaluating stigma experienced by PWUD, 81.8% found no relationship between gender and substance use-related stigma and 18.2% found female PWUD experience greater levels of stigma. Additionally, only 5.7% moved past the binary measurement of gender, and none tested the impact of intersecting gender and substance use stigma on substance use-related outcomes.

Conclusion: The literature is inconclusive regarding the influence of gender on substance use-related stigma. Consequently, this review identifies potential areas for methodological improvement and future research. Specifically, the use of validated stigma measures, the disaggregation of stigma measures by gender, and assessments of the effect of intersectional stigma on substance use-related outcomes are needed to understand the role of stigma in heightening the disproportionate harms experienced by women who use drugs.

EXAMINATION OF SEASONALITY IN HEALTH INDICATORS AND RISK BEHAVIORS AMONG ALASKA NATIVE MEN AND WOMEN IN NORTHWEST ALASKA

Derek Searcy, BA¹, Jordan D. Skan, M.S.², Mariah A. Knox, BA¹, Matthew Schnellbaecher, MD¹, Neal Benowitz, MD³, Judith J. Prochaska, PhD, MPH⁴¹Alaska Native Tribal Health Consortium, Anchorage, AK; ²Alaska Native Tribal Health Consortium, Anchorage, AK; ³University of California, San Francisco, San Francisco, CA; ⁴Stanford University, Stanford, CA

Introduction: Seasonality is a pattern of changes in behaviors and/or mood related to the season or time of year, such as seasonal affective disorder in winter. While the specific mechanisms of seasonality are not fully understood, variations in daylight and temperature are believed to play a role. The current study examined seasonal differences in health status and cardiovascular disease (CVD) risk behaviors among Alaska Native men and women smokers in the Norton Sound Region of Alaska. The existence of seasonal differences in behavioral patterns would suggest the need to control for season in longitudinal analyses of behavioral outcome data in the main trial.

Methods: Data were collected at baseline in the Healing and Empowering Alaskan Lives towards Healthy Hearts (HEALTHH) Project (N=299). We examined participants' self-reported health status, depressive symptoms (10-item CESD), alcohol and cannabis use, cigarettes per day and time to first cigarette (TTFC) upon waking, physical activity, and sleep to assess seasonality and associations with hours of daylight and temperature. We compared data from participants enrolled in winter (October 15 – April 30, n=149, 50%) versus the rest of the year (n=150, 50%). Data on hours of daylight and average daily temperatures for the region were collected from timeanddate.com and wunderground.com.

Results: As expected, the winter season averaged significantly less hours of daylight ($M = 7$ hours 48 min, $SD = 3$ hours 55 min) than the rest of the year ($M = 17$ hours 43 min, $SD = 3$ hours 34 min, $p < .001$) and colder average daily temperatures ($M = 19.8^\circ\text{F}$, $SD = 14.0^\circ\text{F}$ vs. $M = 47.8^\circ\text{F}$, $SD = 7.3^\circ\text{F}$, $p < .001$). Past month alcohol and cannabis use, smoking quantity, physical activity, sleep, and global health rating did not differ for winter versus other seasons. Significantly shorter latency in time to first cigarette (TTFC) after waking was observed for winter (W) than other (O) seasons (< 5 mins: 33% W vs. 21% O; 6-30 mins: 38% W vs. 39% O; 30+ mins: 14% W vs. 20% O, $p = .050$) and was significantly correlated with colder daily temperature (Spearman $r = .14$, $p = .014$) and fewer hours of daylight (Spearman $r = .15$, $p = .009$). CESD depression scores were significantly higher in winter ($M = 6.7$, $SD = 5.8$) than other seasons ($M = 5.1$, $SD = 4.6$, $p = .009$) and significantly correlated with colder temperature ($r = -.13$, $p = .024$) and fewer hours of daylight ($r = -.13$, $p = .030$). TTFC and CESD scores were not significantly correlated with each other, $r = -.11$, $p = .073$.

Conclusions: Most CVD risk behaviors were found invariant by season among Alaska Native men and women in the sample. The notable exceptions were depressive symptoms and TTFC, an indicator of nicotine addiction severity; both related significantly to temperature and daylight hours but not to each other. While seasonal mood effects are well documented, the observed seasonal difference in nicotine addiction severity is novel and warrants further study.

HIGH NICOTINE DEPENDENCE AT BASELINE PREDICTS CHANGES IN DEPRESSION DURING A SMOKING CESSATION ATTEMPT

Ashley B. Cole, PhD¹, Chaelin K. Ra, PhD², Summer G. Frank-Pearce, PhD, MPH³, Emily Hébert, DrPH⁴, Darla E. Kendzor, PhD³, Michael S. Businelle, PhD³

¹Oklahoma State University, Stillwater, OK; ²University of Oklahoma Health Science Center, Oklahoma City, OK; ³University of Oklahoma Health Sciences Center, Oklahoma City, OK; ⁴Stephenson Cancer Center, University of Oklahoma Health Sciences Center, Oklahoma City, OK

Background: The relationship between depression and smoking is complex; while some literature suggests that depression precedes smoking (i.e., those who are depressed use smoking to cope), other literature indicates that smoking precedes depression. Studies have indicated that depression symptoms increase during early phases of a quit attempt (e.g., on the quit-date), but return to baseline as the cessation attempt progresses. This study aimed to examine whether baseline nicotine dependence predicts changes in depression symptoms among adult smokers during a smoking cessation attempt.

Method: This study was part of a larger 13-week pilot randomized controlled trial that compared three smoking cessation interventions (in person counseling, NCI QuitGuide app, and Smart-T2 app). All participants received combination nicotine replacement therapy (i.e., nicotine patches and gum) and completed ecological momentary assessments on smartphones. Participants reported demographic characteristics and nicotine dependence (HSI; Kozlowski et al., 1994) at baseline. HSI was dichotomized as high [≥ 5] vs. low/moderate [< 5]. Participants reported depression symptoms (CES-D; Radloff, 1977) at baseline, on the quit-day, and at 4-weeks post-quit. A repeated measures analysis with fixed effects examined whether depression symptoms across the first 5-weeks of the study differed by HSI level.

Results: Participants (N=81) were male (51.2%), White (67.9%), and 49.4 years old (SD=12.2). Baseline depression symptoms were significantly lower among smokers with low/moderate HSI compared to smokers with high HSI ($p=0.0002$). Compared to smokers with low/moderate HSI, whose depression symptoms were consistent across time ($M=-6.5$), smokers with high HSI were significantly more likely to experience changes in depression symptoms ($p=.046$) that generally decreased over time (baseline $M=12.8$; quit-day $M=8.5$; 4-weeks post-quit $M=10.0$). This relationship remained significant after accounting for treatment group, sex, race/ethnicity, education, and 7-day biochemically confirmed abstinence status at 4-weeks post-quit ($p=.04$).

Conclusions: Compared to those with low/moderate nicotine dependence, highly dependent smokers had higher levels of depression at baseline and experienced a reduction in depression symptoms during the smoking cessation attempt. Future smoking cessation interventions may benefit from tailoring treatment based on individual history of depression and level of nicotine dependence.

E-CIGARETTE FLAVOR BAN POLICY SUPPORT AND PREDICTED BEHAVIORAL INTENTIONS AMONG U.S. E-CIGARETTE USERS.

Minal Patel, PhD, MPH¹, Alison F. Cuccia, MSPH¹, Barbara Schillo, PhD¹

¹Truth Initiative Schroeder Institute, Washington, DC

Background: E-cigarette use has grown substantially, with 27.5% of high school students and 7.6% of young adults reporting current e-cigarette use in 2019. Research indicates that flavors play a vital role in tobacco initiation, and 72%-97% of current youth and young adult e-cigarette users report using flavors. In September 2019, the U.S. government suggested enacting a policy to ban all flavored e-cigarettes, including menthol, in an effort to curb youth and young adult e-cigarette use. This study examines support for this policy, and the predicted behavioral intentions if flavored e-cigarettes were banned.

Methods: We surveyed a national sample of U.S. youth and adults ages 15-34 (n=2049). Behavioral intention analyses were limited to ever e-cigarette users (n=1083). Descriptive analyses examined policy support and likelihood of behavioral intentions. Chi-square analyses examined differences in demographic characteristics (age, gender, race/ethnicity, region, perceived income, and education) and tobacco use status by 1) policy support and 2) behavioral intentions.

Results: Approximately 52% of respondents supported/strongly supported a ban on flavored e-cigarettes. Policy support significantly differed by smoking status (current 36%, non-current 59%, $p<0.05$), and e-cigarette use status (current 61%, non-current 35%, $p<0.05$). Support was also significantly associated with education, income, age, and gender ($p<0.05$). Ever e-cigarette users reported likely/very likely to the following behavioral intentions if flavored e-cigarettes were banned: quit tobacco altogether (58%), stockpile (42%), use tobacco flavored e-cigarettes (37%), smoke menthol cigarettes (36%), and smoke non-menthol cigarettes (36%). Intention to: 1) quit tobacco was significantly associated with current cigarette use and race/ethnicity, 2) stockpile was significantly associated with current cigarette use, current e-cigarette use, education, income, age, and gender, and 3) use tobacco flavored e-cigarettes was significantly associated with current cigarette use, current e-cigarette use, education, income, age, and gender ($p<0.05$).

Discussion: Over half of US adults surveyed supported a flavored e-cigarette ban, but support is significantly lower among current e-cigarette and cigarette users. Although most ever e-cigarette users indicated an intention to quit if flavored e-cigarettes were banned, over a third indicated intentions to continue using tobacco products. This may moderate the public health benefit of a flavored e-cigarette ban, especially if e-cigarette users turn to combustible products. Attention needs to be paid to treat youth and young adults who are addicted to nicotine to minimize tobacco product substitution. This research further points to a need to regulate all flavored tobacco to reduce nicotine exposure and tobacco use behaviors among youth and young adults.

EXAMINATION OF DEPRESSIVE SYMPTOMS AND STRESS AS PREDICTORS OF QUIT ATTEMPTS IN A CESSATION INDUCTION TRIAL

Evelyn Arana-Chicas, DrPH¹, Delwyn Catley, PhD², Ana Paula Cupertino, Ph.D.¹¹John Theurer Cancer Center, Hackensack Meridian Health, Hackensack, NJ; ²Children's Mercy Kansas City, Kansas City, MO

Introduction: Quitting smoking involves multiple behavioral steps, and factors predictive of initiating a quit attempt may not be the same as those predictive of maintaining long-term abstinence. Perceived stress and depressive symptoms, which have been shown to reduce the likelihood of cessation, have yet to be examined as predictors of a quit attempt.

Objective: The objective of this study was to examine the association between depressive symptoms or stress and the likelihood of making a quit attempt when in a smoking cessation induction intervention.

Methods: A secondary data analysis was conducted using data from a randomized smoking cessation induction trial. Smokers with low motivation to quit (N=255) received Motivational Interviewing, health education or brief advice. Depressive symptoms were assessed with the 20-item Center for Epidemiologic Studies Depression Scale (CES-D) and perceived stress was assessed with the 14-item Perceived Stress Scale (PSS). Analyses focused on whether depressive symptoms and perceived stress (assessed at baseline, week 12, and week 26) was associated with a quit attempt (assessed at baseline, week 12, and week 26), regardless of treatment received.

Results: Results revealed few significant associations between perceived stress or depressive symptoms and quit attempts across all time points. Logistic regression models that adjusted for treatment group and gender revealed weak positive associations between baseline stress, baseline depressive symptoms and week 12 stress and making a quit attempt by week 12 (OR= 1.52, 95% CI [1.04, 2.21]; OR=1.03, 95% CI [1.01, 1.06]; OR=1.49, 95% CI [1.04, 2.13], respectively). There were no significant associations between the predictors and quit attempts at or between any other time points. A model that included baseline depressive symptoms and baseline stress as predictors in the same model revealed that neither was an independent predictor of quit attempts.

Conclusion: Higher levels of depressive symptoms and perceived stress may have a weak short-term association with quit attempts. In contrast to prior findings related to cessation, higher distress was associated with a greater likelihood of making a quit attempt. This suggests that these smokers, while more easily encouraged to try to quit, are less likely to succeed in their attempt. Findings highlight the potential importance of distinguishing between the different phases of the quitting process in research and treatment.

INFLUENCE OF RACIAL/ETHNIC DISCRIMINATION EXPERIENCES ON CIGARETTE CRAVING AMONG AFRICAN AMERICAN AND LATINO CIGARETTE USERS

Darius B. Dawson, Ph.D.¹, Yessenia Castro, Ph.D.², Terri L. Fletcher, Ph.D.¹, Manuel Ramirez, Ph.D.³¹Michael E. DeBakey VAMC/Baylor College of Medicine, Houston, TX; ²The University of Texas at Austin, Austin, TX; ³The University of Texas at Austin Department of Psychology, Austin, TX

Despite African American and Latino individuals generally smoking equal to or fewer cigarettes than White individuals, they have a higher smoking-attributable mortality rate, experience more smoking-related diseases later in life, and have lower cessation rates than White smokers. Research supports that experiences that elicit negative affect are associated with increases in cigarette craving. The current study examined the influence of racial/ethnic discrimination experiences on cigarette craving among African American and Latino smokers. Thirty-four African American and Latino smokers completed two writing tasks. One task elicited distressing experiences of racial/ethnic discrimination, and the other elicited distressing experiences of job- or academic-related failure. Order of the writing task completion was counterbalanced. Participants completed pre- and post-task measurements of the Questionnaire of Smoking Urges-Brief (QSU-B) and the negative affect subscale of the Positive and Negative Affect Schedule (PANAS-NA), and were asked to retrospectively rate the level of distress produced by each experience about which they wrote. A series of ANOVAs were computed to assess differences in the QSU-B and PANAS-NA in each condition. Cigarette craving measured by the QSU-B significantly increased from baseline to post racial/ethnic discrimination task [$F(1, 33) = 4.23, p < .05$] and post academic/job failure task [$F(1, 33) = 5.43, p < .05$]. Negative Affect as measured by the PANAS-NA did not increase from baseline to post-task for either experimental group (p 's > 0.05). The post- academic/job-related failure writing task QSU-B score was significantly related to the distress rating of the academic/job-related failure experience when controlling for PANAS-NA scores [QSU-B: $\beta = 0.04, p < 0.05$], but not the racial/ethnic discrimination task. These results suggest that recollection of racial/ethnic discrimination experiences have a similar impact on cigarette craving compared to recollection of academic/job-related failure experiences. The study highlights the importance of examining cultural experiences that are linked to cigarette use among ethnic minorities and the continued need for experimental research among ethnic minority smokers.

FACTORS ASSOCIATED WITH A SMOKERS' WILLINGNESS TO ENGAGE A PARTNER IN SMOKING CESSATION

Catherine S. Nagawa, M.S.¹, Jamie M. Faro, PhD², Rajani Shankar Sadasivam, PhD³, Kate L. Lapane, MS, PhD², Oluwabunmi M. Emidio, MD, MPH², Thomas K. Houston, MD MPH⁴

¹UMASS Medical School, Worcester, MA; ²University of Massachusetts Medical School, Worcester, MA; ³University of Massachusetts Medical School, Worcester, MA; ⁴Wake Forest University School of Medicine, Winston-Salem, NC

Background: Although observational studies suggest a positive association between positive support and successful quitting, the effectiveness of partner support on long-term smoking abstinence has not been demonstrated in behavioral interventions. Individuals who seek out social support for health purposes may benefit more from partner support interventions.

Methods: We explored factors associated with a smoker's willingness to engage a partner in smoking cessation efforts to inform the development of suitable partner support cessation interventions. We conducted a cross-sectional study using data collected from a current online randomized controlled smoking cessation trial. We assessed willingness to engage a partner using the question, "Would you be interested in a program that also includes your partner or spouse in smoking cessation?" and binary responses. Unadjusted and adjusted odds ratios (aOR) with 95% confidence intervals (CI) were derived from logistic models. Adjusted odds ratios account for demographic and smoking behaviors.

Results: Of the 983 participants, 27.7% (n=272) were willing to engage a partner. Compared to men, women tended to have lower odds of willingness to engage a partner (aOR; 0.82; 95% CI: 0.58 – 1.16), although the 95% confidence interval included one. Smokers who reported electronic cigarette use were more likely to report willingness to engage a partner in cessation efforts, (aOR: 1.51; 95% CI: 1.02-2.25) compared with smokers who did not report electronic cigarette use. The odds of willingness to engage a partner were more than two-fold for participants with smokers in the immediate family (aOR, 2.18; 95% CI: 1.51 – 3.15 for having 1-3 smokers; aOR, 3.12; 95% CI: 1.95 – 4.98 for ≥ 4 smokers) compared to having no smokers in the immediate family. Smokers who visited a smoking cessation website were more likely to be willing to engage a partner in cessation (aOR, 1.62; 95% CI: 1.18 – 2.21) than those who had not visited a website.

Conclusions: There are characteristic differences between those who were willing to engage their partner in a smoking cessation intervention and those who were not. Future research is needed to assess whether enhancing partner support among smokers in close relationships with other smokers can be achieved.

IMPLICATIONS FOR DEVELOPING AN INTERACTIVE MOBILE DOCTOR (iMD) INTERVENTION TO ENGAGE ASIAN FEMALE SMOKERS TO QUIT SMOKING

Isabel V. Nguyen, BS¹, Khanh Hoa Nguyen, B.A.², Edgar P. Yu, BS³, Jane Hwang, BA/MA⁴, Tung T. Nguyen, MD⁵, Thu Quach, PhD⁶, Janice Y. Tsoh, PhD³

¹University of California, San Francisco, San Jose, CA; ²Asian Health Services, Berkeley, CA; ³University of California, San Francisco, San Francisco, CA; ⁴University of California- San Francisco, San Francisco, CA; ⁵Department of Medicine, UCSF, San Francisco, CA; ⁶Asian Health Services, Oakland, CA

Background: There are few effective cessation strategies targeting Asian female smokers. A multi-lingual interactive mobile doctor (iMD) developed by our practice-based and academic research partnership has shown promises in increasing patient-provider discussions on tobacco use among Asian male patients in primary care. This study was designed to use qualitative formative research to guide iMD expansions to engage Asian female smokers.

Methods: We conducted 8 in-depth interviews with Chinese-, Korean-, and Vietnamese-speaking female smokers recruited from a federally-qualified health center in Oakland, California. Participants were interviewed about their smoking-related experiences and attitudes and asked for feedback on iMD that delivers interactive videos. Interviews were transcribed in English and thematic analysis was conducted.

Results: Participants were 3 Chinese, 3 Korean, and 2 Vietnamese female smokers with a mean age of 44.5 years (range: 32 – 63). Only one indicated an intention to quit. Key themes centered on how intervention could engage Asian female smokers were categorized into "6 Rs," which was expanded from the "5 Rs" model for smoking cessation. **Relevance:** Participants emphasized the importance of discussing smoking in the context of personal health conditions by age or family's health. **Risk:** Videos should explain how smoking could impact their physical appearance, exacerbate diseases, or harm their family. **Rewards:** In addition to the health benefits of quitting, quitting could reduce stress from the stigma against Asian women's smoking and needs to hide their smoking and could improve confidence and self-image. **Roadblock:** Coping with stress and nicotine withdrawal symptoms were most frequently mentioned. A few felt reluctant to discuss with their provider details about their smoking due to stigma and fear of disclosing smoking. **Resource:** Participants wanted the video to discuss specific healthy lifestyle changes to help them resist smoking. Information on nicotine replacement therapy was perceived as helpful. **Repetition:** Participants indicated that seeing video messages and images on health risks of smoking were helpful reminders to consider quitting. Most participants emphasized the importance of viewing the iMD in a private setting, and some indicated they would be more willing to provide details of their smoking via an app or online interface.

Conclusion: Asian female smokers experience strong stigma of smoking that present unique barriers to accessing needed clinical support for quitting. Mobile intervention was acceptable for delivering tailored cessation education while providing the privacy needed to engage them. Future interventions should incorporate elements of 5 Rs and provide information on evidence-based cessation treatments and alternative coping strategies for stress and withdrawal symptoms.

KOREAN IMMIGRANT WOMEN'S CAREGIVING IN THE CONTEXT OF TOBACCO USE: IMPLICATIONS FOR INTERVENTIONS

Edgar P. Yu, BS¹, Jane Hwang, BA/MA², Janice Y. Tsoh, PhD¹, Tung T. Nguyen, MD³, Isabel V. Nguyen, BS⁴, JiWon Choi, PhD, RN¹, Keo Chui, N/A⁵¹University of California, San Francisco, San Francisco, CA; ²University of California- San Francisco, San Francisco, CA; ³Department of Medicine, UCSF, San Francisco, CA; ⁴University of California, San Francisco, San Jose, CA; ⁵UCSF, San Francisco, CA**Background:** Korean American men with limited English proficiency have high smoking prevalence. This study explores Korean family communication between Korean American smokers and their family or peers in the context of tobacco.**Methods:** In-depth interviews were conducted in Korean with 10 dyads of a smoker and their interview partner of the same household. Each interview was audio-recorded, transcribed and translated into English. Using grounded theory method, two researchers coded each transcript.**Results:** The sample included 11 daily smokers (2 females), 2 former male smokers, and 7 female never-smokers with median age of 56 (range: 24-77 years old). All female participants, regardless of smoking status, communicated their desires for their loved ones to quit smoking in a form of caregiving, which they described as an expected role as wives or mothers in the Korean culture. The behavioral forms included verbalizing support or concerns, and doing personal favors. The cognitive forms included being cognizant of smoking behaviors and worrying about their smokers' health. Behavioral forms, categorized as goal-oriented actions or statements that directly facilitate towards smoking cessation, were mostly correlated with positive outcomes of smokers taking attempts towards smoking cessation. Behavioral forms, categorized as generalized actions or statements, and cognitive forms, such as worrying about smokers' health, were associated with women internalizing feelings of unworthiness and hopelessness because smokers continued to smoke. This can attribute to the cycle of unhelpful interactions, and ultimately, it can have relational consequences of avoidance in communication and conflicts. In addition, depending how smokers perceived caregiving and the impacts of smoking, smokers responded to caregiving forms with mixed feelings of anger and gratitude.**Conclusion:** Korean women engage in behavioral and cognitive forms of caregiving to advocate and express their expectant hope for smoking cessation. When smokers continued to smoke, Korean women tend to negatively internalize the impacts of behavioral and cognitive forms of caregiving.

Implications: In order to facilitate productive interactions towards smoking cessation, Korean women should be encouraged to minimize generalized caregiving forms and focus on goal-oriented forms. Korean male smokers should be encouraged to partake in caregiving forms and perceive the relational and health impacts of smoking on family members.

RACIAL/ETHNIC DIFFERENCES IN SWITCHING BEHAVIOR AMONG ADULT CURRENT SMOKERS WHO USE THE NICOTINE SALT POD SYSTEM (NSPS)

Yining Z. Malloch, n/a¹, Gem M. Le, n/a², Joshua Vose, MD, MBA², Erik Augustson, PhD, MPH²¹JUUL Lab Inc., San Francisco, CA; ²JUUL Labs, Inc., San Francisco, CA**Objective:** This study examined racial/ethnic differences in switching to NSPS only over a 6-month period among current smokers who newly purchased an NSPS.**Methods:** Longitudinal survey data from an IRB approved behavioral study of U.S. adults (age 21 or older) who recently purchased a NSPS (JUUL Labs, Inc.) starter kit was analyzed. Current smokers were defined as subjects who had smoked more than 100 lifetime combustible cigarettes (CC) and reported smoking some days/every day at baseline. Follow-up assessments of past 30-day NSPS and CC were completed at 1-, 2-, 3- and 6-months (i.e., efficacy sample, n = 9903). Switching behavior was defined as abstaining from CC and using only NSPS in the past 30 days. Analyses were stratified by race/ethnicity (7308 non-Hispanic White (NHW), 296 non-Hispanic Black, 805 Hispanics, 772 non-Hispanic Asian or Pacific Islanders (API), 361 multi-race). Multivariate generalized estimation equations (GEE) modeled switching behavior, adjusted for time, race and other demographics, smoking history, and NSPS use days.**Results:** Most current smokers were males (53.9%) with the mean age of 32.7 (SD = 11) years. At 6-months of follow-up, minority racial/ethnic groups had higher switching rates than non-Hispanic Whites (API, 51.7%; non-Hispanic Black, 53.4%; Hispanic, 53.7%; multi-race, 55.4%; NHW, 47.7%). Switching rates in the multi-race group had the largest increase (19.4%) in switching rates over the follow-up period, from 36% at 1-month to 55.4% at 6-months, followed by NHW (18%), non-Hispanic API (17.7%), non-Hispanic Black (14.9%) and Hispanic (13.9%). Results of GEE revealed significant and positive associations between time and switching (aOR = 1.16, CI[1.14,1.18]) and that non-Hispanic Blacks (aOR = 1.36, CI[1.14, 1.61]) and multiple races (aOR = 4.84, CI[1.004, 1.36]) were more likely to switch than non-Hispanic whites.**Conclusions:** Although complete switching from cigarettes to NSPS increased for all groups over the 6-month follow-up, higher rates of switching were demonstrated among racial/ethnic minority current smokers. Although suggestive, additional research is needed to further assess the impact of NSPS to switch racial/ethnic minority groups from CC.

LONGITUDINAL ASSOCIATIONS BETWEEN ADOLESCENT SMOKING AND INTERGENERATION UPWARD EDUCATIONAL MOBILITY BY PARENTAL EDUCATION

Aniruddh Ajith, B.S.¹, Denise L. Haynie, PhD, MPH², Kelvin Choi, PhD, MPH³¹National Institute on Minority Health and Health Disparities Division of Intramural Research, Ellicott City, MD; ²Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; ³National Institute on Minority Health and Health Disparities Division of Intramural Research, Bethesda, MD

Intergenerational upward educational mobility represents increasing educational and economic opportunities in subsequent generations, which are often related with better health. A few European studies found cigarette smoking to be inversely associated with intergenerational upward mobility. The current study assesses the association of smoking during high school years on intergenerational upward educational mobility in a U.S. longitudinal study of youth.

Data were collected annually from a nationally representative cohort of 10th graders who participated in the NEXT Generation Health Study (2010–2017; N=1,503). Participants reported if they smoked in the past 30 days annually during 2010–2013. Those who reported any smoking in 2010–2013 were classified as adolescent smokers; those who reported no smoking during the same time period were classified as adolescent nonsmokers. Parent educational attainment was assessed in 2010, and participant educational attainment was measured in 2017. Upward education mobility was defined as participants obtaining a bachelor's degree by 2017. Weighted multivariable logistic regression was used to assess the association between smoking during high school years and upward educational mobility, stratified by parent educational attainment, adjusted for gender, ethnicity/race, region, urbanicity, family affluence and alcohol use in 2010.

We found that upward educational mobility varied by parent educational attainment (parents had a high school education or less=14%, parents had some college education=23%, parents had college education=49%). We also found that adolescent smoking was negatively associated with upward educational mobility, but only among participants whose parents did not complete college. Specifically, among participants whose parents had high school education or less, 4% of adolescent smokers vs. 19% of adolescent nonsmokers completed college (AOR: 0.11; 95% CI: 0.03–0.38). Among participants whose parents had some college education, 7% of adolescent smokers vs. 30% of adolescent nonsmokers completed college (AOR: 0.13; 95% CI: 0.06–0.30).

Our results indicate that adolescent smoking may inhibit upward educational mobility for people whose parents have had less than a complete college education, implying that smoking behaviors may perpetuate socioeconomic and health disparities. Effective strategies to reduce smoking among adolescents from low socioeconomic families may promote socioeconomic and health equity.

THE ROLE OF DISCRIMINATION IN SUBSTANCE USE BEHAVIORS IN HISPANIC YOUNG ADULTS: A LONGITUDINAL STUDY THROUGH EMERGING ADULTHOOD

Christopher J. Rogers, M.P.H.¹, Myriam Forster, BA;MPH;PhD², Steven Vetrone, MPH³, Jennifer B. Unger, Ph.D.⁴¹Keck School of Medicine University of Southern California, Castaic, CA; ²California State University, Northridge, Santa Monica, CA; ³California State University, Northridge, Santa Fe Springs, CA; ⁴University of Southern California, Los Angeles, CA

Purpose: Associations between discrimination and substance use have been identified cross-sectionally in multiple populations including Hispanics. However, there is limited research exploring this phenomenon longitudinally in Hispanic youth over the transition from adolescence through emerging adulthood (EA).

Methods: Hispanic youth in Southern California (n=1457) completed surveys over 11 years, from 2006 to 2017, including three high school collection waves and five EA collection waves. Multinomial logistic regression models were used to explore the associations between perceived discrimination and cigarette and marijuana use cross-sectionally in high school and longitudinally in EA, controlling for gender, socioeconomic status, acculturation, and EA discrimination.

Results: Compared with those who never used cigarettes or marijuana in high school and EA, perceived discrimination in high school was a significant predictor of two patterns of use: high school initiators who discontinued use of smoking (RRR=1.677, 95%CI=1.292–2.176) and/or marijuana (RRR=1.464, 95%CI=1.162–1.844), and high school initiators who continued smoking (RRR=1.492, 95%CI=1.196–1.861) and/or marijuana use (RRR=1.249, 95%CI=1.052–1.482) into EA. For late initiators who did not use in high school but started in EA, perceived high school discrimination was a significant predictor for cigarette smoking (RRR=1.193, 95%CI=1.036–1.373) but not for marijuana use.

Conclusions: Perceived discrimination during adolescence is associated with substance use trajectories across both adolescence and EA. Culturally tailored prevention programs that provide training in skills to cope with psychosocial stressors could improve Hispanic adolescent health.

RELATIONSHIPS BETWEEN PREGNANCY-RELATED WEIGHT CHANGES AND POSTPARTUM PSYCHOSOCIAL WELLBEING

Meghan Sharp, PhD¹, Chelsey Solar, PhD², Robert A. Carels, PhD, MBA, ABPP³, Christyn Dolbier, Ph.D.³¹Women's Medicine Collaborative, Lifespan, Providence, RI; ²VA Boston Healthcare System, Boston, MA; ³East Carolina University, Greenville, NC

Introduction: Healthy weight gain in pregnancy is important for maternal-fetal health. Postpartum, there is a high degree of societal pressure to lose residual gestational weight. Gestational weight gain and postpartum weight retention have been associated with increased experiences of weight discrimination and poor maternal wellbeing, but research in this area is scarce. Furthermore, internalized weight bias, or the application of stigma associated with high body weight to the self, is poorly understood in this population.

Method: Women ($N = 251$) who were between 6 and 12 months postpartum were recruited via social media advertisements for an online survey about perinatal weight experiences. The majority were White (93%), married (79%), and primiparous (61%) with $Mage = 29.02$. Measures: percent gestational weight gain, percent postpartum weight retention, modified Weight Bias Internalization Scale, Edinburgh Postnatal Depression Scale, Body Surveillance, and two subscales from the Childbearing Attitudes Questionnaire, Relationship with Husband and Interest in Sex.

Results: Women with lower prenatal BMI gained more weight in pregnancy ($r = -.63$, 95% CI $-.70$, $-.55$). Gestational weight gain and postpartum weight retention were positively correlated ($r = .33$, 95% CI $.20$, $.44$). In linear regression analyses using standardized variables, only partner relationship was associated with gestational weight gain ($B = .12$, 95% CI $.00$, $.25$). In contrast, postpartum weight retention demonstrated significant relationships with internalized weight bias ($B = .59$, 95% CI $.48$, $.71$), depression ($B = .22$, 95% CI $.84$, $.36$), body surveillance ($B = .17$, 95% CI $.04$, $.29$), and lower interest in sex ($B = -.28$, 95% CI $-.40$, $-.16$).

Conclusion: Postpartum weight retention and not gestational weight gain was significantly associated with poorer postpartum wellbeing. Healthy pregnancy weight is a recommended topic of conversation in routine perinatal care, while no recommendations exist for postpartum weight management. Results identify postpartum weight retention as an important health factor for discussion in postpartum medical care and an area of needed maternal health research.

EXPERIENCES OF WEIGHT BIAS AND REPRODUCTIVE HEALTHCARE UTILIZATION

Aubrey L. Borgen, BA¹, Shayesteh Jahanfar, n/a², Sarah Domoff, PhD²¹Central Michigan University, Mt Pleasant, MI; ²Central Michigan University, Mount Pleasant, MI

Recent qualitative research (Bombak et al., 2016) has found that women of child-bearing age experience weight stigma and fat shaming from their obstetrician-gynecologists. Although weight stigma has been found to be associated with other health and treatment-seeking behaviors, we know little about whether experiencing weight stigma or internalizing weight bias predicts reproductive healthcare. Utilizing a large sample from X Twin Registry, women of child-bearing age (i.e. 18-40 years of age) were recruited. A total of 1458 participants completed a scale of perceived weight discrimination (Hatzenbuehler et al., 2009) and a modified version of the Weight Bias Internalization Scale (WBIS-M; Pearl & Puhl, 2014). Participants were asked to report the date of their most recent Papanicolaou (Pap) smear test, pelvic exam, and mammogram. Results indicated that 7.2% ($n = 98$) of the women ever experienced weight-based discrimination while receiving medical care; a similar number reported experiencing weight-based discrimination in public ($n = 134$; 9.8%). Chi-square tests were used to examine differences among reception of reproductive healthcare based on history of weight-based discrimination. Results indicated that the reception of Pap smear tests did not differ based on history of experiencing weight-based discrimination in public settings, with 23.1% of women endorsing fairly often experiencing such discrimination and having never received a Pap smear test (compared to 4.4% of those who never experienced weight-based discrimination; $\chi^2(4) = 12.64$, $p < .05$). These results have implications for improving the interactions between reproductive healthcare providers and female patients, and will inform healthcare systems in understanding which obstacles women face in obtaining crucial medical services.

PREIMPLANTATION GENETIC TESTING FOR ANEUPLOIDY: AN IN-DEPTH, QUALITATIVE STUDY OF THE DECISION-MAKING EXPERIENCE

H. Deniz Kocas, MA MSc MPharm¹, Samantha L. Klein, B.A.¹, Margaux Genoff Garzon, MA¹, Lisa R. Rubin, PhD², Marci Lobel, PhD³, James Stelling, MD HCLD⁴, Lisa M. Pastore, PhD⁵

¹The New School for Social Research, New York, NY; ²New School for Social Research, New York, NY; ³Stony Brook University, Stony Brook, NY; ⁴SUNY Stony Brook, Blue point, NY; ⁵Stony Brook Medicine, Stony Brook, NY

Objective: Individuals using *in vitro* fertilization (IVF) are faced with an expanding array of medical decisions, including the decision of whether or not to pursue preimplantation genetic testing for aneuploidy (PGT-A). PGT-A is a specialized technique to identify, before implantation, embryos created through IVF with an abnormal number of chromosomes, with the aim of improving pregnancy outcomes. For some, PGT-A may be a source of hope in an otherwise stressful process; however, it also presents a complex choice for individuals who may already feel decisional burden. Research on decision-making for PGT-A is sparse. To address this limitation, this study focuses on the decision-making experience of individuals undergoing IVF and considering PGT-A.

Methods: In-depth, qualitative interviews were conducted with eleven women and four men ($N = 15$) from 6 different states (mean age 37.6+/-6.2 years). Interviews were performed through hour-long video conference. Participants were predominantly White and non-Hispanic (94%) and highly educated. All were considering or had recently considered (< 6 months) PGT-A. Interviews were coded by four researchers using thematic analysis.

Results: Individuals considering whether or not to use PGT-A described the following as key sources of decisional conflict: (1) navigating differing information across healthcare providers, online forums, and personal networks; (2) weighing values opposing testing/selection against the goal of having a healthy baby; (3) balancing the cost of testing with other expenses and attempting to quantify the “value-added” of PGT-A; (4) anticipating and/or managing sub-optimal outcomes (e.g., having insufficient embryos); and (5) anticipating judgment by others. Decisional conflict was a source of stress, which was exacerbated or attenuated by individuals’ informational needs, support network, financial resources, and trust in provider, and varied according to the person’s stage of fertility treatment.

Conclusion: The decision whether or not to use PGT-A, while offering hope, can also increase decisional burdens for individuals going through IVF. Identifying those who face such difficulties and understanding how they manage decisional conflict can guide the development of appropriate strategies to support the increasing population that consider this option.

HYSTERECTOMY STATUS DOES NOT IMPACT ABILITY TO LOSE AND MAINTAIN WEIGHT LOSS DURING A WEIGHT MANAGEMENT INTERVENTION

Anna M. Gorczyca, PhD¹, Felicia Steger, PhD, RD¹, Lauren T. Ptomey, PhD, RD¹, Richard A. Washburn, PhD¹, Joseph Donnelly, EdD¹

¹University of Kansas Medical Center, Kansas City, KS

Background: Women who have had a hysterectomy are at a higher risk of weight gain compared to women who have not had a hysterectomy. Hysterectomies are often conducted in women in their 40s as they are premenopausal or perimenopausal, a time point where weight gain is common. The combination of age, hormonal changes and surgery may make it difficult for women to maintain weight. Thus, weight management interventions could be helpful for women to lose weight following a hysterectomy. To our knowledge, there has been no research comparing weight loss and weight maintenance in women who have had a hysterectomy versus women who have not had a hysterectomy.

Methods: This was a secondary analysis conducted in overweight/obese women ($N=145$) initiating a 3-mo. behavioral weight loss intervention which included weekly face-to-face behavioral counseling, reduced energy intake (~1200-1500kcal/d) and increased exercise (100 min/wk). Participants completing the 3-mo. intervention and achieving clinically meaningful weight loss ($\geq 5\%$) began a 12 mo. behavioral weight maintenance intervention and were randomized to 150, 225, or 300 min/wk of moderate intensity exercise. At baseline, participant’s history of a hysterectomy and hormone therapy use was self-reported. Anthropometrics were measured by trained research staff and body composition was measured using DXA. Analysis of variance was conducted to compare weight regain, physical activity, dietary intake and body composition in women who had a hysterectomy and did not have a hysterectomy using SAS 9.4.

Results: Thirty women self-reported having a hysterectomy while 115 did not have a hysterectomy. Women who had a hysterectomy (H+) were older (47.3 ± 5.0 years old) compared to women without a hysterectomy (H-) (41.7 ± 8.7 years old) ($p=0.001$). There were no differences in group randomization by hysterectomy status ($p=0.532$). There were no differences in initial percent weight loss ($-3 - 0$ mo.) H+ ($-8.28\% \pm 2.78$) compared to H- ($-9.24\% \pm 2.78$) ($p=0.234$) or weight regain ($0 - 12$ mo.) in H+ ($2.75\% \pm 7.2$) compared to H- ($2.75\% \pm 7.3$) ($p = 0.452$) after controlling for age and hormone replacement therapy use. Percentage change in fat mass did not differ between H+ ($-1.74\% \pm 4.73$) and H- ($-2.78\% \pm 4.22$) ($p=0.591$). There were no differences in physical activity and dietary intake ($p=0.685$, $p=0.729$).

Conclusions: Women who have had a hysterectomy can successfully lose and maintain weight loss just as well as women who have not had hysterectomy.

EXPLORING THE RELATIONSHIP BETWEEN MATERNAL PERCEIVED DISCRIMINATION DURING CHILDBIRTH AND LABOR DURATION

Rachel C. Uri, B.A.¹, Jodie Lisenbee, B.S.¹¹University of North Carolina at Charlotte, Charlotte, NC

Prolonged labor is associated with risks of extensive and prevalent adverse maternal and neonatal health outcomes, including an increased risk of cesarean delivery. Maternal psychological stress during childbirth leads to increased catecholamine production (i.e., epinephrine), which is associated with slower labor progression due to lower uterine contractility. Perceived discrimination from healthcare providers may be one such source of stress. The present study explores whether maternal perceived discrimination during childbirth due to 1) race, ethnicity, cultural background or language, 2) health insurance status, or 3) a patient-provider difference of opinion regarding care might explain additional variance in labor duration above and beyond the influence of known predictors of labor duration (e.g., nulliparity, birthweight, labor induction, labor augmentation, and epidural use). Cross-sectional, retrospective data from a sample of 1854 sociodemographically diverse women ($M=29.02$, $SD=6.00$) were utilized to complete three hierarchical multiple regression analyses to test this prediction. Contrary to hypotheses, the present study revealed no evidence of a unique relationship between perceived discrimination and labor duration. These results suggest that further research, utilizing more rigorous methodology including objective measures (e.g., ecological momentary assessment (EMA) of perceived discrimination and use of medical record data to reliably determine labor duration) that may complement traditional self-report indices, is required in order to explore this question adequately and comprehensively.

MALE PARTNERS' ANTENATAL CARE ATTENDANCE AND ASSOCIATED FACTORS AMONG PREGNANT WOMEN IN NORTHERN TANZANIA

Jessica N. Coleman, BA¹, Saumya Sao, n/a², Godfrey Kisigo, MD², Rimel Mwamba, BA², James S. Ngocho, MD, MSc³, Blandina T. Mmbaga, MD, Mmed, PhD⁴, Haika Osaki, MPH⁵, Linda Minja, MSc⁵, Jenny Renju, PhD, MPH⁶, Melissa H. Watt, PhD, MPH²

¹Duke University, Durham, NC; ²Duke Global Health Institute, Durham, NC; ³Kilimanjaro Christian Medical University College, Moshi, Kilimanjaro, Tanzania; ⁴Kilimanjaro Clinical Research Institute, Moshi, Kilimanjaro, Tanzania; ⁵Kilimanjaro Clinical Research Institute, Moshi, Kilimanjaro, Tanzania; ⁶London School of Hygiene and Tropical Medicine & Kilimanjaro Christian Medical University College, Moshi, Kilimanjaro, Tanzania

In Tanzania, men are encouraged to attend the first antenatal care (ANC) appointment and test for HIV with their pregnant partner. Research has indicated the value of male engagement in pregnancy care, including for outcomes related to prevention of mother-to-child transmission of HIV (PMTCT). Despite the potential value of male engagement, some women face barriers to bringing a male partner to care, which may lead them to being disadvantaged in receiving clinical services. The goal of this study was to examine male partner engagement in ANC and identify psychosocial characteristics of pregnant women that are associated with bringing a male partner to the first ANC appointment. Participants ($n=579$) were pregnant women with a negative or unknown HIV status attending a first ANC appointment at one of two government clinics in Moshi, Tanzania. Participants completed a structured survey prior to receiving standard of care and routine HIV testing, which included questions about whether they presented that day with a male partner, sociodemographic characteristics, and psychosocial constructs (e.g., history of interpersonal violence, depression, partner support, anticipated HIV stigma). Factors that were significantly associated with presenting to ANC with a male partner in univariate analyses ($p < 0.10$) were included in a multiple logistic regression model. Participants ranged in age from 18 to 43 ($M=25.7$, $SD=5.6$). Less than half (48.7%) had education beyond the primary level. Most participants had been tested for HIV previously (68.9%). Over half of participants (57.5%) presented to ANC with a male partner. In univariate analyses, presenting with a male partner was associated with age, religion, level of education, marital status, first pregnancy, prior HIV testing, history of interpersonal violence, partner support, and anticipated HIV stigma. The final multivariable model indicated that women had significantly greater odds ($p < .05$) of presenting with a male partner if they were of the Muslim religion ($OR=1.7$, 95% CI: 1.2-2.5) or married ($OR=4.1$, 95% CI: 2.7-6.2); women had less odds of presenting with a male partner if they were older ($OR=.92$, CI: .88-.96). Findings suggest that older pregnant women and women with less stable partnerships may be disadvantaged by policies and procedures encouraging partner attendance in Tanzania. Existing policy may lead some women to present late to ANC, which has implications for maternal and child health, including PMTCT.

PRESIDENTIAL SYMPOSIUM: ACCELERATING SCIENCE AT THE INTERNATIONAL LEVEL: BEHAVIORAL MEDICINE IN INTEGRATED PRIMARY CARE

William Sieber, Ph.D.¹, Christopher L. Hunter, Ph.D., ABPP², Wilson D. Pace, MD³, Henriëtte E. van der Horst, prof.dr.⁴

¹UC San Diego Collaborative Care, SAN DIEGO, CA; ²Defense Health Agency, Arlington, VA; ³DARTNet Institute, Aurora, CO; ⁴Amsterdam UMC, Amsterdam, Noord-Holland, Netherlands

While SBM and ICBM members have often led the scientific advances in promoting people's health through research and promoting public policy, the challenges are daunting as to how to accelerate the demonstration of behavioral medicine interventions in real-world settings. Integrated behavioral health in primary care is a major opportunity for behavioral medicine researchers to show impact on patient populations who have historically had low access to services. Translating behavioral medicine research into health care settings is difficult due to fragmented healthcare systems and numerous factors that affect implementation in any given setting. Aggregation of data across health systems will accelerate translational research and such data aggregation at both national and international levels will advance our understanding of the elements important to effecting health behavior globally.

In this Presidential symposium speakers from various health systems and countries will share their lessons learned as to implementing behavioral medicine research to clinical populations, identify challenges, and propose next steps in building collaborations that facilitate progress. Each speaker will address the clinical, operational, methodological, and technical challenges of this work. At the end, a framework for international collaboration will be proposed, inviting symposium attendees to participate in an international research network designed to accelerate behavioral medicine as a science.

BEHAVIORAL MEDICINE STANDARDIZATION AND IMPLEMENTATION IN THE MILITARY HEALTH SYSTEM: POLICY AND PATHWAY IMPLEMENTATION

Christopher L. Hunter, Ph.D., ABPP¹

¹Defense Health Agency, Arlington, VA

The military health system provides services for over 3 million people in military treatment facility primary care clinics. Since 2013, policy has mandated the integration of full-time primary care behavioral health providers (psychologist and social workers) into primary care clinics with 3000 or more empaneled adults. This presentation will cover: 1) Health system policy as a necessary, but not sufficient baseline for behavioral medicine clinical quality improvement. 2) EHR standardization in 278 clinics, to include behavioral medicine clinical decision support and ability to pull discrete data to assess population penetration and patient outcome. 3) The development and implementation of a system wide primary care stepped-care pain pathway designed to change patient-centered medical home evidence-based assessment and intervention for acute and chronic pain. 4) Discuss implementation and patient outcome evaluation and how data from multiple sites can be used to analyze patterns of impact to provide actionable data for continued quality improvement and service delivery. 5) End with a discussion of how system EHR and training standardization and implementation outcome can be shared with other systems to accelerate best practice dissemination and implementation efforts.

2

8:00 AM-9:15 AM

ELECTRONIC DATA EXTRACTION AND CURATION FOR CLINICAL CARE AND RESEARCH

Wilson D. Pace, MD¹

¹DARTNet Institute, Aurora, CO

To assist attendees in understanding the technical aspects of establishing and leveraging a network of clinical sites contributing data for accelerated science. The presenter will talk about all phases of data acquisition and curation from multiple electronic sources (i.e., healthcare systems). The talk will include extraction activities from multiple different EHRs, from data repositories and other electronic data sources. The use of CCDs and CCDAs for data extraction as well as the use of FHIR will be covered as data sources. Transformation activities across these disparate sources will be discussed in terms of both data structure and nomenclature perspective (e.g., shared behavioral medicine terminology). Data loading to a common data model will be discussed, with the OMOP v6 model to be used for demonstration purposes. Current experience with a national project on integrated behavioral health (IBH-PC) collecting data from over 40 clinics across the U.S. will also be highlighted. Handling of linked data, such as PHQ-9 scores, will be outlined. Finally, data quality approaches will be highlighted for dealing with large data sets, as well as ideas for data sharing back out to participating sites for their own quality improvement/research activities. The data quality discussion will cover differences between classic, RCT statistical data sets and data science approaches to handling data.

HOW TO AGGREGATE AND USE ROUTINE CARE DATA FROM PRIMARY CARE TO OPTIMIZE CARE

Henriëtte E. van der Horst, prof.dr.¹

¹Amsterdam UMC, Amsterdam, Noord-Holland, Netherlands

For several decades now, all Dutch university general practice departments closely collaborate with general practitioners in academic networks of general practices. All departments have large databases of routine care data at their disposal. A constant effort is being made to optimize the quality of the recording and coding of the routine care data. The departments have, in collaborations with the general practitioners, developed methods to use these routine care data for answering research questions, for identifying participants for specific research projects, for optimizing care through providing information on how practices perform in specific areas and in the last few years also for teaching purposes. The aggregation of data collected at multiple sites all over the country contributes to quality improvement in the care for people with highly prevalent conditions such as obesity, diabetes and medically unexplained symptoms, and thus to the science of behavioral medicine. In my presentation I will provide an overview and examples of the ways in which these routine care databases are being used. I will address some issues of clinical quality and implementation of evidence-based interventions in primary care in the Netherlands. I will also elaborate on facilitators and barriers in the interaction between research and practice, bi-directionally.

ADVANCING THE RESEARCH AGENDA: CURRENT EPIDEMIOLOGY, MEASURES AND INTERVENTIONS FOR SEDENTARY BEHAVIOR

Dori E. Rosenberg, PhD, MPH¹, Sarah K. Keadle, PhD, MPH², Matthew P. Buman, PhD³, Whitney A. Welch, PhD⁴, Jason Fanning, PhD⁵, Lisa Cadmus-Bertram, PhD⁶

¹Kaiser Permanente Washington Health Research Institute, Seattle, WA; ²Cal Poly San Luis Obispo, San Luis Obispo, CA; ³Arizona State University, Phoenix, AZ; ⁴Northwestern University Feinberg School of Medicine, Chicago, IL; ⁵Wake forest university, Winston salem, NC; ⁶University of Wisconsin - Madison, Madison, WI

High sedentary time in the general population has prompted a plethora of new research in the field of sedentary behavior change science. In this session, we will host a series of brief presentations to update audience members on current measurement approaches, epidemiologic evidence, and interventions to address high sedentary time. In this symposium, sponsored by SBM's Physical Activity SIG, we have assembled a series of brief presentations (10 minutes each) to update audience members on current measurement approaches, epidemiologic evidence, and interventions to address high sedentary time. Dr. Kozey Keadle will provide an overview of epidemiologic evidence to date. Dr. Matthew Buman will review measurement issues in sedentary behavior research. Dr. Welch will describe the findings of an ecological momentary assessment study examining sedentary behaviors in relation to chemotherapy-related symptoms. Dr. Fanning will provide an overview and results of a pilot trial using an iterative user-centered development process to promote movement throughout the day. Dr. Rosenberg will review the methods of a randomized controlled trial to reduce sedentary time in older adults with obesity. Finally, our discussant (Dr. Cadmus-Bertram) will summarize key themes and future research directions. The presentations will be followed by an interactive discussion with attendees.

CORRESPONDING AUTHOR: Dori E. Rosenberg, PhD, MPH, Kaiser Permanente Washington Health Research Institute, Seattle, WA; Dori.E.Rosenberg@kp.org

METHODS FOR A RANDOMIZED CONTROLLED TRIAL TO REDUCE SITTING TIME IN OLDER ADULTS WITH OBESITY

Dori E. Rosenberg, PhD, MPH¹, Mikael Anne Greenwood-Hickman, MPH², Jing Zhou, PhD², Callie Walsh-Bailey, MPH², Julie Cooper, MPH², Andrea Cook, PhD², David Arterburn, MD, MPH², Bev Green, MD, MPH², Jacqueline Kerr, PhD³, Jennifer McClure, PhD¹

¹Kaiser Permanente Washington Health Research Institute, Seattle, WA; ²Kaiser Permanente Washington Health Research Institute; ³The Grant Doctor, Poway, CA

Background: Older adults with obesity have high levels of sitting time and substantial barriers to physical activity. Small sitting reduction trials have demonstrated efficacy in older adults, but larger and longer trials are needed to establish whether sitting reductions are maintained over time and to elucidate health effects. This presentation will provide an overview of the methods and sample characteristics for an on-going trial of sitting reduction in older adults with obesity.

Methods: Participants will include 284 older adults with a body mass index greater than 30 kg/m². Participants will be randomized to a sitting reduction intervention (i-STAND) or a healthy living attention control condition for 6 months and will be followed for 6 additional months (12 total). The i-STAND group will receive 10 health coaching contacts, workbooks, portable standing desks and wrist-worn inactivity prompting devices to reduce their sitting. At 6 months i-STAND participants will be re-randomized to receive 5 booster sessions or no further coaching contact. The attention control group will receive 10 health coaching contacts, a workbook, and content on various healthy living topics unrelated to sedentary behavior. The primary outcomes are comparative changes in activPAL measured sitting time and blood pressure. Additional outcomes include standing time, steps, fasting glucose, and HbA1c.

Results: As of August 31, 2019, 50 participants have been randomized (24 to i-STAND; 26 to Healthy Living). Recruitment will continue through September 2021. The population has a mean age of 67 (range 60-85), is 63% female, 94% white, and has a mean BMI of 34.8 (SD = 4.9). Mean baseline activPAL sitting time is 10.7 (SD 1.9) hours/day, standing time 3.7 (SD 1.6) hours/day, average sitting bout length = 17.1 (SD 8.2) minutes/day, stepping time 1.3 (SD 0.5) hours/day, steps per day = 5902 (SD 2478), summarized from 46 people to-date.

Results and Conclusion: This long-term trial of sitting reduction will provide novel data on the maintenance of sedentary behavior change. Furthermore, we will examine the cardiometabolic health effects of sitting reduction in a population at high risk for cardiovascular and metabolic conditions.

8:00 AM-9:15 AM

STATE OF THE OBSERVATIONAL EVIDENCE LINKING SEDENTARY BEHAVIOR WITH POOR HEALTH: GAPS AND INTERVENTION TARGETS.

Sarah K. Keadle, PhD, MPH¹

¹Cal Poly San Luis Obispo, San Luis Obispo, CA

The 2018 Physical Activity Guidelines (PAG) for Americans included, for the first time, a comprehensive review of the evidence linking sedentary behavior and health. Based primarily on the observational evidence linking sedentary behavior with several chronic diseases, the PAG includes a recommendation for all adults to “move more, sit less”. Gaps in epidemiologic studies and a lack of randomized clinical trials precludes more specific recommendations. Several recent studies have applied analytic techniques such as physical behavior indexes, compositional and isotemporal techniques to estimate the impact of replacing sedentary behavior with different types of physical activities on health outcomes. These studies have consistently demonstrated that the least active (i.e., those engaging in little or no exercise) have greater reduction in chronic disease risk or mortality when replacing sedentary time with light intensity activity. There is also a need to consider the differential health risks and determinants of different types of sedentary behavior when designing interventions. The PAG report identified moderate evidence for the efficacy of workplace interventions to reduce sedentary time, but fewer studies have successfully reduced discretionary time, and relatively few have targeted television viewing, which has the strongest health risks and consumes most of leisure time. This presentation will provide an update on the observational evidence linking sedentary behavior and negative health outcomes and conclude with the implications of this evidence for designing interventions to reduce sedentary behavior.

8:00 AM-9:15 AM

SITTING, STANDING, AND MOVING: CONCEPTS AND MEASUREMENT OF SEDENTARY BEHAVIOR IN BEHAVIORAL INTERVENTIONS

Matthew P. Buman, PhD¹

¹Arizona State University, Phoenix, AZ

Sedentary behavior - which has been defined by the Sedentary Behavior Research Network (SBRN, 2018) as waking behaviors in the seated/lying position at a low energy expenditure (< 1.5 metabolic equivalents) - has emerged as an important public health target. Epidemiologic and experimental evidence depends on valid and reliable measurement to accurately inform the evidence-based guidelines and recommendations and the evaluation of intervention strategies. The majority of the current evidence base relies on self-report or device-based measures. Self-report measures of sedentary time have recall bias limitations and typically do not comprehensively assess contexts of sedentary time (e.g., screen time, workplace, transport, social activities), thus suffer from substantial underreporting. There also appears to be differential bias by context, such that television time is often more accurately reported than other common forms of sedentary behavior. Device-based measures - both research and consumer grade devices - often rely on a movement-based threshold to determine sedentary time and therefore do not capture the postural component of the SBRN definition. Furthermore, these devices may misclassify important behaviors related to sedentary behavior including lying, sleeping, standing, or may not fully capture the patterns in which sedentary behavior is accrued including sedentary bout duration and sit-stand transitions. This presentation will provide an update on the current best practices and emerging methods in sedentary behavior measurement, including: optimal uses of self-report methods for assessing sedentary behavior, a review of commonly used device-based measures of sedentary behavior (both research and consumer grade) and their strengths and weakness, and emerging methods to improve sedentary behavior measurement and its contexts (e.g., machine-learning) and the accessibility of these methods for behavioral researchers. Data from self-report and device-based measures in several large behavioral intervention trials that targeted sedentary behavior will be used to illustrate these concepts and to reinforce some of the practical considerations of implementing sedentary behavior measures for evaluating behavioral interventions.

4

8:00 AM-9:15 AM

LONGITUDINAL EXAMINATION OF SEDENTARY BEHAVIOR AND SYMPTOM REPORTING IN BREAST CANCER PATIENTS UNDERGOING CHEMOTHERAPY

Whitney A. Welch, PhD¹, Kara L. Gavin, PhD², Juned Siddique, DrPH¹, Jason Fanning, PhD³, Payton E. Solk, BA¹, Marilyn Lu, BA¹, Jennifer H. La, Bachelor of Science in Health Systems Management¹, Cesar A. Santa-Maria, MD, MSCI⁴, William Gradishar, MD⁵, Seema A. Khan, MD⁵, Swati Kulkarni, MD¹, Siobhan M. Phillips, PhD, MPH¹

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²University of Wisconsin, Madison, WI; ³Wake forest university, Winston salem, NC; ⁴Johns Hopkins, Baltimore, MD; ⁵Northwestern University, Chicago, IL

Introduction: Emerging data suggest chemotherapy (CT) induced symptoms may be associated with greater daily time spent in sedentary behavior (SB) post-treatment for breast cancer. However, little is known about the relationship between symptom burden and SB during CT. The purpose of this study was to examine the relationship between daily fluctuations in symptoms and SB during CT for breast cancer.

Methods: Breast cancer patients (N=68, Mage= 48.5±10.4 years) undergoing chemotherapy (CT) wore an Actigraph accelerometer for 24hours (on the hip during the day, wrist while sleeping) to assess daily SB and completed prompts assessing symptoms (affect, anxiety, depression, fatigue, pain, and physical and cognitive functioning) for 10 consecutive days (3 days pre-, day of, and 6 days post-CT) at the beginning, middle and end cycles of CT. Separate mixed models assessed the between person (BP) and within person (WP) associations of current day symptoms with minutes of SB measured on 1) the same day and 2) the next day, controlling for relevant covariates.

Results: BP ratings of affect (b=-14.65, p=0.01), fatigue (b=41.42, p=0.01), activities of daily living (ADL) (b=26.43, p=0.03) and walking (b=29.61, p=0.02) physical function were significant for same day SB, such that those with worse symptom ratings spent more time in SB. WP results revealed a significant association between affect (b=-10.42, p< 0.001), anxiety (b=5.88, p=0.002), fatigue (b=27.31, p< 0.001), ADL (b=29.02, p< 0.001) and walking (b=28.86, p< 0.001) physical function, pain (b=5.93, p< 0.001), and cognitive functioning (b=-19.94, p< 0.001) with same day SB. Poorer than average symptom ratings on a given day were associated with more SB that day. Previous day reported symptoms and next day SB results indicated a significant BP association for ADL (b=25.93, p=0.03) and walking (b=28.60, p=0.03) physical function (i.e. those with poorer physical functioning spent more time in SB). WP results indicate a significant relationship between previous day anxiety (b=-10.26, p< 0.001) ADL physical function (b=-6.01, p=0.001) and next day SB (i.e., worse than average symptom ratings the prior day were associated with more SB the next day).

Conclusion: Daily WP and BP variations in symptoms were associated with SB during CT for breast cancer. Future work should further explore the temporal relationship between symptoms and SB to identify SB reduction intervention approaches that incorporate tailoring to daily symptom burden during CT for breast cancer.

8:00 AM-9:15 AM

PROMOTING DAY-LONG MOVEMENT IN OLDER ADULTS WITH CHRONIC PAIN: THE MORPH STUDY

Jason Fanning, PhD¹, Amber Brooks, MD², W. Jack Rejeski, PhD³, Barbara Nicklas, PhD²¹Wake forest university, Winston salem, NC; ²Wake Forest School of medicine, Winston-Salem, NC; ³Wake Forest University, Winston-Salem, NC

Sitting is a common response to the sensation of pain, but extended bouts of sitting often produce stiffness, weight gain, and inflammation. This cycle results in high rates of sedentary behavior among individuals with chronic pain and increases the individual's risk for a host of chronic diseases. One unique strategy for reducing the presence of sustained bouts of sitting in older adults with chronic pain is to promote the accumulation of light- and moderate-to-vigorous intensity physical activity throughout the day. To accomplish this goal, individuals must develop an awareness of how they pattern their movement and sitting during the day and should be given access to intervention tools that incentivize consistent movement rather than in a single discrete bout. The purpose of the MORPH pilot trial is to leverage an iterative user-centered development process to build a digital health-supported, social cognitive theory-driven program meant to promote weight loss and movement throughout the day. MORPH is comprised of 12 weekly group telecoaching sessions discussing topics related to pain, physical activity, and healthy eating. These sessions are supported by a smartphone application paired with a Fitbit activity monitor. Fitbit data are streamed into the app in real time, providing visual feedback on activity patterning, and participants set multiple daily activity goals that promote movement before lunch, before dinner, and after dinner. During the first phase of the trial, the MORPH intervention was developed in conjunction with a small group ($N = 5$) of older adults with chronic pain. Each participant provided feedback on use and usability of the smartphone app, and then utilized the intervention materials for one week in the home to ensure real-world usability and to provide feedback on experiences. Changes were made between participants, and recruitment ceased when no substantive changes were required. Next, a second small group ($N=5$) piloted the full 12-week intervention to identify lingering use and usability issues. A final sample ($N=30$) were recruited to participate in the second phase of the study wherein these individuals were randomly assigned to an immediate 12-week intervention condition or to a wait-list control. This presentation will focus on intervention-related changes in physical activity parameters (i.e., daily steps, minutes of physical activity) and sedentary behavior parameters (i.e., average bout length, sedentary breaks) collected before and after the 12-week intervention using ActivPAL devices. Additionally, changes in these parameters during the intervention will be explored using the Fitbit data collected serially throughout the program.

Symposium 37

8:00 AM-9:15 AM

FEMALE SEXUAL HEALTH AND CANCER: BRIDGING THE GAP TO EFFECTIVE EVIDENCE-BASED BEHAVIORAL INTERVENTIONS

Jennifer B. Reese, PhD¹, Kristen M. Carpenter, PhD², Sharon L. Bober, Ph.D.³, Stephen J. Lepore, PhD⁴¹Fox Chase Cancer Center, Philadelphia, PA; ²Ohio State University, Upper Arlington, OH; ³Dana-Farber Cancer Institute, Boston, MA; ⁴Temple University, Philadelphia, PA

Purpose: Despite decades of observational research demonstrating that sexual dysfunction is a prevalent source of distress for women with cancer, effective evidence-based interventions addressing this problem still lag. As more women become long-term survivors, it is essential that efforts move from describing this problem to developing effective interventions. Understanding what may lead women to seek help for sexual problems and developing targeted interventions to meet women's needs are essential for bridging this significant gap in cancer care. The objective of this symposium is to describe several projects at the cutting edge of research developing and evaluating novel behavioral interventions for cancer-related sexual problems for women with cancer.

Method: The following empirical findings will be presented: (1) Data from a sample of breast cancer outpatients participating in a sexual health communication intervention characterizing baseline levels of sexual help-seeking and examining the extent to which self-efficacy for communicating clinically about sexual concerns is associated with sexual help-seeking ($N=144$); (2) Results of a single-arm trial evaluating a brief, targeted psychosexual intervention for young breast cancer survivors on ovarian suppression (OS) treatment ($N = 20$); and (3) Results of a replication study testing the feasibility and preliminary efficacy of a group psychosexual intervention for improving sexual outcomes among women with breast cancer ($N = 28$).

Results: Findings clarify key aspects of women's sexual help-seeking after cancer, including the role of self-efficacy for communicating about sexual issues, and demonstrate positive effects of novel behavioral interventions for female cancer survivors across a variety of sexual and psychosocial outcomes, including clinically significant sexual dysfunction and emotional distress.

Conclusion: Results underscore the importance of developing that can address sexual health for women with cancer from different angles, including through offering education and skills directly, as well as through educating women and providers on how to communicate effectively about sexual health after cancer. Research implications and important future directions will be discussed. The discussant, an expert in clinical trials of psychosocial interventions in cancer, will bring his perspective to the discussion of how to bridge the gap to effective evidence-based behavioral interventions addressing sexual health for women after cancer.

8:00 AM-9:15 AM

UNDERSTANDING SEXUAL HELP-SEEKING FOR WOMEN WITH BREAST CANCER: HOW DO WOMEN WHO SEEK HELP DIFFER FROM THOSE WHO DO NOT?

Jennifer B. Reese, PhD¹, Kristen A. Sorice, BA¹, Whitney Pollard, BA², Lauren A. Zimmaro, PhD³, Mary Catherine Beach, MD, MPH⁴, Stephen J. Lepore, PhD⁵

¹Fox Chase Cancer Center, Philadelphia, PA; ²Fox Chase Cancer Center; ³Fox Chase Cancer Center, Harleysville, PA; ⁴Johns Hopkins School of Medicine, Baltimore, MD; ⁵Temple University, Philadelphia, PA

Background/Objectives: There are considerable barriers to women surviving breast cancer (BC) in seeking help for sexual concerns. The objectives were to determine, in a sample of BC outpatients, (1) how commonly women sought help for sexual concerns, either from a health care provider (HCP), a non-HCP (spouse/partner/relative/friend), or alternate sources (internet/print materials/radio), and (2) whether women who sought help versus did not seek help differed in their level of sexual concerns or in their confidence in talking with their BC provider about sexual health (communication self-efficacy).

Methods: As part of a sexual/menopausal health communication intervention trial, BC patients completed baseline web-based self-report surveys assessing socio-demographic characteristics, help-seeking behavior for sexual concerns in the past 30 days [3 items; 1: discussed with HCP; 2: discussed with non-HCP; 3: sought information from alternate sources], and communication self-efficacy (score range [0-20]). Sexual concerns were measured during screening using a validated item assessing problems with sexual interest, enjoyment or performance (score range [0-10]). Comparisons between women who sought help versus did not were conducted using Chi-square analyses or t-tests.

Results: 144 women (M age=56.0; 62% partnered; 67% White; 15% Stage IV) participated, with 67% reporting sexual concerns (M=4.7). More women sought help from non-HCPs (59%) than from HCPs (24%) or alternate sources (21%). Women who sought help from any source reported significantly worse sexual concerns (M=6.1) than those who did not (M=3.3, $p<.001$). Surprisingly, women who discussed sexual concerns from their HCP reported comparable communication self-efficacy (M=14.4) as women who did not (M=15.3, $p=.38$). However, women who sought help from a non-HCP or alternate sources had significantly lower communication self-efficacy (M=13.6 and 13.0, respectively) than those who did not seek help from a non-HCP (M=16.1, $p=.004$) or alternate sources (M=15.6, $p=.03$), respectively.

Conclusions: Findings suggest that women tend to seek help for sexual concerns when such concerns are more severe, that they most often seek help from non-HCPs as compared to HCPs, and that they may seek help from sources other than HCPs partly because they lack the self-efficacy to do so from a HCP. Interventions are needed to improve women's communication self-efficacy and to educate both HCP's and women's caregivers on BC-related sexual health so these groups can effectively provide such support.

2

8:00 AM-9:15 AM

SEXUAL HEALTH AND RELATIONSHIP ENHANCEMENT (SHARE) FOR WOMEN WITH BREAST CANCER: RESULTS FROM A CLINICAL TRIAL

Kristen M. Carpenter, PhD¹, Hannah Holmes, PhD², Lora Black, PhD³, Katherine Conroy, BA⁴

¹Ohio State University, Upper Arlington, OH; ²Appalachian State University; ³University of Kansas Medical Center; ⁴University of Washington

Objectives: Test a group psychosexual intervention -- Sexual Health and Relationship Enhancement (SHARE) -- designed for gynecologic cancer survivors in a sample of breast cancer survivors to determine feasibility and efficacy.

Methods: Participants were breast cancer survivors (N = 28). The majority (53.6%) was diagnosed at stage I (stage II: 35.7%, stage III: 10.7%). The participants were primarily Caucasian (75%) with an average age of 50.6 years (SD = 11.7, range = 29-79) and the majority were partnered (75%). Intent-to-treat (ITT) analyses were conducted for treatment outcomes. Using all available data, mixed effects modeling tested for change in treatment outcomes from the initial assessment to 3-, 6-, and 9-month assessments. Cohen's d effect sizes were reported at post-treatment (6 months) and follow-up (9 months). The reliable change index was used to determine whether reliable clinical change had been achieved for each patient.

Results: The 12-session attendance rate was 23%. The mean number of SHARE sessions attended was 9 (SD=3.2). The rate therapy dropout was 10% (n=3). The patients viewed the treatment as helpful; average helpfulness ratings were 2.5 out of 3.0 (SD=0.4) and 84% of ratings fell in the moderately to very helpful range. Using a 0 to 10 point scale for cohesion, the means were 8.0 (SD=1.1) for involvement in the therapy experience and 9.2 (SD=1.1) for felt support. Significant linear effects of time (improvements) were seen for sexual function, satisfaction, and distress ($p<.001$); sexual behavior did not change. Effect sizes of change from baseline to post-treatment and follow-up on significant outcome measures were large ($d=0.75-1.06$). Most participants' improvement in sexual function (65.2%) and sexual distress (66.7%) was reliable. Almost half of participants reported clinical levels of sexual distress at baseline that decreased to sub-clinical levels at follow-up, and 16.7% of participants had baseline clinical sexual dysfunction that was sub-clinical at follow-up.

Conclusions: SHARE-B is feasible and efficacious for addressing sexual morbidity following breast cancer, indicating it is likely possible to deliver to women with a variety of disease sites improving scalability of the intervention.

3

8:00 AM-9:15 AM

IMPROVEMENT IN SEXUAL FUNCTION AFTER OVARIAN SUPPRESSION: SEXUAL HEALTH AND REHABILITATION AFTER OVARIAN SUPPRESSION TREATMENT FOR YOUNG BREAST CANCER SURVIVORS (SHARE-OS).

Sharon L. Bober, Ph.D.¹, Christopher Recklitis, Ph.D, MPH¹¹Dana-Farber Cancer Institute, Boston, MA

Objectives: Each year, tens of thousands of young breast cancer (BC) patients confront the difficult decision to medically suppress their ovarian function and undergo abrupt, premature menopause to reduce their risk of cancer recurrence. Unlike natural menopause, young women undergoing ovarian suppression (OS) face severe and disruptive side effects. Profound sexual dysfunction is one of the most prevalent and distressing side effects of OS for young BC survivors. Unmanaged OS-related sexual dysfunction is also the primary predictor for non-adherence to this potentially life-saving treatment. The need for targeted sexual health intervention for this population is pressing because the use of OS in young women is rapidly expanding. We developed and tested a brief, psychosexual intervention targeted to manage sexual dysfunction after OS in young BC survivors.

Methods: 20 young BC survivors with sexual dysfunction received a single half-day group intervention that included sexual health rehabilitation strategies, body awareness exercises and elements of mindfulness-based cognitive therapy (MBCT) skills to address sexual symptoms. The 4-hour group meeting was followed by a single tailored booster telephone call one-month later. Assessment measures were completed at two time points: Baseline and 2-months post-group intervention. The Female Sexual Function Index (FSFI) assessed sexual functioning and the Brief Symptom Inventory (BSI-18) captured psychological distress.

Results: Analyses examined changes from Pre- to Post-intervention. Total FSFI scores improved significantly from baseline to follow-up ($n=19$, $p<.02$). Effect sizes were moderately large indicating a significant improvement in women's sexual function post- intervention ($d=.5$). Anxiety as measured by the BSI-18 was also significantly improved at the 2 -month ($p<.000$) time-point, compared to Baseline 1.

Conclusions: Significant improvements in overall sexual functioning and psychological distress were observed 2 months post-intervention, suggesting preliminary efficacy of this brief, targeted intervention to reduce distressing sexual dysfunction in young BC survivors on OS treatment. These promising results demonstrate that a randomized trial of START-OS is warranted.

Symposium 38

8:00 AM-9:15 AM

THE ROLE FOR SBM IN 'THE LANCET PSYCHIATRY COMMISSION: A BLUEPRINT FOR PROTECTING PHYSICAL HEALTH IN PEOPLE WITH MENTAL ILLNESS'

Philip B. Ward, PhD¹, Joseph Firth, PhD², Scott B. Teasdale, PhD; BNutrDiet; BAppSci (Nutr&Food)³, Felipe Schuch, NA⁴, Simon Rosenbaum, BSc, PhD⁵, Jacob D. Meyer, PhD⁶

¹UNSW, Sydney, New South Wales, Australia; ²University of Manchester, Manchester, England, UK; ³UNSW Sydney, Vevey, Vaud, Switzerland; ⁴Federal University of Santa Maria, Santa Maria, Rio Grande do Sul, Brazil; ⁵UNSW Sydney, SYDNEY, New South Wales, Australia; ⁶Iowa State University, Ames, IA

All across the world, people with severe mental illness die 15-30 years younger than the general population. However, this gap in life expectancy is primarily due to physical diseases, rather than mental health causes. Although these severe inequalities in physical health is gaining more attention than ever, the large disparities in health outcomes for those with mental illness have persisted overtime, and may even be worsening in some regions. For these reasons, the 2019 Lancet Psychiatry Commission¹ was assembled to create "A Blueprint for Protecting Physical Health in People with Mental Illness". To do this, The Lancet Psychiatry Commission brought together an international team of researchers, clinicians, and key stakeholders, aiming to summarize advances in understanding on this topic, and present clear directions for health promotion, clinical care and future research.

The Commission's aims are addressed across five separate Parts, as follows;

- Part 1: "Its More Than Premature Mortality"; Determining the scope and burden of physical health inequalities in psychiatric disorders.
- Part 2: "Identifying Key Pieces of the Puzzle"; Identifying modifiable factors and promising behavioral health targets for improving health outcomes.
- Part 3: "Improving Prescribing Practices"; Understanding, avoiding and mitigating side-effects of psychotropic treatment.
- Part 4: "Going Multi-Disciplinary on Multi-Morbidity"; Implementing health behavior change for staff and service-users, and
- Part 5: "Innovations in Integration"; examining how physical health interventions can be integrated flexibly across mental health settings.

Collectively the findings of the Commission have produced an array of novel and promising directions for health policy, clinical services and future research for protecting physical health in people with mental illness. For this symposium, key findings from Parts 1-5 of the Commission will be presented with specific relevance to actionable implications for SBM, and behavioral health initiatives in general. Discussion with the audience will be encouraged, and hard printed copies of the full Commission will be available following the event.

¹ Firth J, Siddiqi N, Koyanagi A, Siskind D, Rosenbaum S, Galletly C, et al. (2019). The Lancet Psychiatry Commission: A Blueprint for Protecting Physical Health in People with Mental Illness. *The Lancet Psychiatry*, 6(8): 675-712.

CORRESPONDING AUTHOR: Philip B. Ward, PhD, UNSW, Sydney, New South Wales, Australia; p.ward@unsw.edu.au

- 1** **8:00 AM-9:15 AM**
- THE BURDEN OF POOR PHYSICAL HEALTH IN MENTAL ILLNESS: BACKGROUND TO THE COMMISSION**
- Philip B. Ward, PhD¹
- ¹UNSW, Sydney, New South Wales, Australia
- In order for the Lancet Psychiatry Commission to present novel solutions for improving physical health outcomes in people with mental illness, it was firstly important to aggregate and improve our understanding on the co-occurrence of physical and mental illness. Thus, the first talk of the symposium will describe the background and rationale for Part 1 of the Commission, and explain the outcomes of the priority-setting activities undertaken to determine the Commission's scope. In order to identify the need for physical health improvement across many different classes of mental illness, we applied a systematic methodology for aggregating the findings from all meta-analyses on this topic. This systematic overview brought together the data from almost 100 systematic reviews/meta-analyses examining the prevalence of physical comorbidities in mental illness. Results showed that around 70% of the meta-research focused on cardiometabolic diseases; consistently reporting that mental illnesses were associated with 1.4- to 2-fold increased risk for obesity, diabetes and cardiovascular diseases compared to the general population. Although mostly studied in 'severe mental illness' (and particularly psychotic disorders), the prevalence of cardiometabolic diseases was similarly elevated across a broad range of other diagnoses, including substance use disorders, and 'common mental disorders' (such as depression and anxiety). These findings will be discussed in the context of not only how physical diseases contribute to premature mortality in mental illness, but also add to the personal, social, and economic burden of these conditions across the entire lifespan.
- 2** **8:00 AM-9:15 AM**
- TACKLING BEHAVIORAL RISK FACTORS EARLY: TO PREVENT PHYSICAL COMORBIDITIES IN MENTAL ILLNESS**
- Joseph Firth, PhD¹
- ¹University of Manchester, Manchester, England, UK
- To identify the key modifiable risk factors driving the health disparities, Part 2 of the Commission built from the findings of Part 1; producing a hierarchical evidence synthesis of the top-tier evidence for modifiable risk factors for physical diseases in people with mental illness. The available evidence from meta-analyses, systematic reviews and population-scale studies identified that smoking, excessive alcohol consumption, sleep disturbance, physical inactivity and dietary risks were elevated across a broad range of mental health diagnoses, and across various economic settings (i.e. both low, middle and high income countries). Additionally, the evidence highlighted how behavioral risk factors such as smoking, poor diet and inactivity are elevated from the first diagnosis of mental illness, even prior to psychotropic treatment. These findings will be discussed with regards to their implications for behavioral health initiatives. Specifically, it will be explained as to: (i) Why the pre-diagnostic prevalence of behavioral risk factors could represent a failure at policy (rather than health service) levels, (ii) How the disparities in health behaviors between people with mental illness and the general population may be due to both a willful abandonment of health promotion initiatives to reach these marginalized groups, combined with targeted marketing towards mental illness by big tobacco and fast-food giants, and (iii) That there is an urgent need for national health strategies and public policy to provide further consideration and legislation towards protecting those with (or at high risk of) mental illness - who have so far been 'left behind' from population-gains in public health. Finally, it will be discussed how recent advances in digital health technologies may provide new possibilities for wide-scale deliver of behavioral health initiatives for marginalized groups, such as those with mental illness.
- 3** **8:00 AM-9:15 AM**
- UNDERSTANDING AND ADDRESSING DIETARY RISKS IN MENTAL ILLNESS**
- Scott B. Teasdale, PhD; BNutrDiet; BAppSci (Nutr&Food)¹
- ¹UNSW Sydney, Vevey, Vaud, Switzerland
- Dietary risks as one of the key contributors to the development of obesity, cardiovascular disease and diabetes, and consistent evidence is showing less healthy dietary intakes are linked to poorer mental health and cognition. Strong evidence has shown that people living with mental illness have more excessive and less healthy dietary intakes compared to people without mental illness. The unhealthy dietary intake is apparent early in course of illness, with psychotropic medication appearing to exacerbate the problem, and appears to continue throughout the course of the illness and treatment. The reasons for the excessive and unhealthy dietary intakes are often multifactorial with patients and clinicians presented with additional unique challenges compared to people without mental illness. Despite these challenges, the Commission found robust evidence for dietary interventions as a core component of lifestyle interventions for people living with mental illness. Exploration of study components found that interventions were highly variable, particularly in terms of profession delivering the intervention, timing of intervention in the course of illness, and delivery method. This presentation will cover the following components: (i) describe the dietary intake and eating behaviours of people living with mental illness, (ii) highlight factors that driving the excessive and unhealthy dietary intake which are unique to people living with mental illness, and (iii) define the Commissions findings for effective dietary interventions in routine care for people living with mental illness.

- THE EFFICACY AND IMPLEMENTATION OF PHYSICAL ACTIVITY FOR PREVENTING PHYSICAL-MENTAL COMORBIDITY**
- Felipe Schuch, NA¹
- ¹Federal University of Santa Maria, Santa Maria, Rio Grande do Sul, Brazil
- Among the various modifiable factors identified by the Commission, physical inactivity is prevalent across a range of mental illnesses, and contributes to a broad range of physical. Indeed, substantial evidence demonstrates the protective role of physical activity and exercise against the emergence of both physical and mental illness. Similarly, the Commission presents the robust evidence that PA and exercise programs should be incorporated to the treatment of people with mental illness, both to protect their physical health, reduce psychiatric symptoms, improve their functional and, increasing their quality of life. Unfortunately however, translation of this body evidence to clinical practice is still slow, and exercise is under-recognized and under-recommended by mental health professionals. One of the reasons is the information gap, in which mental health professionals or does not have the proper knowledge to prescribe or recommend exercise to their patients. This scenario is even worse in middle-income countries. To close the information gap and facilitate the implementation of exercise programs, we outlined an international training program for mental health professionals regarding exercise prescription and recommendation with the most updated evidence available. The program consists of 10 topics: diagnostic features of the most prevalent mental illness (anxiety, mood, psychotic, eating, substance use disorders); main trans-diagnostic treatments; communication with people living with mental illness; physical health of people with mental illness; evidence on exercise as a preventative factor; evidence of exercise as a treatment; underlying biopsychosocial mechanisms of exercise effects; exercise prescription; motivation and behavioral change; and culture change. Along with describing the supporting evidence and design of such programs, this talk will present evidence-based strategies for implementing physical activity and exercise within the mental healthcare and service.

INTEGRATING HEALTH BEHAVIOR CHANGE THROUGH EVIDENCE-BASED LIFESTYLE INTERVENTIONS FOR PEOPLE WITH MENTAL ILLNESS

Simon Rosenbaum, BSc, PhD¹¹UNSW Sydney, SYDNEY, New South Wales, Australia

Despite the strong efficacy of evidence-based lifestyle interventions in people with mental illness (discussed in talks 3 and 4), people receiving treatment for mental illness rarely have access to evidence-based lifestyle programs, through either primary-care or secondary-care services. This is also at-odds with multiple national and international guidelines (such as the World Health Organization), which now recommend the use of lifestyle interventions for improving health outcomes in mental illness. Thus, Part 4 of the Commission focuses on the efficacy and implementation of multidisciplinary lifestyle interventions in mental healthcare. To do this, the Commission reviews key 'Lessons learned' from large scale trials and real-world implementation efforts of lifestyle interventions for psychiatric populations, and presents the Diabetes Prevention Program (DPP) as an example of a gold-standard lifestyle intervention that has broadly been successful in the general population. This presentation will explain how and why future lifestyle interventions in mental healthcare must adopt the core principles of the DPP; by partnering with appropriately trained physical health professionals, and by providing sufficient access to supervised exercise services. Within this, it must be remembered that "Prevention" sits at the centre of the DPP. Similarly, lifestyle interventions for people with mental illness should be available pre-emptively, in order to protect metabolic health from first illness presentation. Priorities for future initiatives and research include (i) translating DPP-based interventions for people with mental illness - across primary care, secondary services and LMIC settings, and (ii) using implementation science and cost-effectiveness evaluations to develop a business-case for integrating DPP-based interventions as standard in mental healthcare.

Symposium 39

8:00 AM-9:15 AM

ILLNESS PERCEPTIONS: CURRENCY OF LEVENTHAL'S COMMON-SENSE MODEL OF SELF-REGULATION IN BEHAVIORAL MEDICINE

Barbara L. Andersen, PhD¹, Howard Leventhal, PhD², Olayinka O. Shiyabola, PhD BPharm³, Deepika Rao, BPharm. M.S.⁴, Jo-Hsin Chen, BPharm⁵, Meng-Jung Wen, BS Pharm⁶, Lisa McAndrew, PhD⁷, Wilfred Pigeon, PhD⁸, Karen S. Quigley, Ph.D.⁹, David R. Litke, Ph.D.¹⁰, Shou-En Lu, PhD¹¹, L. Alison Phillips, PhD¹², Thomas R. Valentine, MA¹³, Stephen B. Lo, MA¹, Nicole A. Arrato, M.A.¹

Several decades after its origin, Howard Leventhal's *Common-Sense Model of Self-Regulation* (CSM) remains a widely used theoretical framework for understanding how individuals respond to and manage physical symptoms and illness. The CSM proposes that when faced with a health threat, an individual generates cognitive and emotional representations of said threat which guide coping. Subsequently, the individual appraises the effects of his/her responses and, via a dynamic feedback loop, adjusts. Among the model's many strengths are its empirical base, broad applicability to health populations, and its utility to hypothesize, test, and discover processes underlying important illness-related outcomes.

Chaired by Dr. Barbara L. Andersen, the symposium presents ongoing behavioral medicine research capitalizing on the Model's strengths and then invites Dr. Leventhal's commentary. First, guided by the CSM, Dr. Lisa McAndrew details a study examining how the degree of concordance between patients' and providers' beliefs about persistent physical symptoms (i.e., medically unexplained symptoms) relates to satisfaction with healthcare and treatment adherence using a sample of Gulf War Veterans. Second, Dr. Olayinka Shiyabola will discuss the methodology of assessing illness perceptions in African Americans—particularly those with type II diabetes—and describes the development of a culturally-adapted measure of illness perceptions. Third, Thomas Valentine and Stephen Lo have studied individuals with advanced lung cancer and detail patients' illness perception schemas at diagnosis and their importance for understanding patients' later mental health and physical symptomatology. Last but not least, Discussant Dr. Howard Leventhal will consider these studies within the broader field of health behavior research and offer his perspective on how behavioral medicine professionals can utilize the CSM to guide future study and clinical practice.

AN EXPLORATORY SEQUENTIAL MIXED METHODS STUDY TO ADAPT THE ILLNESS PERCEPTION QUESTIONNAIRE-REVISED FOR USE WITH AFRICAN AMERICANS

Olayinka O. Shiyabola, PhD BPharm¹, Deepika Rao, BPharm. M.S.², Jo-Hsin Chen, BSPharm³, Meng-Jung Wen, BS Pharm⁴

¹University Of Wisconsin-Madison, Madison, WI; ²University of Wisconsin-Madison, MADISON, WI; ³University of Wisconsin-Madison, Banqiao Dist., New Taipei, Taiwan (Republic of China); ⁴University of Wisconsin-Madison, Taipei, Taipei, Taiwan (Republic of China)

Data suggest that the Illness Perception Questionnaire-Revised (IPQ-R) may have limitations of its reliability and validity when used with African Americans/Blacks (AAs), prompting the need for examination and development of a culturally-adapted (CA) version of the IPQ-R. Using sequential mixed methods, there were three objectives of the research: 1) discover and characterize beliefs about type 2 diabetes mellitus (T2DM) among AAs; 2) Using this information, write new CA IPQ-R items; and, 3) determine the psychometric properties of the CA IPQ-R.

Methods: Forty AAs with T2DM participated in six focus groups to explore their perceptions of diabetes and sociocultural factors which may be influential, using the Self-Regulatory Model as a framework. A content analysis revealed themes, and actual phrases of individuals were used to write new CA IPQ-R items. Next, cognitive interviews were done to explore CA item meaning/interpretations with a sample of 10 AAs. The CA IPQ-R was then administered to 123 AAs in a survey which included the Adherence to Refills and Medication-Diabetes scale, beliefs in medicines, and the IPQ-R. Correlational analyses were used to determine convergent validity of the CA IPQ-R, and multiple linear regression analyses were used for predictive validity studies. Internal consistency (Cronbach's alpha) is reported.

Results: Themes related to the existing IPQ-R and a new sociocultural domain showing AA perceptions were influenced by their discrimination experiences, AA community, and perceived role of race in relation to personal control. Findings were used in adapting the IPQ-R. Five questions from the CA IPQ-R were problematic and revised. Illness perceptions as assessed with the CA IPQ-R showed a moderate correlation with IPQ-R ($r = -0.68$, $p = 0.00$) and concern beliefs regarding medicines ($r = 0.60$). Individual items of the CA IPQ-R---consequences, personal control, emotional representation, causes and sociocultural influences---were significantly correlated with concern beliefs (range=0.28 to 0.60). Cronbach alphas ranged from 0.37-0.89. Illness perceptions and concern beliefs covaried with medication adherence ($B = -0.29$, $p = 0.003$; $B = -0.29$, $p = 0.013$, respectively).

Conclusions: These early data show the culturally adapted (CA) IPQ-R for use with AAs to converge with the IPQ-R and related measures. These data provide an empirical basis for pursuing further psychometric analyses with larger AA samples, including those with and without type 2 diabetes mellitus.

8:00 AM-9:15 AM

THE IMPORTANCE OF CONCORDANT PERCEPTIONS OF PERSISTENT PHYSICAL SYMPTOMS: A STUDY OF GULF WAR VETERANS AND THEIR VA HEALTH CARE PROVIDERS

Lisa McAndrew, PhD¹, Wilfred Pigeon, PhD², Karen S. Quigley, Ph.D.³, David R. Litke, Ph.D.⁴, Drew Helmer, M.D.⁵, Shou-En Lu, PhD⁶, Alison Phillips, PhD⁷

¹War Related Illness and Injury Study Center, Veterans Affairs New Jersey Healthcare System, East Orange, NJ; ²Veteran Affairs, Canandaigua, NY; ³Northeastern University, Needham, MA; ⁴VA NJHCS, East Orange, NJ; ⁵Veterans Administration New Jersey Health Care System, East Orange, NJ; ⁶Rutgers University, Piscataway, NJ; ⁷Iowa State University

More than half of patients with persistent physical symptoms (PPS; also termed medically unexplained symptoms, e.g., chronic pain) are dissatisfied with their care and oftentimes, relationships with their medical provider. Consistent with Leventhal's Common-Sense Model of Self-Regulation, such dissatisfaction may be due to discordant beliefs between patients and providers about the cause, consequences, and nature of PPS and the appropriate treatment approach. What is not known is if the development of greater concordance about PSS between patients and providers during treatment would be associated with higher satisfaction and adherence.

Method: Using a two-treatment group randomized trial (N=91), Veterans with Gulf War Illness (i.e., PSS) to receive 12-weeks of health education vs. 12-weeks of problem-solving treatment. Using a validated measure, patients and their providers were asked if they perceived concordance about PSS at 4-weeks and 12-weeks. Also assessed at 12 weeks was patient's satisfaction with treatment, adherence to treatment, and perception of their relationship with their provider.

Results: Patients were similarly satisfied and adherent to both treatments and the outcomes described did not differ between groups. Patients' perception of concordance with their provider about PSS at 4-weeks and 12-weeks was related to satisfaction ($r = .25$, $p < .05$ & $r = .64$, $p < .01$), self-report adherence ($r = .08$, ns & $r = .22$, $p < .05$), and perception of their relationship with their provider ($r = .27$, $p < .01$ & $r = .53$, $p < .01$). Providers' perceptions of concordance about PSS with their patient was unrelated to patients' satisfaction, treatment adherence, or perceptions of their relationship with their provider. However, patients' perception of concordance about PPS was a stronger predictor of treatment satisfaction and adherence than perceptions of their relationship with their provider.

Conclusion: The development of concordant beliefs between patients and providers about PSS can improve satisfaction and adherence. Also, achievement of concordance may be an important goal of treatment, providing support for Leventhal's Common-Sense Model of Self-Regulation as a guide treatment development.

8:00 AM-9:15 AM

THE WHOLE IS GREATER THAN THE SUM OF ITS PARTS: ILLNESS PERCEPTION SCHEMAS PREDICTING HEALTH OUTCOMES IN PATIENTS WITH LUNG CANCER

Thomas R. Valentine, MA¹, Stephen B. Lo, MA², Nicole A. Arrato, M.A.²¹The Ohio State University, Birmingham, AL; ²Ohio State University, Columbus, OH

According to Leventhal's Self-regulatory Model (SRM), upon facing an illness stimulus, an individual forms a mental representation of the stimulus (illness perception; IP) which impacts illness outcomes. Studies typically analyze IP data at the item/component level. However, the SRM suggests that IPs do not exist in isolation; rather, they comprise schemas. This study compared two perspectives on patients' IP data—individual components (i.e., item by item) vs. empirically determined schemas—and then tested their differential contribution to predicting mental and physical health outcomes.

Method: Stage-IV Non-Small Cell Lung Cancer (NSCLC; N=164) patients completed the Brief Illness Perception Questionnaire which includes IP items/components of illness consequences, timeline, personal control, treatment control, identity (symptoms), coherence (understanding), concern, and emotional response at diagnosis. Also completed at diagnosis and four months later were measures of eight outcomes: anxiety (GAD-7) and depressive (PHQ-9) symptoms, physical symptoms (dyspnea, cough, pain, and overall symptoms), and an overall health rating (EQ5D5L and EQVAS). First, IPs at diagnosis were used in a latent profile analysis (LPA) to determine patients' shared IP schemas. Next, linear regression analyses examined associations of IP components and schemas with baseline and follow-up outcomes. For each, analyses compared component and schema model fit (R^2 and BIC).

Results: LPA revealed three schemas: "positive" (n=28), "negative" (n=52), and "mixed" (n=84). Groups differed on all IP components except coherence. At baseline and 4-months, NSCLC patients with a negative schema exhibited the most severe mental health and physical symptoms and the poorest health status ($p < .05$). Although component models (adjusted $R^2 = .11-.36$) explained significantly more variance in outcomes (n=5; 63%) at baseline compared to models using schema groups (adjusted $R^2 = .06-.23$), schema models had either equivalent (n=2; 25%) or better fit (n=6; 75%). With 4-month data, schema models explained equivalent amounts of variance (n=8; 100%) and had better fit (n=8; 100%).

Conclusion: Patients with advanced NSCLC exhibit multiple patterns of IP at diagnosis that are not identifiable via traditional IP component analyses. Importantly, a negative IP schema at diagnosis is prognostic for worse mental and physical health, and is a potential modifiable target for interventions to improve lung cancer outcomes.

Symposium 40

8:00 AM-9:15 AM

SOCIAL LISTENING: HARNESSING BEHAVIORAL HEALTH INSIGHTS FROM REAL-TIME ORGANIC CONVERSATIONS

Rachel N. Ingersoll, MPH¹, Sam Liu, Ph.D.², Anuja Majmundar, M.B.A., M.A.³, Christine Lee, PharmD PhD⁴, Miriam H. Eisenberg Colman, Ph.D.¹, Ronne Ostby, MA¹¹Fors Marsh Group, Arlington, VA; ²University of Victoria, Victoria, BC, Canada; ³University of Southern California, Orange, CA; ⁴FDA, Fulton, MD

Social listening, tracking of what people are discussing around a specific topic on social media, can provide real time insight into the attitudes, beliefs, values, and conversations of the general public. Social listening data can inform formative research, public health interventions, and messaging campaigns, and track their effectiveness. Traditionally used by marketers, this applied research approach to social listening allows researchers to gain insights from real time data while maintaining appropriate academic rigor.

This symposium will present different perspectives and experiences using social listening to understand how people are engaging with content in real time, what this data can inform, and how this can be used to accelerate science and research. Presentations will cover a variety of social listening strategies and applications and discuss the benefits, challenges, and lessons learned from incorporating social listening into their research.

Rachel Ingersoll will present a brief overview of Digimind, a social media analytics platform, and how it can be used to assess the frequency and context around social media conversations on specific health topics. She will discuss how researchers can use social listening platforms like Digimind to follow, engage, analyze, and report trends across different populations and social media platforms and how they can be used to inform interventions and public health campaigns.

Sam Liu will share research on finding innovative methods of using social media data (e.g. Instagram) to monitor and predict health-related outcomes. The findings suggest that Instagram data may be used to estimate a person's levels of physical activity and their exercise identity. He will discuss how social listening can be used to provide real-time monitoring of psychological and behavioural outcomes that inform health behaviors.

Anuja Majmundar will present research that explores whether posting about the health-effects of e-cigarettes on Twitter is associated with a subsequent change in stance toward e-cigarettes, and will provide data showing the utility of computational epidemiology to understand individual-level trajectories in health attitudes. She will discuss how social listening was used to describe user experience with emerging tobacco products and to improve population health surveillance.

Dr. Christine Lee will present research that mined unstructured data collected by the FDA from advisory committees, as well as the social media platform, Twitter, and transformed it into meaningful data. She will discuss how social listening was used to gain insights to help advance communication strategies for minorities with diabetes.

8:00 AM-9:15 AM

USING DIGIMIND TO ENGAGE IN SOCIAL LISTENING OF PUBLIC HEALTH TOPICS

Rachel N. Ingersoll, MPH¹¹Fors Marsh Group, Arlington, VA

Social listening allows researchers to identify trends in publicly available social media discussions and gain real time understanding into people's attitudes, beliefs, and priorities on a wide variety of topics. Using these insights, researchers can develop or refine public health messaging and tactics to align with consumers' mindsets. Digimind, a social listening tool, allows researchers to aggregate public data from social media platforms over time and analyze the who, what, when, where, and how.

Of the many benefits of social listening tools like Digimind, the three that have been most useful in our research have been aggregating data across platforms, obtaining data in real time, and identifying signals. Digimind's coverage of 21 digital media platforms (e.g. Twitter) and ability to aggregate data across platforms facilitated rapid data collection and analysis. Digimind's ability to provide real-time data has allowed us to track in-the-moment discussion, from snapshots in time to trends over time. Lastly, using "noise filtering" capabilities, filtering out unrelated posts containing similar keywords, allows us to more easily assess signals. The ability to refine filtering as Digimind compiles data has minimized the likelihood that unrelated discussions could skew results.

Case studies are used to show how this tool can facilitate research. Digimind shows researchers not only if a topic is being discussed but how and in what context. For example, while examining parents of young children's views on anchoring furniture, we found that what often drives these social media discussions are stories about deaths or injuries related to furniture and TV tip-overs. Digimind also helps organize results to generate insights using big datasets. In a study on people's views on telehealth resources, we found that people responded favorably to using telehealth resources as an alternative to an in-person visit to the doctor's office.

We will also review the challenges faced and the lessons learned using Digimind for social listening, including allocating sufficient time for topic monitoring, limited scope to certain channels, and generalizability limitations.

Incorporating social listening into research can help researchers accelerate their science by taking advantage of the wealth of publicly available information that can provide valuable insights. Findings can be timely and triangulated against other studies. Implications for future research include audience insights on specific interventions, enhance digital strategies to better engage with the target audience, and process evaluations.

2

8:00 AM-9:15 AM

EVALUATING THE RELATIONSHIPS BETWEEN SOCIAL MEDIA POSTS AND EXERCISE IDENTITY

Sam Liu, Ph.D.¹¹University of Victoria, Victoria, BC, Canada

Background: The growing body of social media data is becoming a central part of big data research as these data can be modelled alongside other datasets (e.g. physical activity data) and used to predict outcomes from these datasets. Previous research has shown that social media data could be used to provide real-time monitoring of psychological and behavioural outcomes that inform health behaviours. Currently, it is unclear whether a person's Instagram data can be used to predict a person to physical activity level and exercise identity.

Objective: This study seeks to examine the feasibility of using a person's physical activity related to Instagram posts as a method to monitor physical activity levels and exercise identity.

Methods: Eligible participants were asked to complete questionnaires that assessed their physical activity level, exercise identity and perceived social comparison. Participants' Instagram data (12-month) were downloaded using Instagram's Application Program Interface. Instagram pictures were coded by two research assistants using a set of standardized criteria to determine whether the posts were related to physical activity. The ratio between the physical activity-related posts and the total number of posts were calculated for each participant. Linear regression models were used to evaluate the relationship between a person's physical activity related to Instagram posts as a method to monitor physical activity levels and exercise identity

Results: 40 participants (age \pm SD: 19 \pm 2.1; female: n=25) completed the study. Participants made on average 29.6 posts (range 5-190) over one year before completing the questionnaire. We found that increase in the ratio of the physical activity related Instagram posts were significantly associated with a person's exercise identity (b=.35; 95%CI=.01, .20; p=0.02) and physical activity levels (b=.20; 95%CI=.01, .22; p=0.03) after controlling for age, sex and sense of social comparison.

Conclusion: Using social media data to monitor physical activity level can be a valuable tool for eHealth researchers to help tailor and target physical activity interventions. Future research needs to examine whether additional Instagram data variables (e.g. number of followers, likes, comments) can also be used to predict physical activity-related outcomes.

3

8:00 AM-9:15 AM

IS POSTING ABOUT HEALTH EFFECTS OF E-CIGARETTES ASSOCIATED WITH ATTITUDES TOWARDS E-CIGARETTES?

Anuja Majmudar, M.B.A., M.A.¹, Jon-Patrick Allem, Ph.D.², Tess Cruz, Ph.D.², Jennifer B. Unger, Ph.D.³, Mary Ann Pentz, Ph.D.⁴¹University of Southern California, Orange, CA; ²University of Southern California, Department of Preventive Medicine; ³University of Southern California, Los Angeles, CA; ⁴University of Southern California, Department of Preventive Medicine, Los Angeles, CA

As e-cigarette use (vaping) has grown in popularity in the U.S, misconceptions about the health effects of vaping have also increased. Recent research suggests that vaping may be associated with cancer and respiratory diseases, while other research also demonstrates that vaping may help current smokers quit or reduce cigarette consumption. E-cigarette devices have also evolved to facilitate the use of nicotine and cannabis e-juices, posing an additional challenge in assessing and communicating scientific findings to the public. Social media users contextualize discussions about vaping in light of information from news articles, personal experiences, marketing messages, and peer discussions. To gain a holistic understanding of public experience with tobacco content on social media, it is crucial to examine whether specific characteristics of such messages are associated with subsequent tobacco-related attitudes. Social media data offer an opportunity to infer attitudes towards e-cigarettes (pro-, anti-, neutral) by the public. This study will investigate whether topics associated with perceived health effects of vaping (e.g., pain, cancer, heart disease) are associated with attitudes toward e-cigarettes over time. Posts to Twitter (January 2019–December 2019) will be analyzed using machine learning methods to infer attitude toward e-cigarettes. Based on estimates from ongoing data collection, the expected sample size is 1500 Twitter accounts. Multinomial multi-level logistic regression analyses will then evaluate the association between posting about health effects of vaping and subsequent attitudes towards vaping. Each tweet (Level 1) will be nested under Twitter user accounts (Level 2). Covariates will include mentions of cannabis (yes/no), number of health-related tweets posted per account, and the number of e-cigarette-related tweets posted per account. Findings will offer insights for scalable, personalized social media health interventions.

4

8:00 AM-9:15 AM

UTILIZING SOCIAL MEDIA AND FDA DATA TO ADVANCE COMMUNICATION STRATEGIES FOR MINORITIES WITH DIABETES.

Christine Lee, PharmD PhD¹, chardae Arajo, PharmD², Christine Merenda, RN²¹FDA, Fulton, MD; ²FDA

The FDA has a wealth of data, and a significant amount is unstructured data such as advisory committee (AC) meeting transcripts and public docket comments. Additionally, there is a plethora of unstructured data created by minority group users of social media. Analysis of these types of data is critical to FDA's regulatory mission. This pilot study applied qualitative research methods to unstructured FDA data as well as social media data to understand the audience and gaps in communication to minority groups about diabetes.

This novel research project mined unstructured data collected by the FDA from advisory committees, focus groups, and public dockets, as well as the social media platform, Twitter, and transforming it into meaningful data. Unstructured narrative data was collected from the transcripts of two FDA Advisory Committee Meetings and from approximately six months of Twitter tweets. They were parsed into structured data sets using Python scripts and analyzed using techniques including Valence Aware Dictionary and Sentiment Reasoner (VADER) to compute polarity scores, the Porter Stemmer algorithm to conduct linguistic stemming, and Latent Dirichlet Allocation for topic modeling. Interactive data visualizations were created to track the polarity and importance of sentences across the two transcripts.

The overall sentiment of the advisory committee meetings was positive; the polarity varied by type of speaker (e.g., physician, patient advocate). Combining those topic models with race/ethnicity data and Twitter data, revealed that minority groups communicate about diabetes topics in different ways.

Symposium 41

8:00 AM-9:15 AM

INNOVATIVE METHODS FOR STUDYING THE DYNAMICS OF EMOTIONS AND WELL-BEING

Zita Oravecz, PhD¹, Emilio Ferrer, N/A², Philippe Rast, PhD³, Siwei Liu, PhD⁴, Michael Pavel, Ph.D.⁵¹Pennsylvania State University, State College, PA; ²University of California, Davis, Davis, CA; ³University of California Davis, Davis, CA; ⁴University of California at Davis, Davis, CA; ⁵Northeastern University, Boston, MA

Behavioral sciences have seen a surge in studies where self-reports on psychological states are collected repeatedly over time from many people (i.e., ecological momentary assessment; EMA), yielding intensive longitudinal data (ILD). These data can provide nuanced insights into the within-person processes of emotions and well-being, and individual differences therein. In turn, linking these to health outcomes can inform behavioral interventions. However, analyzing ILD involves methodological challenges. This symposium presents and illustrates the applicability of a series of innovative methodological approaches for examining affective health with ILD from EMA studies. Dr Emilio Ferrer will present on how the dynamic signature underlying the interactions between dyadic units, such as patient-caregiver and parent-child, can make predictions of the behavior of the dyadic system. Dr. Philippe Rast will discuss how individual differences in measurement reliability across time and conditions can be accounted for, and the practical consequences of such individual differences on well-being. Dr Siwei Liu will compare multilevel approaches in the context of relating negative health outcomes and emotional reactivity. Dr Zita Oravecz will show how continuous-time modeling for irregularly spaced, imbalanced longitudinal data can be used for capturing within-person affect dynamics and their links to emotional health.

8:00 AM-9:15 AM

STUDYING LINKS BETWEEN DAILY LIFE AFFECT DYNAMICS AND HEALTH OUTCOMES VIA CONTINUOUS TIME MODELING

Zita Oravecz, PhD¹¹Pennsylvania State University, State College, PA

Affective experiences in daily life have been linked to health outcomes in ecological momentary assessment (EMA) studies. This talk will focus on core affect, which is an integral blend of momentary valence and arousal levels, and can be measured in EMA settings by prompting participants to provide self-reports on how pleasant and active they feel at the moment. Capturing relevant aspects of core affect dynamics is methodologically challenging, as in EMA studies participants often follow different (semi-random) data collection schedules, resulting in irregularly spaced, imbalanced longitudinal data. I will introduce a multilevel continuous-time model for capturing within-person affect dynamics, as well as interindividual differences in these. For example, I will show how we can quantify affect regulation by modeling the individual's tendency to return to their baseline levels. The proposed approach makes it possible to link the sources of individual differences in affect dynamics to time-varying and time-invariant predictors in a one-stage analysis. I will illustrate the approach with data from a four-week long EMA study in which participants provided self-reports on their affective states six times daily at randomly prompted time points. Individual differences in affect dynamics, such as in within-person variability, showed meaningful links to health outcomes.

2

8:00 AM-9:15 AM

MODELS FOR STUDYING AFFECT DYNAMICS OF MACRO- AND MICRO-PROCESSES IN DYADIC INTERACTIONS

Emilio Ferrer, N/A¹¹University of California, Davis, Davis, CA

Two important goals when examining data from dyadic interactions are: (a) the identification of patterns representative of the dynamics between the two dyadic units (e.g., patient-caregiver, parent-child), and (b) the use of such patterns to make predictions about the (future) state of the dyadic system. In this talk, I present models to identify dynamics from intensive data reflecting dyadic interactions. I describe theoretical models that can capture such interactions and offer approaches to apply those models to empirical data. The approaches include statistical and mathematical models as well as exploratory techniques. Some of these models focus on the entire time span of the data, attempting to capture general dynamics between the two individuals in the dyad. These approaches are typically confirmatory and consist of specifying a mathematical expression that pertains to the sample and the entire data set. Other models focus on specific events that take place within concrete data windows, sometimes disregarding the remaining data as not representative of the pertinent process. In this talk, I describe both approaches and then combine them with the goals of obtaining an accurate dynamic signature underlying the interactions across the dyads, as well as making predictions of the behavior of the dyadic system.

3

8:00 AM-9:15 AM

PREDICTING INDIVIDUAL CHANGES IN MEASUREMENT RELIABILITY IN DAILY AFFECT

Philippe Rast, PhD¹¹University of California Davis, Davis, CA

Intensive longitudinal data (ILD) are typically analyzed with time-series models that capture the response over time, conditioned on previous responses and external variables. When multiple time series, or participants, are involved, variations of mixed effects models are often applied. Most of these models focus on the mean structure, that is, the most likely response over time. Hence, residuals reflect the unexplained portion and are typically assumed to originate from a common error variance. In this work we relax the assumption of a common error variance by applying a mixed effects location scale model. Doing so allows one to model the error variance as a function of individual differences, dynamic effects and external variables. This also implies that the residual variance itself still contains relevant information. As illustrated with affect data from the Daily Stress Interview Study (DAISI), these models can be used to relate location and scale effects and predict within-person variability. Moreover, as a result of allowing heterogeneous error variances, we show how measurement reliability can change as a function of time and/or conditions. In other words, reliability is different for different individuals, changes throughout the study and we can identify occasions when measurements are more reliable compared to other times or conditions. Implications for applied researcher are discussed.

4

8:00 AM-9:15 AM

USING REACTIVITY AS A PREDICTOR OF HEALTH AND WELL-BEING: A COMPARISON OF TWO APPROACHES

Siwei Liu, PhD¹¹University of California at Davis, Davis, CA

Intensive longitudinal data, such as daily diary data and experience sampling measurements, enable researchers to examine how people react to various contextual stimuli in their everyday life. Research in this vein has demonstrated important implications of such reactivity on health and well-being. For example, emotional reactivity to stress (e.g., the strength of association between daily emotion and stress of an individual) has been showed to predict negative health outcomes such as elevated inflammation and higher mortality risk. Similarly, an individual's emotional inertia (e.g., the strength of association between negative affect measured on two consecutive days) has been shown to predict mental health indicators such as depression. In this talk, I discuss and compare two different approaches that allow researchers to use reactivity as a predictor of health and well-being. In the multilevel modeling (MLM) approach, reactivity is treated as an observed variable, whereas in the multilevel structural equation modeling (MLSEM) approach, reactivity is modeled as a latent variable. I will present results from Monte Carlo simulations to show that MLM generally leads to biased regression estimates but often yield higher statistical power than MLSEM. As such, MLM may be more appropriate when researchers are interested in evaluating whether a relation exists, whereas MLSEM is more appropriate when the research question concerns about assessing the magnitude of a relation. The differences between the two approaches are illustrated with an empirical example where reactivity to daily stress in food consumption is used to predict indicators of weight status (BMI; waist-to-hip ratio).

8:00 AM-9:15 AM

TRACKING FOR SUCCESS: PREDICTORS AND MECHANISMS OF SELF-MONITORING OF DIET AND PHYSICAL ACTIVITY IN BEHAVIORAL INTERVENTIONS

Kathryn M. Ross, Ph.D., M.P.H.¹, Dori Steinberg, PhD, RD², Rebecca Krukowski, PhD³, Gary Bennett, PhD²¹University of Florida, Gainesville, FL; ²Duke University, Durham, NC;³University of Tennessee Health Science Center, College of Medicine, Memphis, TN

Regular self-monitoring of dietary intake and physical activity are key components of gold-standard behavioral programs for weight loss and chronic disease management. Self-regulation theory posits that self-monitoring promotes behavior change by allowing individuals to observe progress toward goals, providing reinforcement when goals are met and cueing additional changes when they are not. In line with this theory, the empirical literature has demonstrated a consistent association between adherence to self-monitoring and success at changing dietary intake and activity behaviors. Despite strong evidence supporting the role of self-monitoring in behavioral interventions, many important research questions remain, such as: 1) what are potential mechanisms and moderators of the association between self-monitoring and behavior change?; 2) what baseline and early-treatment characteristics and behaviors can predict adherence to self-monitoring?; and 3) how can interventions promote greater adherence to self-monitoring? As part of this symposium, we will present three recent studies that address these important questions. The first presentation will examine the role of self-monitoring in helping individuals stay on track with dietary intake goals despite experiencing temptation to eat foods not consistent with those goals, and further will investigate whether these associations are different for individuals who achieve clinically-significant weight losses during a behavioral intervention, compared to those who do not. The second presentation will identify patterns of adherence to self-monitoring observed during a digital behavioral intervention designed to improve diet quality, and further examine baseline and early-treatment predictors of adherence to self-monitoring. The third presentation will examine how the length and content of tailored feedback messages regarding diet and physical activity self-monitoring can affect intention to continue self-monitoring. Taken together, these presentations address three ways of understanding the predictors and mechanisms of self-monitoring; with these results, it may be possible to design interventions that improve self-monitoring adherence and promote successful behavior change. The discussant will end the symposium by synthesizing results across the three presentations, integrating key findings with the broader behavioral self-monitoring literature and exploring important implications for the development of future studies and interventions.

LEAD US FROM TEMPTATION: THE ROLE OF SELF-MONITORING IN PROMOTING DIETARY ADHERENCE DURING AND AFTER A WEIGHT LOSS PROGRAM

Kathryn M. Ross, Ph.D., M.P.H.¹¹University of Florida, Gainesville, FL

Within the weight management literature, greater adherence to self-monitoring of dietary intake has been shown to improve adherence to dietary intake goals, ultimately promoting greater weight loss. Conversely, experiences of temptation to eat foods that are not consistent with dietary goals has been shown to predict lower dietary adherence. Theoretically, self-monitoring should help individuals who are experiencing temptation to stay on track with dietary intake goals; however, no empirical studies have examined this theoretical link. Moreover, little is known regarding other moderators of the effect between self-monitoring and dietary adherence. The current study addressed these gaps by investigating proximal (week-to-week) associations between self-monitoring, temptation, and dietary adherence in 74 adults (age = 50.7 years, BMI = 31.2 kg/m², 69% Female, 87% White) who completed a 12-week Internet-based weight loss program followed by a 9-month maintenance period. Each week, via a study website, participants reported days of self-monitoring and rated perceived temptation and dietary adherence on 7-point Likert-style items. Linear mixed models were used to assess associations between frequency of self-monitoring, temptation (centered within individual), and dietary adherence within the same week. As an exploratory aim, moderation of these effects by success at achieving clinically-significant weight loss ($\geq 5\%$ from baseline at the end of 12 months) was examined. Results demonstrated that, during a given week, each additional day of self-monitoring was associated with a 0.2 point increase in ratings of dietary adherence, $p < .0001$; in contrast, a 1 point higher than average rating of temptation was associated with 0.5 point lower rating of dietary adherence, $p < .0001$. There were no differences in these associations between individuals who were or were not successful at weight loss, $p > .05$. There was also not a significant interaction between self-monitoring and temptation across all participants, $p = .052$; however, there was a significant three-way interaction with these constructs, $p = .023$, such that greater self-monitoring attenuated the magnitude of the association between temptation and dietary adherence only in individuals who were successful at weight loss. Taken together, results confirm proximal associations between self-monitoring, temptation and dietary adherence and demonstrated that, in individuals who are successful at weight loss, self-monitoring may help individuals stay on track with dietary changes despite the experience of temptation to consume foods not consistent with dietary intake goals. While existing literature has demonstrated that individuals who are not successful at weight loss engage in less self-monitoring, future studies should investigate whether self-monitoring may also be less effective for these individuals.

8:00 AM-9:15 AM

TRACKING EARLY MATTERS: PREDICTORS OF DIETARY SELF-MONITORING WITHIN A DIGITAL BEHAVIORAL INTERVENTION TRIAL AIMED TO IMPROVE DIET QUALITY

Dori Steinberg, PhD, RD¹, Jacob Christy, MS¹, Sandy Askew, MPH², Gary Bennett, PhD¹

¹Duke University, Durham, NC; ²Duke University, Ocoee, FL

Background: Consistent engagement with self-monitoring is a key predictor of successful behavior change. Yet, consistent engagement can be particularly challenging for individuals tracking dietary intake. Understanding predictors of dietary self-monitoring engagement is necessary to determine what strategies work best for promoting consistency. The objective of the current analysis was to understand patterns and predictors of dietary self-monitoring engagement among adults enrolled in the DASH Cloud randomized-controlled trial.

Methods: DASH Cloud was a 3-month digital health intervention aimed at improving adherence to the DASH diet among women with hypertension. Participants (n=59) were randomized to the DASH Cloud (n=30), or attention control (n=29) arms. Both groups received publicly available booklets about the DASH diet and were asked to self-monitor their diet using a commercially available diet tracking app, Nutritionix. Only the intervention arm received personalized feedback about their adherence to the DASH diet and skills training videos. Self-monitoring engagement was operationalized as the proportion of valid days tracked in the app. Descriptive statistics analyzed patterns of tracking over time and linear regression models evaluated sociodemographic and early tracking predictors of overall dietary self-monitoring engagement.

Results: Women had a mean (SD) age of 49.9 (11.9) years and were primarily Non-Hispanic White (69%), and college-educated (83%). Overall, the median (IQR) proportion of self-monitoring engagement for 12 weeks was 76% (IQR: 27-95). Those who tracked every day within the first 2 weeks were more likely to have higher overall engagement [94% (IQR: 69-99) vs. 32% (IQR: 13-76); $p < .001$] compared to those who tracked less often. Similar trends were seen for those who tracked daily in the first month. Engagement was significantly higher among individuals who were married [85% (IQR: 44-98) vs. 44% (IQR: 25-92); $p=.03$], had a lower BMI, college educated [83% (IQR: 39-95) vs. 31% (IQR: 20-60); $p=.04$], insured [76% (IQR: 35-95) vs. 11% (IQR: 6-17); $p = .04$], were comfortable with using apps [92% (IQR: 85-96) vs. 49% (IQR: 24-94); $p = .01$] and more likely to not use an app to track medication adherence [82% (IQR:35-95) vs. 24% (IQR:15-44); $p = .03$].

Conclusion: Engagement with dietary self-monitoring was moderate-to-high among adults enrolled in the DASH Cloud trial. Many sociodemographic variables predicted higher engagement, but the strongest predictor was early engagement; those who tracked every day in the first two weeks had higher engagement overall. Interventions aimed at promoting self-monitoring should consider how to best promote high rates of tracking at the start.

8:00 AM-9:15 AM

NOT ALL FEEDBACK IS CREATED EQUAL: OPTIMIZING DIETARY AND EXERCISE SELF-MONITORING FEEDBACK

Rebecca Krukowski, PhD¹, Xuyang Tang, PhD², Delia West, PhD³, Melissa L. Stansbury, M.S., EP-C⁴, Qian Li, BS⁵, Saunak Sen, PhD⁶

¹University of Tennessee Health Science Center, College of Medicine, Memphis, TN; ²University of Tennessee Health Science Center; ³University of South Carolina, Columbia, SC; ⁴University of South Carolina, West Columbia, SC; ⁵University of Memphis; ⁶University of Tennessee Health Science Center

Background: Tailored dietary and physical activity self-monitoring feedback is a core element of behavioral weight loss interventions and associated with clinically significant weight loss. Providing this feedback is time-consuming for counselors, however, with about 30 minutes needed per message. To our knowledge, no studies have evaluated participants' perspectives on the composition of feedback messages and how the composition of feedback may impact intention and motivation to self-monitor. The purpose of this study was to assess how participants perceived self-monitoring feedback emails depending on the number of positive comments or areas for change suggested by the counselor and the best combination of these components.

Methods: The dietary and physical activity feedback in the e-mails followed a factorial design with 2 factors (i.e., positive comments and areas for change), each with 3 levels (i.e., 1 comment, 4 comments, and 8 comments). Two hundred and fifty participants with overweight and obesity (age= 52.9 years, 52% women, 58% identified as White, 42% with a college degree or more) were recruited from Qualtrics research panel and read 9 emails presented in random order. For each of the 9 emails, participants answered 8 questions about their motivation and intention to self-monitor as well as their perception of the counselor and the emails. Ordered logit regressions were performed to determine the main effects and interactions. Predictive margins of e-mails were computed to indicate the changes in outcomes given different combinations.

Results: Main effects showed that the emails with more positive comments or areas for change were better received by participants, with small incremental benefits for 8 versus 4 positive comments/areas for change. Interactions indicated that the best combination for 4 out of 8 the concepts assessed (i.e., motivation to self-monitor, counselor's concern for their welfare, perceiving the counselor likes them, perceiving the email is tailored) was the email with 8 positive comments and 4 areas for change. Emails with 4 positive comments and 4 areas for change resulted in the highest average probability of reporting being very likely to continue self-monitoring.

Conclusions: Results demonstrated potential for optimizing self-monitoring feedback for efficacy and cost-effectiveness. Future studies should explore how the composition of feedback emails translates to actual self-monitoring among individuals engaged in a weight control program.

Symposium 43

8:00 AM-9:15 AM

PREVENTING TOMORROW'S DISPARITIES TODAY: ADDRESSING EARLY LIFE RISKS TO PROMOTE HEALTH ACROSS THE LIFESPAN

Leigh Ann Simmons, PhD, MFT¹, Jewel Scott, MSN, FNP-C², Benjamin Laufer, PhD³, Rebecca Schmidt, PhD⁴¹University of California, Davis, Davis, CA; ²Duke University School of Nursing, Durham, NC; ³University of California, Davis, USA, CA; ⁴University of California Davis, Davis, CA

Although the United States spends nearly 50% more on health care than other developed nations in the world, the US ranking in health outcomes has declined in past decades, in large part due to disparities in rates of common chronic disorders (e.g., obesity, heart disease, neurodevelopmental disorders) and associated morbidity and mortality. These disparities are shaped by the complex interrelationships among factors across the developmental continuum, ranging from biological (e.g., genes, cell metabolism) to behavioral (e.g., nutrition, physical activity) to social and environmental influences (e.g., neighborhood stress, pollution). Importantly, data are increasingly showing that disparities in health outcomes originate early in life, with intrauterine exposures, early childhood events, and social environments during adolescence all playing key roles in adult health trajectories. This purpose of this symposium is to present findings from one non-human primate investigation and two human studies that characterize how early life exposures increase risk for poor health across the lifespan, specifically autism spectrum disorders and hypertension. The first study will present epigenetic data from a macaque model that utilizes whole genome sequencing of cell free fetal DNA methylation in maternal blood to assess the impact of maternal obesity on offspring brain and behavior. The second study will report on two cohort studies of autism spectrum disorder (ASD) risk that investigated relationships between maternal environmental contaminant exposures and maternal nutritional intake on child ASD diagnosis. The third study will present findings from a nationally representative, longitudinal study of Black adolescents that examined the association of social stress in the form of discrimination and parental relationships on hypertension in young adulthood. Findings will be synthesized to better understand the intergenerational transmission of health disparities, including: (1) discussion of the complex interplay of early life influences on later life health using neurodevelopmental disorders/autism spectrum disorders and hypertension as exemplar disorders; (2) consideration of how to holistically address multiple influences simultaneously to mitigate disparities in vulnerable populations; and (3) presentation of a model of health equity that capitalizes on advances in technology with the goal of eliminating disparities in the next generation.

PERCEIVED DISCRIMINATION, PARENTAL RELATIONSHIPS, AND HYPERTENSION IN YOUNG BLACK FEMALES

Jewel Scott, MSN, FNP-C¹, Susan Silva, PhD², Leigh Ann Simmons, PhD, MFT³¹Duke University School of Nursing, Durham, NC; ²Duke University School of Nursing; ³University of California, Davis, Davis, CA

Background: Hypertension (HTN), a leading contributor to cardiovascular morbidity and mortality, disproportionately affects Black females. The chronic stress hypothesis posits that the toll of various stressors, beginning in early life, may contribute to the earlier development of HTN in Black women. Perceived discrimination and associated stress are linked with various health outcomes, although a strong parental relationship may buffer the physiologic response. We assessed the hypothesis that experiencing discrimination contributes to elevated blood pressure in Black women, and parental relationships may moderate this relationship.

Methods: Participants are 608 Black females from the National Longitudinal Study of Adolescent to Adult Health, a nationally representative study of youth in the US initially enrolled between 7th-12th grades and followed for 2.5 decades. Exposure to discrimination was measured in adolescence with two questions about prejudiced peers and unfair teachers, and in young adulthood with one question about experiences of being treated with less courtesy and respect than others. We examined the following five characteristics of a supportive maternal relationship in youth as potential stress buffers: warmth, caring, closeness, communication, and quality of the overall relationship. Participants were classified as having HTN (>130/90) or not in early adulthood (24-32 years). Bivariate and multivariable logistic regression were used to evaluate the association of HTN and discriminatory experiences, and to test for moderation by maternal relationship.

Results: Mean age of participants was 28.9 years; 34% met criteria for HTN. High perceived discrimination in young adulthood was associated with greater likelihood of having HTN, (OR 1.90, p=0.001), while exposure during adolescence was not. Only maternal communication moderated the relationship with HTN such that women who reported high communication with their mothers in adolescence and experienced discrimination were more likely to have HTN in young adulthood.

Conclusions: Rates of HTN in this group of young Black women were high and demonstrate need for innovative approaches to eliminating this disparity. Interestingly, high maternal-adolescent communication was associated with increased odds of HTN in the face of discrimination, suggesting there is a need to better understand how families talk about and counter the stress of discrimination to develop appropriate interventions.

8:00 AM-9:15 AM

A PRENATAL EPIGENOMIC INVESTIGATION OF THE IMPACT OF MATERNAL OBESITY ON INFANT NEURODEVELOPMENT

Benjamin Laufer, PhD¹, Cheryl Walker, MD², Catherine VandeVoort, PhD², Janine LaSalle, PhD³

¹University of California, Davis, USA, CA; ²UC Davis; ³University of California Davis

Background: Exposures to negative prenatal environmental conditions like maternal obesity increase the risk for neurodevelopmental disorders (NDDs), which include autism spectrum disorders (ASDs). These exposures represent a public health crisis: 1 in 3 pregnant women is obese; 1 in 10 children are diagnosed with an NDD; and 1 in 68 are diagnosed with an ASD. Further, people with ASD experience health disparities, including increased morbidity and lower life expectancy. Thus, robust understanding of the maternal obesity-offspring neurodevelopment link may reduce disparities in the incidence and outcomes of ASDs.

Methods: Genomic technologies allow us to examine the unique molecular signature of obesity on the genomes of mother and child. DNA methylation is an epigenetic modification that both reflects and regulates gene expression during development. The placenta is a birth byproduct that contains important clues about early brain development due to the presence of unique DNA methylation landscapes. During pregnancy, placental DNA, which is of fetal origin, is released into the maternal bloodstream as cell free fetal DNA (cffDNA). The placental DNA methylation profiles can be examined non-invasively from maternal blood samples. This study leveraged naturally obese rhesus macaques with a rigorously defined body composition score that gave birth to offspring with altered behavior in approximately 50% of male offspring. Lean control dams pregnant with male fetuses were matched to obese dams distributed into three groups: (1) untreated, (2) calorie restricted, and (3) treated with pravastatin (a statin medication). CffDNA was collected from maternal blood at 4 time points. DNA was isolated from the cortex and hippocampus of 6-month old infants after behavioral testing.

Results: cffDNA methylation profiles can distinguish obese from lean-exposed fetuses. These profiles represent alterations to genes involved in neurodevelopment, metabolism, and the regulation of gene expression. Matched brain samples are currently being sequenced and analyzed for integration with infant behavioral analyses.

Conclusions: This work is the first to generate epigenetic profiles of both placental and brain DNA in a non-human primate model of obesity. Findings may be translated to identify the risk for NDDs and ASDs in human pregnancies, and to guide behavioral interventions to mitigate the disparities associated with prenatal obesity and ASDs.

8:00 AM-9:15 AM

POTENTIAL PREGNANCY PREVENTION PATHWAYS FOR AUTISM SPECTRUM DISORDER

Rebecca Schmidt, PhD¹, Amanda Goodrich, PhD², Daniel Tancredi, PhD², Ana-Maria Iosif, PhD², Yihui Zhu, PhD Candidate², Kelly Bakulski, PhD³, Janine LaSalle, PhD²

¹University of California Davis, Davis, CA; ²University of California Davis; ³University of Michigan

Background: Gestational environment and nutritional exposures have critical influences on neurodevelopment and growing evidence suggests a role in autism etiology.

Methods: Children born in California from 2000-2007 and enrolled in the population-based CHARGE (Childhood Autism Risks from Genetics and Environment) case-control study at ages 2-5 years were clinically confirmed to have autism spectrum disorder (ASD) or typical development (TD) at the MIND Institute. Younger high-risk siblings of children with ASD, born in the MARBLES (Markers of Autism Risk in Babies: Learning Early Signs) prospective cohort study from 2006-2013 were clinically assessed at the MIND Institute at 3 years of age for ASD, other non-typical development (non-TD), or TD. In each study, average daily folic acid and other nutrient intakes were quantified for mothers based on reported vitamin and supplement use for each month before and during pregnancy. Air pollution and pesticide exposures were linked to addresses. In MARBLES, whole-genome bisulfite sequencing and EPIC umbilical cord blood and placenta tissue DNA methylation were examined across exposures and outcomes.

Results: In CHARGE we found a 40% reduced risk for ASD in the children of mothers taking prenatal vitamins and higher average daily (600+ mcg) folic acid near conception. There was evidence for a linear dose-response trend and gene-environment interactions. In MARBLES, we found a significant association between taking prenatal vitamins in the first pregnancy month and half the recurrence risk of ASD in younger siblings (RR_{adjusted}=0.47; 95% CI, 0.27 to 0.83). In both studies, the associated effects were specific to the first month of pregnancy and appeared specific to ASD symptoms and diagnosis. Folic acid appeared to attenuate ASD risk associated with prenatal environmental contaminant exposures, including air pollution, pesticides, and phthalates.

Conclusion: Maternal contaminant exposures that are linked with increased risk for the child developing ASD are more common in populations that experience health disparities, while potentially protective maternal prenatal vitamin intake is less common. ASD risk could be reduced by taking folic acid supplements early in pregnancy, especially for those who are genetically or environmentally susceptible. Shared underlying mechanisms behind these associations could inform pathways for prevention and public health recommendations to reduce the disease burden of autism.

Symposium 44

8:00 AM-9:15 AM

8:00 AM-9:15 AM

CHRONIC DISEASE SELF-MANAGEMENT FOR COMPLEX AND CHALLENGING CLINICAL POPULATIONS

Martha Sajatovic, MD¹, Mark S. Bauer, MD², Bethany M. Kwan, PhD, MSPH³, Jeanette Waxmonsky, PhD³¹University Hospitals Cleveland Medical Center, Gates Mills, OH; ²Harvard Medical School, Roslindale, MA; ³University of Colorado Anschutz Medical Campus, Aurora, CO

Despite considerable progress in the development and efficacy of behavioral interventions for chronic health conditions, self-management for people with multi-morbidity or specific challenging conditions is often suboptimal. Additionally, some approaches may not be practical for implementation in real-world settings and thus fail to be widely used. This symposium will describe self-management approaches as applied to individuals who are challenged with stigmatizing and or complex comorbidity, and emerging research that applies self-management on a broad scale and which is patient need-driven. All these approaches include personal goal-setting and alignment with healthy behaviors. The first speaker will describe developing, testing and implementing a collaborative /chronic care model to address multi-morbidity in patients with mental disorders. Life Goals Collaborative Care (LGCC) is a clinician-facilitated self-management approach based on social cognitive theory. LGCC sessions feature interactive discussions on personal goals, healthy behavior changes and action planning to cope with current symptoms. Next, our second speaker will describe iterative work based upon a self-management curriculum that blends elements of LGCC combined with diabetes education and self-management training for individuals with serious mental illnesses such as schizophrenia, bipolar disorder and major depression and comorbid diabetes. This intervention, Targeted Training in Illness Management (TTIM) uses peer educators to co-deliver this group-format self-management program in conjunction with a nurse educator. Finally, our third speaker will describe adaptation and implementation of TTIM for the Invested in Diabetes study, a pragmatic comparative effectiveness trial of patient-driven vs standardized diabetes Shared Medical Appointments (SMAs). Guided by the Replicating Effective Programs implementation framework, adaptations to the instructor's manual, patient handbook, practice trainings, outcomes assessments, and fidelity monitoring were made to fit the "real-world" primary care diabetes context. Following completion of the 3 presentations, our discussant, an expert on implementing interventions in real-world practice settings will pull together the presentations by pointing out the shared and differing elements of the various interventions, which depend on both the intervention curriculum, patient characteristics, target outcomes, and intervention delivery context.

SELF-MANAGEMENT APPROACHES TO PROMOTE MENTAL AND PHYSICAL HEALTH AMONG INDIVIDUALS WITH CHRONIC HEALTH CONDITIONS

Martha Sajatovic, MD¹¹University Hospitals Cleveland Medical Center, Gates Mills, OH

Chronic disease self-management has emerged as an evidence-based set of practices that are effective in improving the health of people with multiple morbidities. Incorporating these practices into standard clinical care may be a way to enhance uptake and impact. Targeted Training in Illness Management (TTIM) was originally developed as a group-format self-management curriculum that blends elements of Life Goals /Collaborative Care (LGCC) and the Diabetes Awareness and Rehabilitation Training Program (DART) to provide diabetes education and self-management training for individuals with serious mental illnesses (SMI) such as schizophrenia, bipolar disorder and major depression and comorbid diabetes. TTIM uses trained peer educators to co-deliver this intervention in conjunction with a nurse educator. TTIM also targets behaviors directly or indirectly related to diabetes vulnerability among people with SMI including social isolation/stigma, inactivity, poor diet, and recreational use of drugs or alcohol. A prospective 1-year randomized controlled trial (RCT) comparing TTIM vs. usual care in 200 individuals with SMI, mean age 52.7 years, 64% women, 54% African-American, found that compared to usual care, individuals in TTIM had significant improvement in depressive symptom severity and overall functioning. While outcomes for participants in TTIM and TAU were similar on general health and overall serum HbA1c, a standard measure of longer-term diabetes control, TTIM was associated with better glycemic control for those with at least fair baseline glycemic control defined as an HbA1c ≤ 7.5 . The study team has subsequently adapted TTIM for use in other research samples with complex comorbidity including individuals with SMI and epilepsy, individuals with Parkinson's disease and comorbid depression and in young (< age 65 years) African-American men who have experienced a stroke or transient ischemic attack. Key study design elements have included qualitative methods to evaluate barriers and facilitators to self-management in target populations and iterative intervention refinement using key stakeholder input (patients, family members and clinicians). Summative findings suggest that evidence-based self-management approaches can reduce depression, chronic disease complications and improve disease-specific health outcomes. A future challenge is to determine how these approaches are best scaled-up and embedded into current models of care.

8:00 AM-9:15 AM

THE LIFE GOALS SELF-MANAGEMENT PROGRAM TO ENHANCE SELF-MANAGEMENT SKILLS FOR INDIVIDUALS WITH MOOD DISORDERS: HISTORY, EVIDENCE, PRINCIPLES, AND METHODS

Mark S. Bauer, MD¹

¹Harvard Medical School, Roslindale, MA

Bipolar disorder is characterized by persistent symptoms, high risk for suicide, and low rates of treatment adherence. In the 1990s our work with individuals with bipolar disorder made clear the limitations of the traditional medical model alone (focusing primarily on medications and support) in improving outcome for this condition. In consultation with experts in the field, and individuals with the condition, we developed and tested the Life Goals Collaborative Care program, a self-management intervention for bipolar disorder. We subsequently conducted 13 randomized controlled trials and program evaluations of Life Goals in various iterations, including group or individual, embedded in a collaborative care model or as a stand-alone, and via clinical video teleconferencing for individuals or groups.

Life Goals is based on Bandura's Social Cognitive Theory and draws heavily on motivational interviewing and cognitive-behavioral techniques. Unlike traditional treatments, Life Goals begins with a facilitator helping the individual to elucidate their life's values and goals, prior to focusing on symptom management. Next, individuals work with their facilitator to develop a Personal Symptom Profile, review their coping responses to symptoms, and strengthen their healthy coping responses and revise their less-healthy coping responses in light of their previously identified values and goals. Finally, individuals develop an Action Plan, and strategize ways to make the best use of their visits with their clinicians.

Although Life Goals was developed initially for manic and depressive symptoms, Life Goals modules have been developed to address common comorbidities, both mental and physical. The emphasis in all Life Goals modules is on wellness and maximizing an individual's potential both in managing their symptoms and in their wider life. Free on-line Life Goals facilitator training is now available to clinicians and peer specialists.

8:00 AM-9:15 AM

ADAPTATION AND IMPLEMENTATION OF THE INVESTED IN DIABETES STUDY: A PRAGMATIC TRIAL OF THE TARGETED TRAINING IN ILLNESS MANAGEMENT CURRICULUM

Bethany M. Kwan, PhD, MSPH¹, Jenny Rementer, MA², Dennis Gurfinkel, MPH², Natalie Ritchie, PhD³, Phoutdavone Phimphasone-Brady, PhD¹, Martha Sajatovic, MD⁴, Jeanette Waxmonsky, PhD¹

¹University of Colorado Anschutz Medical Campus, Aurora, CO; ²University of Colorado Anschutz Medical Campus; ³Denver Health and Hospital Authority, Denver, CO; ⁴University Hospitals Cleveland Medical Center, Gates Mills, OH

Background: Diabetes group visits are historically challenging to implement in primary care. Pragmatic trials optimally use existing staff to deliver the intervention and allow flexibility in adherence and delivery.

Methods: The Invested in Diabetes study is an ongoing pragmatic cluster randomized comparative effectiveness trial testing two group visit models for delivering the Targeted Training in Illness Management (TTIM) curriculum for diabetes in primary care. In the standardized model, TTIM is delivered by a health educator, with topics in a set order. In the patient-driven model, TTIM is delivered by a multidisciplinary care team (health educator, behavioral health provider, and peer mentor), with topic order selected by patients. As a pragmatic trial, group visits are delivered by existing clinic staff in real-world settings. To support the 22 practices randomly assigned to condition, we used the Replicating Effective Programs (REP) implementation framework plus intensive practice facilitation. With practice stakeholder input, we adapted TTIM and the study protocol to fit their needs and context. Patient-reported outcomes were streamlined to those with clinical utility. We revised content, structure, and visual appeal of the TTIM instructor's manual and patient handbook. We developed and refined trainings and outcome assessments to ensure feasibility, sustainability, and scalability for both the current project and future dissemination. Nine in-person and virtual trainings have been conducted with 44 practice staff. Around 80 practice coaching sessions have been done to help practices start and sustain their group visits. Research staff dedicated to electronic health records extracts collaborated with practices to identify efficient and feasible data request processes. Finally, the study team observes one session per practice/quarter to monitor fidelity to the TTIM curriculum and assigned group visit model features, and document adaptations to content or delivery of the intervention.

Results: Practices preferred 6 two-hour sessions over 12 one-hour sessions. Training evaluations showed satisfaction with the trainings increasing over time as trainings became more efficient and engaging, and more accessible via remote options. Practices delivered test data extracts in summer 2019; data quality assessments revealed variability in accuracy and completeness. Eight months into the 24-month implementation period, 42 cohorts have gone live, with 295 patients enrolled and 175 completed, out of the goal of 1440.

Conclusion: To retain rigor in the study design, the REP framework allowed for adaptation to context while establishing core elements that must remain in place for hypothesis testing. The Invested in Diabetes study implementation processes help to ensure rigor of the design as well as feasibility of delivery in real-world primary care practices.

Symposium 45

8:00 AM-9:15 AM

CURRENT STATE OF THE ART IN DIGITAL INTERVENTIONS FOR ADDICTIVE BEHAVIORS

Anne H. Berman, N/A¹, Bridgette Bewick, PhD², Marina C. Fodor, MA³, Claes Andersson, PhD⁴, Jason Satterfield, PhD⁵, Meredith Meacham, PhD, MPH⁶, Derek D. Satre, PhD⁶

¹Karolinska Institutet, Stockholm, Stockholms Lan, Sweden; ²University of Leeds, Leeds, England, UK; ³Wayne State University, Detroit, MI; ⁴Malmö University, Malmö, Skane Lan, Sweden; ⁵UCSF, San Francisco, CA; ⁶University of California San Francisco, San Francisco, CA

Two years ago, a *Special Issue on E-health Interventions for Addictive Behaviors* was published in the *International Journal of Behavioral Medicine*. The issue included 16 articles, addressing topics like methodologies for developing e-health interventions, how to engage intervention users and establish a working alliance, and empirical findings from randomized controlled trials and a naturalistic study. The issue began with two articles offering a wide perspective on the field, with a systematic review of reviews on digital interventions for problematic alcohol use, as well as a too for describing e-health interventions as a step towards standardized reporting in order to facilitate communication about the interventions and comparisons between them. This symposium will follow up on the Special Issue by bringing together some of the contributors for presentations of their current work and a discussion on the current state-of-the-art in digital interventions for addictive behaviors. This symposium is sponsored by SBM's Scientific and Professional Liaison Council (SPLC), in partnership with the International Society of Behavioral Medicine (ISBM).

Background: Problematic alcohol use in Sweden occurs among 16 % of the adult population. Digital interventions of varying intensity have shown positive effects in contributing to reductions in problematic use, and the TeleCoach app has shown positive effects in non-treatment-seeking university students with excessive drinking (Gajecki et al., 2017). This pilot study evaluated the app among adult internet help-seekers, and motivated continued data collection in the current target group.

Methods: Adult internet-help seekers, recruited via advertisement, were included if they scored ³6 (women) or ³8 (men) on the Alcohol Use Disorders Identification Test (AUDIT). Those with depression scores of ³31 on the Montgomery Åsberg Depression Rating Scale (MADRS-S) or problematic drug use scores of ³8 on the Drug Use Disorders Identification Test (DUDIT) were contacted for a telephone interview and included following clinical assessment; if not reached they were excluded. Participants randomized at a 1:1 ratio to the TeleCoach™ web-based app or to a web-based app with information texts from primary care-based self-help material for changing problematic alcohol use. At six-week follow-up, the primary outcome was the number of standard drinks per past week (Timeline-Followback).

Results: Of 147 persons assessed for eligibility, 89 were assigned to the intervention group (n=42) or control group (n=47). Average AUDIT levels at baseline were ³18. The baseline number of standard drinks per week was 32.73 (SD 21.16) for the intervention group, and 26 (4.08) for the control group; at 6-week follow-up it was 12.73 (10.52) and 13.48 (11.13) for the intervention and control groups, respectively. No significant between-groups effects occurred, but within-group changes over time were significant ($F(1, 55)=43.98$; $p<0.000$), with an effect size of 1.37 for the intervention group and 0.92 for the control group.

Conclusions: The results suggest that web-based apps can be of help to internet help-seekers motivated to reduce problematic alcohol use. We have proceeded with the planned larger randomized, controlled study and will present 6-week follow-up data for the entire study sample (n=1000) in this presentation.

REALISING THE POTENTIAL OF ELECTRONIC BRIEF PERSONALIZED FEEDBACK INTERVENTIONS FOR ALCOHOL USE: CURRENT STATE OF THE EVIDENCE

Bridgette Bewick, PhD¹, John McAlaney, PhD², Robert Dempsey, PhD³, Helen Crosby, PhD⁴

¹University of Leeds, Leeds, England, UK; ²Bournemouth University, Bournemouth, UK; ³Staffordshire University, Staffordshire, UK; ⁴University of Leeds/Leeds Trinity University

Developing and implementing effective measures to prevent and intervene with harmful alcohol use remains imperative if we are to reduce the global burden of alcohol related harms and improve the lives of those affected. Brief alcohol interventions offer one means of rapidly intervening to reduce and avoid harmful alcohol use, particularly when delivered electronically (eBAIs). Delivery of electronic personalized feedback has been heralded as affording effectiveness of scalability and implementation for eBAIs. This presentation will present findings from a recent rapid review investigating the effectiveness and efficacy of electronic brief personalized feedback interventions (ePFIs).

Whilst there has been a rapid growth in the use and sophistication of ePFIs aiming to improve alcohol use outcomes, there remain a number of challenges for the field to address. There is a relative paucity of information on what motivates individuals to engage with these online programs under voluntary conditions. Studies in general populations often struggle to recruit, retain and engage participants and similar issues with participant attrition are seen amongst university student samples. If we are to realize the potential for ePFIs to contribute to reducing the global burden of alcohol misuse we must advance our understanding of how to successfully engage individuals with such interventions. Further evidence is required to ascertain the impact of additional booster sessions to maintain positive changes over the medium-to-longer term. An additional challenge is the cloud of skepticism around the use of self-report data when evaluating the effectiveness of eBAIs that include personalized feedback.

In this presentation we will consider future directions of the field and how these might advance our understanding of the behavioral science behind ePFIs. In addition we will consider the potential for new technologies to increase the effectiveness and successful implementation of personalized feedback, allowing us to intervene early and thereby contribute to a reduction in the global burden of alcohol related harms and improve the lives of those affected.

PARTICIPANT SATISFACTION WITH COMPUTER-DELIVERED INTERVENTION COMPONENTS AND ITS RELATION TO ALCOHOL USE OUTCOMES

Marina C. Fodor, MA¹, Emily R. Grekin, PhD², Jessica R. Beatty, PhD², Steven J. Ondersma, PhD³

¹Wayne State University, Detroit, MI; ²Wayne State University; ³Wayne State University School of Medicine

Background: Participant satisfaction has long been considered a key criterion in the development and evaluation of behavioral interventions. This is particularly true of computer-delivered brief interventions (CDBIs), which often incorporate user-centered design principles from the larger software development community. However, previous attempts to maximize participant satisfaction have rarely used experimental optimization techniques, such as factorial trials, to examine the association between intervention elements and satisfaction. Further, there is little evidence clearly demonstrating that participant satisfaction is associated with increased change in behavioral outcomes.

Method: This study used a factorial design to examine (1) participant satisfaction with individual elements of a CDBI for heavy alcohol use, both alone and in combination; and (2) whether these subjective reactions were associated alcohol use outcomes at 3-month follow-up. Data were drawn from a larger CDBI optimization study involving 378 university undergraduates. This study used a factorial design to test the efficacy of 16 combinations of four distinct intervention components: (1) empathic reflections, (2) motivational interviewing strategies, (3) presence of a spoken voice, and (4) presence of an animated narrator.

Results: Separate 2x2x2 ANOVAs showed no main effects for any of the four intervention components on participant satisfaction. However, there was a significant two-way, empathic reflections X spoken voice interaction ($F(1, 324) = 5.57, p = .019, \eta^2 = .017$). An examination of means revealed that a spoken voice had a larger positive effect (i.e., produced greater increases in liking) when empathic reflections were absent versus when they were present. Regarding the association between participant satisfaction and alcohol use, we found that higher participant satisfaction was associated with greater reductions in mean drinks per day over the course of the study ($\beta = -.18, t(316) = -3.25, p < .01; R^2 = .07, F(7, 316) = 3.33, p < .01$).

Discussion. CDBI components, both individually and in combination, were largely unrelated to participant satisfaction. However, participant satisfaction was associated with greater reductions in alcohol use. Although the importance of participant satisfaction is supported by these findings, it is unclear which intervention components are most strongly associated with satisfaction.

8:00 AM-9:15 AM

EFFICACY OF A FACEBOOK INTERVENTION ADDRESSING CIGARETTE SMOKING AND HEAVY EPISODIC DRINKING

Meredith Meacham, PhD, MPH¹, Danielle Ramo, PhD², Larissa Maier, PhD³, Judith J. Prochaska, PhD, MPH⁴, Kevin Delucchi, PhD³, Derek D. Satre, PhD⁵¹UCSF, San Francisco, CA; ²Hopelab, San Francisco, CA; ³University of California San Francisco; ⁴Stanford University, Stanford, CA; ⁵University of California San Francisco, San Francisco, CA

Background: Co-occurrence of tobacco use and heavy episodic drinking (HED; 5+/4+ drinks per occasion for men/women) is common among young adults; both warrant attention and intervention. This randomized trial investigated whether a Facebook-based smoking cessation intervention addressing both tobacco use and HED would increase smoking abstinence compared to a similar intervention only addressing tobacco.

Methods: Participants were 179 young adults (ages 18-25) in the United States recruited from Facebook and Instagram who reported cigarette smoking at least 4 days/week and past-month HED. Participants were randomized to the Smoking Tobacco and Drinking (STAND) intervention (N=85) or the Tobacco Status Project (TSP), a tobacco-only intervention (N=94), stratified on readiness to quit smoking and daily smoking status. Both interventions included 90 daily Facebook posts and weekly live counseling sessions in secret Facebook groups tailored to readiness to quit. Biochemically verified smoking abstinence was assessed at 3-, 6-, and 12-months follow up.

Results: Neither biochemically verified nor self-reported smoking abstinence differed significantly between STAND and TSP conditions at any time point or in longitudinal analyses. Retention (83% at 3 months, 66% at 6 months, 84% at 12 months) did not differ by condition. At 12-months, abstinence rates by condition (intent to treat) were 3.5% in STAND vs. 0% in TSP (biochemically-verified) and 29.4% in STAND vs. 25.5% in TSP (self-reported). Challenges with readability of test strips and nicotine vaping in remote biochemical verification may have contributed to these differences in abstinence rates. Significant reductions over time were observed for cigarette use and dependence (Fagerstrom Test of Cigarette Dependence), alcohol use and problematic use (AUDIT-C), but these did not significantly differ by condition. At 3 months only, STAND participants were more likely to be in a preparation or higher stage of change for quitting smoking ($p=0.025$) and were less likely to report vaping nicotine ($p=.01$). In post-hoc moderation analyses, participants who reported more frequent HED at baseline (15-30 days/month) (N=37) had greater reduction in FTCD scores from baseline to 3-months in STAND compared to TSP ($p=.031$).

Conclusions: Addressing both alcohol and tobacco did not lead to significant differences in smoking abstinence compared to addressing only tobacco. Future interventions targeting both alcohol and tobacco use may be more effective for young adults who engage in frequent HED.

Symposium 46

8:00 AM-9:15 AM

RETURNING GENOMIC INFORMATION TO PATIENTS AND FAMILIES: IMPLICATIONS FOR RESEARCH, POLICY AND PRACTICE

Megan A. Lewis, PhD¹, Christine M. Rini, PhD², Ryan S. Paquin, PhD³, Barbara B. Biesecker, PhD, MS⁴, William Klein, PhD⁵¹RTI International, Seattle, WA; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³RTI International, Minneapolis, MN; ⁴RTI International, Washington DC, DC; ⁵National Cancer Institute, NIH, Bethesda, MD

Genome sequencing is increasingly used in research and specific clinical contexts to predict health risks and identify the cause of rare disease. Due to plummeting costs and greater accuracy of results, sequencing is anticipated to be integrated into mainstream clinical practice in the near future. Results from sequencing provide information on gene variants that are both related (primary findings) and unrelated (secondary findings) to the indication for testing. Little is known about the best practices for returning results and the ways patients respond to the information. Across studies, evidence suggests that a majority of research participants are interested in learning secondary findings, whether they are actionable or not. Participants report that they value the information, for example, believing it will help them protect their own and their family's health in the future. Further evidence suggests that research participants may confuse primary and secondary findings. To minimize this confusion and realize health benefits from results, evidence is needed to guide patients in making informed decisions whether to receive secondary findings, and whether to act on them when they are actionable. This symposium will address the psychological and behavioral responses of adults who receive secondary findings either about themselves or their child. Collectively, the results presented may be used to guide future research, policy, and clinical practice. The first presentation will describe results from The North Carolina Clinical Genomic Evaluation by NextGen Exome Sequencing study designed to inform return of non-medically actionable secondary findings to patients. The second presentation will share findings from the North Carolina Newborn Exome Sequencing for Universal Screening study that examined if a decision aid, that was tailored and responsive to parental input, could support parents in making informed decisions to receive secondary genomic information about a child's genetic risk that varied by age (newborn to adult) and medical actionability (treatment available or not). The third presentation will describe findings from two NIH sequencing cohorts on participants' responses to return of medically actionable secondary findings and negative secondary finding reports. The discussant will highlight the research, policy and practice implications of the findings and what they suggest about social and behavioral research in genomics.

8:00 AM-9:15 AM

IS IT HARMFUL FOR RESEARCH PARTICIPANTS TO LEARN ABOUT AND BE ABLE TO REQUEST NON-MEDICALLY ACTIONABLE SECONDARY FINDINGS FROM DIAGNOSTIC EXOME SEQUENCING?

Christine M. Rini, PhD¹¹Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Diagnostic genomic sequencing examines possible genetics cause of suspected genetic disorders. It analyzes numerous genes simultaneously to provide diagnostic findings that are positive, uncertain, or negative. Yet, it can also yield unexpected “secondary” findings about health risks or conditions that are unrelated to the primary goal of sequencing. Experts have debated how and whether to return secondary findings to patients. Consensus supports returning medically actionable secondary findings—those revealing a risk that can be avoided or mitigated—but debate continues for those with less or no medical actionability (non-medically actionable secondary findings; NMAFs). For example, there are no evidence-based ways to reduce elevated genetic risk for the common form of Alzheimer’s disease.

Methods: The North Carolina Clinical Genomic Evaluation by NextGen Exome Sequencing (NCGENES) study was designed to inform the debate about whether to return NMAFs to patients. Pediatric and adult patients with suspected genetic disorders were enrolled in NCGENES to evaluate the clinical utility of diagnostic exome sequencing and best practices for returning diagnostic findings. Nested within NCGENES was a randomized trial for eligible adult patients (n=335): half were randomized to be educated about 6 categories of NMAFs and were able to request them (Decision group); the other half did not receive this education or the ability to request NMAFs (Control group). Psychosocial and behavioral outcomes were assessed at baseline (Time 1), 2 weeks after an in-person meeting at which we returned diagnostic findings and educated the Decision Group about NMAFs and how to request them (Time 2), then 3 and 6 months later (Times 3 and 4).

Results: General estimating equations examined effects of group (Diagnostic vs Control) and time. The Decision group had lower test-related distress and generalized anxiety than the Control group at Time 2 ($p < .05$), but these differences were not significant at Times 3 or 4. There were no group differences in test-related positive experiences or uncertainty, depressive symptoms, decision regret, lifestyle behaviors, healthcare utilization, or information seeking.

Conclusions: We observed no adverse psychosocial or behavioral effects of educating adult patients about, and offering them the ability to request, NMAFs. Next we will investigate effects of actually requesting and learning these findings.

8:00 AM-9:15 AM

DOES USING A DECISION AID SUPPORT PARENTAL DECISION MAKING ABOUT WHOLE EXOME SEQUENCING OF THEIR CHILDREN? RESULTS FROM THE NC-NEXUS STUDY

Ryan S. Paquin, PhD¹, Christine M. Rini, PhD², Rita Butterfield, PhD³, Katherine Souris, MPH⁴, Laura Milko, PhD⁵, Myra Roche, MS, CGC⁶, Donald Bailey, Jr., PhD⁷, Jonathan Berg, MD, PhD⁸, Cynthia Powell, MD⁹, Megan A. Lewis, PhD¹⁰

¹RTI International, Minneapolis, MN; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³Duke University School of Medicine; ⁴Gillings School Of Global Public Health University of North Carolina at Chapel Hill; ⁵Department of Genetics, University of North Carolina at Chapel Hill; ⁶Department of Pediatrics, University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; ⁷RTI International; ⁸Department of Genetics, University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁹Departments of Genetics and Pediatrics, University of North Carolina at Chapel Hill, Chapel Hill, NC; ¹⁰RTI International, Seattle, WA

Background: Little is known about whether or not parents experience negative psychological outcomes from learning about their child’s genetic risk or how interventions can support decision making and outcomes. In response, the NICHD and NHGRI funded four centers in the United States as part of their Newborn Sequencing in Genomic Medicine and Public Health (NSIGHT) program. These centers explored the implications, challenges and opportunities of genomic sequencing in the newborn period. The North Carolina Newborn Exome Sequencing for Universal Screening study (NC NEXUS) examined if decision aids, which were tailored and responsive to parental input, could help support informed decision making and mitigate negative consequences of making decisions to receive information about a child’s genetic risk.

Methods: 204 families (190 couples and 14 single mothers) participated in this part of the study. All parents completed a decision aid that provided educational information and values clarification about receiving medically actionable genetic risk information. Then roughly 2/3 were randomized to complete a second decision aid that provided education and values clarification about additional findings related to carrier status, medically actionable adult genetic risk, and non-medically actionable childhood genetic risk information. All parents completed questionnaires at baseline, and either three or four follow-up periods according to their randomization and choice to receive additional findings or not. Questionnaires measured decision making outcomes, distress, and decision aid perceptions.

Results: Overall, parents found the decision aids to be supportive of their decision making (scale range 1-6; $M = 4.93-5.08$). On average, parents who were given the option to request additional information about their child’s genetic risk related to carrier status, medically actionable adulthood information or non-medically actionable childhood information did not experience significantly more decision regret ($M = 1.56$, $SE = 0.08$ vs. $M = 1.54$, $SE = 0.11$, $t(73) = 0.15$, $p = .881$), distress ($M = 1.46$, $SE = 0.04$ vs. $M = 1.44$, $SE = 0.06$, $t(73) = 0.35$, $p = .728$) or concerns about their child’s future health ($M = 2.52$, $SE = 0.11$ vs. $M = 2.19$, $SE = 0.16$, $t(73) = 1.65$, $p = .103$ compared to parents who received medically actionable information only).

Conclusions: Bioethicists argue that parents should not be given the choice to receive non-medically actionable or adulthood genetic risk information about their children because the process of deciding whether or not to receive this information can be detrimental to parents’ well-being. The results of this study do not support this viewpoint. Very few studies have examined decision support in this context, and future research should continue to probe if certain parental subgroups experience negative outcomes.

8:00 AM-9:15 AM

PERCEIVED UTILITY AND INTENTIONS TO CHANGE HEALTH BEHAVIORS AND SCREENING AMONG AFRICAN DESCENDANTS FOLLOWING RECEIPT OF NEGATIVE SECONDARY FINDINGS FROM GENOME SEQUENCING

Barbara B. Biesecker, PhD, MS¹, Priscilla Chan, MS², Paul KJ Han, MD, MA, MPH³, William M Klein, PhD⁴, Leslie B Biesecker, MD⁵, Katie Lewis, ScM, CGC²

¹RTI International, Washington DC, DC; ²NHGRI Intramural Program NIH; ³Maine Medical Center; ⁴Behavioral Research Program, National Cancer Institute, NIH; ⁵NHGRI Intramural Program, NIH

Purpose: Genome sequencing is similar to other health screening tests in that it aims to identify individuals at higher risk for cancer, heart disease and other conditions. Interrogating exomes for actionable secondary findings (SFs) most often leads to negative results, meaning no pathogenic variant has been identified among 59 genes endorsed by the American College of Medical Genetics as actionable SFs. Although negative results indicate lower risk for heritable conditions, they do not eliminate other risk factors. A theoretical concern is that the return of negative results might decrease routine disease prevention and screening behaviors, particularly among African descendants who already have lower rates of screening. The purpose of this study was to assess responses to negative results among participants from this under-represented population.

Methods: Data were received from 285 adults enrolled in the NIH ClinSeq® cohort study who self-identify as African descendants. Negative SF results were returned by FedEx with a link to a website explaining the results. Two weeks after logging into the website, participants were emailed a link to an on-line survey to assess understanding and the perceived utility of the information.

Results: Respondents all logged into the website, for an average of 7 mins., 15 secs. When asked how likely they were to change their health-related behaviors based on their negative results, 26.4% were unsure and the remainder of responses were normally distributed. When asked about their intentions to pursue future screening, 81.5% reported no change in mammography; 74.2% reported no change in colonoscopy; and 71.3% no change in cholesterol screening. The remainder intended to increase their screening. Forty one percent of participants self-rated their understanding of their results as “quite a bit” or “extremely well,” whereas only 56.8% rated their value as “very worthwhile.”

Conclusions: Generally, participants had little intention to change their health behaviors and high intentions to continue cancer and cholesterol screening following receipt of a negative SFs report, suggesting sound understanding of their residual disease risks. Although there was no indication of intentions to decrease routine screening, the perceived value of learning negative heritable risk results among this under-represented population remains unclear.

Symposium 47

8:00 AM-9:15 AM

WE DON'T SUFFER ALONE: THE SOCIAL CONTEXT OF FEAR OF CANCER RECURRENCE

Emily C. Soriano, M.A.¹, Jean-Philippe Laurenceau, PhD¹, Andrea Cohee, PhD, RN², Tracey A. Revenson, PhD³, Lauren C. Heathcote, PhD⁴

¹University of Delaware, Newark, DE; ²Indiana University School of Nursing, Indianapolis, IN; ³Hunter College, City University of New York, New York, NY; ⁴Stanford University Medical School, Palo Alto, CA

Fear of cancer recurrence (FCR) is among the most commonly reported and important concerns of not only cancer survivors, but also their loved ones. Despite increased efforts to understand and treat FCR in recent years, its social/interpersonal context has received little empirical attention. The Social-Cognitive Processing Model posits that self-disclosing cancer-related fears, worries, and concerns is a critical mechanism by which survivors and their loved ones adapt and adjust over the course of survivorship. In support of this model, a number of studies have shown links between inhibited disclosure and cognitive processing, avoidance, and psychological distress among cancer patients. However, very little work has examined the association between disclosure—or rather, *inhibited disclosure*—and FCR. In this symposium, we will integrate these literatures by presenting cutting-edge findings linking interpersonal communication processes to FCR among cancer survivors, their loved ones, and their health providers, across the lifespan. First, using a longitudinal design with childhood cancer survivors, Heathcote will present findings uncovering the nature of communication about FCR in parent-child dyads, showing that maternal distress and coping near the time of the child's diagnosis predict future communication styles. Second, using a cross-sectional sample of breast cancer survivors, Cohee will discuss findings linking survivors' perceptions of their health care providers as unavailable, unresponsive, or uninterested in their disclosure of cancer-related concerns (*social constraints*) to their own FCR. Third, Soriano will review and integrate recent empirical studies from their research team using both short- and long-term longitudinal designs. These recent studies examined links between forms of *inhibited disclosure* (including social constraints and *protective buffering*, which occurs when one inhibits disclosure in order to protect a loved one) and FCR among cancer survivors and their spouses/partners, using the Social-Cognitive Processing Model as a unifying theoretical framework. Finally, Revenson will act as discussant to identify cross-cutting themes, suggest future directions for research in this new topic area, and describe implications for treatment of FCR across the lifespan.

8:00 AM-9:15 AM

INHIBITED DISCLOSURE AND FEAR OF CANCER RECURRENCE: A REVIEW OF RECENT EVIDENCE

Emily C. Soriano, M.A.¹, Jean-Philippe Laurenceau, PhD¹, Christine Perndorfer, M.S.², Amy K. Otto, PhD³, Scott Siegel, PhD, MHCD⁴

¹University of Delaware, Newark, DE; ²University of Delaware, Philadelphia, PA; ³Moffitt Cancer Center, Tampa, FL; ⁴Christiana Care Health System, Newark, DE

Background: Fear of cancer recurrence (FCR) is increasingly recognized as among the most important aspects of psychological adjustment among survivors and their loved ones. Recently, several studies have found that *inhibited disclosure* of cancer-related concerns is linked to increased FCR. The goal of this talk is to summarize and integrate this recent work under a unifying theoretical framework: The Social-Cognitive Processing Model.

Methods: We summarize findings from five empirical studies of two forms of inhibited disclosure (i.e., *social constraints* and *protective buffering*) as predictors of FCR. *Social constraints* occur when one perceives the other as unresponsive, unavailable, or uninterested in one's disclosure, while *protective buffering* occurs when one inhibits disclosure in order to protect the other. Four studies focused on adult survivors of breast cancer and one on parents of adolescent and young adult cancer survivors.

Results: Three studies focused on social constraints and two studies examined protective buffering. Both forms of inhibited disclosure were linked to greater FCR among cancer survivors and/or their loved ones across studies. One of the studies examined both forms of inhibited disclosure simultaneously as predictors of FCR; results suggested that both social constraints and protective buffering are significant, independent within-person predictors of greater FCR.

Conclusions: Results support the Social-Cognitive Processing Model, which argues that self-disclosure is critical to psychological adjustment (including FCR) in survivorship. To date, FCR interventions have not targeted communication processes and few have utilized a family- or couple-focused approach. Yet, findings point to the importance of interpersonal relationship and communication processes for understanding and potentially regulating FCR.

8:00 AM-9:15 AM

HEALTH CARE PROVIDER SOCIAL SUPPORT, CONSTRAINTS, AND COMMUNICATION QUALITY AS PREDICTORS OF FEAR OF RECURRENCE

Andrea Cohee, PhD, RN¹, Susan Storey, PhD, RN, AOCNS¹, Victoria Champion, PhD, RN, FAAN²

¹Indiana University School of Nursing, Indianapolis, IN; ²Indiana University, Indianapolis, IN

Background: Fear of cancer recurrence (FCR) is experienced by 55-90% of breast cancer survivors (survivors). While the effect of significant others' behaviors (social support and constraints—attempts to limit discussions about cancer) on survivors' FCR has been studied, less is known about the effect of health care providers' (HCP) behaviors, such as social support and constraints on long-term FCR. The purpose of this study was to determine the relationship between survivors' FCR and HCP's behaviors in response to long-term survivors attempting to discuss cancer. Additionally, we sought to identify survivors who may be at risk for FCR, which has implications for clinical assessment.

Methods: Survivors who were 3-8 years post-diagnosis and treatment were invited to participate in a descriptive, cross-sectional study about FCR. Women were queried about their perceptions of HCP social support, HCP social constraints, and satisfaction with HCP communication at diagnosis. Means and frequencies were analyzed to describe the sample. Pearson correlations analyzed survivor demographic and HCP factors related to FCR. Variables that significantly correlated with FCR were then entered into a linear regression model.

Results: Survivors were predominantly white (92%), well educated (m=14.5 years, SD=2.7), reported high income (39% earning \$75,000 or more), were an average of 6 (SD=1.5) years from diagnosis, and ranged in age 28-78 years (m=57 years, SD=11.6). Using bivariate analysis, FCR was significantly correlated with HCP social constraints ($r=.22$, $p<.001$), HCP social support ($r=-0.13$, $p<.001$), HCP communication at diagnosis ($r=-0.09$, $p<.001$) and demographic factors including years of education ($r=-0.06$, $p<.05$), current age ($r=-0.34$, $p<.001$), and time from diagnosis ($r=-0.10$, $p<.001$). The final linear regression model was composed of all significantly correlated factors [$F(1, 1103)=37.0$; $r^2=.17$; $p<.001$]. Factors significantly predicting FCR in the model were current age ($\beta=-.33$, $p<.001$), years of education ($\beta=-.12$, $p<.001$), and HCP social constraints ($\beta=.16$, $p<.001$). HCP social support neared significance at $p=.06$.

Conclusions: HCP should be aware that discouraging discussions about cancer may increase FCR. Survivors may worry less about recurrence if HCP have a communication style that is supportive and allows women to talk about breast cancer. Furthermore, survivors who are younger and have fewer years of education are at greater risk for FCR.

3

8:00 AM-9:15 AM

DYNAMICS AND LONGITUDINAL PREDICTORS OF PARENT-CHILD COMMUNICATION ABOUT FEAR OF CANCER RECURRENCE

Lauren C. Heathcote, PhD¹, Lexa K. Murphy, PhD², Kemar Prussien, MS³, Erin Rodriguez, PhD⁴, Amanda Ferrante, BA⁵, Rachel Fisher, BA⁵, Cindy Gerhardt, PhD⁵, Kathryn Vannatta, PhD⁶, Bruce Compas, PhD⁷

¹Stanford University Medical School, Palo Alto, CA; ²Seattle Children's Research Institute, Seattle, WA; ³Vanderbilt University; ⁴UT Austin, Austin, TX; ⁵Nationwide Children's Hospital; ⁶Nationwide Children's Hospital, Columbus, OH; ⁷Vanderbilt University, Nashville, TN

Background: Although 80% of children diagnosed with cancer will survive their disease, many will experience severe, clinically significant fears of cancer recurrence (FCR) that impair quality-of-life. Opportunities to communicate about FCR are likely adaptive for youth, yet parents may experience difficulty knowing how to discuss potential disease recurrence with their children. There are virtually no studies on parent-child communication about FCR to guide the development of supportive interventions. This study had two aims: 1) to characterize mother-child discussions about potential cancer recurrence during childhood cancer survivorship; 2) to determine child medical and parent psychological predictors of communication style (including presence and length of discussion, and maternal positive and negative affect during discussion).

Methods: Mothers (N=67) self-reported psychological distress (post-traumatic stress symptoms) and coping (disengagement) near the time of their child's cancer diagnosis (child ages 5-17 years). Three to four years later, during survivorship, mothers were observed communicating with their children about cancer during a video-recorded 15-minute study task; dyads were not prompted to talk about recurrence. Discussion about recurrence was characterized using theoretical models of FCR as well as established parent-child communication coding schemes.

Results: Almost three-quarters of mother-child dyads discussed potential cancer recurrence; mothers initiated the topic 74% of the time. Higher maternal distress and disengagement coping near the time of initial diagnosis predicted briefer mother-child discussions about recurrence ($\beta = -.28$, $p < .05$). Higher maternal distress near the time of diagnosis was associated with lower levels of maternal positive affect during discussion of recurrence ($\beta = -.41$, $p < .05$), while older child age was associated with higher levels of maternal negative affect during discussion of recurrence ($\beta = .31$, $p < .05$). Medical factors did not predict the presence or nature of recurrence discussions.

Conclusions: Parent psychological factors during their child's cancer diagnosis may impact how they communicate with their child about FCR years later during cancer survivorship. Maternal distress and coping, and developmental factors such as child age, are important to consider when developing guidance to support parents in providing opportunities for their child to communicate about their fears of cancer recurrence.

“WE’RE IN THIS TOGETHER”: NOVEL DYADIC INTERVENTIONS FOR MEDICAL PATIENTS

Talea Cornelius, PhD, MSW¹, Lixin Song, PhD, RN, FAAN², Ethan G. Lester, PhD³, Ana-Maria Vranceanu, PhD⁴, Kelly M. Shaffer, PhD⁵

¹Columbia University Irving Medical Center, New York, NY; ²UNC-CH, Chapel Hill, NC; ³Massachusetts General Hospital, Boston, MA; ⁴Massachusetts General Hospital/Harvard Medical School, Boston, MA; ⁵University of Virginia School of Medicine, Charlottesville, VA

Psychosocial research for medical patients has traditionally focused on the individual experiences of patients or their informal caregivers (e.g., family and friends providing care), neglecting the context of their interpersonal relationships. Recent observational and intervention research has provided preliminary evidence for a dyadic framework in which patients and caregivers are viewed as a unit. This framework emphasizes the interaction between patient and caregiver coping, emotional functioning, and health behaviors. The presentations in this symposium provide applications of this dyadic framework in the setting of novel clinical trials, specifically exploring how dyadic interventions address the psychosocial needs and experiences of both patients and their caregivers. In the spirit of SBM's 2020 annual meeting theme: “Finding Innovative Solutions for Tomorrow's Health Challenges”, this symposium focuses specifically on methods of delivering interventions and improving psychosocial outcomes in dyadic samples across diverse medical settings. First, *Ethan Lester* will present results from a proof of concept, single blind, randomized controlled trial (RCT) of a dyadic intervention (Recovering Together) versus an attention placebo educational control, both delivered from hospitalization through discharge. He will report the feasibility, acceptability, and preliminary effect of the intervention in improving symptoms of depression, anxiety and post-traumatic stress in dyads of patients with acute brain injury and their family caregivers. Next, *Talea Cornelius* will present results from an RCT comparing a couples-based behavioral weight loss (BWL) intervention to a BWL plus training in autonomy support (AS) intervention. She will specifically report on changes in perceived social support and associations with weight loss, as well as perception of others' support. Last, *Lixin Song* will discuss the protocol of an RCT of a couples-focused mHealth intervention for symptom management and enhancing quality of life versus usual care plus education (website) among prostate cancer patients and their spouses. Finally, our discussant *Kelly Shaffer* will place these studies within the larger context of dyadic research and will discuss future directions of such clinical research programs.

PERCEIVING SUPPORT FOR WEIGHT LOSS AND THE IMPACT OF A SUPPORT-BASED INTERVENTION IN COUPLES

Talea Cornelius, PhD, MSW¹, Emily P. Wyckoff, M.S.², Katelyn Gettens, PhD³, Theodore Powers, PhD⁴, Amy A. Gorin, Ph.D.²

¹Columbia University Irving Medical Center, New York, NY; ²University of Connecticut, Storrs, CT; ³Massachusetts General Hospital; ⁴University of Massachusetts - Dartmouth, N Dartmouth, MA

Objective: Social support from a romantic partner is generally considered beneficial to health, however, recognizing support receipt can be harmful under some circumstances. Given the increasing focus on the potential power of couples-based interventions to change health behavior, the goal of the present study was to elucidate how couples' perceptions of support receipt were impacted by a support-based randomized control trial for weight loss.

Methods: Participants were couples (N = 62; 96.8% married) between ages 18-70 with a BMI between 25-45 kg/m². Couples received 6 months of behavioral weight loss treatment (BWL) or BWL plus training in autonomy support (AS) provision (SDT-WL). Couples self-reported provision and receipt of AS at three, six, and 12 months. Couples also self-reported provision and receipt in directive support (DS) at these interviews. The Truth and Bias Model of Judgment was implemented in SAS v 9.4 (PROC MIXED) to estimate "truth" (i.e., when an individual reports receiving support that a partner reports providing) and similarity "bias" (i.e., when an individual reports receiving support based on the support that they themselves report providing).

Results: Compared to BWL couples, couples in SDT-WL more truthfully perceived the AS that their partner reported providing (SDT-WL: $B = 0.38$, 95% CI [0.22, 0.54], $p < .001$; BWL: $B = 0.14$, 95% CI [-0.02, 0.30], $p = .078$; p -interaction = .042). At 12 months, SDT-WL were also less biased in their perceptions of AS (SDT-WL: $B = 0.42$, 95% CI [0.24, 0.61], $p < .001$; BWL: $B = 0.72$, 95% CI [-0.54, 0.89], $p < .001$; p -interaction = .041). Effects were restricted to AS and not to other types of support that were not targeted by the intervention (i.e., there were no differences in perceptions of DS across conditions).

Conclusion: Couples trained in AS provision more truthfully perceived partner-provided AS and exhibited a decrease in biased perception of partner-provided AS over time. Truthfully perceiving AS may not be harmful within this context due to mutuality, goal orientation, or the fact that AS is a particularly responsive form of support. Future research should parse these possibilities. Perceptions of other types of support, which may be harmful to truthfully perceive (e.g., DS), were not impacted by the intervention.

8:00 AM-9:15 AM

TESTING THE EFFICACY OF A COUPLE-FOCUSED, TAILORED MHEALTH INTERVENTION FOR SYMPTOM SELF-MANAGEMENT AMONG MEN WITH PROSTATE CANCER AND THEIR PARTNERS

Lixin Song, PhD, RN, FAAN¹, Xianming Tan, PhD¹, Matthew Nielsen Nielsen, MD, MS², Ronald Chen, MD, MPH², Thomas C Keyserling, MD, MPH³, Christine M. Rini, PhD⁴, Mary Palmer, PhD⁵

¹UNC-CH, Chapel Hill, NC; ²School of Medicine & Lineberger Comprehensive Cancer Center UNC-CH; ³School Of Medicine UNC-CH; ⁴Northwestern University Feinberg School of Medicine, Chicago, IL; ⁵School of Nursing UNC-CH

Although prostate cancer treatment with curative intent (surgery or radiation with/without hormone therapy) provides long-term cancer-free survival, survivors experience urinary, sexual, bowel and hormonal symptoms, general distress, pain, fatigue, and sleep disturbance. For men in an intimate relationship, these symptoms disrupt couple's relationships and intimacy, and reduce quality of life (QOL) of both patients and their partners who are often their primary caregivers. Symptom effects may have as great or greater impact on their partners' QOL than on patients' own QOL. Management of the negative effects of cancer and its treatment is a significantly under-addressed supportive care need for these men and their intimate partners. Based on the adapted stress-coping theoretical framework and developed with stakeholder involvement, our interdisciplinary team has developed and pilot tested the usability and feasibility of an evidence-based, couple-focused, tailored mobile health (mHealth) intervention, "Prostate Cancer Education & Resources for Couples" (PERC). We are currently testing the efficacy of PERC using a population-based, geographically and demographically diverse cohort (N=250 patient-partner dyads) in a randomized controlled trial. Our research aims are:

Primary Aim: Assess if patients and partners receiving PERC will report greater improvement in their cancer-related QOL scores than those in the control group (usual care plus the National Cancer Institute (NCI) prostate cancer website) at 4, 8, and 12 months post-baseline.

Secondary Aim: Test if patients and partners in PERC will report significantly more positive appraisals and higher levels of coping resources at follow-ups than those in the control group.

Exploratory Aim: Determine if patient race and ethnicity, education, type of treatment, or couples' relationship quality moderate the effects of PERC on patient and partner QOL at follow-ups. This study will provide a novel model for self-managing chronic illness symptoms that impact couples' relationships, intimacy, and QOL.

8:00 AM-9:15 AM

RECOVERING TOGETHER: A FEASIBILITY RCT TO PREVENT CHRONIC EMOTIONAL DISTRESS IN PATIENTS WITH AND THEIR INFORMAL CAREGIVERS ADMITTED FOR AN ACUTE NEUROLOGICAL ILLNESS

Ethan G. Lester, PhD¹, Sarah Bannon, MS², Ryan Mace, MS¹, Melissa V. Gates, BA³, Paula Popok, BA⁴, Sofia Distefano, MS⁴, Danielle Salguiero, RN⁴, Tarah Tehan, MS, MBA, RN⁴, Jonathan Rosand, MD⁵, Ana Maria Vranceanu, PhD⁴

¹Massachusetts General Hospital, Boston, MA; ²Massachusetts General Hospital, MA; ³Massachusetts General Hospital, South Boston, MA; ⁴Massachusetts General Hospital; ⁵Massachusetts General Hospital - Department of Neurology, Boston, MA

Admission to the Neuroscience Intensive Care Unit (Neuro-ICU) for an acute neurological illness (ANI; e.g., stroke, tumor, TBI) is prevalent, and often associated with decreased well-being and chronic heightened emotional distress among patients (pts), which lead to slower functional recovery and higher all-cause mortality. The adverse effects of ANIs often ripple out to the emotional functioning of the pts' family caregivers (cgs). Psychosocial research regarding ANIs has traditionally focused on understanding the individual experiences of the pt or the cg *outside* of the context of their interpersonal relationship. For the past 5 years, our research program has provided evidence toward a *dyadic framework* for understanding post-Neuro-ICU distress, in which the pt-cg dyad is viewed as a unit, and an emphasis is placed on the interactions between pt-cg coping and emotional factors and on their interpersonal relationship. Using a mixed methods approach, we developed a manualized dyadic resiliency program ("Recovering Together") focused on teaching dyads resiliency skills (e.g., mindfulness, coping, interpersonal bond) which we found to be protective against the development of chronic depression, anxiety and post-traumatic stress in both pts and cgs. Here we report on a feasibility, proof of concept single blind RCT of Recovering Together against an attention placebo control. Both intervention and control start in the hospital with 2 dyadic sessions at bedside and continue after discharge with 4 dyadic sessions via secure live video. We enrolled 43 complete dyads (86 participants). Of these, 22 were randomized to the intervention and 21 control. One dyad dropped out after randomization (intervention), and two dropped out after completing the two in-hospital sessions (1 intervention and 1 control). Forty dyads provided post-test (20 intervention, 20 control). Feasibility of recruitment was high (~75% of dyads who met study criteria agreed to participate), and adherence to sessions was high and comparable between intervention and control (~80% completed 4 or more sessions). Satisfaction with the program was also high (10.36/12; SD = 1.73). Participants in the intervention reported significant decrease in symptoms of depression, anxiety and PTS between baseline and post-test compared to those in control. We also observe similar improvement in the resiliency factors targeted by the program. Notably, nurses highly endorsed the program and reported low burden of incorporation of study procedures within the Neuro-ICU. Methodological challenges, novel recruitment and retention strategies, and the pivotal role of the partnership with the Neuro-ICU staff, as well as limitations and future directions will be discussed.

Symposium 49

8:00 AM-9:15 AM

PSYCHOLOGICAL, NEUROBIOLOGIC AND FAMILIAL FACTORS THAT SHAPE LONG-TERM OUTCOMES OF CHILDREN WITH CHRONIC PAIN

Susmita Kashikar-Zuck, PhD¹, Caitlin B. Murray, PhD², Laura E. Simons, PhD³, Tonya M. Palermo, PhD⁴

¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH; ²Seattle Children's Research Institute, Seattle, WA; ³Stanford University School of Medicine, Palo Alto, CA; ⁴University of Washington School of Medicine; Seattle Children's Research Institute, Seattle, WA

Pediatric chronic pain is a highly prevalent public health problem. Although evidence-based interventions for the treatment of chronic pain in childhood are available and can be quite beneficial in reducing pain and disability, chronic pain symptoms tend to persist into adulthood for the majority of youth. Recent research has suggested that long-term outcomes can be highly variable in pediatric chronic pain with some patients adapting well over the years with relatively low levels of impairment. Others suffer from increasing pain-related disability over time. More systematic investigation - including prospective longitudinal studies, are needed to understand the biobehavioral predictors of this variability in long-term outcomes of youth with chronic pain. Dr. Murray and Dr. Kashikar-Zuck will discuss results from two separate longitudinal studies in pediatric chronic pain which show converging evidence of the importance of depressive symptoms and familial factors that confer greater risk for poor pain-related outcomes at 6-8 years follow-up. Dr. Kashikar-Zuck will also discuss critical developmental periods in which these risks must be addressed and the potential resilience factors that could be promoted to mitigate the negative impacts of pain into adulthood. Dr. Simons will present new research identifying neurobiologic risk factors that affect responsivity to treatment in pediatric pain as well as screening tools that can be used to adapt treatments to patients' specific needs. Dr. Tonya Palermo, an expert in behavioral intervention research in pediatric chronic pain will provide an overview and lead a discussion about the implications of findings from these studies. In particular, she will focus on how results might be incorporated into designing even more effective treatments and developing tailored treatment strategies for youth with chronic pain.

8:00 AM-9:15 AM

EMERGING EVIDENCE OF PREDICTORS OF LONG-TERM OUTCOMES IN PEDIATRIC CHRONIC PAIN: RESULTS FROM A LONGITUDINAL STUDY OF ADOLESCENTS WITH FIBROMYALGIA

Susmita Kashikar-Zuck, PhD¹¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Research has shown that chronic pain in childhood persists into adulthood for the majority of youth. However, there is marked variability in long-term outcomes with regard to the impact of pain on physical and emotional functioning over time. This presentation will focus on results from a longitudinal study of adolescents with juvenile fibromyalgia (JFM) from adolescence ($M_{age} = 15.9$ years) to young adulthood ($M_{age} = 24.2$ years) demonstrating variability in long-term trajectories of outcomes. Over 100 adolescent JFM participants were followed over a period of approximately 8 years with longitudinal assessments of pain, mood symptoms and physical impairment. Initial assessments during the adolescence also included measures of family functioning, psychological comorbidities, and adverse childhood experiences for a subset of participants. Pain was persistent into adulthood, although pain severity tended to decrease over time. Mood symptoms followed distinct trajectories with increasing depressive symptoms over the years being predictive of increasing physical impairment in adulthood. Sub-analyses identified risk factors such as a controlling family environment and early adverse experiences being associated with mood difficulties. The period of emerging adulthood (~19-21 years) appeared to be especially important developmentally, marking a life stage where trajectories tended to become established. A qualitative study with focus groups of adult participants from this cohort is ongoing - examining risk and resilience factors participants' perceive to have influenced their pain and functional outcomes. Results from these interviews will be combined with quantitative results from the prospective longitudinal study to present a more comprehensive and patient-informed view of the developmental course of JFM. Implications for more tailored interventions that target specific risk profiles and promote key resilience factors in youth with chronic pain will be discussed.

8:00 AM-9:15 AM

INTRAPERSONAL AND INTERPERSONAL VULNERABILITIES IN ADOLESCENCE THAT AMPLIFY LONG-TERM RISK FOR CHRONIC PAIN IN YOUNG ADULTHOOD.

Caitlin B. Murray, PhD¹, Tonya M. Palermo, PhD²¹Seattle Children's Research Institute, Seattle, WA; ²University of Washington School of Medicine; Seattle Children's Research Institute, Seattle, WA

Introduction: Despite the high likelihood for adolescents with chronic pain to continue to live with pain in adulthood, there is a paucity of research into early vulnerabilities that amplify long-term risk for chronic pain. This study aims to determine intrapersonal (e.g., depression) and interpersonal factors (e.g., protective parenting) in adolescence that may increase risk for continued chronic pain in young adulthood.

Methods: This is a long-term follow-up study of 221 young adults (ages 18-25, 78% female) with a history of adolescent chronic pain who participated in a randomized controlled trial of an internet-delivered pain management program (Palermo et al., 2016) during adolescence. Adolescents were originally recruited from 15 pediatric pain clinics across North America. At baseline, adolescents completed diary measures of pain intensity and disability and measures of depression and anxiety (Bath Adolescent Pain Questionnaire); parents completed measures of protective parenting (Adult Responses to Children's Symptoms) and miscarried helping (Miscarried Helping Scale). At follow-up, 6 years later, young adults reported on chronic pain (defined as pain present at least once per week over the past 3 months). Initial treatment condition, adolescent age, sex, race, and family income were included as covariates.

Results: The majority of the sample (72%) reported continued chronic pain in young adulthood. In logistic regression analyses there were no significant main effects of adolescent pain intensity or disability on young adult chronic pain status. However, significant pain intensity X depression and pain intensity X parent protectiveness interaction effects emerged; post-hoc analyses revealed that adolescent pain intensity predicted increased likelihood for continued chronic pain in young adulthood, but only for those who experienced high levels of co-morbid depression ($b=0.43$ $p=.02$) and protective parenting ($b=0.73$, $p=.03$) in adolescence.

Conclusion: This study has several key findings. The majority (over 70%) of adolescents with chronic pain in this sample report continued chronic pain in young adulthood (6 years later). Moreover, results indicate that emotional vulnerabilities and maladaptive parenting behaviors in adolescence may amplify risk for the persistence and maintenance of chronic pain into adulthood. This study provides key insight into processes that could be targeted in psychosocial interventions to prevent a lifelong trajectory of pain and disability.

8:00 AM-9:15 AM

PREDICTING RECOVERY OR PERSISTENCE IN PEDIATRIC PAIN: INNOVATIVE TOOLS AND NOVEL STRATEGIES

Laura E. Simons, PhD¹¹Stanford University School of Medicine, Palo Alto, CA

Up to 5% of adolescents (~3.5 million in the US alone) suffer from high impact chronic pain, affecting all life domains and posing a significant economic burden. Current treatments for chronic pain are suboptimal and have been tied to the opioid crisis. Only ~50% of adolescents with chronic MSK pain who present for multidisciplinary pain treatment recover, as measured by clinical endpoints of pain severity and functional disability. Discovery of robust markers of the recovery vs. persistence of pain and disability is essential to develop more resourceful and patient-specific treatment strategies and to conceive novel approaches that benefit patients who are refractory. Given that chronic pain is a biopsychosocial process, the discovery and validation of a prognostic and robust signature for pain recovery vs. persistence requires measurements across multiple dimensions. This presentation will include introduction of brief screening tools for youth with chronic pain and their parents to rapidly assess risk factors and enhance targeted treatment allocation. Additionally, neurobiological risk factors of brain structure and functional patterns will be presented in relation to responsiveness to treatment in youth with chronic pain. Overall, the presentation will take into account psychosocial and neurobiological factors associated with treatment responsiveness on pain in youth.

Symposium 50

8:00 AM-9:15 AM

8:00 AM-9:15 AM

RESULTS FROM A RANDOMIZED PREFERENCE TRIAL OF CBT AND YOGA FOR OLDER ADULTS

Gretchen Brenes, PhD¹, Suzanne Danhauer, PhD², Stephanie J. Sohl, PhD¹, Lisa A. Uebelacker, PhD³¹Wake Forest School of Medicine, Winston-Salem, NC; ²Wake Forest School of Medicine, Winston Salem, NC; ³Brown University and Butler Hospital, Providence, RI

Among older adults, anxiety is more common than depression, yet research on the nature and treatment of anxiety and worry has lagged far behind that of depression. Two interventions, cognitive-behavioral therapy (CBT) and yoga, have been shown to decrease worry and anxiety. However, no one has conducted a comparative effectiveness trial of CBT and yoga for treating worry in older adults. The purpose of this study was to compare the effects of two different treatments, CBT and yoga, on worry (PSWQ-A), anxiety (PROMIS-Anxiety) and sleep (ISI) in older (>60 years) adults with high levels of worry (PSWQ-A > 26). Another purpose of this study was to determine if there were participant preference and selection effects on these outcomes. In this randomized preference trial, 500 older adults were randomized to the randomized controlled trial arm (N = 250; 125 in CBT and 125 in Yoga) and the preference arm (N = 250; N = 120 chose CBT and N = 130 chose yoga). The study sample (N=500) had a mean age of 66.5 (SD=5.2) years (86.6% female, 78.8% Caucasian, 53% married/partnered). In this symposium, we discuss the findings of this trial. In the first paper, Dr. Brenes presents the results of the interventions on worry, anxiety, and sleep. While CBT and yoga both resulted in a decline in worry and anxiety, there were no significant differences between the two interventions. However, CBT was superior to yoga in improving sleep outcomes. Further, there were no significant preference nor selection effects for worry, anxiety, and sleep indicating that choice of interventions did not impact the outcomes. In the second paper, Dr. Danhauer presents the results of the interventions on exploratory outcomes including depressive symptoms, generalized anxiety, fatigue, pain, and physical function. Similar to worry and anxiety, symptoms of depression and generalized anxiety declined, but there was no differential effect of the interventions. However, CBT was superior to yoga in reducing pain. Further, there was little change in physical function with either intervention. There were no preference nor selection effects for any of these outcomes. In the final paper, Dr. Sohl discusses how yoga fidelity was established. Yoga class instructors were found to be adherent and competent in their delivery of the intervention. She also discusses how the skills needed for teaching yoga classes for a research study differ from those needed for teaching community classes. The discussant will address lessons learned from a randomized preference trial and how to implement an effectiveness study.

THE IMPACT OF CBT AND YOGA ON LATE-LIFE WORRY, ANXIETY, AND SLEEP

Gretchen Brenes, PhD¹, Jasmin Divers, PhD², Michael Miller, PhD³, gena Hargis, MPH³, Andrea Anderson, MS³, Suzanne Danhauer, PhD⁴¹Wake Forest School of Medicine, Winston-Salem, NC; ²New York University School of Medicine; ³Wake Forest School of Medicine; ⁴Wake Forest School of Medicine, Winston Salem, NC

Although cognitive-behavioral therapy (CBT) and yoga have been shown to decrease worry and anxiety, no one has conducted a comparative effectiveness trial of the two for treating worry in older adults. The aim of this study was to compare the effects of two interventions, CBT and yoga, on worry (PSWQ-A), anxiety (PROMIS-Anxiety), and sleep (ISI) in older (>60 years) adults. Other aims of this study were to determine participant preference for CBT vs. yoga, and examine participant preference and selection effects on worry, anxiety, and sleep. Five hundred older adults were randomized in a 1:1 two-stage randomized preference trial. Treatment assignment was also 1:1 in the randomized clinical trial (RCT) with 125 older adults in CBT and 125 in yoga. In the preference trial, 120 chose CBT and 130 chose yoga. In the RCT, outcome assessment at week 11 showed significant reductions in the mean PSWQ-A scores in both interventions. The mean PSWQ-A score dropped from 31.7 to 22.9 among participants randomized to CBT for a decline of -8.8 with 95% confidence interval (-10.0, -7.5). Among participants randomized to yoga, the decline was -7.2 (-8.5, -6.0). The overall intervention effect of yoga compared with CBT was 1.6 (-0.2, 3.3), $p=0.08$. Similar results were observed with the PROMIS Anxiety. At week 11, the reduction in means, relative to their baseline values, were -7.5 (-8.8, -6.1) and -7.1 (-8.5, -5.8) for the CBT and yoga arms, respectively. The overall intervention effect on the PROMIS-Anxiety was 0.3 (-1.5, 2.2), $p=0.73$. There were significant differences in the ISI. At week 11, the reduction in means, relative to their baseline values, were -5.4 (-6.3, -4.4) and -3.0 (-3.9, -2.0) for the CBT and yoga arms, respectively. The overall intervention effect on the ISI was 2.4 (1.1, 3.7), $p < 0.01$. Overall, the preference and selection effects for the PSWQA were -1.7 (-5.5, 2.1), $p=0.38$ and -1.1 (-4.9, 2.7), $p=0.57$, respectively; for the PROMIS-Anxiety they were -0.5 (-5.1, 4.2), $p=0.84$ and 0.2 (-4.4, 4.9), $p=0.92$, respectively; and for the ISI they were -1.1 (-5.0, 2.7), $p=0.57$ and -1.1 (-4.9, 2.8), $p=0.59$, respectively. Both CBT and yoga produced declines in worry and anxiety symptoms, with no significant differences between the two interventions. However, CBT was superior to yoga in improving sleep outcomes. Further, there were no significant preference or selection effects for worry, anxiety, and sleep.

8:00 AM-9:15 AM

A RANDOMIZED PREFERENCE TRIAL COMPARING COGNITIVE-BEHAVIORAL THERAPY (CBT) AND YOGA FOR THE TREATMENT OF LATE-LIFE WORRY: EXAMINATION OF ADDITIONAL OUTCOMES

Suzanne Danhauer, PhD¹, Michael Miller, PhD², Jasmin Divers, PhD³, gena Hargis, MPH², Andrea Anderson, MS², Gretchen Brenes, PhD⁴

¹Wake Forest School of Medicine, Winston Salem, NC; ²Wake Forest School of Medicine; ³New York University School of Medicine; ⁴Wake Forest School of Medicine, Winston-Salem, NC

The purposes of these analyses were to determine and compare the effects of CBT and yoga on depression, generalized anxiety, fatigue, physical function, and pain; and to determine if there are preference and selection effects for these treatments. In this randomized preference trial, participants were randomized to: (1) a randomized controlled trial (RCT) of CBT or yoga (n=250); or (2) a preference trial in which they select their treatment (CBT or yoga; n=250). Exploratory outcomes included self-reported depressive symptoms (PROMIS depression), generalized anxiety symptoms (GAD-7), fatigue (PROMIS fatigue), pain (PROMIS pain interference and intensity), and physical function (PROMIS physical function) measured at baseline and post-intervention (Week 11). In the RCT, depressive symptoms, generalized anxiety, and fatigue declined in both groups (no significant differences between CBT or yoga groups). The intervention effect (difference of change between intervention groups) on depressive symptoms was 0.5 (95% CI: -1.6, 2.6) greater improvement in CBT, $p=0.65$. Similar patterns were noted for fatigue [intervention effect was 1.0 (-1.2, 3.2), $p=0.37$] and generalized anxiety symptoms [intervention effect was 0.7 (-0.03, 1.8), $p=.17$]. There were significant between-group differences for both pain interference and intensity. The mean pain interference score dropped from 53.5 to 50.9 among participants randomized to CBT for a difference of -2.6 (-4.1, -1.0). Among participants randomized to yoga, the difference was -0.1 (-1.7, 1.4), resulting in an intervention effect of 2.4 (0.3, 4.5), $p=0.02$. The mean pain intensity score dropped from 3.1 to 2.8 among participants randomized to CBT for a difference of -0.04 (0.8, 0.0). Among participants randomized to yoga, the average score increased by 0.3 (-0.1, 0.7), resulting in an intervention effect of 0.7 (0.2, 1.2), $p<0.01$. There was no change in physical function for either group and no significant between-group difference was noted ($p=0.14$). No preference or selection effects were found for any of these outcomes. Both CBT and yoga produced improvements in depressive symptoms, generalized anxiety symptoms, and fatigue. The CBT group showed greater improvements in both pain interference and intensity compared with the yoga group. Both CBT and yoga may be useful for older adults for improving psychological symptoms and fatigue. CBT may offer even greater benefit than yoga for decreasing pain.

8:00 AM-9:15 AM

ENSURING YOGA INTERVENTION FIDELITY IN A RANDOMIZED PREFERENCE TRIAL FOR THE TREATMENT OF WORRY IN ANXIOUS OLDER ADULTS

Stephanie J. Sohl, PhD¹, Gretchen Brenes, PhD¹, gena Hargis, MPH², carol Krucoff, C-IAYT, E-RYT 500³, Suzanne Danhauer, PhD⁴

¹Wake Forest School of Medicine, Winston-Salem, NC; ²Wake Forest School of Medicine; ³Duke University; ⁴Wake Forest School of Medicine, Winston Salem, NC

Yoga is an important option to evaluate for the treatment of worry in anxious older adults because yoga is an intervention that is likely to translate into real-world practice. Assessing treatment fidelity when translating interventions to real-world settings allows researchers to determine if any null results for effectiveness of the intervention are because the intervention did not work or if it was not implemented as intended. This study focused on establishing treatment fidelity of a yoga intervention implemented in a randomized preference trial that compared the effectiveness of cognitive-behavioral therapy (CBT) and yoga for the treatment of worry, anxiety, and sleep in worried older (≥ 60 years) adults. Established methods for assessing treatment fidelity of CBT guided our methods for ensuring that the yoga intervention was robust and delivered as intended. The yoga intervention consisted of 20, 75-minute in person group gentle yoga classes held twice weekly. Instructors were trained in the Relax into Yoga approach designed for older adults. We adapted a measure developed for use with CBT that assessed adherence to the treatment manual (0=no adherence to 8=optimal adherence) and teaching competency (0=none to 8=excellent). We calculated the average instructor adherence and competency scores, variability in scores over time, and frequency that additional skills not included in the protocol were taught (yes/no). We also qualitatively summarized topics reviewed with instructors to enhance fidelity. Six female instructors (mean age=64 years) taught 660 yoga classes that were videotaped over the study period (May 2017- February 2019). Ten percent of these classes (n=66) were randomly selected for review. The average adherence score for yoga instructors was 6.84 (range 4-8), which increased over time. The average competency scores were consistently high with an average score of 7.24 (range 6-8). Teaching content not in the protocol occurred in 26 (38.1%) of the sessions and decreased over time. The higher variability in adherence versus competence scores demonstrated that teaching a yoga class according to a protocol requires different skills from competently teaching a yoga class in the community and that such skills improved with feedback. These results may foster dialogue between the research and yoga practice communities by providing insight into the hiring, study management, and training practices needed to support optimal intervention fidelity.

PROMOTING PREVENTIVE CARE TO ELIMINATE DIABETES DISPARITIES AND ACHIEVE POPULATION HEALTH IMPACT

Susan D. Brown, PhD¹, Obidiugwu K. Duru, MD, MS², Pamela L. Thornton, PhD³, Phoutdavone Phimphasone-Brady, PhD⁴, Alicia Fernandez, MD⁵¹Kaiser Permanente Northern California, Oakland, CA; ²UCLA, Los Angeles, CA; ³National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; ⁴University of Colorado Anschutz Medical Campus, Aurora, CO; ⁵University of California, San Francisco, San Francisco, CA

The goal of this symposium is to expand the national conversation about eliminating population health disparities in diabetes through the equitable provision and uptake of preventive healthcare services. Adults from racial/ethnic minority and low-income backgrounds face disproportionate burdens of type 2 diabetes and diabetes complications. Low patient engagement in guideline-recommended preventive services, such as diabetes screening and behavioral weight management programs, exacerbate these inequities. In this symposium, presenters will a) examine evidence on disparities in healthcare services to prevent diabetes and its complications and b) identify innovative strategies to increase patient engagement in preventive services. The first presenter will discuss the National Institutes of Health 2019 Pathways to Prevention Workshop, which identified research gaps and priorities for engaging underserved and at-risk populations in guideline-recommended diabetes preventive care. The second presenter will discuss a shared decision making intervention to promote uptake of evidence-based diabetes prevention (i.e., medication and/or the Diabetes Prevention Program for lifestyle behavior change and weight management) among racially/ethnically diverse patients with prediabetes; a key focus of this work is to promote equity in weight loss and other clinical outcomes. The third presenter will provide key findings of a qualitative study examining barriers to participation in the National Diabetes Prevention Program within a safety net healthcare system. The fourth presenter will discuss the rationale and development of an outreach intervention to increase uptake of guideline-recommended postpartum diabetes screening among women with gestational diabetes, who face high lifetime risk for type 2 diabetes. Finally, the Discussant will summarize and critique the current research, with a focus on accelerating interventions to promote preventive care and eliminate downstream health disparities in diabetes.

CORRESPONDING AUTHOR: Susan D. Brown, PhD, Kaiser Permanente Northern California, Oakland, CA; susan.d.brown@kp.org

PROMOTING EQUITABLE UPTAKE OF POSTPARTUM DIABETES SCREENING: RATIONALE AND DEVELOPMENT OF AN OUTREACH INTERVENTION

Susan D. Brown, PhD¹, Mara Greenberg, MD², Ai-Lin Tsai, MS¹, Charles Quesenberry, PhD³, Jenna Ritchie, BA³, Assiamira Ferrara, MD, PhD⁴¹Kaiser Permanente Northern California, Oakland, CA; ²The Permanente Medical Group; ³Kaiser Permanente Northern California; ⁴Division of Research, Oakland, CA

Gestational diabetes mellitus (GDM) is a common pregnancy complication that elevates women's lifetime risk for type 2 diabetes. Clinical guidelines thus recommend an oral glucose tolerance test to screen for diabetes at 4-12 weeks postpartum—screening which is now a covered benefit under the Affordable Care Act. Yet screening uptake remains suboptimal and uneven across racial/ethnic groups, delaying diabetes prevention and early treatment. Uptake is lowest among African Americans, who face higher risk for progression to type 2 diabetes after GDM as compared to other racial/ethnic groups. Here we describe the rationale and design of intervention research, in partnership with clinical leaders in a large integrated health system, to promote guideline-recommended postpartum diabetes screening among diverse women with GDM. In the first study, results suggest that a focus on risk communication may be warranted. Among women identified with GDM in a 1-year period (N=1,614; 2011-2012), we classified risk for type 2 diabetes according to an American Diabetes Association algorithm of factors assessed via electronic health records and a self-report survey. Only 41% of those at “increased risk” completed guideline-recommended screening (n=121/297) vs. 55% of those not at increased risk (n=725/1,317; p<.0001). In a logistic regression accounting for race/ethnicity and other demographic and clinical factors, those at increased risk had 25% lower odds of completing screening than those not at increased risk (odds ratio 0.75, CI 0.58-0.96). The second study is a factorial experiment in a largely minority sample to pilot the feasibility and acceptability of a multi-component outreach intervention. At the health system level, it seeks to build upon existing population health strategies (e.g., ordering screening tests for all eligible patients and systematic patient reminders). At the patient level, it focuses on risk communication and motivations to engage in preventive care in the demanding postpartum period. Some intervention components were previously piloted among English- and Spanish-speaking African American and Latina women with a history of GDM. Results will be used to refine the intervention for future research. Targeting patient-level factors while leveraging resources at the health system level may be a promising approach to promote equitable uptake of guideline-recommended postpartum diabetes screening among diverse women at high risk for type 2 diabetes.

SHARED DECISION MAKING IN DIABETES PREVENTION: WORKING TOWARD RACIAL EQUITY IN KEY PATIENT OUTCOMES

Obidiugwu K. Duru, MD, MS¹, Tannaz Moin, MD, MBA, MSHS¹, Norman Turk, MS², Amanda Vu, PharmD², Dominick Frosch, PhD³, Kia Skrine Jeffers, PhD, RN⁴, Yelba Castellon-Lopez, MD⁵, Chi-Hong Tseng, PhD², Keith Norris, MD, PhD², Carol Mangione, MD, MSPH²

¹UCLA, Los Angeles, CA; ²UCLA Division of General Internal Medicine/Health Services Research; ³Palo Alto Medical Foundation Research Institute; ⁴UCLA School of Nursing; ⁵UCLA Department of Family medicine

More than 84 million Americans are at risk for diabetes, and incidence rates are rising more quickly among African Americans and Latinos. The Diabetes Prevention Program (DPP) trial showed that both metformin and lifestyle change can help prevent diabetes, but results from the real-world National Diabetes Prevention Program indicate that minority participants may lose less weight than white participants. A potential patient-centered strategy to enhance clinical outcomes in diabetes prevention is for patients and healthcare providers to work together in a shared decision making (SDM) approach, to decide which strategy best aligns with patient risk as well as the patient's needs and preferences. Our research team conducted a cluster-randomized trial of SDM led by clinical pharmacists in 20 primary care practices in a large healthcare system, enrolling a multi-racial sample. The pharmacists used an online decision aid to help patients choose a diabetes prevention strategy. We found that in an intention-to-treat analysis, patients with prediabetes who engaged in SDM (n=515) were more likely than matched controls with prediabetes (n=1,526) to take up evidence-based diabetes prevention, defined as either attending DPP sessions and/or starting metformin as reported during a clinic visit (32.8% vs. 2.5%, $p < 0.001$). Examining uptake within the intervention sample by racial/ethnic group, we found similar rates by racial/ethnic group (uptake of 34% for whites, 28% for African Americans, 40% for Latinos and 28% for Asian Americans, $p = \text{NS}$ for pair-wise comparisons for each minority group compared to whites). Overall, participants in the intervention lost more weight than controls (-4.7 lbs. vs. -0.4 lbs., $p < .001$). However, there were significant differences in weight loss by racial/ethnic group within the intervention, as white participants (-6.6 lbs) lost more weight than African American participants (-1.8 lbs, $p = .002$ vs. whites) and Latino participants (-3.1 lbs, $p = 0.017$ vs. whites). These differences persisted after controlling for age, clinic and a zip code-level measure of income. We are currently scaling up this protocol for all eligible patients in 40 clinics across two health systems with funding from the Patient-Centered Outcome Research Institute (PCORI). A key goal of this next phase of our work is to achieve health equity in weight loss and other clinical outcomes by adding modifications to the intervention approach based on patient and clinician feedback.

ACHIEVING HEALTH EQUITY IN PREVENTIVE SERVICES: INSIGHTS FROM AN NIH WORKSHOP

Pamela L. Thornton, PhD¹, Richard Berzon, DrPH, PA², Melissa C. Green Parker, Ph.D.³, Carrie Klabunde, Ph.D., MBA, MHS⁴, Antoinette Percy-Laurry, DrPH, MSPH⁵, LeShawndra Price, PhD⁶, Kate Winseck, MSW⁷, Xinzhi Zhang, MD, PhD⁸

¹National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; ²National Institute on Minority Health and Health Disparities; ³NIH/NHLBI, Bethesda, MD; ⁴National Institutes of Health/Office of Disease Prevention, Rockville, MD; ⁵National Cancer Institute; ⁶National Heart, Lung, and Blood Institute; ⁷NIH Office of Disease Prevention; ⁸National Center for Advancing Translational Sciences

Background: Evidence-based guidelines for preventive services are developed by expert groups such as the U.S. Preventive Services Task Force (USPSTF) to help Americans stay healthy. Despite the proven value of many evidence-based preventive services, implementation by providers and uptake by patients vary, contributing to disparities in disease burden and life expectancy. The NIH convened a workshop with multidisciplinary and multisector participants in June 2019 to assess the available scientific evidence on achieving health equity in the use of clinical preventive services for three leading causes of death: diabetes, heart disease, and cancer.

Methods: The workshop focused on 5 key questions (KQs), and included a systematic evidence review, speaker presentations, and public discussion. KQ 1-2 considered the effects of barriers on the part of providers and patients to adopting and implementing evidence-based preventive services, and how they contribute to health disparities. KQ 3-5 addressed the effectiveness of health information technology and health care organization interventions to reduce disparities in preventive services use. An unbiased, independent panel of experts prepared a report of findings for addressing disparities in the use of 10 clinical preventive services recommended by the USPSTF. Findings: Findings of the report included the need for more research on the effects of barriers to the adoption of clinical preventive services, strategies for bundling preventive services and implementing Health IT, and the integration of social and medical care. The recommendations along with implementation examples will be discussed.

REPORT FROM THE FIELD: PERCEIVED BARRIERS AND POTENTIAL SOLUTIONS TO ENGAGEMENT FOR THE UNDESERVED IN THE NATIONAL DIABETES PREVENTION PROGRAM

Phoutdavone Phimphasone-Brady, PhD¹, Natalie Ritchie, PhD², Katherine Sauder, PhD³, Claudia Amura, PhD⁴

¹University of Colorado Anschutz Medical Campus, Aurora, CO; ²Denver Health and Hospital Authority, Denver, CO; ³Department of Pediatrics – Nutrition, University of Colorado School of Medicine, Aurora, CO; ⁴College Of Nursing, University of Colorado Anschutz Medical Campus

The National Diabetes Prevention Program (NDPP) has achieved wide-scale dissemination, yet effort is needed to reduce racial/ethnic and socioeconomic disparities in outcomes. Poor attendance in the yearlong program is a major concern, especially in under-resourced communities. Strategies to improve engagement appear needed to both increase weight loss and support sustainability under current performance-based reimbursement models. In this qualitative study, we evaluated type and frequency of perceived barriers among 225 enrollees in a safety net healthcare system in 2018. Nearly all enrollees anticipated at least one barrier to engagement (92.9%), of whom 37.3% anticipated multiple barriers ($M = 2.39$; $SD = 0.56$). Main themes of barriers were 1) challenges with scheduling and planning (reported by 61.3% of enrollees), 2) challenges traveling to/from NDPP classes (30.2%), 3) challenges with health behavior change (25.3%), and 4) challenges due to other health conditions (18.7%). The NDPP has achieved wide-scale dissemination and optimization is now needed to reduce diabetes and related disparities. Assessing anticipated barriers to NDPP engagement may be important at enrollment, in addition to re-assessing actual barriers upon attendance. NDPP delivery may require tailoring based on individual need, such as offering childcare or transportation support, and adaptation to meet more general population needs, such as adopting policies supporting virtual delivery.

Paper Session 26 10:45 AM-11:00 AM

LUNG CANCER STIGMA: DOES SMOKING HISTORY MATTER?

Timothy J. Williamson, Ph.D., MPH¹, Diana M. Kwon, BA², Kristen E. Riley, Ph.D.³, Megan Shen, PhD⁴, Heidi Hamann, PhD⁵, Jamie Ostroff, PhD¹

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Fred Hutchinson Cancer Research Center, University of Washington, Seattle, WA; ³Rutgers University, Piscataway, NJ; ⁴Weill Cornell Medicine, New York, NY; ⁵University of Arizona, Tucson, AZ

Background: Most lung cancer patients (95%) report experiences of stigma, which are associated with adverse psychological and physical health outcomes. Theory and research suggest that patients' history of smoking may differentiate patients' experience of stigma. However, there is inconsistent evidence as to whether stigma varies by smoking history, owing to limitations in the literature, including: 1) low enrollment of participants who currently smoke; 2) use of stigma measures that vary across studies regarding their psychometric properties; and 3) omission of important covariates.

Purpose: This study tested differences in levels of lung cancer stigma by patients' history of smoking.

Method: Participants (N=266, 63.9% female) were men and women with lung cancer who completed validated questionnaires. Addressing previous study limitations, this study used a lung cancer stigma measure that incorporated patient feedback and evidenced strong psychometric properties, recruited a relatively large subsample of participants who currently smoke (n=49), and included depressive symptoms and sociodemographic characteristics as covariates. Multivariable regression models characterized relationships between smoking history (currently, formerly, never smoked) and lung cancer stigma.

Results: Clinically meaningful lung cancer stigma was experienced by the majority of participants who currently (93.9%), formerly (85.4%), and never smoked (60.0%). Participants who currently smoked reported significantly higher total, internalized, and perceived lung cancer stigma, compared to those who formerly or never smoked (all $p < .05$). Additionally, participants who formerly smoked reported significantly higher total and internalized stigma, compared to those who never smoked ($p < .001$). Participants reported similar levels of constrained disclosure (discomfort in sharing their disease status with others), regardless of smoking history ($p = .630$).

Conclusions: Lung cancer stigma is experienced by most patients, particularly among (but not limited to) those who currently smoked. Patients' constrained disclosure is a pervasive aspect of lung cancer stigma across smoking history groups. Most lung cancer patients may benefit from psychosocial support to address stigma (particularly around constrained disclosure). Additionally, lung cancer patients who smoke at diagnosis might be identified for additional support that aims to reduce internalized stigma and promote engagement with smoking cessation interventions.

CORRELATES OF SUN PROTECTION BEHAVIORS AMONG ADULTS IN PUERTO RICO

Zhaomeng Niu, PhD¹, Carolina I. Lozada, MPH², Carolyn Heckman, PhD², Elliot J. Coups, PhD³

¹Rutgers Cancer Institute of New Jersey, Edison, NJ; ²Rutgers Cancer Institute of New Jersey, New Brunswick, NJ; ³Rutgers Cancer Institute of New Jersey, South Orange, NJ

Introduction: The incidence of skin cancer has been increasing in Puerto Rico in recent years. Approximately 99% of the Puerto Rican population is Hispanic. Hispanic individuals in the United States do not sufficiently engage in sun protection behaviors, which can reduce the risk of skin cancer. However, there are limited data regarding factors associated with Puerto Rican adults' sun protection behaviors.

Methods: A population-based sample of 667 Puerto Rican adults (47.7% response rate; M age = 48.5 years; 61% female) completed a telephone survey. An index of sun protection behaviors was created by averaging participants' responses to questions about their frequency of using sunscreen, staying in the shade, and wearing wide-brimmed hats and long-sleeved shirts. Further survey items addressed potential correlates of sun protection behaviors, including variables in the following categories: demographics; social influence factors; sun protection attitudes; skin cancer risk factors; and knowledge and attitudes about skin cancer. Multivariable regression analyses examining correlates of the sun protection behaviors index were conducted separately for each category of variables.

Results: Higher levels of sun protection behaviors were found among English language acculturated compared to Spanish language acculturated individuals ($p < .05$) and among individuals with private versus public health insurance ($p < .001$). Among the social influence variables, having talked with a doctor about sun protection ($p < .001$) and sun protection norms ($p < .01$) were positively associated with sun protection behaviors. In terms of sun protection attitudes, higher levels of sun protection behaviors were found among participants with fewer sun protection barriers ($p < .01$), greater sun protection self-efficacy ($p < .001$), and greater photo-aging concerns ($p < .05$). Individuals with a greater number of skin cancer risk factors reported engaging in more sun protection behaviors ($p < .001$). For the skin cancer knowledge and attitudes category, higher levels of sun protection behaviors were found among individuals with greater skin cancer knowledge ($p < .001$) as well as higher perceived skin cancer risk ($p < .01$) and worry ($p < .05$).

Conclusions: By identifying correlates of Puerto Rican adults' sun protection behaviors, this timely study provides insight on potential subgroups and factors to target in future skin cancer prevention interventions in this understudied population.

RACE/ETHNICITY AND CANCER INFORMATION SEEKING: EVIDENCE FROM A NATIONALLY REPRESENTATIVE SAMPLE

Gilberto Lopez, ScD; MPH; MA¹, Heather Mattie, PhD², Nikesha J. Gilmore, PhD³¹University of Rochester Medical Center, ROCHESTER, NY; ²Harvard T.H. Chan School of Public Health, Boston, MA; ³University of Rochester, New York, NY

Introduction: Cancer is the second leading cause of death in the United States, with smoking being its leading cause. Despite decreases in smoking and cancer mortality overall, rural populations continue to have a higher prevalence and slower reduction of cancer death rates. As a preventive approach to combat cancer, the National Cancer Institute continues to prioritize providing the public with health information. Yet, little is known about cancer information seeking among smokers in rural America—even less how this varies by race/ethnicity.

Methods: Using data from two iterations of the Health Information National Trends Survey (HINTS 4 and HINTS 5) we analyze the odds of looking for information about cancer by smoking status and rurality. We tested for the interaction of race/ethnicity to see if the association between smoking status and information-seeking differs for Whites and non-Whites in both rural and urban areas. Using an established social determinants framework, a series of logistic regression models were fitted to estimate odds ratios (OR) and 95% confidence intervals (CIs).

Results: Smokers were less likely to seek cancer information compared to non-smokers, with those living in rural areas having lower odds compared to urban dwellers. Non-White smokers had lower odds of seeking cancer information compared to White smokers. Additionally, non-Whites in rural areas are less likely to seek cancer information than Whites in rural areas.

Conclusions: In this study, compared to urban-dwellers, smokers living in rural areas have lower odds of seeking cancer information. This relationship was worse for ethnic minorities. Understanding this relationship between race, place, and cancer information-seeking has implication for the allocation of resources and the design of interventions aimed at increasing information about cancer.

11:30 AM-11:45 AM

CULTURALLY-TARGETED MESSAGE-FRAMING AND RECEPTIVITY TO COLORECTAL CANCER SCREENING AMONG AFRICAN-AMERICANS

Todd Lucas, PhD¹, Hayley S. Thompson, Ph.D.², Louis A. Penner, PhD³, Mark Manning, Ph.D.⁴¹Michigan State University, Flint, MI; ²Karmanos Cancer Institute - Wayne State University, Detroit, MI; ³Wayne State University/Karmanos Cancer Institute, Detroit, MI; ⁴Karmanos Cancer Institute, Detroit, MI

Background: In the United States, African Americans have the highest colorectal cancer (CRC) incidence and death rate of any ethnic group, with lower rates of CRC screening playing a critical role. Identifying health communication strategies that effectively reduce screening disparities may be vital. Building on recent research, this study further examines use of gain and loss-framed messaging to compel African Americans to participate in recommended CRC screening, and whether culturally targeted personal prevention messaging can be added to framing to augment receptivity to CRC screening.

Objective: To examine 1) simultaneous use of messaging-framing and culturally-targeted personal prevention messaging to compel African Americans to participate in recommended CRC screening; 2) arousal of perceived racism in response to message framing and personal prevention messaging strategies.

Methods: CRC screening deficient African Americans ($n = 429$) watched a brief online tutorial about CRC risks, prevention and screening, and were either randomly assigned to view either a gain-framed or loss-framed message about CRC screening. Half of African Americans were exposed to an additional and culturally-targeted personal prevention message. Theory of Planned Behavior measures of attitudes, normative beliefs, perceived behavioral control, and intentions to obtain CRC screening served as outcomes. The effect of messaging on perceived racism in completing CRC screening was also measured as an outcome.

Results: Contrary to theoretical predictions, but consistent with recent cross-cultural research, African Americans were more receptive to CRC screening when exposed to a gain rather than loss-framed message. The contrary effect of loss-framed messaging on receptivity to screening among African Americans was mediated by an increase in perceived racism. However, including an additional and culturally targeted prevention message mitigated the adverse effect of a loss-framed message on both perceived racism and receptivity to CRC screening.

Conclusion: This study further supports a recently identified cultural difference in the effect of message framing on cancer screening among African Americans, while further corroborating a culturally relevant linking mechanism. This study also suggests developing culturally-targeted versions of general health communication strategies may be most compelling in addressing racial health disparities stemming from behavioral prevention, including CRC screening.

DEVELOPMENT AND ACCEPTABILITY OF AN EDUCATIONAL SMOKING CESSATION VIDEO FOR USE IN OUTPATIENT MENTAL HEALTHCARE IN LOUISIANA

Laura M. Perry, MS¹, Adina S. Kazan, B.S.², Wasef Atiya, n/a³, Seowoo Kim, n/a¹, Hallie M. Voss, n/a⁴, Hannah Mercorella, BS⁵, Sanjana Easwar, N/A², James L. Rogers, N/A⁶, Ashley Lewson, BS⁷, Michael Hoerger, PhD, MSCR¹

¹Tulane University, New Orleans, LA; ²Psycho-Oncology Research Program at Tulane University, New Orleans, LA; ³Psycho-Oncology Research Program, New Orleans, LA; ⁴Tulane University, Oak Park, IL; ⁵Tulane University, RIDGEFIELD, CT; ⁶Tulane University Psycho-Oncology Research Program, New Orleans, LA; ⁷Indiana University - Purdue University Indianapolis, Indianapolis, IN

Background: Tobacco use is a leading preventable risk factor for early mortality and is prevalent among adults with mental health diagnoses in Louisiana. However, many available resources do not target individuals most receptive to changing their behavior. We aimed to develop and test the acceptability of a video intervention for outpatient mental healthcare settings designed to increase utilization of the Louisiana Tobacco Quitline among “ready to quit” smokers (in the “preparation” stage of the Stages of Change model).

Methods: A secondary analysis of the 2016 Louisiana Adult Tobacco Survey was conducted to characterize the demographics and smoking behaviors of Louisiana smokers who indicated they were “ready to quit” (expressed a desire to quit and had a quit attempt in the past year). These results informed the development of an educational video, in conjunction with iterative feedback from four stakeholder advisory board meetings. Stakeholders included current smokers, mental health clinicians, and public health advocates. After the last meeting, our stakeholder advisory board ($n=10$) and external stakeholders ($n=20$) rated a 6-item summative evaluation on a 5-point Likert scale to assess the acceptability of the final video.

Results: Our analysis found that ready to quit smokers in Louisiana (52.3% female, 60.2% White, 13.3% college-educated) were more likely than non-ready to quit smokers to use menthol cigarettes (48.3% vs. 38.4%, $p<.001$) or e-cigarettes/vaping devices (14.2% vs. 9.6%, $p=.030$), and bought cigarettes in smaller quantities ($p<.001$). This study ended in a 2-minute video that provides information about the Louisiana Tobacco Quitline. The video was found highly acceptable by stakeholders, as 96.7% felt the video was both helpful ($M=4.50$, $SD=0.57$) and engaging ($M=4.53$, $SD=0.57$). Stakeholders also felt that they would recommend others use the quitline ($M=4.17$, $SD=0.91$) and watch the video ($M=4.27$, $SD=0.87$). Those who participated in the advisory board felt that their ideas were heard ($M=4.80$, $SD=0.42$) and enjoyed participating ($M=5.00$, $SD=0.00$).

Conclusions: This study demonstrates the acceptability of combining theory and iterative stakeholder feedback to develop an mHealth video that links the target population with a tobacco quitline. Follow-up studies should assess the feasibility of implementing the intervention in outpatient mental healthcare and its effectiveness for increasing quitline utilization and tobacco cessation.

EFFECT OF EXPOSURE TO AN ANTI-VAPE MASS MEDIA CAMPAIGN ON VAPING KNOWLEDGE AND INTENTIONS

Alexa R. Romberg, PhD¹, Morgane Bennett, DrPH(c), MPH¹, Bethany Simard, MPH¹, Shreya Tulsiani, MPH¹, Elizabeth C. Hair, PhD¹, Donna Vallone, PhD, MPH¹

¹Truth Initiative, Washington, DC

Mass media campaigns are effective tobacco prevention tools. With the dramatic increase in the prevalence of youth e-cigarette use in recent years, the national, counter-tobacco truth® campaign shifted the focus of campaign messages from prevention of combustible tobacco use to prevention of e-cigarette use. This study assessed differences in vaping-related knowledge and intentions between those who were exposed to truth’s anti-vaping digital ads and those who were not.

Participants ($N=815$, age 18-34) were Dynata panel members. Those who were served a truth ad as part of their natural web activity were randomly selected to receive an online survey. A matched control group that had not been exposed to the digital campaign was also recruited.

The survey assessed vape-related knowledge that was included in truth ads: “Vaping makes people more likely to try cigarettes” (try cigs) and “vapes/e-cigarettes have as much or more nicotine as cigarettes” (nicotine) on a 4-point agreement scale. Participants also reported intentions to use an e-cigarette in the future, with response options definitely not, probably not, probably yes, and definitely yes. Those who responded with anything except definitely not were coded as intending to vape.

Those in the exposed group had, on average, significantly higher agreement with the “try cigs” ($M(\text{exposed})=2.4$; $M(\text{control})=2.1$, $p<.01$) and “nicotine” ($M(\text{exposed})=2.7$, $M(\text{control})=2.5$, $p<.01$) knowledge items compared to the control group. These differences remained significant in regression models when controlling for covariates ($b(\text{try cigs})=0.20$, $p<.01$; $b(\text{nicotine})=0.19$, $p<.05$). There were no significant differences in the proportion of participants who intended to vape between the two groups (exposed=62.9%, control=65.0%, $p=0.5$). Additional regression models indicated that those participants with greater agreement with the “try cigs” knowledge item had lower odds of intending to vape ($OR=0.69$, $p<.001$). The association between the “nicotine” knowledge item and intentions to vape was not significant ($p=.07$).

The ultimate goal of mass media campaigns, like truth, is to change behavior, a precursor to changes in knowledge and intentions to perform that behavior. Results suggest the truth anti-vape campaign was effective at communicating facts and that knowledge was associated with lower intentions to vape. Future evaluations will determine whether ongoing campaign exposure successfully reduces vaping behavior.

11:15 AM–11:30 AM

DROPOUT, RESPONSE, AND ABSTINENCE OUTCOMES OF A NATIONAL TEXT-MESSAGING SMOKING CESSATION INTERVENTION FOR TEENS, SFTEEN

Charmaine Chan, BA¹, Kristyn Kamke, PhD, MS¹, Sherine El-Toukhy, PhD, MA¹¹National Institutes of Health, Bethesda, MD

Background: Adolescence marks cigarette smoking initiation for 90% of US adult smokers. Although text messaging interventions are effective for smoking cessation in adults, few exclusively target teens in the United States and little is known about their effectiveness.

Purpose: Examine correlates of dropout, response rates to smoking-status prompts, and abstinence among SmokeFreeTeen subscribers on quit day through one-month follow-up. These correlates included demographics, smoking frequency, cigarettes smoked per day, pre-quit intervention time (i.e., maximum of 14 days of pre-quit day preparation), and number of quit attempts.

Methods: We performed logistic regressions on a sample of teens, aged 13–19, who subscribed to SmokeFreeTeen ($n = 2685$), a free, publicly available text messaging smoking cessation intervention sponsored by the National Cancer Institute's SmokeFree.Gov initiative.

Results: Two thirds of subscribers ($n = 1733$, 64.5%) dropped out before intervention end, with dropout rates peaking on quit day at 13.1%. Response rate to smoking-status prompts remained below 30% throughout the intervention. Abstinence was 2.7% at intervention end and 2.6% at one-month post-quit. Dropout, response rate, and abstinence did not differ by subscriber characteristics. Among those who dropped out of the intervention, time from quit day to dropout averaged 8 days. Pre-quit time was associated with decreased likelihood of dropping out (adjusted odds ratio [aOR] 0.91, 95% CI 0.90–0.93), responding to smoking-status prompts (aOR 0.94, CI 0.92–0.96), and being abstinent on quit day (aOR 0.96, CI 0.93–0.99). Those with two or more quit attempts were more likely to respond (aOR: 1.79, 1.61) on quit day and day 7 and to be abstinent on day 7 (aOR: 1.92) than those who attempted to quit only once.

Conclusions: In a first assessment of SmokeFreeTeen outcomes, we document high dropouts and low response and abstinence rates. SmokeFreeTeen produced abstinence rates lower than comparable text-messaging interventions targeting teens and young adults. Improving SmokeFreeTeen's reach, engagement, and effectiveness is needed to reduce teen smoking.

Paper Session 27

11:30 AM–11:45 AM

THE EFFECTS OF INTERMITTENT COACHING WITHIN A SECOND-HAND SMOKE JUST-IN-TIME ADAPTIVE INTERVENTION

Vincent Berardi, PhD¹, Melbourne Hovell, MA, Ph.D. MPH², Ehsan Yaghmaei, PhD Candidate³¹Chapman University, Long Beach, CA; ²School of Public Health SDSU, Jamul, CA; ³Chapman, Pasadena, CA

Background: Indoor smoking generates fine particulate matter, which poses severe health risks, particularly for children. In a recently completed just-in-time adaptive intervention (JITAI), we demonstrated that indoor particulate matter was reduced via the immediate presentation of aversive feedback in response to indoor smoking and other particle-generating behaviors. During the deployment of the measurement/feedback system, participants also received four in-home coaching sessions. The independent effects of each of these coaching sessions on indoor particulate matter has not yet been determined.

Methods: We recruited 149 predominately low-income households that contained at least one adult smoker and at least one child aged < 14 years. In each home, two Dylos air particle monitors were installed for ~3 months and measured indoor air particle concentrations every ten seconds. After an ~2 week Baseline period where indoor air concentrations were passively recorded, monitors began delivering aversive visual/auditory feedback in response to the exceedance of a particle concentration threshold that was consistent with cigarette smoking. At four different occasions in the study, RAs performed motivational interviewing coaching sessions where they provided participants with a detailed visual summary of air particle concentrations over the previous weeks and discussed particle sources, mitigation efforts, and goals for upcoming weeks. The first coaching session corresponded with the activation of the aversive feedback system at the end of the Baseline, while the three others occurred at roughly two-week intervals. To assess the effect of the coaching sessions on air particle levels, an interrupted time-series, random-intercept hierarchical linear model was constructed. Within this model, time was rescaled on an individual basis so that each of the four coaching visits were temporally aligned over all participants.

Results: As expected, relative to the Baseline, air particle levels were significantly lower ($p=0.001$) after the first coaching visit, which corresponded with the onset of real-time feedback. Air particle levels were also significantly lower ($p < 0.001$) after the third coaching session, relative to the time period immediately preceding it. The reduction in air particle concentrations associated with the third coaching visit was larger than that of the first. The second and fourth coaching visits had no effect on air particle levels.

Discussion: The impact of the third coaching session on air particle levels was completely unexpected and may be associated with a slow buildup of intervention effect. Based on this result, audio recordings of all coaching sessions are being transposed so that a qualitative analysis of coaching visits can be performed.

IMPLEMENTATION OUTCOMES OF WEBMAP MOBILE: AN MHEALTH SOLUTION FOR PEDIATRIC CHRONIC PAIN

Rocio de la Vega, PhD¹, Tonya M. Palermo, PhD², Lee M. Ritterband, PhD³¹Seattle Children's Research Institute, Seattle, WA; ²University of Washington School of Medicine; Seattle Children's Research Institute, Seattle, WA; ³University of Virginia School of Medicine, Charlottesville, VA

Introduction: Chronic pain is common in adolescents, affecting one in four. Behaviorally based treatments are effective for reducing pain and disability; however, access is limited. Remotely-delivered pain self-management programs, which have also been found to be efficacious, can reduce barriers to care. The current work aims to evaluate the implementation strategy for a smartphone application for adolescents with chronic pain called WebMAP Mobile.

Methods: We conducted a hybrid effectiveness-implementation cluster randomized controlled trial with a stepped wedge design in which the intervention was sequentially implemented in 9 specialty clinics, following a usual care period. Participants were 173 youth (mean age 14.5, 82% female) with chronic pain, from which 73 were randomized to receive WebMAP Mobile and are analyzed here. Implementation outcomes were assessed with the Behavior Interventions using Technology (BIT) framework, which is based on: Acceptability, Adoption, Appropriateness, Feasibility, Fidelity, Implementation costs, Penetration and Sustainability.

Results: Acceptability (i.e., perception of the treatment as useful or satisfactory): 86% of adolescents rated the app as at least a moderately acceptable treatment on the Treatment Evaluation Inventory. Adoption (i.e., initiation of use of the intervention): 94% of adolescents downloaded the app, and all of them used it after their first log-in. Appropriateness (i.e. perceived relevance of fit of the intervention within a context): adolescents spontaneously reported (in open-ended questions) positively on: 1) usability and ease of navigation (37%); 2) design, layout and interface (35%); and 3) content was easy to understand, fun, and useful (83%). Feasibility (i.e., extent to which the intervention can be successfully used in a specific context): no technical issues were reported. Fidelity (i.e., intended use versus the actual use): 40% of adolescents completed the treatment. Penetration (i.e., integration of the practice within the service): 49 new users accessed the app in the six months after the study finished. Sustainability (i.e., extent to what the practice is maintained): 78% of clinics continued recommending the app after the end of the study.

Conclusions: According to the BIT framework, the implementation of WebMAP Mobile was successful but further work is needed to increase app usage (fidelity).

PAIN CATASTROPHIZING PREDICTS LESS PHYSICAL ACTIVITY THROUGHOUT THE DAY IN KNEE ARTHRITIS

Ruixue Zhaoyang, PhD¹, Lynn M. Martire, Ph.D.¹¹Penn State University, University Park, PA

Chronic or persistent pain affects approximately one-third of adults in the United States and the prevalence is twice as high in those 60 years and older. Musculoskeletal disorders such as knee osteoarthritis (OA) are the primary cause of chronic pain in older adults. Recommended self-management strategies for knee OA include staying physically active in the face of pain, but many patients avoid activities they are capable of doing. Previous research shows that pain catastrophizing (i.e., negative cognitive-emotional responses to real or anticipated pain) varies from day to day and predicts increased pain; one important but unexamined question is the extent to which patients are less physically active on days in which they catastrophize more about their pain. The current study utilized data from 145 knee OA patients who completed electronic daily diaries for 22 days and wore an accelerometer on their hip to capture the number of steps per day and minutes of moderate-vigorous physical activity (> 760 activity counts per minute). At the beginning of each day, patients reported their pain catastrophizing regarding the day ahead using two items from the Coping Strategies Questionnaire (e.g. Today I feel that the pain is terrible and is never going to get any better). Consistent with our predictions, on mornings when patients catastrophized more than usual about their pain in the day ahead, they engaged in fewer minutes of moderate to vigorous physical activity that day (estimate = -3.23, $p = .022$) and tended to take fewer steps (estimate = -158.15, $p = .055$). These analyses controlled for patients' morning negative affect and self-efficacy for managing pain, as well as daily pain severity and accelerometer wear time. To our knowledge, this is the first study to show that daily negative thoughts regarding pain are associated with less subsequent physical activity as measured objectively. Cognitive-behavioral interventions that reduce pain catastrophizing may also enhance physical activity, with longer-term benefits for weight management and physical function.

11:15 AM-11:30 AM

COGNITIVE BEHAVIORAL THERAPY FOR PEDIATRIC ABDOMINAL PAIN DISORDERS REDUCES CAREGIVER ANXIETY

Natoshia R. Cunningham, Ph.D.¹, Anne E. Kalomiris, M.A.²¹Michigan State University, Grand Rapids, MI; ²Nationwide Children's Hospital, Columbus, OH

Pediatric functional abdominal pain disorders (FAPD) are associated with increased rates of anxiety in affected youth and their caregivers. CBT can improve pain-related outcomes, and a CBT approach (i.e., Aim to Decrease Anxiety in Pain Treatment [ADAPT]) targeting both pain and anxiety improves pain-related outcomes and anxiety symptoms in youth with FAPD. However, caregiver anxiety is common in youth with FAPD and is associated with poorer functioning in pediatric FAPD, though it is unknown if child-focused CBT may also impact caregiver anxiety. The current study examined 1) if ADAPT reduces caregiver anxiety and 2) the relation between caregiver anxiety and child symptoms (i.e., pain, disability, anxiety) following treatment. A total of 79 caregiver-child dyads completed this randomized clinical trial, with 40 of those dyads randomized to receive ADAPT. Caregiver anxiety (anxiety subscale of the Depression Anxiety and Stress Scale; DASS) as well as child symptoms of pain (Visual Analog Scale; VAS), Functional Disability (Functional Disability Inventory; FDI), and anxiety (Screen for Child-Anxiety Related Emotional Disorders; SCARED) were assessed at baseline and following treatment. Multiple linear regression in Stata version 15 was used to assess differences in anxiety symptoms for caregivers whose children completed ADAPT versus medical TAU using maximum likelihood estimation (MLE). Child clinical symptoms (i.e., VAS, FDI, SCARED, separately) at post-treatment were regressed on caregiver anxiety at post-treatment, controlling for the child's respective baseline symptom (i.e., VAS, FDI, SCARED) and caregiver anxiety at baseline. Caregivers of children assigned to ADAPT demonstrated lower anxiety symptoms following treatment when compared to those receiving treatment as usual (TAU), $b = -1.42$, $SE = 0.68$, $t = -2.10$, $p = .036$, 95% CI = [-2.75, -0.09]). In addition, caregivers with more reported anxiety symptoms following treatment also had children who reported more pain ($b = 0.21$, $SE = 0.07$, $t = 3.24$, $p = .001$, 95% CI = [0.08, 0.34]), and anxiety ($b = 1.05$, $SE = 0.49$, $t = 2.15$, $p = .032$, 95% CI = [0.09, 2.01]) following treatment. The relation between caregiver anxiety and child functional disability was non-significant. Results reveal that a brief, effective, multi-method child-focused intervention targeting pain and anxiety may also potentially improve caregiver anxiety, which is also related to child pain and anxiety. Directions for future work are suggested that may improve outcomes for youth with FAPD.

Paper Session 28

11:30 AM-11:45 AM

VETERAN PERSPECTIVES ON USING SOCIAL ROBOTS FOR AT-HOME CHRONIC PAIN MANAGEMENT

Erin D. Reilly, Ph.D.¹, Arielle Scoglio, MPH², Shelley Kind, M.S.³, Elina Talis, MA⁴, Karen S. Quigley, Ph.D.⁵¹Bedford VA Medical Center, Bedford, MA; ²Edith Nourse Rogers Memorial Veterans Hospital, Cambridge, MA; ³Suffolk University, Boston, MA; ⁴William James College, Brighton, MA; ⁵Northeastern University, Needham, MA

Social robots (SR) are increasingly being investigated as tools to engage patients in at-home mental and physical interventions through personal interactions. Our study's objective was to understand veteran patient responses and usability concerns for using an-home SR (Jibo) to manage chronic pain. The 2.5-hour one-on-one SR interaction included: 1) an introduction, 2) setting an exercise goal, 3) a stretching exercise, and 4) discussing recent stressors. Participant SR feedback was evaluated using the Intrinsic Motivation and Perceived Usefulness Scale (ITAM), System Usability Scale (SUS), and Robotic Social Attribute Scale (RoSAS). Videotaped interviews were coded to identify user reactions and usability issues of the SR interface. Participants were 12 veterans (mean age=59.5, 83% male) with an average pain rating of 5.8 (range=1–10).

On the ITAM, veterans reported high levels of perceived motivation for SR use ($m=4.9$, $SD=0.2$), ease of use ($m=4.7$, $SD=0.5$), and usefulness for health management ($m = 4.7$, $SD=0.4$). Veterans also reported high usability for the human-robot interaction ($m=40.4$, $SD=4.9$) on the SUS (range=10-50). In terms of affective response, RoSAS scores (range=1-9) indicated that veterans found the SR to be competent ($m=8.3$, $SD=0.9$), warm ($m=7.7$, $SD=1.8$), and comforting ($m=8.5$, $SD=1.3$).

Veterans reported multiple comorbidities (e.g., partial paralysis, tinnitus) that could make SR use difficult and suggested that the SR should understand their specific challenges. Suggestions for improvement included audio changes (e.g., tone, gender) and more options for interactions (e.g., touchable icons). Some veterans (56%) reported data security/privacy concerns and requested the ability to lock/protect their SR data. Most participants (89%) reported highly enjoying the SR's personality ("funny", "friendly", "like a person"), and reported that this helped them feel motivated and supported through management of exercise, medication, and daily stress. All participants reported that they would be comfortable and interested in having SRs at home with them.

Overall, veterans with chronic pain found the SR highly usable, potentially useful, and enjoyed their interactions enough to want their own at-home SR. Feedback indicated that usability, usefulness, and "personhood" may be uniquely linked for SR interventions. Findings suggest that using social, interactive robotic platforms may be an effective approach for chronic pain and emotional care management.

Paper Session 29

10:45 AM–11:00 AM

USING MIXED METHODS TO UNDERSTAND PATIENT EXPERIENCES ASSOCIATED WITH PERCEIVED RACIAL/ETHNIC DISCRIMINATION IN HEALTHCARE

Leslie R. M. Hausmann, PhD¹, Audrey L. Jones, PhD², Shauna E. McInnes, BA¹, Susan L. Zickmund, PhD³¹VA Pittsburgh Healthcare System, Pittsburgh, PA; ²VA Salt Lake City Health Care System, Salt Lake City, UT; ³University of Utah School of Medicine, Salt Lake City, UT

Healthcare experiences that contribute to perceptions of discrimination due to one's race or ethnicity are poorly understood and have primarily been examined in small qualitative studies. Our objective was to identify healthcare domains that are associated with perceived discrimination using data from a large mixed-methods study of racial/ethnic and gender disparities in patient satisfaction. White, African American, and Latino patients sampled from 25 Veterans Affairs (VA) Medical Centers completed semi-structured interviews on their healthcare experiences and a measure assessing whether they ever experienced racial/ethnic discrimination while seeking VA healthcare. We derived nine domains of dissatisfaction with care from interviews and entered the domains as binary predictors of perceived discrimination in a multilevel model adjusting for patient characteristics and site. We conducted a thematic analysis to further understand the significant domains. Of 622 participants (30.4% White, 37.8% African American, 31.8% Latino; 57.4% female; mean age=53.4), 233 (37.4%) perceived racial/ethnic discrimination in healthcare. Individually, 6 of 9 domains correlated with perceived discrimination: dissatisfaction with care quality, facilities, continuity of care, interactions with providers/staff, provider/staff demeanor, and pharmacy services (all $p < 0.006$). In a combined model, poor interactions with providers/staff (OR=2.91, 95% CI=1.85–4.56) and negative provider/staff demeanor (OR=2.32, 95% CI=1.52–3.56) remained significant. In the domain of poor interactions, the most frequent themes of dissatisfaction were that providers or staff were rude, condescending, or hostile; did not listen to patients; and were not informative. For negative demeanor, the most frequent themes involved lack of care/concern from providers or staff, feeling stigmatized, and perceiving providers or staff as untrustworthy. For both domains, participants referenced clinicians more often than non-clinical staff in dissatisfaction statements (poor interactions: 51% vs. 30%, respectively; negative demeanor: 46% vs. 15%). Our study suggests that negative interpersonal experiences while obtaining healthcare are strong correlates of perceived racial/ethnic discrimination. The findings underscore the need for interventions that strengthen the soft skills of both clinical and non-clinical staff, and/or structural changes that create a more welcoming, caring, and patient-centered culture.

IMPACT OF FATHERHOOD IDENTITY, FATHER SELF-EFFICACY, AND MACHISMO ON PARENT-CHILD CONFLICT AMONG PROBLEM DRINKING LATINO MEN

Alberto Cifuentes, LMSW¹, Cristina Mogro-Wilson, PhD, MSW²¹University of Connecticut, West Haven, CT; ²University of Connecticut, Hartford, CT

Latino men are more likely to binge drink and, consequently, engage in risky behavior than their non-Latino male counterparts in the United States. While the literature consistently supports the relationship between positive father-child relationships and decreased adolescent alcohol use, there is a gap in the knowledge base regarding how fatherhood affects alcohol use for Latino men. The current study analyzed the impact of two Latino cultural constructs, traditional machismo and caballerismo, as well as fatherhood identity and father self-efficacy on the parent-child relationship among Latino fathers with problem drinking behaviors. This study explored data from 309 Latino fathers who participated in a web-based questionnaire administered by Qualtrics, a third-party online survey company. Of the sample, about 51% of the sample ($n=157$) identified as Mexican American while 22% identified as Puerto Rican, 8% as Central American, 7% as Cuban, 7% as South American, and 5% as Dominican. The average age of the father was 37 years old. Multiple regression was used to assess the ability of traditional machismo, caballerismo, child-parent relationship (closeness and conflict), father self-efficacy, and fatherhood identity to understand problem drinking after controlling for the father's acculturation, father's age, and youngest child's age. Latino fathers with higher levels of traditional machismo and child-parent conflict and lower levels of fatherhood identity significantly predicted higher problem drinking ($p < .01$). Moreover, the overall model including an interaction term of fatherhood identity and traditional machismo was significant. For Latino fathers, fatherhood identity moderated the relationship between traditional machismo and problem drinking ($p < .05$). High levels of traditional machismo and low levels of fatherhood identity were related to increased problem drinking. However, high levels of caballerismo, a close parent-child relationship, and high levels of father self-efficacy were not related to less problem drinking. This study's findings highlight the importance of social identity for Latino men and offer a strengths-based perspective for prevention of alcohol misuse. With the large expansion of the Latinx population in the U.S. coupled with the growth of alcohol misuse among Latino males, it is crucial to find innovative and culturally competent models of fatherhood intervention for this population.

“BREAST IS BEST” MESSAGE PENETRATES, LIP SERVICE DOMINATES: PERSPECTIVES FROM AFRICAN AMERICAN WOMEN IN WASHINGTON, D.C.

Aubrey Villalobos, MPH, MEd, DrPHc¹, Catasha R. Davis, PhD², Sahira Long, MD, IBCLC, FAAP, FABM³, Anayah Sangodele-Ayoka, CNM, MSN, MSEd⁴, Monique M. Turner, PhD⁵, Shawnika J. Hull, MA, PhD⁶, Maria Lapinski, PhD⁵

¹George Washington University Cancer Center, Washington DC, DC; ²FrameWorks Institute, North Bethesda, MD; ³Children's National Health System, Washington, DC; ⁴George Washington University, Clinton, MD; ⁵Michigan State University, East Lansing, MI; ⁶George Washington University, Washington, DC

Background: Breastfeeding is a behavior that has many benefits for mother and child, yet rates of initiation, duration and exclusivity for non-Hispanic Black women and babies are lower than HealthyPeople 2020 targets. Complex factors across social ecological levels influence breastfeeding. Generations of racialized economic and gender oppression, limiting opportunities for and visibility of human milk feeding, contribute to health disparities over the life course of African Americans.

Aim: As part of a study exploring infant feeding norms and decision making, we aimed to document current breastfeeding attitudes in Washington, D.C., where rates of breastfeeding among African American women are low and health disparities are high, and explore what social, environmental, and policy contextual factors correlate with attitudes.

Methods: Five focus groups were conducted with African American mothers living in Washington, D.C. who had at least one child between 2016–2019 (N=30). Transcripts were coded deductively, by the first two co-authors, for constructs in the Theory of Normative Social Behavior and inductively with a Black Feminism lens.

Results: Participants shared overwhelmingly positive attitudes, using the “breast is best” idiom often. Regardless of socioeconomic status (SES), participants agreed that breastfeeding norms have shifted over time to be more common and favorable in African American communities. However, many participants also described insincerity in breastfeeding promotion; they perceived breastfeeding is generally encouraged yet there is often a lack of emotional, informational and tangible support to make breastfeeding feasible. Socioeconomic context, driven largely by geographic racial segregation in D.C., was related to divergent attitudes about availability of support. Changes in policies and messaging from the Special Supplemental Nutrition Program for Women, Infants, and Children (WIC) were perceived by many participants with lower SES as a driving force in shifting attitudes and norms recently. Perceptions of local laws regarding workplace policies to protect breastfeeding also differed by SES.

Discussion: These findings suggest progress has been made in D.C., thanks in part to WIC's efforts, to shift attitudes and norms about breastfeeding in African American communities. Differences in actual or perceived availability of support for breastfeeding and protection under legislation offer opportunities for interventions to continue improving breastfeeding rates and reducing health disparities for African American Washingtonians.

PRENATAL PREDICTORS OF INFANT SLEEP AND HEALTH DISTURBANCES AMONG LATINO FAMILIES

Guido Urizar, PhD¹

¹California State University Long Beach, Long Beach, CA

Sleep disturbances during infancy are among the most common concerns reported to pediatricians and are linked to a number of subsequent behavioral and health problems later in childhood. However, few studies have examined sleep patterns among Latino infants who have been shown to sleep approximately 30 minutes less per day than non-Latino White infants. Consequently, more studies are needed to examine what factors may predict infant sleep disturbances in Latino families. The purpose of the current study was to investigate whether certain characteristics during pregnancy (i.e., maternal stress and depression, quality of the relationship with one's romantic partner, and maternal health status) and the postnatal period (i.e., infant temperament and stress level) were associated with the sleep behaviors (e.g., co-sleeping) and sleep quality of Latino infants and their families participating in a longitudinal study on the effects of stress on maternal and infant health outcomes. Our sample consisted of 100 low-income pregnant women (75% annual income < \$19K; 71% Latina) who completed stress (Perceived Stress Scale) and depression (Edinburgh Postnatal Depression Scale) assessments during their first trimester of pregnancy (mean gestational age=10+4 weeks). At three months postpartum, women completed an assessment on their infant's sleep patterns/behaviors and health status. Results showed that 50% of our sample had elevated stress levels and 17% had high depressive symptoms during pregnancy. At postpartum, 63% of mothers reported co-sleeping with their infants in the same bed, with 11% reporting that their infants had difficulty sleeping. Hierarchical regression analyses revealed that: (1) co-sleeping with one's infant occurred more often among mothers who had a poor relationship with their romantic partner and among infants who had a difficult temperament ($R^2=.23, p<.01$); and (2) poorer sleep quality was observed among infants of mothers who had higher levels of stress and depression during pregnancy and among infants experiencing higher levels of postnatal stress ($R^2=.23, p<.01$). Our results provide growing evidence for the role of prenatal stressors and depression in having persisting, long-term effects on infant sleep and health outcomes during the early postnatal period. Specific to Latino families, these results support the need to examine cultural variations in parenting style and expectations with respect to perceptions of infant sleep behaviors, sleep quality, and health status.

ASSOCIATIONS BETWEEN MILK CONSUMPTION AND BMI WITHIN MEXICAN-AMERICAN AND NON-HISPANIC WHITE POPULATIONS

Sara E. Fleszar-Pavlovic, n/a¹, Katie E. Alegria, MA², Jacqueline N. Hua, n/a¹, Anna V. Song, PhD³¹University of California, Merced, Merced, CA; ²University of California, Merced, CA; ³UC Merced, Merced, CA

As of 2016, 39% of the U.S. adult population are classified as obese (CDC, 2017). The prevalence of obesity is a growing concern because it is a precursor for other negative health outcomes such as diabetes, stroke, and heart disease. Although diet modification is critical in treating and preventing obesity, dietary guidelines are unclear. In particular, there is a permeating belief that milk consumption is protective against obesity. However, findings from the literature on the associations between milk consumption and BMI are mixed. Further, research in this domain largely focuses on ethnically homogeneous populations even though the cultural significance of milk may vary across ethnic groups. For example, despite recommendations that adults consume non-fat or low-fat milk, whole milk is an important commodity of traditional Mexican culture and 85% of Mexican Americans consume whole milk daily. Furthermore, Mexican Americans are at the highest risk for obesity. The current study examines associations between BMI and milk consumption within Mexican American and non-Hispanic White populations via a secondary data analysis of the 2015-2016 survey cycle of the National Health and Nutrition Examination Survey (NHANES). Adults who self-identified as Mexican American or non-Hispanic White and were > 18 years old were included in the analyses (N= 2,853; 50.9% female; M_{age} = 51.1). Logistic regression quantified the relationship between obesity/overweight classification (BMI), milk consumption, ethnicity, and covariates. In this study, non-Hispanic Whites were less likely to be overweight/obese compared to Mexican Americans, OR = 0.81 (95% CI: 0.76 - 0.86). Participants who reported greater milk consumption over the past 30 days were less likely to be classified as overweight/obese than those who indicated that they did not consume milk, OR = 0.87 (95% CI: 0.79 - 0.96). Milk consumption was negatively associated with overweight/obese status, but only for non-Hispanic Whites, OR = 0.85 (95% CI: 0.79 - 0.99). Milk consumption did not significantly relate to overweight/obese status for Mexican Americans (OR = 1.06, 95% CI: 0.85 - 1.32). For non-Hispanic Whites, milk consumption is a protective factor against being overweight/obese. However, this protective factor was not observed for Mexican Americans. There may be a more complicated relationship between milk consumption and BMI. Further, the health benefits of milk consumption may differ by racial/ethnic group.

EFFECT OF A CULTURALLY ADAPTED BEHAVIORAL WEIGHT LOSS INTERVENTION AMONG LATINO ADULTS: THE VIDA SANA RANDOMIZED CLINICAL TRIAL

Lisa Goldman Rosas, PhD, MPH¹, Lan Xiao, PhD¹, Nan Lv, PhD², Elizabeth M. Venditti, PhD³, Megan A. Lewis, PhD⁴, PATRICIA ZAVELLA, n/a⁵, Kristen Azar, RN, MSN/MPH⁶, Jun Ma, MD, PHD²¹Stanford University, Palo Alto, CA; ²University of Illinois at Chicago, Chicago, IL; ³University of Pittsburgh School of Medicine, Pittsburgh, PA; ⁴RTI International, Seattle, WA; ⁵University of California, Santa Cruz, Santa Cruz, CA; ⁶Sutter Health, Palo Alto, CA

Background: Latinos are one of the fastest growing racial/ethnic groups in the US and are more likely to be obese and at elevated cardiometabolic risk compared to non-Hispanic whites. Identifying effective approaches for weight management is of critical importance for preventing chronic disease in this population.

Methods: Adult Latinos with a body mass index (BMI) of 25 or higher and metabolic syndrome, prediabetes, and/or a history of gestational diabetes were recruited in primary care and randomized to receive the 12-month Vida Sana intervention or usual care and followed for 24 months. Vida Sana was a culturally adapted coach-facilitated lifestyle intervention that included a family-based orientation session and 22 group sessions over 12 months (12 weekly, 4 biweekly, and then 6 monthly). Participants received monthly email messages for an additional 12 months. The primary outcome was weight loss at 24 months (97% retention). Secondary outcomes included weight loss and achieving ≥5% weight loss at 12 months. Associations of intervention adherence and baseline characteristics with weight loss outcomes were also examined.

Results: Participants (n=191) were middle aged (50.2 [SD 12.2] years), 62% female, 57% of Mexican origin, and had a mean BMI of 32.4 (SD 5.7) at baseline. Weight loss did not differ significantly by group at 24 months (-1.1 kg [SD 5.7] vs. -1.1 kg [SD 7.1]; p=0.93). However, weight loss was significantly greater in the intervention group (-2.6 kg [SD 6.0]) than the control group (-0.3 kg [SD 4.2]) at 12 months (mean difference -2.1 (95% CI -3.6, -0.7); p=0.005). At 12 months, 26% of intervention participants compared to 9% of control participants achieved ≥5% weight loss (p=0.003). Those who achieved ≥5% weight loss at 12 months attended more intervention sessions (16.6 [SD 7.6]) compared to those that did not (12.4 [SD 7.6], p=0.03). Baseline characteristics associated with greater weight loss over 24 months included older age (β=-0.1 [SD 0.04], p=0.02), living with ≥3 people versus fewer (β=-2.5 [SD 1.2], P=0.04), higher acculturation (β=-1.5 [SD 0.6], p=0.02), and higher body dissatisfaction (β=-0.8 [SD 0.4], p=0.05).

Conclusions: Among Latino adults at risk for chronic disease, a culturally adapted behavioral lifestyle intervention was effective for weight loss over 12 months but not 24 months. Weight loss was greatest among those who attended more intervention sessions and those who were older, more acculturated, living with more people, and with a greater body dissatisfaction.

INSIGHTS TO NEURAL RESPONSE TO FOOD CUES IN CLASS III AND CLASS I/II OBESITY FROM ENDOMETRIAL CANCER SURVIVORS SEEKING WEIGHT LOSS

Nora L. Nock, PhD¹, Anastasia Dimitropoulos, PhD¹¹Case Western Reserve University, Cleveland, OH

The rates of severe obesity (Class III: BMI ≥ 40.0 kg/m²) and endometrial cancer (EC) incidence and mortality have been increasing significantly in the U.S. Women with severe obesity have a higher risk of EC development and mortality compared to those with Class I/II obesity (BMI: 30 to < 40 kg/m²) or those of normal weight (BMI: 18.5 to < 25 kg/m²). Although it is well-known that adults with severe obesity are more likely to die and be more metabolically unhealthy compared to those with lower classes of obesity, only a few neuroimaging studies have focused solely on adults with severe obesity and no prior studies have evaluated the neural response to food cues by class of obesity in adults with or without cancer. Therefore, we conducted a functional magnetic resonance imaging (fMRI) visual food cue task in 85 Stage I EC survivors with obesity seeking weight loss who were enrolled in a lifestyle intervention (NCT01870947) at baseline prior to starting the intervention. We evaluated the neural response to high-calorie compared to non-food images after an overnight fast and after eating a standardized luncheon meal and, for analyses, grouped patients by their obesity class at baseline (Class I/II: n=38; Class III: n=47). In the fasted state, we observed differences in the neural activation patterns by obesity class. Specifically, we found increased activation in the orbitofrontal cortex (OFC) and precuneus among Class III patients and, decreased activation in the insula and posterior cingulate (PC) among Class I/II patients (whole brain cluster corrected, $p < 0.05$). In the fed (satiated) state, we found increased activation in the dorsolateral prefrontal cortex (dLPFC) among Class III and Class I/II patients (whole brain cluster corrected, $p < 0.05$). The increased activation observed in regions associated with cognitive control/inhibition (dLPFC) and motivation (OFC) in patients with Class III obesity are consistent with the summative literature in obesity but the decreased activation found in regions associated with taste information processing (insula) and memory (PC) among Class I/II obese in the fasted state provides new insights. In this first study evaluating the neural response to high-calorie food cues by obesity class in EC survivors, our results highlight the need for further examination of food-related neural circuitry among different classes of obesity and reinforce the importance of targeting frontal brain regions, in particular, the dLPFC, in weight loss interventions.

ADHERENCE MATTERS: PREDICTING WEIGHT LOSS AMONG OVERWEIGHT ADULTS WITH KNEE OSTEOARTHRITIS

Alexis Oliveira, n/a¹, Shannon L. Mihalko, PhD²¹University of South Carolina, Columbia, SC; ²Wake Forest University, Winston Salem, NC

Introduction: Nearly 57% of obese U.S. adults have knee osteoarthritis (KOA). Treatment recommendations for adults with KOA include dietary weight loss and exercise. However, adherence rates to these recommendations vary, with low attendance consistently reported in the literature. Although adherence is a predictor of weight loss among overweight adults, there is a lack of studies that have examined whether adherence predicts weight loss among overweight adults with KOA. Further, the mechanistic underpinning of this relationship has not been studied in this population. Therefore, the objectives of this study were to examine whether adherence predicted weight loss among overweight adults with KOA and to determine whether exercise self-efficacy or pain mediated the relationship between adherence and weight loss.

Methods: The Intensive Diet and Exercise for Arthritis (IDEA) study was an 18-month, randomized control trial for overweight adults with KOA. To examine the outcome of intentional weight loss, only participants randomized to the diet-induced weight loss or the combined diet-induced weight loss plus exercise interventions were included in the analysis. Adherence was calculated as a ratio of attendance to the number of prescribed sessions. Diet adherence, exercise adherence, and weight loss were measured over 18 months. Multiple regression analyses were used to determine the associations between intervention adherence and weight loss at 18 months. Mediation analyses were used to determine whether change in self-efficacy or pain over the course of the intervention mediated the association between adherence and weight loss.

Results: There were 304 adults (65.5 ± 6.1 yrs; 33.6 ± 3.7 kg/m²) included in these analyses. Adherence to both interventions was high at 18 months ($\geq 60\%$). Adherence at 18 months was significantly associated with 18-month weight change for the diet-only and diet plus exercise groups ($r = -0.52$ and $r = -0.38$, respectively). Neither change in self-efficacy nor pain mediated the relationship between adherence and weight loss (Sobel $p > .05$).

Conclusions: Individuals with higher intervention attendance lost more weight during the study. Increased exercise self-efficacy and decreased pain were associated with better attendance; however, neither factor helped to explain the mechanism underlying the relationship between adherence and weight loss. Since adherence plays an important role in weight loss, future studies should examine how self-efficacy, pain, and program variables impact adherence to weight loss interventions among overweight adults with KOA.

PERCEPTIONS OF PUBLIC HEALTH PRIORITIES AND ACCOUNTABILITY AMONG U.S. MAYORS

Monica Wang, ScD, MS¹, Luisa Godinez Puig, N/A², Katharine Lusk, MPP³¹Boston University School of Public Health, Newton, MA; ²Boston University, Washington, DC; ³Boston University, Boston, MA

Objective: Mayors play a pivotal role in advancing the health of their cities, yet little is known about mayors' priorities and attitudes regarding public health challenges. This study aims to assess mayors' perceptions of top health challenges facing their cities, examine mayors' perceptions of accountability for public health challenges, and explore predictors of perceived accountability.

Methods: Data are from a nationally representative survey of U.S. mayors (N=110) and publicly available data repositories and sources on city-level health metrics. Participants were asked to identify the greatest health challenge facing their city (open-ended). Perceived accountability for nine public health issues (asthma, gun violence, hunger/malnutrition, mental health, lead and other toxicants, obesity, opioids, other substance abuse, and traffic accidents) was assessed by asking participants to rate the extent to which they believe constituents hold them accountable for each of the nine public health issues (not at all, a little, somewhat, or very accountable). City-level health metrics were derived from the City Health Dashboard 500 Cities, the Centers for Disease Control and Prevention, and the US Department of Transportation's National Highway Traffic Safety Administration. We conducted descriptive analyses and a series of ordinary least squares multivariable regression models to examine associations between mayoral and city-level characteristics (predictors) and level of perceived accountability (outcome) for each of the nine public health issues.

Results: Mayors most frequently cited obesity/chronic diseases (25%), opioids/addiction (24%), health care access (15%), and mental health (14%) as the top health challenges facing their cities, yet identified traffic accidents, gun violence, and environmental toxins as health issues for which they believe constituents hold them most accountable (obesity ranked lowest). Democratic mayors rated higher accountability from constituents for gun violence ($\beta=0.78$; $SD=0.26$; p -value $p<0.01$), hunger/malnutrition ($\beta=0.75$; $SD=0.25$; $p<0.01$), asthma ($\beta=0.40$; $SD=0.18$; $p<0.05$), and obesity ($\beta=0.46$; $SD=0.18$; $p<0.05$), than Republican mayors. Compared to female mayors, male mayors rated lower accountability for hunger/malnutrition ($\beta=-0.029$; $SD=0.016$; $p<0.1$), other substance abuse ($\beta=-0.026$; $SD=0.015$; $p<0.1$), and mental health ($\beta=-0.033$; $SD=0.23$; $p<0.05$). Prevalence of opioid deaths in a city was the only health outcome that was positively associated with perceived accountability ($\beta=0.019$; $SD=0.010$; $p<0.05$).

Conclusions: Findings indicate a discrepancy between mayors' perceptions of pressing public health challenges vs. perceived accountability to address such challenges. Findings can inform strategies to engage local policymakers in cross-sector collaborations to improve city and community health.

DOES WHERE YOU LIVE MATTER? THE BUILT ENVIRONMENT AND INTERVENTION-RELATED CHANGES AMONG RURAL ADULTS WITH OBESITY

Brittney N. Dixon, MPH¹, Abraham J. Eastman, M.S.¹, Umelo A. Ugwoaba, B.S.¹, Andrea N. Brockmann, M.A.¹, Charlayne A. Scarlett, M.P.H.¹, Vivian Bauman, M.S.¹, Meena N. Shankar, MS, RD, CCRC¹, Michael Perri, PhD², Kathryn M. Ross, Ph.D., M.P.H.¹¹University of Florida, Gainesville, FL; ²University of Florida, College of Public Health and Health Professions, Gainesville, FL

Background: The built environment may play a critical role in weight regulation as it can facilitate or restrict individual ability to engage in key weight-related behaviors. To date, research results have been equivocal; while most studies have found that participants in more favorable environments experience greater improvements in eating and activity behaviors compared to those in less favorable environments, others have showed the opposite pattern of effects. Moreover, most of this work has focused on urban areas; there has been limited research regarding how built environment factors may influence intervention outcomes in rural areas.

Methods: The current study combined intervention outcome data from the Rural Lifestyle Eating and Activity Program (Rural LEAP) with data from the United States Census Bureau, the Florida Geographic Data Library, and other publicly available datasets in order to examine associations between key built environment factors and weight loss. Rural LEAP included 445 adults with obesity ($M \pm SD$ age = 55.4 years, $BMI = 36.5 \text{ kg/m}^2$, 79% White, 83% Female) who completed a 4-month, in-person behavioral weight loss program. For the current study, participant addresses were geocoded and a 2-mile buffer was established to identify key built environment factors (e.g., food establishments, modified retail food environment index [mRFEI], fitness/recreation facilities, parks, and trail length). Multilevel models were used to examine the association between built environment and weight status during the initial weight loss program (baseline to Month 4).

Results: Participants lost an average (mean \pm SD) of $8.3 \pm 4.9 \text{ kg}$ from baseline to Month 4. Greater numbers of convenience stores, $\beta=0.42$, $p=.030$, dollar stores, $\beta=1.26$, $p=.042$, and full-service restaurants, $\beta=0.16$, $p=.020$, were associated with higher weight across time points; however, there were no associations between these food environment features and weight loss from baseline to Month 4, all $ps > .05$. There were no significant associations between the number of supermarkets, fruit/vegetable markets, fast food restaurants, or mRFEI and either weight across time or weight losses from baseline to Month 4, all $ps > .05$. Further, there were no significant associations between any physical activity environment factors and either weight across time or weight change from baseline to Month 4, all $ps > .05$.

Conclusion: Results demonstrated that certain built environment features may be associated with greater body weight; however, no built environment features included in the current study promoted or hindered intervention-related weight losses. Future research should investigate whether these built environment features may impact maintenance of lost weight after the end of initial intervention.

EFFECT OF PATIENT-PHYSICIAN RACE/ETHNICITY CONCORDANCE ON HPV VACCINE INITIATION

Sharice Preston, PhD¹, Sharon Coan, BA, MS², Erica L. Frost, BA, MPH³, C. Mary M. Healy, MD⁴, Maria E. Fernandez, PhD⁵, Ross Shegog, PhD⁶

¹University of Texas Health Science Center at Houston, Houston, TX;

²UTHealth Houston, Houston, TX; ³The University of Texas Health Science

Center at Houston, Houston, TX; ⁴Baylor College of Medicine, Houston, TX;

⁵University of Texas Health Science Center, Houston, TX; ⁶University of Texas, Houston, TX

Background: Physicians play a critical role in influencing parent acceptance of the HPV vaccine. Patient-physician racial/ethnic concordance has been found to be a factor influencing the patient-physician relationship and subsequent outcomes in numerous contexts but, to date, little has been done to investigate concordance on vaccination outcomes. Concordance may influence HPV vaccination initiation rates by improving patient-physician communication and fostering trust. We examined the association between patient-physician race/ethnicity concordance on HPV vaccine initiation.

Methods: We studied pediatricians (n=121; mean age 46.5; non-Hispanic White 56.8%) and their patients (n=46,964; mean age 13.8; non-Hispanic White 52%) from a Texas pediatric clinic network from 2014 to 2015. Multinomial logistic regressions, adjusted for physicians' individual differences, were used to assess the association between patient and physician race/ethnicity on HPV vaccination rates.

Results: Overall, HPV vaccine initiation varied across groups (64% of non-Hispanic Black, 65% of Hispanic, and 53% of non-Hispanic White patients). Forty-two percent of non-Hispanic Black, 48% of Hispanic, and 61% of non-Hispanic White physicians were racially/ethnically concordant with their patients. Racial/ethnic concordance was associated with higher rates of HPV vaccine initiation compared to discordant physician-patient relationships. Non-Hispanic White patients had a lower odds of initiating HPV vaccination than patients of all other races (OR 0.64, CI[0.61-0.66]), although these odds increased when they saw a non-Hispanic White physician (aOR 0.72, CI[0.62-0.84]). Non-Hispanic Black (aOR 2.28, CI[1.47-3.53]) and Hispanic (aOR 2.42, CI[1.67-3.49]) patients were more likely than non-Hispanic White patients to initiate HPV vaccination with non-Hispanic Black and Hispanic doctors, respectively.

Conclusion: It is important that providers understand the potential impact their personal demographics may have on their relationship with their patients. These findings suggest sustained support for initiatives to increase provider diversity. Research is needed to further understand the mechanisms that drive discordant patient-physician relationships and affect outcomes like HPV vaccination.

Paper Session 31

11:30 AM-11:45 AM

PLURALISTIC IGNORANCE AND INTERDISCIPLINARY PHYSICIANS' ATTITUDES ABOUT ABORTION

Nicholas B. Schmuhl, PhD¹, Jenny A. Higgins, PhD, MPH¹, Laurel W. Rice, MD¹, Cynthia K. Wautlet, MD, MPH¹, Kelsey Wright, n/a¹, Helen L. Zukin, n/a¹

¹University of Wisconsin-Madison, Madison, WI

Introduction: Abortion is stigmatized in the U.S. Perhaps due in part to stigma, little evidence exists about physicians' attitudes about abortion—especially beyond specialists involved in reproductive healthcare. Pluralistic ignorance—a perceived gap between group members' own attitudes and other group members' attitudes—has been observed among professionals and healthcare providers who work with stigmatized populations. Little is known about pluralistic ignorance in the context of abortion attitudes, including whether it perpetuates abortion stigma. Physicians are an excellent population in which to examine this issue because pluralistic ignorance may impact practices and professional quality of life among those who participate in any aspect of abortion care, including referrals.

Methods: We used both mail and online recruitment methods to survey the entire clinical faculty of the largest academic medical center in a Midwestern state about their own and other physicians' attitudes toward abortion access. Specifically: Please tell us if the following groups of people oppose or support unrestricted access to abortion: Yourself Your peers on the clinical faculty. Participants were asked to respond on a seven-point Likert-type scale, ranging from “oppose a lot” to “support a lot,” with “neither oppose nor support” as a midpoint.

Results: 913 physicians representing more than 20 medical specialties completed the survey (67% response rate). A strong majority (80.2%) supported abortion access at least to some degree, while 16.6% were opposed to some degree, and 3.3% claimed neutrality. When asked to estimate support among their professional peers, a slightly smaller majority (77.5%) perceived a supportive climate of opinion. Meanwhile, 16.1% perceived a neutral climate, and 6.4% perceived a climate of opposition to abortion among their peers. A chi-square test of independence found this inconsistency between own attitudes and perceived climate of opinion among professional peers to be statistically significant, $\chi^2(4, N=861)=225.15, p<0.001$. Those who supported abortion access themselves slightly overestimated support among their peers (86.2%), while neutral participants and abortion opponents vastly underestimated support (18.5% and 44.7%, respectively). Participants in every category overestimated neutrality, with neutral participants incorrectly perceiving themselves as a strong majority (70.4%). Interestingly, abortion opponents perceived themselves to be a much larger minority (27.0%) than self-appraisals suggest.

Discussion: Across specialties and socio-demographics, physicians in our sample overwhelmingly supported unrestricted access to abortion and the efforts of abortion providers. Discrepancies between own support and perceived peer support for abortion is indicative of pluralistic ignorance, and possibly anti-choice stigma.

10:45 AM–11:00 AM

CAN CLINICAL DECISION SUPPORT HELP “RESCUE” PATIENTS FROM NONRESPONSE TO ONLINE OBESITY TREATMENT? PRIMARY CARE PERSPECTIVES

Hallie M. Espel-Huynh, PhD¹, Carly M. Goldstein, PhD², Rena Wing, PhD³, Graham Thomas, PhD⁴¹Alpert Medical School of Brown University/The Miriam Hospital, Providence, RI; ²The Miriam Hospital/Alpert Medical School of Brown University, Providence, RI; ³Alpert Medical School of Brown University, Providence, RI; ⁴Brown Medical School, Providence, RI

Background: Online behavioral obesity treatment (OBOT) is an efficacious, low-cost approach for weight management in primary care. However, when OBOT is delivered pragmatically, many patients experience treatment nonresponse (e.g., poor initial weight loss; early disengagement). Clinical Decision Support (CDS) tools could identify early risk for OBOT nonresponse in primary care, inform providers of risk, and facilitate prompt “rescue” intervention, thereby improving OBOT outcomes. The present study sought to explore primary care clinicians’ perspectives on a hypothetical CDS tool for OBOT.

Method: Semi-structured qualitative interviews were conducted with $N = 14$ primary care-based nurse care managers (NCMs) who use OBOT with their patients. Interviews described a CDS tool designed to alert NCMs of a patient’s risk for poor OBOT outcome, then explored the NCM’s beliefs about the helpfulness of such alerts, preferred alert format, and desired frequency. Interviews were audio-recorded and transcribed, then coded according to valence of attitudes toward each CDS component discussed.

Results: Among NCMs, 12 of 14 (86%) believed the CDS would be useful in clinical practice; 2 were ambivalent. Of those with favorable views of CDS, 100% desired alerts for patients at risk for early disengagement from OBOT, 92% for patients who remain engaged but struggle to lose weight, and 75% for patients failing to follow through on a recommendation to begin OBOT. NCMs also expressed a desire to receive alerts for patients achieving successful weight loss milestones. Concerns about CDS also emerged, particularly regarding the time required to deliver rescue interventions in response to alerts and a need to streamline the CDS system into existing clinic workflow. Email alerts were the most commonly preferred alert format (50%), followed by electronic health record (25%) or OBOT clinician dashboard (25%) alerts. Most NCMs (80%) preferred alerts to be delivered in “digest format” at a frequency of every 1–2 weeks.

Conclusion: NCMs in primary care view CDS as a potentially useful tool to guide outreach to patients at risk for early disengagement or insufficient weight loss in OBOT, and to a lesser extent failure to follow through on OBOT referral. CDS alerts must be delivered such that NCM burden is minimized and interventions are streamlined with existing clinic infrastructure.

BELIEFS ASSOCIATED WITH HEALTH INFORMATION AVOIDANCE

Heather A. Orom, PhD¹, Elizabeth A. Schofield, MPH², Erika A. Waters, PhD, MPH³, Marc T. Kiviniemi, PhD CPH⁴, Jennifer L. Hay, PhD⁵¹University at Buffalo, BUFFALO, NY; ²Memorial Sloan-Kettering Cancer Center, New York, NY; ³Washington University in St Louis, St Louis, MO; ⁴University of Kentucky, Lexington, KY; ⁵Memorial Sloan Kettering Cancer Center, New York, NY

Background: The tendency to avoid health information is relatively common and is associated with lower knowledge of health risks, greater uncertainty about personal risk, and lower engagement in protective health behavior. Health information avoiders pose challenges for health communication interventions and therefore merit greater understanding. We tested whether low health agency beliefs and/or risk perceptions underlie health information avoidance.

Methods: We conducted two studies with representative samples ($Ns = 1005$ & 600) testing whether beliefs that differentiate people with high and low agency with respect to health (e.g., locus of control, time orientation, fatalism, cognitive causation or the belief that thinking about a disease could increase the likelihood of getting it) and perceived risk (worry, perceived absolute and comparative risk, perceived disease severity, disease unpredictability, family history of disease) were related to avoiding health information about diabetes and colon cancer. Avoidance was assessed with adapted versions of Howell & Shepperd’s (2016) information avoidance scale. We conducted exploratory factor analyses (EFA) to group the beliefs measures thematically followed by hierarchical regressions testing relations to avoidance.

Results: The EFA yielded 4 factors: *internal locus of control*, *belief in fate* which were both related to agency and *risk perception*, and *dread* which were related to risk perception. Information avoidance was common; in samples 1 and 2, 30% and 34% indicated they preferred to avoid information about diabetes and 20% and 19% of respondents preferred to avoid colorectal cancer information. Results were largely consistent across studies and diseases. As indicated by AIC and BIC fit statistics, most blocks of variables improved fit over and above those previously entered. In the final models, beliefs indicating lower internal locus of control or a belief that fate influences health were consistently associated with more avoidance; the dread variables, having a family history of the disease and worry about getting the disease, were associated with less avoidance. Perceived absolute and comparative risk perceptions were not reliably associated to avoidance.

Discussion: Beliefs that underlie low health agency are associated with avoiding information about diabetes and colon cancer. Given that health information avoidance likely undermines a wide range of health communication and self-regulation strategies, health communication efforts might be advanced by developing intervention approaches that involving enhancing perceived control over health prior to offering health messages. These interventions could have applications across a range of health threats yielding significant public health impact.

VISUAL RISK DEPICTIONS IN ONCOLOGY: A SYSTEMATIC REVIEW

Dannielle E. Kelley, PhD, MPH¹, Megan C. Roberts, PhD², Elizabeth L. Seaman, PhD, MHS³, Erin M. Ellis, MPH, PhD⁴, William Klein, PhD⁵

¹National Cancer Institute, Bethesda, MD; ²UNC Eshelman School of Pharmacy, Chapel Hill, NC; ³Behavioral Research Program, National Cancer Institute, Rockville, MD; ⁴NIH, Rockville, MD; ⁵National Cancer Institute, NIH, Bethesda, MD

Background: As cancer risk is increasingly communicated through graphic and digital means, a better understanding of effective cancer risk communication across diverse audiences is needed. A small number of literature reviews highlight at least 3 gaps: 1) absence of cancer-specific reviews; 2) text and numerical expressions were not independently examined as components of visual risk depictions; 3) affective outcomes were rarely examined despite the important role of affective response in interpreting risk information. This systematic review of visual cancer risk depictions maps the state of the science and provides a prescriptive summary of effective approaches.

Methods: Forty-eight peer-reviewed studies across 45 articles published from 2001-2018 were identified for inclusion across 3 databases (PubMed, PsychINFO, EMBASE) with 5 criteria for inclusion: 1) English language, 2) full-text articles, 3) empirical research, 4) cancer-related, and 5) accessible visual risk depictions. Characteristics of study samples, designs, visual risk depictions, and outcome measures were extracted.

Results: Across studies, most participants were White ($M = 72\%$) and female ($M=72\%$). Most studies employed quantitative designs (71%), followed by qualitative (19%), and mixed methods (10%). Studies of breast cancer risk were most common (43%), followed by colorectal (19%), general cancer (14%), lung (6%), prostate (4%), and other cancer sites (14%). Most studies (73%) included textual and/or numerical information within the visual risk depiction. Primary outcomes assessed were risk perceptions (44%), knowledge (35%), preference/liking (25%), intentions (17%), affective responses (10%), self-efficacy (8%), and trustworthiness (4%). While icon arrays (60%) and bar graphs (40%) were the most common visual risk depictions across studies, heterogeneity across studies in terms of visual composition, outcomes measured, and risks inherent to cancer site, individual, and contextual factors preclude formal comparison of effectiveness across types of visual risk depictions.

Conclusion: Results suggest optimal visual risk communication strategies depend on population, cancer, and contextual characteristics. Future research should consider a wide range of primary outcomes, as well as mediating and moderating factors, to aid understanding of the mechanisms through which visual depictions of risk operate across cancer sites and populations to move towards more effective cancer risk communication.

Paper Session 32

11:30 AM-11:45 AM

A COPING SELF-EFFICACY MANIPULATION TO DISCOURAGE HEALTH INFORMATION AVOIDANCE

Jacqueline N. Hua, n/a¹, Jennifer L. Howell, PhD¹

¹University of California, Merced, Merced, CA

Although early detection and diagnosis of disease are critical in promoting long-term health outcomes, people sometimes avoid learning their risk for disease. Past research suggests that people who report fewer coping resources are more likely to avoid learning their risk for disease. Other studies suggest that people are more likely to avoid learning their risk when the disease is untreatable than when it is treatable. Taken together, we think that these studies implicate coping self-efficacy, or confidence in one's ability to cope with life's challenges, as a possible factor in avoidance. In two studies, we investigated 1) whether coping self-efficacy correlated with avoidance of disease risk feedback and 2) whether a manipulation to increase coping self-efficacy would reduce avoidance.

In Study 1, participants ($N=107$; $M_{age}=18.74$, $SD_{age}=1.78$; 58.4% women) completed a risk calculator for a fictitious disease that they believed was real. They then received the option to learn or avoid their risk for that disease. They also completed measures of general and coping self-efficacy. A logistic regression predicting participants' decision to learn or avoid their risk revealed that coping self-efficacy, but not general self-efficacy, was related to avoidance of disease risk feedback. In Study 2, participants ($N=270$; $M_{age}=19.5$, $SD_{age}=2.27$; 78.5% women) completed a risk calculator for type 2 diabetes. They were then randomly assigned to reflect on positive past coping strategies (*high coping self-efficacy* condition), negative past coping strategies (*low coping self-efficacy* condition), or to move on to the next part of the study (*control* condition). Next, as in Study 1, participants received the option to learn or avoid their risk. Significantly fewer participants in the high coping self-efficacy condition (41.5%) avoided learning their diabetes risk as compared to those in the control condition (57.0%). Surprisingly, those in the low coping self-efficacy condition fell between these two groups (51.1%). We suspect that this is because considering one's abilities at all, even if considering generally ineffective strategies, prompted people to feel more capable of coping with bad news. Taken together, these results suggest that coping self-efficacy is likely a good target for interventions aimed at reducing health information avoidance and suggest a need for future research examining possible interventions.

Paper Session 33

10:45 AM-11:00 AM

IMPACT OF DIFFERENT TYPES OF UNCERTAINTY ON PUBLIC WILLINGNESS TO PARTICIPATE IN PRECISION MEDICINE RESEARCH

Chelsea L. Ratcliff, MA¹, Bob Wong, PhD², Janie DeFriez, n/a², Kimberly Kaphingst, ScD²¹University of Utah, Bluffdale, UT; ²University of Utah, Salt Lake City, UT

Precision medicine research is critical to finding solutions for health challenges now and in the future. Such research will depend on the ability to recruit large cohorts of participants to share their genetic, environmental, and lifestyle data. How patients and the broader public interpret information about these research programs and decide whether to participate is largely unknown. This mixed-method study examined prospective responses, focusing in particular on reactions to two types of uncertainty: (a) uncertainty about the scientific utility of sharing one's biospecimens and other health data for research, and (b) uncertainty about the privacy, security, and intended uses of such data. We conducted an online survey experiment with a national sample of U.S. adults ($N = 709$; 56% white; 53% male; ages 18–81, $M_{age} = 38.2$) recruited by Qualtrics Panels. Participants read a news article published by a national news outlet about the All of Us Research Program, which was adapted to convey either certainty or uncertainty of each type in a 2 x 2 design. After reading the article, respondents rated their attitudes toward precision medicine research and willingness to join a cohort, then elaborated on their choices using text responses. Direct and mediated paths between condition and outcomes were tested. Overall attitudes were positive ($M = 5.5$ out of 7) and the majority of participants (65%) reported being somewhat or very likely to join a cohort. Communicating (un)certainly of either type did not have a direct impact on outcomes. Instead, uncertainty perceptions mediated outcomes, with higher perceived uncertainty leading to lower attitudes and willingness to join. Decision-maker characteristics (e.g., health and biomedical science literacies, prior research experience, and sociodemographics) significantly influenced both uncertainty perceptions and decision outcomes. To further examine the impact of uncertainty, two authors conducted thematic coding of open-ended responses (intercoder reliability ranged from $\alpha = .70$ – 1). Participants expressed both optimism about the scientific utility of participating and concerns or uncertainty about future use of their data. Notably, data uncertainty did not preclude overall positive comments or willingness to join. More often, individuals' reluctance came from uncertainty about other factors, such as logistics (e.g., travel to research facilities), compensation, and possible side effects from treatments—frequently signaling misconceptions about the nature of participation in this type of research. Overall, findings suggest the public will be comfortable with a degree of uncertainty about scientific utility and data governance in precision medicine research, and that successful participant enrollment will be well-supported by transparent and literacy-enhancing approaches to communicating with prospective participants.

CHARACTERIZING PHYSICIAN-PATIENT COMMUNICATION IN GENOMIC MEDICINE: INFLUENCES ON SHARED DECISION-MAKING

Suzanne C. O'Neill, PhD¹, Susan Vadaparampil, PhD², Richard Street, PhD³, Tanina Foster Moore, PhD⁴, Claudine Isaacs, MD¹, Hyo Han, MD⁵, Bianca Augusto, BS², Jennifer Garcia, MA², Katherine Lopez, B.A.¹, Matilda M. Brilleman, n/a⁶, Susan Eggly, PhD⁴

¹Georgetown University, Washington, DC; ²Moffitt Cancer Center, Tampa, FL; ³Texas A&M University, College Station, TX; ⁴Wayne State University/Karmanos Cancer Institute, Detroit, MI; ⁵Moffitt cancer center, Tampa, FL; ⁶Georgetown University, Washington Crossing, PA

Introduction: Tumor genomics increasingly informs cancer treatment planning. Clinical guidelines for women diagnosed with early-stage, ER+ breast cancer incorporate genomic profiling tests, such as the Oncotype DX Recurrence Score (RS) test, to guide treatment decisions. Women with high RS tumors benefit from combined chemo- and hormonal therapy, whereas patients with low RS tumors receive hormonal therapy alone. Overall, patients with an intermediate RS can forgo chemotherapy, but some uncertainty remains. Little is known about how patients and oncologists discuss test results and treatment plans. We examined RS- and treatment-related content and the variation of shared decision-making (SDM) and patient-centeredness across the three RS categories.

Methods: As part of a larger intervention trial to support patient-oncologist communication, a subset of clinical encounters ($N=46$) were audiorecorded, transcribed and coded for 1) RS- and treatment-related content, 2) SDM using the OPTION-5 and 3) patient-centeredness using the PCC Global. We examined differences by RS category using mixed models, adjusting for nesting within oncologist.

Results: Patients ($M_{age}=60$ years; 80% White) received low (33%), intermediate (52%) or high (15%) RS. Chemotherapy rates increased with RS (low=0%; intermediate=13%; high=71%). Patients with a high RS were more likely to receive a chemotherapy recommendation ($p < .001$), hear about the risks/side effects ($p=.003$), and have their preferences elicited ($p=.04$) than those with intermediate or low RS. Women with high RS also were less likely to be counseled about the risks/side effects of hormonal therapy ($p < .001$), as these were likely delayed until chemotherapy completion. The importance of hormonal therapy adherence was discussed infrequently across all categories (13%). Elements of SDM increased with RS, including eliciting patient preferences ($F=5.42$, $p=.03$), integrating preferences ($F=8.23$, $p=.009$) and the quality of SDM ($F=5.98$, $p=.02$). Patient-centeredness was uniformly high ($M=4.09/5$, $SD=.25$) and did not vary across RS ($p=.61$).

Discussion: Despite treatment recommendations for intermediate RS being less certain and perhaps more aligned with SDM tenets, encounters of women with high RS contained more SDM elements. Our results underscore that in the larger scope of translational genomic medicine, there is a need for further examination of patient-provider communication to understand its impact on health and behavioral outcomes.

Paper Session 33

11:15 AM-11:30 AM

EXAMINING FAMILY DISCLOSURE AND PSYCHOLOGICAL STATE AFTER RECEIVING ACTIONABLE RESULTS FROM A GENOMIC SCREENING PROGRAM

Gemme Campbell-Salome, M.A., Ph.D.¹, Adam Buchanan, MS, MPH, CGC², Cara Z. McCormick, MPH³, Amy C. Sturm, MS⁴¹Geisinger Medical Center, Danville, PA; ²Geisinger, Hillsborough, NC; ³Geisinger, Forty Fort, PA; ⁴Geisinger, Lewis Center, OH

Currently research examining family communication about genetic testing and psychological reactions to positive results provides a working understanding for indication-based settings. However, as healthcare systems prioritize precision medicine and genetic screening, further investigation on such topics is needed in genomic screening programs for unselected populations. This study examined family communication and psychological state after receiving actionable results from a genomic screening program. For this study, MyCode participants were contacted to complete a survey 5-19 months after receiving a result ($M = 10.1$, $SD = 3.44$). MyCode is a community health initiative enrolling patients in a research biobank and genomic screening program to return clinically actionable results. Of those contacted ($N = 1067$), 104 female and 70 male ($N = 174$, 16.3%) participants completed a survey. Survey questions asked who participants shared results with and disclosure motivations. Participants disclosed results to 0-14 relatives ($Mdn = 4$, $SD = 2.73$). Most frequent reasons to disclose included feelings of obligation (73%), providing relatives with risk information for medical decision-making (77%), and encouraging cascade testing (54.6%). Disclosing results among family was predicted by feeling obligated to share ($\beta = 2.18$, $t(173) = 4.98$, $R^2 = .13$, $p < .001$) and providing risk information for relative's medical decision-making ($\beta = 1.50$, $t(173) = 3.13$, $R^2 = .05$, $p < .01$). Surveys also included measures of decisional regret about testing and receiving results ($\alpha = .92$) as well as positive feelings about receiving results ($\alpha = .82$) and uncertainty about what results meant for participants and family ($\alpha = .64$) from the FACToR scale. When participants felt less decisional regret about receiving results, they were 1.7 times more likely to disclose their results to encourage cascade testing ($\chi^2 = 14.80$, $df = 5$, $R^2 = .03$, $p < .05$). Feeling uncertain about what results meant made it 1.15 times more likely a participant would share to encourage cascade testing ($\chi^2 = 5.97$, $df = 1$, $R^2 = .05$, $p < .05$). Examining psychological state, future optimism was predicted by less decisional regret ($\beta = .20$, $t(169) = 3.48$, $R^2 = .09$, $p < .001$) and more positive feelings about receiving results ($\beta = -.03$, $t(169) = -3.29$, $R^2 = .09$, $p < .001$). Uncertainty about what results meant for the participant and their family also predicted future optimism ($\beta = .03$, $t(169) = 2.06$, $R^2 = .06$, $p < .05$). Interestingly, less decisional regret about testing predicted more uncertainty about what results meant ($\beta = 1.24$, $t(168) = 3.67$, $R^2 = .09$, $p < .001$), suggesting a complex relationship between uncertainty and emotions regarding receiving results from a genomic screening program. Overall, findings provide salient reasons patients disclose results, which providers can use in counseling to motivate patients to share results with family and promote cascade testing.

Paper Session 33

11:30 AM-11:45 AM

COMMUNICATION OF OBESITY GENOMICS INFORMATION TO PARENTS

Susan Persky, PhD¹, Rebecca Ferrer, PhD², Megan R. Goldring, MA³, Haley E. Yaremych, BA⁴, Brittany M. Hollister, PhD, BA⁵, Margaret K. Rose, n/a⁶¹National Human Genome Research Institute, Bethesda, MD; ²National Cancer Institute, Pittsburgh, PA; ³Columbia University, New York, NY; ⁴Vanderbilt University, Nashville, TN; ⁵National Institute of Health, Bethesda, MD; ⁶Indiana University School of Medicine, Indianapolis, IN

Background: Effective implementation of precision medicine for behavioral change in the future will require understanding people's responses to complex, multifactorial information about genomic risk for common diseases. This may be especially true for diseases with a behavioral risk component, such as obesity. Although previous work suggests that providing family history-based genomic obesity risk information may alter parents' child-feeding behavior, more research is needed to understand the effects of providing complex, genomic information as well as the mechanisms through which such communication influences feeding behavior change.

Method: 184 mothers and fathers who self-identified as overweight and had children aged 3-7 were randomly assigned to receive information related to genetic and/or family environment (FE)-based factors in children's obesity risk. Parents then chose foods for their child using a validated virtual reality (VR)-based feeding measure. Parents were re-contacted one week later to complete a food frequency questionnaire.

Results: Mothers who received information about genetic factors in their child's future obesity risk fed more calories from the VR buffet than when genetics was not discussed [$F(1,171) = 5.13$, $p = .025$], and both mothers and fathers fed fewer calories when FE was discussed [$F(1,171) = 4.92$, $p = .028$]. Parents also reported feeding their child more junk food and fatty meats at follow-up when they received genetic content without accompanying FE risk content [$F(1,174) = 4.79$, $p = .030$; $F(1,174) = 5.64$, $p = .019$]. Although parents reported feeling increased guilt when provided with FE-oriented information [$F(1,178) = 13.19$, $p < .0001$], guilt did not emerge as a mediator of feeding behavior change.

Conclusions: Our findings suggest that the multifactorial risk information pertaining to the interaction of both genetics and FE resulted in the most favorable pattern of outcomes, compared to information where only one cause (genetics or FE) was discussed. Although this multifactorial information type is the most complex to convey, it is also the most accurate and appears to temper feeding detriments associated with genetic-only information as well as increased guilt associated with FE-only information.

KEEP THEM COMING BACK: STRATEGIES FOR SUPPORTING ENGAGEMENT WITH DIGITAL HEALTH INTERVENTIONS

Emily G. Lattie, PhD¹, Rachel Kornfield, PhD¹, Joanna Buscemi, PhD², Brie Turner-McGrievy, PhD, MS, RD³, Evan M. Forman, PhD⁴

¹Northwestern University, Chicago, IL; ²DePaul University, Chicago, IL; ³University of South Carolina, Columbia, SC; ⁴Drexel University, Philadelphia, PA

Digital health intervention programs, including those delivered by text messaging, mobile apps, and websites, offer the potential to expand the reach and availability of evidence-based behavioral interventions. However, digital health intervention programs are frequently plagued by low levels of adherence and high rates of dropout. An emerging body of literature supports that there are multiple methods for increasing engagement with these types of programs, including methods to involve users in the design process, strategies to tailor content and services to specific users, and provision of human support. In this panel, experienced digital health researchers with backgrounds in clinical psychology, health communications, and nutrition will come together to discuss strategies for supporting user engagement with digital health interventions. The panel will examine the application of user-centered design strategies to guide the development of user interfaces and program features, as well as service and implementation plans. Opportunities to tailor automated text messaging programs to individuals will also be reviewed, including developing messaging strategies that deliver mental health-related content on the basis of individuals' characteristics (e.g. gender, depression/anxiety severity, self-efficacy). The panel will discuss the use of telephone-based coaching, and a stepped care approach to coaching intended to support use of an app-based intervention. The use of social support strategies, app features, and wearables will be discussed in the context of digital health interventions aimed at weight loss. The panel will also discuss the challenge of asking participants to engage with mHealth interventions that require sustained, burdensome user input, in particular weight loss apps which require detailed logging of eating, drinking and perhaps risk behaviors over a matter of months or even years. Additionally, the panel will discuss lessons learned from attempts to use gamification to enhance interest and compliance with interventions requiring repeated training sessions, such as daily computerized neurocognitive interventions. There will be ample time for questions and discussion. Panelists will reflect on the barriers and facilitators of engagement in past digital health intervention studies and provide guidance on forthcoming research in this field.

Panel 17

12:45 PM-1:45 PM

OPEN SCIENCE IN BEHAVIORAL MEDICINE: MULTIPLE PERSPECTIVES AND PROVOCATIVE QUESTIONS

Katherine Chabalko, n/a¹, Michael A. Hoyt, Ph.D.², Kyra Hamilton, PhD³, Bradford W. Hesse, PhD⁴, Jacob J. Keech, Assoc MAPS, BPsych(Hons)³, Ian Sullivan, n/a⁵, A. J. Tomiyama, Ph.D.⁶

¹Springer, New York, NY; ²University of California, Irvine, Irvine, CA; ³Griffith University, Mt Gravatt, Queensland, Australia; ⁴National Cancer Institute, Kailua Kona, HI; ⁵Center for Open Science, Charlottesville, VA; ⁶University of California, Los Angeles, Los Angeles, CA

Understanding and embracing the tenets of “open science” is garnering traction among researchers in behavioral medicine, including SBM’s “Task Force on Open Science”. Open science is seen as a scientific movement aimed at increasing openness, integrity, and reproducibility of scholarly research. It calls upon behavioral medicine researchers to consider complex, and often provocative, questions related to data sharing, registration of research plans and methods, and transparency in publishing. At the same time, many researchers are unsure about how to adopt these practices, and are concerned about how to “do” open science across commonly used behavioral medicine research designs, including longitudinal observational studies and experimental research.

This panel, organized by the International Journal of Behavioral Medicine, aims to provide both practical knowledge about open science practice as well as useful discussion from multiple perspectives. Panelists will include behavioral medicine principal investigators, a graduate student, a publisher (from Springer Publications), an NIH Representative (National Cancer Institute), journal editors/associate editors, as well as a representative from the Center for Open Science.

We will use “Slido”, a smartphone platform that allows the audience to ask and rate questions. The most highly rated questions will be asked of the panel. The moderator will also maintain a list of questions. Examples include:

- Will open science change how I do research?
- How will open science affect publishing for me?
- Is the evidence base strong enough to begin to shift incentive structures toward rewarding and acknowledging open science practices?
- How can we guard against public humiliation when studies are not replicated?
- How can the time required for pre-registration and other open science practices be built into student research programs?
- When communicating our research to lay people and the media, how can we convey the difference between a pre-registered and entirely transparent study, and studies that have not followed these practices?
- How can we balance openly sharing resources and with protecting our ideas and intellectual property given that not all researchers engage in open science practices?
- What are the special considerations of open science for observational research? Does open science mean I cannot conduct secondary analyses?
- What does it mean to register a study beforehand with a journal or study registry?
- What is a badge?
- How long should I wait before sharing data? How do I even share my data?
- How can an open science approach in medicine be cultivated to include behavioral outcomes as an indispensable part of systemic change?
- What are some of the “big solutions” related to open science for persistent problems in behavioral medicine that SBM could encourage?

*Note. This panel was invited as a presidential panel session.

Panel 18

12:45 PM-1:45 PM

THE SCIENCE OF PERSONALIZATION: SEPARATING THEORY, APPLICATION AND HYPE

Kate Wolin, ScD¹, Gary Bennett, PhD², David E. Conroy, PhD³¹Coeus Health, Chicago, IL; ²Duke University, Durham, NC; ³The Pennsylvania State University, University Park, PA

For decades, behavioral medicine has been attuned to the promise of personalization. Interest has only grown over time, with modern technologies providing new avenues of personalization and a combination of investment and hype from the private sector amplifying it. This panel will feature a look back at in personalization science from behavioral medicine, HCI and marketing followed by a discussion of the implications of the varying conceptualizations of personalization. The panel will then define current methods and modes of personalization in behavioral medicine from the most generic customization strategies (e.g., putting a patient's name in a message) to the most sophisticated model-based strategies (e.g., artificially intelligent systems that adapt decision rules in response to evolving dynamic models of behavioral responses). These strategies will be compared across a range of criteria including alignment with behavior change models, technologic and data requirements, and ease of adaptability to research or business needs. Examples of research and consumer applications will be highlighted to illustrate the penetration of personalization strategies in behavioral medicine and clinical practice. Key considerations for whether and how to select personalization strategies, as well as approaches to evaluating whether that strategy is succeeding, will be discussed. Finally, the panel will discuss practical approaches to using personalization in the development of commercial and research applications before facilitating a discussion with the audience. The panelists have experience in both research and commercial personalization strategies

Panel 19

12:45 PM-1:45 PM

DEBATING 4 INNOVATIONS 4 HEALTH IMPACTS

James Prochaska, Ph.D.¹, Julian M. Saad, M.Ed.²¹University of Rhode Island, Kingston, RI; ²University of Rhode Island, Newport, RI

This proposal will debate four innovative strategies for accelerating breakthroughs in population health. The first debate topic will focus on treating the “Big 4” (+1) risk behaviors (1. smoking, 2. alcohol misuse, 3. unhealthy eating, 4. inadequate exercise, and +1 stress management), separately, in multiple behavior clusters, or as a total system. The second topic will focus on whether Medicare for all or “Preventive Behavioral Care” is best for population health progress, with an emphasis within each position on what age groups should be prioritized for each intervention. The third topic will focus on whether financial incentives for participation in evidence-based programs or incentives for behavior change outcomes have greater impacts, with an emphasis on return on investment for healthcare insurers and/or employers. The fourth topic will consider treatments delivered by clinicians versus treatments delivered by robots (AI), with the emphasis on treatment engagement and outcomes.

Each presenter will use a 15x20 methodology (i.e. 15 slides, each slide delivered in 20 seconds) to present works that have been used in innovative population health conferences. This method will allow each debater to present their respective theoretical and empirical innovations for population health in quick but clear communication. After both debaters present, the audience will be asked questions (e.g. Is one case more compelling? Would the audience like to integrate the two positions?). A debate scoring/reflection card will be provided to all audience members to guide participation, collaboration, and progress.

This panel was formed to debate timely healthcare issues relevant to the 2020 presidential and general elections. It presents strategies for producing and assessing breakthroughs in population health (e.g. What percentage of risk populations are reached *and* what is the ROI for employees and insurers?). It models the 15x20 methodology to present engaging, time efficient, and teachable information that can be quickly used to make a compelling case to lawmakers, laypersons, funders, and potential collaborators. It speaks to issues of differential importance across professional generations by creating a collaborative model for mentors and mentees (Ph.D. students and major professors; interns and advisors; residents and veteran doctors). Most important, this panel addresses the conference theme of accelerating innovations to enhance the health and wellbeing of a range of populations.

Panel 20

12:45 PM-1:45 PM

THE BEHAVIOUR CHANGE TECHNIQUE TAXONOMY AND THE MULTIPHASE OPTIMIZATION STRATEGY: HOW DO THEY WORK TOGETHER?

Sara Hoffman Marchese, M.S.¹, Angela F. Pfammatter, PhD², Susan Michie, BA, MPhil, DPhil³, Kate Guastafarro, PhD, MPH⁴, Bonnie Spring, PhD⁵¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, Chicago, IL; ³University College London, London, England, UK; ⁴Pennsylvania State University, University Park, PA; ⁵Northwestern University Feinberg School of Medicine, CHICAGO, IL

The Multiphase Optimization Strategy (MOST) is an engineering-inspired framework seeking to optimize the development and implementation of intervention studies. It consists of three iterative phases: preparation, optimization, and evaluation. The Behavior Change Technique Taxonomy (BCTT) is an expertly researched hierarchy of behavior change techniques (BCTs) used in behavior change interventions, with the end goal of creating a common language through which interventionists can define techniques of interest in their interventions in a consistent way. The purpose of this panel discussion is to explore ways in which MOST and the BCTT may align conceptually, and suggest how interventionists may wish to consider different BCTs during different phases of MOST. This panel discussion will primarily focus on the utilization of the BCTT as applied to the preparation phase of the MOST framework, but will consider the optimization and evaluation phases of MOST as well. The panelists will first overview the MOST framework, its phases, and the BCTT for the audience. Afterward, the first author will facilitate a discussion among the panelists as to how MOST and the BCTT may work together, and how utilizing clearly-defined BCTs within the MOST framework will help to address gaps in behavior change interventions. For example, within the preparation phase of MOST, the BCTT could help to define intervention targets of interest for future optimization in a consistent manner, such that other behavioral researchers have common terminology. In addition, within the preparation phase, researchers may consider how to identify the most minimal BCTs to use within an intervention component of an experiment, such that a more direct test of the BCT could be achieved. The panel will conclude with open discussion among panelists, and time for questions from the audience.

DOES IT SPARK JOY? NOVEL STRATEGIES FOR PRODUCTIVE AND ENJOYABLE TEAM-BASED SCIENTIFIC WRITING AND CREATION

Jennifer M. Taber, PhD¹, Cynthia A. Berg, Ph.D.², Judi M. Hilman, Ph.D.³, Kathi Mooney, PhD³, Karina W. Davidson, PhD⁴¹Kent State University, Kent, OH; ²University of Utah, Salt Lake City, UT; ³University of Utah, Salt Lake City, UT; ⁴Northwell Health, Roslyn, NY

To conduct meaningful and impactful research, scientists must use a combination of creativity and logic to 1) identify significant questions, 2) develop strong study designs, and 3) communicate effectively through writing. Writing is an integral part of scientists' work; yet, many scientists struggle with writing, which is often slow and requires carving out devoted time to do so. As a result, resources focusing on individual strategies to improve writing accountability and technical skills have proliferated. Resources promoting innovative team approaches to creativity in scientific development have been less widely disseminated. Panelists will share exciting strategies—typically high energy, fast-paced, and involving significant social interaction—for writing effectively and thinking creatively. Panelists have successfully implemented group- and team-based writing and brainstorming strategies in their own labs and departments and are involved in training early-stage scientists in these processes. One panelist will discuss lessons learned from hosting successful annual 3-day multi-site, high-energy writing retreats that bring together vertical multi-site teams. These retreats are the culmination of a months-long planning process at which lab members organize in teams to analyze data and outline and write papers. Two panelists will describe unique courses they have designed: one panelist will discuss their course on creativity, discovery, and innovation in science and another will describe their bootcamp-style scientific writing course for graduate students. Another panelist will share techniques to facilitate collaboration, scientific synergy, and innovative priority setting at the group and organizational level. Finally, an early-career stage panelist will outline how they have used writing groups to enhance their productivity and enjoyment of writing. We argue that there are group-based strategies—at the lab and department level—that foster team science and can improve the quality of the scientific process from creation to dissemination. An overarching theme will include how to effectively connect and collaborate with others. Panelists have worked in a cancer center, traditional psychology departments, and for health service providers. Strategies are relevant for scientists at all career stages and in multiple career settings. Attendees will leave the session with concrete steps they can implement in their own lab/department.

HOW TO DEVELOP AND DELIVER AN EFFECTIVE PITCH

Ellen Beckjord, PhD, MPH¹, Danielle Blanch-Hartigan, PhD, MPH²¹UPMC Health Plan, Pittsburgh, PA; ²Bentley University, Waltham, MA

A pitch is a compelling way to quickly sell an audience on an idea, and is a presentation skill set of increasing value in research and practice. Academically-trained researchers and practitioners get ample support to develop effective presentation skills commonly used in teaching and at academic conferences, but comparatively less support to develop a skill set around pitching. As SBM attendees, particularly those working in digital health, venture more frequently into industry collaborations and environments, it is increasingly important that they know how to effectively pitch their ideas and their research. This *interactive* panel will be led by two SBM members who have received formal training in developing and delivering pitches, including use of pitching to successfully compete for research funding in academic medicine. The panel will function as a *pitch workshop*, giving SBM attendees an opportunity to develop pitching skills and try them out in a safe, low-pressure environment. We will orient attendees to eight core elements of an effective pitch; watch two videos that offer examples of pitches; and then give attendees time to create their own initial pitch using a method called "message mapping." The final part of the workshop will allow attendees to give their initial pitch and receive feedback from the co-presenters and other participants.

EXTENDING SCIENTIFIC REACH: DEVELOPING SBM HEALTH POLICY POSITIONS AND ENGAGING PARTNER ORGANIZATIONS

Carl V. Asche, PhD¹, Judith K. Ockene, MA, MEd, PhD², Laura L. Hayman, PhD, MSN, FAAN, FAHA, FPCNA³, Lisa Kolavennu, MA, LCPC⁴, Akilah Dulin, PhD⁵

¹University of Illinois, Peoria, IL; ²University of Massachusetts Medical School, Worcester, MA; ³UMass Boston, 100 Morrissey Blvd. Boston, MA 02125-3393, Boston, MA; ⁴Wellness House, Hinsdale, IL; ⁵Brown University, Providence, RI

The primary objectives of this panel are to: (1) Describe experiences and best practices related to creating SBM health policy briefs from the perspectives of authors and (2) Explain co-endorsing organizations processes for approving and disseminating SBM health policy briefs from the perspectives of co-endorsing organization representatives. The health policy brief author panelists will briefly discuss their recently published cancer-related and obesity/overweight management-related health policy briefs, respectively. These SBM health policy brief authors will describe how they arrived at the final drafts of their policy briefs, their experiences with reaching out to co-endorsing organizations and dissemination strategies. The authors will discuss their processes for identifying potential co-endorsing organizations whose missions align with the health policy brief position statements. The co-endorsing organizations will describe their experiences working with SBM as it relates to initial contact, processes used to review, approve (or deny) a co-endorsement request, and dissemination strategies for SBM health policy briefs. The session attendees will have the opportunity to engage with health policy brief authors and co-endorsing organizations to understand the processes related to SBM health policy briefs and co-endorsements from external organizations. It is expected that the panel discussions will increase session attendees' self-efficacy related to submitting and drafting SBM health policy briefs that align with and advance the mission of SBM.

Panel 25

12:45 PM-1:45 PM

IMPLEMENTATION OF SOCIAL DETERMINANTS OF HEALTH SCREENINGS IN ROUTINE URGENT CARE

Andrea S. Wallace, PhD RN¹, Jia-Wen Guo, PhD¹, Shawna M. Sisler, MS, MA, MAPP, RN, NP², Brenda Luther, PhD, RN¹, Bob Wong, PhD¹

¹University of Utah, Salt Lake City, UT; ²University of Utah, Park City, UT

Despite decades of evidence linking social determinants to health outcomes, health service providers – incentivized by new integrated payment models – have just begun assessing “social needs” as part of service delivery. However, there is no clear evidence base to guide the implementation of screening and referral processes, much less how to evaluate effects on health outcomes. Our academic-community team developed means of implementing a screening process for busy ED settings, for communicating social needs to service providers, and for cross-walking data from service providers and clinical information systems. This panel explores our “lessons learned” during a Federally-funded HIT-implementation study.

Topic 1. We will propose a theoretical approach for integrating social determinants of health into routine health service delivery to improve health outcomes. The framework addresses 3 critical components: (1) high-quality screening that can take place in a clinical workflow; (2) means of effectively communicating the information to inform clinical decision making; and (3) effective community linkages with resources that meet their needs. The concepts of implementation, including feasibility, sustainability, and evaluation models will be explored as our approach to social needs screening and referrals during emergency service delivery.

Topic 2. Results of data linkages - We piloted the ED screening during 4-week rapid-cycle tests. Over 25 days, 210 patients were screened, of whom, 61% (n=129) indicated having one or more need. Of these, 52% (n=67) wished referral to 2-1-1; 39% of those referred (n=32) were ultimately reached by 2-1-1 specialists and referred to community agencies within 48 hours of discharge. Over 6 months, participants who communicated at least 1 need (N = 107) experienced an increase in ED use (1.07 vs 1.36, $p < 0.05$) while patients with no reported needs (N = 55) experienced an increase in primary care visits (0.24 vs 0.56, $p < 0.05$). The trend of increasing ED use was noted among participants with needs and who had received services from 2-1-1 (N=32, 1.97 vs 2.56, $p < 0.05$). Data on a larger patient sample (approximately 3000 patients) continue to be collected and will be incorporated into the presentation.

Topic 3. Implementation barriers and facilitators - Best practices for assessing social needs during clinical encounters should aim to minimize stigmatization and maximize accuracy while evaluating the impact on patients, providers, and community resources. We conducted semi-structured interviews with staff, including the registration team, guards, and supervisors. Content analysis identified themes of: questioning screening as a priority; assumptions of patient needs; avoidance of certain groups; varying comfort level with “stigmatizing” questions; and, concerns regarding which staff own this workflow.

HOW LESS BECOMES MORE: KEY MOTIVATION AND MESSAGING IMPLICATIONS FROM THE “10-MINUTE BOUT” REMOVAL IN THE UPDATED PA GUIDELINES

Michelle Segar, PhD, MPH, MS¹, David X. Marquez, PhD, FGSA, FACSM, FSBM², Dori E. Rosenberg, PhD, MPH³, Katrina L. Piercy, PhD, RD⁴, Huhman Marian, PhD⁵

¹University of Michigan, Ann Arbor, MI; ²University of Illinois at Chicago, Chicago, IL; ³Kaiser Permanente Washington Health Research Institute, Seattle, WA; ⁴Office of Disease Prevention and Health Promotion, Rockville, MD; ⁵University of Illinois, Urbana, MD

Did you know that the recently updated United States Physical Activity Guidelines (PAG), include a game-changing recommendation that has profound messaging implications for our field? This new PAG opens the door for professionals across fields and countries to communicate in new ways that align with motivation and decision science, better permitting us to support people's psychological needs and ability to fit consistent movement into their lives. This session will focus on the removal of the “10-minute bout” requirement in the updated PAG. It will discuss the reasoning and data for taking this bout requirement out, the motivation and decision making science this change aligns with, and the potential challenges and opportunities it brings to our next-generation physical activity messaging and counseling. We will also consider how this shift in guidelines and the resulting new messaging strategies compare and contrast with other strategically designed physical activity campaigns (e.g., VERB).

BUILDING BEHAVIORAL WORKFORCE CAPACITY: OPPORTUNITIES IN IMPLEMENTATION SCIENCE

Susan D. Brown, PhD¹, Charles R. Jonassaint, PhD, MHS², Melissa C. Green Parker, PhD³, Akilah Dulin, PhD⁴, Tiffany Carson, PhD, MPH⁵, Kirsten Bibbins-Domingo, PhD, MD, MAS⁶

¹Kaiser Permanente Northern California, Oakland, CA; ²University of Pittsburgh, Pittsburgh, PA; ³NIH/NHLBI, Bethesda, MD; ⁴Brown University, Providence, RI; ⁵University of Alabama at Birmingham, Birmingham, AL; ⁶University of California, San Francisco, San Francisco, CA

Academic institutions, federal agencies, healthcare delivery systems, and other stakeholders are increasingly invested in the field of implementation science, which seeks to integrate evidence-based interventions within “real-world” clinical and public health settings. Behavioral scientists are uniquely positioned to contribute to this burgeoning field, given its focus on changing the behaviors of providers, patients, and organizations to achieve wide-spread and sustained improvements in health outcomes. In this panel, diverse mid-career and senior scientists will discuss the varied career paths and disciplinary backgrounds that have prepared them to engage in implementation science; discuss the varied settings in which implementation scientists work; and highlight training resources and funding opportunities designed to build workforce capacity in this area. Positive insights from a federal Program Officer will also be shared. As relevant, panelists will discuss career challenges regarding intersecting identities (e.g., gender, race/ethnicity) and strategies to enhance resilience and commitment to scientific careers. Attendees will have opportunities to debate the resources that may be needed to bolster the next generation of implementation scientists.

TRANSLATING RESEARCH INTO PRACTICE TO CLOSE THE HEALTH DISPARITY GAP IN THE LGBTQIA+ COMMUNITY

Lauren Wiklund, B.A.¹, Kaston D. Anderson-Carpenter, PhD, MPH, BCBA-D, LBA², Jae M. Sevelius, PhD³, Terence Ching, M.Soc.Sci, M.S.⁴, NiCole T. Buchanan, PhD, LP²

¹Michigan State University, Lansing, MI; ²Michigan State University, East Lansing, MI; ³University of California, San Francisco, San Francisco, CA; ⁴University of Connecticut, Storrs, CT

The health and well-being of sexual and gender minoritized (SGM) individuals is a matter of public health concern. LGBTQIA+ individuals continue to experience negative and disparate health outcomes compared to heterosexual, cisgender peers (Rice, Vasilenko, Fish, & Lanza, 2019). Members of this community report overt discrimination and implicit bias from health care providers that interfere with their receipt of high quality, comprehensive care (Rice et al., 2019). The gold standard in clinical science calls for evidenced based practices to inform clinical care; however, most treatment protocols are based, developed, and normed on cisgender, heterosexual, European Americans. As a result, we measure successful treatment outcomes with a ceiling of equivalence to the normed population rather than creating protocols that could be more effective for a specific population (Hall, Yip, & Zarate, 2016). This perpetuates the harmful and oppressive practice of comparing minoritized people to the majority rather than creating a knowledge base that is tailored for their unique needs.

Translating research into policy and practice to address current and reduce future health disparities is of imminent importance. This panel will bring together a diverse group of researchers and activists at the cutting edge of their fields and invite lively audience discussion about innovative ideas for advancing health and well-being for SGM individuals. Topics addressed in this panel discussion will include transgender-specific wellness programs and interventions, psychedelic-assisted psychotherapy, and addiction treatment in marginalized communities. In addition to providing a discussion forum, members of the community are invited to coalesce in this academic forum.

12:45 PM-1:45 PM

THE CO-USE OF TOBACCO AND ALCOHOL IN CANCER CONTROL: CHALLENGES AND SOLUTIONS

Raimee Eck, PhD, MPH, MPA¹, David Wetter, PhD², Judith J. Prochaska, PhD, MPH³, Andrea King, PhD¹National Cancer Institute, Bethesda, MD; ²Huntsman Cancer Institute, University of Utah, Salt Lake City, UT; ³Stanford University, Stanford, CA

Both tobacco and alcohol are well-established risk factors for cancer morbidity and mortality. While awareness of the causal link between tobacco and cancer is widespread, only 30%-40% of the population expresses awareness of the causal link between alcohol and cancer. Consistent with the notion that health risk behaviors rarely occur in a vacuum, current and former tobacco use is a significant predictor of binge alcohol consumption, odds of cigarette use increase in a dose-dependent fashion with heavier alcohol use, and alcohol can serve as a contextual and/or disinhibitory trigger for daily or occasional smoking, leading to poorer quit rates and higher relapse. Co-use of alcohol and tobacco also can lead to a synergistic increase in the risk of some cancers (such as head and neck). Additionally, individuals with mental health disorders are known to be at significantly higher risk for use of multiple licit and illicit substances, as well as for cancer incidence and mortality. Unfortunately, the bulk of epidemiological research and interventions for cessation do not focus on tobacco and alcohol co-use.

This panel will bring together cross-cutting researchers to discuss a) the epidemiology and mechanisms of co-use of alcohol and tobacco and cancer risk; b) interventions addressing co-use of alcohol and tobacco; c) mental health in substance co-use and cancer risk; d) implications for cancer survivors and other vulnerable populations; and e) population level approaches to reducing cancer burden from tobacco that may be applied to alcohol and vice-versa.

Panelists will explore the co-use of alcohol and tobacco along the cancer control continuum, identifying populations at higher risk and the complexity in targeting these populations. The presence of a mental health condition adds another layer of complexity to prevention and treatment interventions. Finally, attitudes towards alcohol and tobacco use differ, which may result in differential bias in self-report of behaviors to providers and may influence framing and receipt of advice. Despite these challenges, there are promising interventions using pharmacological treatments and/or behavioral therapy to aid in cessation. The goal of this discussion is to focus on an often overlooked and neglected risk profile, highlight gaps in knowledge, and identify opportunities for research and interventions to improve prevention, treatment, and survivorship of cancer in the context of co-use of alcohol and tobacco.

Symposium 52

2:00 PM-3:15 PM

PRESIDENTIAL SYMPOSIUM: MANAGEMENT OF PSYCHOLOGICAL DISTRESS IN PATIENTS WITH CANCER – ARE WE DOING THE RIGHT THING?

Joost Dekker, PhD¹, Kristi Graves, PhD², Terry Badger, PhD, RN³, Michael A. Diefenbach, PhD⁴¹Amsterdam University Medical Centers, Amsterdam, Noord-Holland, Netherlands; ²Georgetown University, Washington, DC; ³University of Arizona, Tucson, AZ; ⁴Northwell Health, Manhasset, NY

Distress is highly prevalent among patients with cancer. In patients in the anti-tumor phase of treatment, the reported prevalence rate ranges from 18% to 52%. Identification and treatment of distress is a clinical priority, because distress is a risk factor for non-adherence with medical treatment and for a poor outcome in physical, mental and social life domains. Currently, the dominant care paradigm for the management of distress is 'distress screening and referral for the provision of psychosocial care'. Dissemination and implementation science may guide efforts to optimize the design, implementation, and evaluation of distress screening programs. On the other hand, basic assumptions underlying the paradigm can be questioned. These assumptions concern the nature of support needed in coping with emotions. The overall goal of this symposium is to explore possibilities to improve psychosocial cancer care based on the screening paradigm, and to explore the need for an alternative care paradigm.

The first presenter will explore possibilities to improve psychosocial cancer care based on the screening paradigm, drawing on dissemination and implementation science. The second presenter will present recent data on the actual implementation of screening, addressing barriers and facilitators. The third presenter will present an alternative care paradigm, called 'supporting resilience and case finding'. The discussant will comment on how to advance the science of managing psychological distress in patients with cancer.

MANAGEMENT OF EMOTIONS IN PATIENTS WITH CANCER: INTRODUCING A NEW CARE PARADIGM 'SUPPORTING RESILIENCE AND CASE FINDING'

Joost Dekker, PhD¹¹Amsterdam University Medical Centers, Amsterdam, Noord-Holland, Netherlands

The current paradigm for the management of emotional distress in patients with cancer is 'distress screening and referral for the provision of psychosocial care'. However, systematic reviews did not find evidence to support the effectiveness of the current paradigm. The main reason seems to be that many patients with cancer are unwilling to accept a referral for psychosocial care, thus seriously limiting the usefulness and effectiveness of the screening and referral program.

We argue that there is a need for a fundamental reconceptualization of the management of distress in patients with cancer, leading to a paradigm shift. We describe the rationale and characteristics of a new paradigm, called 'supporting resilience and case finding'. This new care paradigm has two main features. (1) Supporting resilience: (a) The treating team, consisting of doctors, nurses, and allied health staff, is responsive to the emotional needs of patients with cancer and provides emotional support. (b) The treating team provides information on external sources of emotional support. (2) Case finding: The treating team identifies patients in need of mental health care by means of case finding, and provides a referral to mental health care as indicated. Future research should focus on optimization of current clinical practice as directed by the new care paradigm.

2:00 PM-3:15 PM

NEXT STEPS IN SCREENING FOR DISTRESS USING LESSONS FROM DISSEMINATION AND IMPLEMENTATION SCIENCE.

Kristi Graves, PhD¹, Shawna S. Ehlers, PhD, LP, ABPP², Emma Barker, MS³, Angela Mariscalsanchez, MS³, Michael A. Diefenbach, Ph.D.⁴, Kimberly Davis, PhD¹

¹Georgetown University, Washington, DC; ²Mayo Clinic, Rochester, MN; ³Georgetown University; ⁴Northwell Health, Manhasset, NY

As a mandated element for accreditation by the American College of Surgeons Commission on Cancer, cancer distress screening has been implemented in many different ways across centers in the United States. Dissemination and implementation science provides a framework for organizing approaches to initiating, improving and maintaining efficient approaches to distress screening. Use of interdisciplinary teams, recognition of human factor elements important to work flow and high quality care, and engagement with patients and families are important for optimizing the effectiveness of distress screening. Electronic systems for screening distress and communicating scores to providers appear to yield promising results, although challenges exist in many centers given the dearth of mental and behavioral health specialists. A case study at one cancer center highlights the benefits of using multiple measures for screening of distress. At the first visit, patients complete a screening using tablets that consists of the Distress Thermometer (DT), Problem Checklist and PROMIS measures of Anxiety and Depression. Patients are referred to a psychosocial oncology service with scores of 7 or higher on the DT or if they request to discuss an identified problem. Among 1286 patients, 41% reported moderate distress (scores 4-6 on the DT) and 7% reported severe distress (scores 7 or higher). Indication on the Problem Checklist of 'problems communicating with the medical team' was significantly associated with both anxiety ($t=2.68$, $p=.007$) and depression ($t=3.06$, $p=.002$) after controlling for overall distress scores, patient gender and level of education. These results suggest that perceived challenges with communication may underscore patients' unmet psychosocial needs. At this cancer center, facilitators to screening implementation included identification of a distress screening 'champion' with mental and behavioral health expertise and communication between social workers and a clinical psychologist. Challenges to screening included difficulties integrating screening into the electronic health record and a shortage of personnel resources for referral and follow up of patients with high distress. Dissemination and implementation science suggests the need for increased attention to work flow factors and integration of best practices from other disciplines such as human factors engineering to optimize screening, referral and follow-up of cancer patient distress. Questions to be answered include how to optimally design the interface for screening, triage, referral and management of distress over time; how to appropriately compensate providers for consultation time; how to identify and address communication gaps between multidisciplinary cancer care providers; and how to optimally structure multidisciplinary teams to improve outcomes for cancer survivors with distress.

2:00 PM-3:15 PM

IMPLEMENTATION OF DISTRESS SCREENING ACROSS THE UNITED STATES

Terry Badger, PhD, RN¹, Elizabeth Ercolano, DNSc, RN², Mark Lazenby, PhD, RN³, Ruth McCorkle, PhD, RN²

¹University of Arizona, Tucson, AZ; ²Yale; ³University of Connecticut

Background: In 2012, the American College of Surgeons (ACOS) Commission on Cancer (COC) required that accredited cancer centers integrate psychosocial distress screening by the end of 2015 to improve quality of life and prevent morbidity. However, uptake of screening is minimal with only 47% to 73% of eligible patients being screened. The slow rate of compliance to the COC mandate may be the result of institutional barriers including: (a) inadequate administrative support; (b) lack of an interdisciplinary oncology team; (c) no established distress screening protocols; (d) undereducated staff; (e) confusion about which screening tool to use; (f) immature electronic medical systems to aid in integrating the steps of comprehensive distress screening; and (g) inadequate internal or external psychosocial resources to assist in managing psychosocial distress. The Screening for Psychosocial Distress Program (SPDP) was developed to address these issues. We aimed to evaluate the outcomes of the SPDP.

Methods: The SPDP, a 5-year cancer educational and implementation-support program was tested by a one-group pre/post-test design on psychosocial distress screening implementation in a national sample of cancer care institutions. We enrolled five groups of 36 cancer care clinicians (180 total participants representing 90 institutions) from 37 states and Washington DC. Clinicians participated in two in-person workshops taught by content experts and quarterly implementation support conference calls over a two-year period. We evaluated institutions' capacity to implement the five steps of psychosocial distress screening at the start of the project and then every six months. The five steps include: (1) administer the distress screen; (2) evaluate the distress screen results; (3) refer patients with a positive screen to a health care provider; (4) follow-up with the health care provider; and (5) audit medical records for the distress screening.

Results: All 90 institutions reported statistically significant improved compliance in the five steps at 12 months versus 6 months: Step 1 ($p=0.001$); Step 2 ($p=0.001$); Step 3 ($p=0.002$); Step 4 ($p=0.011$) and Step 5 ($p=0.024$). Although compliance increased for all Cohorts between 6 and 12 months, there was lower rates of compliance for Steps 4 and Steps 5-versus the first three steps.

Conclusion: The lower rates of compliance by all five cohorts with Step 4 and Step 5 may be the result of institutional barriers including an: (1) inadequate amount of trained resources and (2) immature integrated electronic medical record. In general, the SPDP was effective in improving the uptake of distress screening by United States based cancer care institutions. Future research is needed on the use of a randomized adaptive design testing the optimal support and education to ensure implementation and maintenance of distress screening programs.

Symposium 53

2:00 PM-3:15 PM

2:00 PM-3:15 PM

EXAMINING THE SCIENCE OF CHILDHOOD OBESITY INTERVENTIONS: THREE RECENT SYSTEMATIC REVIEWS OF CRITICAL CONTEXTS

Joanna Buscemi, PhD¹, Jen Sanchez-Flack, PhD, MPH², Elizabeth Rea, B.A.³, Katherine Arlinghaus, MS, RD, LD⁴, Amy M. Bohnert, Ph.D.⁵

¹DePaul University, Chicago, IL; ²University of Illinois at Chicago, Chicago, IL;

³Loyola University Chicago, Chicago, IL; ⁴University of Houston, Houston, TX;

⁵Loyola University Chicago, Evanston, IL

Childhood obesity remains a public health concern, affecting 18.5% of children nationally. Higher rates of obesity are evidenced among low-income children and children of ethnic and racial minority groups. Over the past few decades, there has been a proliferation of obesity prevention and treatment interventions that have been tested, and intervention strategies to improve diet and increase physical activity have been found to be effective. However, limitations to the literature remain including limited long term effects on body mass index and related health behaviors and barriers to long-term implementation and dissemination of evidence-based interventions. The purpose of the symposium is to highlight findings from three recent systematic reviews of obesity interventions across critical contexts for children, and to provide recommendations for future research based on these findings. First, Dr. Jen Sanchez-Flack will present a systematic review that utilized the RE-AIM framework to examine the implementation of obesity prevention interventions in early childcare/education settings. Limitations to the literature regarding external validity reporting will be discussed, and next steps for researchers will be described. Next, Elizabeth Rea will summarize research on youth's physical activity patterns across the entire calendar year, describe contextual factors that contribute to physical activity fluctuations (e.g., climate/weather, degree of structure, family socio-economic status, and safety), and systematically review research on summertime physical activity interventions to determine key elements of successful interventions for elementary school-aged children. Finally, Katherine Arlinghaus will describe a scoping review of the literature on how individual variation has been included as an intervention evaluation metric of school-based obesity interventions among adolescents. Dr. Amy Bohnert will serve as the discussant and will tie together themes from the three systematic reviews and suggest directions for future research across developmental stages and environmental contexts.

EXAMINATION OF THE IMPLEMENTATION OF OBESITY PREVENTION INTERVENTIONS IN EARLY CHILDCARE/EDUCATION SETTINGS: A SYSTEMATIC REVIEW USING THE RE-AIM FRAMEWORK

Jen Sanchez-Flack, PhD, MPH¹, Annie Herman, MA², Joanna Buscemi, PhD³, Angela Kong, PhD, MPH, RD⁴, Alexis Bains, BA⁴, Shaila Strayhorn, PhD, MPH¹, Marian L. Fitzgibbon, PhD¹

¹University of Illinois at Chicago, Chicago, IL; ²DePaul University; ³DePaul University, Chicago, IL; ⁴University of Illinois at Chicago

Background: Previous systematic reviews have examined the efficacy of obesity prevention interventions for children within early childcare/education settings. Often lacking in these reviews is reporting on external validity, which continues to be underemphasized in contrast to internal validity. More attention to external validity would help to better translate evidence-based interventions to real world settings. Our primary aim is to determine the availability of data on both internal and external validity across dimensions of the Reach, Efficacy/Effectiveness, Adoption, Implementation and Maintenance (RE-AIM) framework in studies reporting on obesity prevention interventions in early childcare/education settings.

Methods: This review used the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) guidelines. Inclusion criteria included: randomized-controlled trial study design, early childcare/education setting, targeted children 2-6 years old, addressed both diet and physical activity, collected measures of weight status and diet and/or physical activity, and published within the last 10-years. Searches were conducted in ERIC, PsychInfo, and PubMed in July 2019 resulting in 831 articles. Upon completion of title, abstract and full-text screening, 23 studies met the inclusion criteria. A validated RE-AIM abstraction tool was then used to code studies according to which indicators of internal and external validity were reported.

Results: The most commonly reported dimensions were Reach (62.3%), Implementation (53.5%) and Efficacy/Effectiveness (48.7%). Adoption (21.7%) and Maintenance (11.6%) were less often reported. All studies reported on primary outcomes, but few reported on RE-AIM indicators of characteristics of participation (8.7%) and adoption (4.3%), quality of life (13.0%), methods used to identify staff to deliver the intervention (13.0%), staff inclusion/exclusion criteria (8.7%), adoption rates (8.7%), implementation fidelity (26.1%), measures of cost to start-up (0%) and deliver (34.8%) the intervention, and indicators of maintenance (0-34.8%).

Conclusions: This systematic review suggests that more focus is needed on external validity so that evidence-based early childcare/education obesity interventions can be generalized to real-world settings. Recommendations for enhancing reporting and design will be discussed.

2:00 PM-3:15 PM

KEEPING KIDS ACTIVE: A SYSTEMATIC REVIEW OF SUMMERTIME INTERVENTIONS TO PROMOTE PHYSICAL ACTIVITY

Elizabeth Rea, B.A.¹, Amy M. Bohnert, Ph.D.², Jenette Moreno, Ph.D.³, Allie Hardin, B.A.⁴¹Loyola University Chicago, Chicago, IL; ²Loyola University Chicago, Evanston, IL; ³USDA/ARS Children's Nutrition Research Center Baylor College of Medicine; ⁴University of Texas, School of Public Health

The number of overweight and obese children has reached unprecedented levels in developed countries across the globe, with recent estimates of 23.8% of boys and 22.6% of girls being overweight or obese. A majority of efforts to address childhood obesity have focused on school year interventions. However, research suggests that children gain a disproportionate amount of weight during summertime when physical activity (PA) may be more limited, particularly for youth with limited access to summertime programming. This study sought to: (1) summarize research on youth's PA patterns across the entire year, (2) consider contextual factors that contribute to PA fluctuations (e.g., climate/weather, degree of structure, family socio-economic status, and safety), and (3) systematically review research on summertime PA interventions in order to determine key elements of successful interventions. Results suggested that summer day camps proved to be successful in keeping children active while they attended camp, and several reported improved fitness outcomes in those who attended. Elements from successful camps include daily, structured opportunities for physical activity and included a wide range of activities, from team games to yoga to dance. Community-level interventions (e.g., VERB Summer Scorecard) also showed some success in physical activity participation while posing physical activity as a fun thing to do with friends. Year-round school was also explored as an option to maintain PA levels, though more research is needed to draw firm conclusions in this area. Recommendations for future researchers include gaining an understanding of barriers to summer day camp participation, accounting for developmental factors, more precise measurement windows, and the need for more follow-up post-intervention to better understand the maintenance of effects over time. In sum, although child overweight and obesity is a complex issue, there is evidence that PA is a modifiable health behavior that can be increased in summertime programs.

2:00 PM-3:15 PM

EVALUATING INDIVIDUAL RESPONSE TO SCHOOL-BASED OBESITY INTERVENTIONS

Katherine Arlinghaus, MS, RD, LD¹, Rachel Helbing, MS², Craig A Johnston, PhD²¹University of Houston, Houston, TX; ²University of Houston

Background: Schools serve as a focal point for obesity treatment because children spend almost half their day in school. However, on average, school-based interventions result in only modest short-term improvements in weight outcomes. One reason for this may be due to the considerable individual variation in intervention response. Although tailoring is often discussed as an important intervention strategy, individual variation is not well understood. Traditional methodology for evaluating interventions relies on assessing mean differences in weight outcomes between intervention and control groups over time. While this is an important evaluation metric, it does not consider individual response variation, which may be critical to design more targeted interventions.

Methods: A scoping review of the literature was undertaken to gain a better understanding for how individual variation has been included as an intervention evaluation metric of school-based obesity interventions among adolescents. This review was intended to answer three main questions: 1. How many interventions report response rates as an intervention evaluation metric? 2. How do interventions define response? and 3. Are there common characteristics among interventions that report response rates?

Results: Preliminarily, it appears that few interventions report response rates in the initial evaluation of the intervention. Response rates are more commonly reported regarding maintenance outcomes. Response is primarily defined as the maintenance or decrease of standardized body mass index (zBMI), as a 5-10% improvement, or as a 0.20 decrease in zBMI.

Conclusions: Individual variation is an important issue to consider to improve outcomes of school-based obesity interventions. However, inconsistent definitions for response and a lack of reporting response rates make it difficult to understand which types of interventions meaningfully improve weight outcomes among the greatest number of youth. This is a critical gap to address to make decisions regarding which interventions should be disseminated and to improve how school-based interventions can be better tailored for and targeted to specific populations.

Symposium 54

2:00 PM-3:15 PM

2:00 PM-3:15 PM

SLEEP AND ALCOHOL USE ACROSS THE LIFESPAN: A PRESENTATION SUPPORTED BY THE SBM SLEEP SIG

Alyssa T. Brooks, PhD¹, Hannah K. Allen, PhD², Louise Thornton, PhD³¹National Institutes of Health Clinical Center, Bethesda, MD; ²Penn State University, University Park, PA; ³University of Sydney, Sydney, New South Wales, Australia

Alcohol use and sleep disturbance are risk factors for multiple chronic diseases, and both impact health-related quality of life. Often, sleep problems co-occur with alcohol misuse/alcohol use disorder (AUD). This symposium will explore the co-occurrence of alcohol misuse and sleep disturbance across the lifespan – from adolescence through adulthood, among individuals with varying patterns of use.

Presentation 1: Dr. Louise Thornton will present baseline and daily self-monitoring data from a multi-site cluster RCT currently underway across 72 schools in Australia. This presentation will explore the ways in which alcohol use and unhealthy sleep patterns occur and are related among 12-13 year old adolescents. Preliminary results suggests that alcohol use is associated with poorer sleep among this age group.

Presentation 2: Dr. Hannah Allen will present on the age-varying association between sleep and alcohol use disorder across adulthood. This presentation will use NESARC-III data to explore whether the existence and magnitude of the association between AUD and sleep varies by age across adulthood. Results provide evidence that adults ages 30 and older might be more susceptible to sleep problems associated with their heavy alcohol use as compared to younger adults, and that AUD is more strongly related to sleep problems as opposed to sleep duration.

Presentation 3: Finally, Dr. Alyssa Todaro Brooks will present pilot work on feasibility/acceptability of a behavioral sleep intervention (CBT-I) for individuals transitioning out of an inpatient alcohol rehabilitation program informed by qualitative work in the same population. Considerations for implementing behavioral sleep interventions among individuals with AUD will be discussed as well as “lessons learned” from past and ongoing work highlighting the importance of retention, trust, financial considerations, and post-discharge environment (including social support).

These presentations highlight the relationship between sleep and alcohol use across the lifespan. Both sleep and alcohol use are potentially modifiable targets for behavioral intervention. Together, panelists will discuss strategies for measuring and intervening in various populations.

Discussant: Tracy Trevorrow

CORRESPONDING AUTHOR: Alyssa T. Brooks, PhD, National Institutes of Health Clinical Center, Bethesda, MD; todaroad@mail.nih.gov

THE COMPLEXITY OF TREATING SLEEP DISTURBANCES WITH CO-MORBID PSYCHIATRIC CONDITIONS IN INDIVIDUALS WITH ALCOHOL USE DISORDER: ONE SIZE CAN'T FIT ALL

Alyssa T. Brooks, PhD¹, Ralph Tuason, RN, BSN, CNRN², Mike Krumlauf, RN, BSN², Gwenyth Wallen, PhD, RN²¹National Institutes of Health Clinical Center, Bethesda, MD; ²NIH Clinical Center

Sleep disturbances are common among individuals with alcohol use disorder (AUD) during phases of drinking, withdrawal, recovery and abstinence, and may be associated with relapse. Sleep-related cognitions and behavior should be carefully considered when designing interventions to improve sleep and/or prevent relapse. Based on pilot work on individuals transitioning out of an inpatient alcohol rehabilitation program, qualitative sub-themes based on semi-structured interviews suggested the importance of timing, structure, and delivery of a future behavioral sleep intervention. These interviews as well as extant literature led us to pursue an internet-delivered cognitive behavioral therapy for insomnia (CBT-I) program among individuals with AUD. Phase I (feasibility/acceptability) of this trial is currently in progress and will inform Phase II, a fully powered randomized controlled trial. Preliminary results on feasibility and acceptability highlight the need for careful consideration of common co-morbid psychiatric conditions when establishing inclusion/exclusion criteria to maximize the potential for participant recruitment, engagement, and retention. When designing behavioral sleep interventions for individuals with AUD, researchers and clinicians should consider novel strategies to improve the likelihood of retention, establishing trust, proximity and/or the use of telemedicine to increase convenience, finances, and post-discharge environment (including social support).

2

2:00 PM-3:15 PM

THE AGE-VARYING ASSOCIATION BETWEEN SLEEP AND ALCOHOL USE DISORDER ACROSS ADULTHOOD: AGES 18 TO 65

Hannah K. Allen, PhD¹, Ashley Linden-Carmichael, PhD¹, Stephanie Lanza, PhD¹¹Penn State University, University Park, PA

Background: Sleep disturbance is common among adults meeting criteria for alcohol use disorder (AUD), with frequent, heavy alcohol use negatively affecting the neurotransmitter systems responsible for sleep regulation. While the relationship between AUD and sleep problems is well-established, less is known about whether the existence and magnitude of the association between AUD and various measures of sleep vary by age across adulthood.

Methods: Data are from $n=23,065$ adults ages 18 to 65 (51% male; 66% non-Hispanic white) who participated in the 2012-2013 National Epidemiologic Survey on Alcohol and Related Conditions-III and had consumed alcohol in the past year. Participants reported typical sleep duration in the past 30 days and whether they had experienced problems falling or staying asleep in the past year. The Alcohol Use Disorder and Associated Disabilities Interview Schedule-5 was used to classify participants as meeting DSM-5 criteria for a past-year AUD. Time-varying effect modeling was used to model age trends in sleep duration, sleep problems, and AUD across adulthood, as well as the associations of AUD with sleep outcomes by age. All analyses controlled for sex and race/ethnicity, and a full sample weight was applied to adjust for sampling and nonresponse.

Results: A fifth of alcohol-using participants met criteria for a past-year AUD (21%), with prevalence peaking among 21-year-olds (37%) and declining through age 65 (6%). Participants slept an average of seven hours per night, and 28% reported past-year sleeping problems. Sleep problems increased with age, with a minimum prevalence of 20% among 21-year-olds and a maximum prevalence of 33% among 51-year-olds. Compared to participants not meeting AUD criteria, there was a significantly higher prevalence of sleep problems among participants meeting AUD criteria who were ages 20 to 23 and 30 to 60 years. There were no significant associations found between AUD and sleep duration at any age.

Conclusions: While the prevalence of AUD steadily declined with age, the significance of the association between AUD and sleep problems varied across adulthood. Findings highlight age groups that might be more susceptible to sleep problems associated with their heavy alcohol use, particularly adults ages 30 years and older. Efforts to prevent problematic alcohol use in young adulthood that extend into the later 20s and early 30s might help to protect against alcohol-related sleep problems later in adulthood.

3

2:00 PM-3:15 PM

ALCOHOL USE AND UNHEALTHY SLEEP AMONG AUSTRALIAN ADOLESCENTS AGED 12-13

Louise Thornton, PhD¹, Katrina Champion, PhD², Matthew Sunderland, PhD³, Maree Teesson, PhD³, Nicola Newton, PhD³, Frances Kay-Lambkin, PhD⁴, Cath Chapman, PhD³, Tim Slade, PhD³, Katherine Mills, PhD³, Lauren Gardner, PhD³, Health4Life Team³

¹University of Sydney, Sydney, New South Wales, Australia; ²University of Sydney; ³The Matilda Centre for Research Excellence in Mental Health and Substance Use, University of Sydney, Sydney, Australia; ⁴School of Medicine and Public Health, The University of Newcastle, Australia, Waratah, New South Wales, Australia

Background: Alcohol use and unhealthy sleep have been identified as key lifestyle risk factors for chronic disease. Both of these risk factors emerge during adolescence, commonly co-occur, and track into adulthood. The current study aims to understand associations between alcohol use and unhealthy sleep patterns among adolescents aged 12-13 years old.

Methods: The Health4Life Initiative is a multi-site cluster randomised controlled trial (RCT) currently underway in 72 schools across Australia. Schools are randomised to receive health education as usual or 'Health4Life' - an eHealth school-based prevention program and accompanying smartphone app concurrently targeting alcohol use, unhealthy sleep, and 4 other key health behaviours. The Health4Life app allows students to record their health behaviours (including alcohol use and sleep) daily, set goals and view progress over time. All students complete online assessments regarding their health behaviours (including alcohol use and sleep patterns). This presentation will use baseline data ($n \approx 7200$) to investigate the proportion of participating students reporting alcohol use and unhealthy sleep patterns and if sleep patterns differ between those students reporting current alcohol use and those not reporting it. Among students using the Health4Life app, we will also investigate patterns of reported alcohol and sleep behaviours over time and how these two behaviours may interact in this population.

Results: This presentation will describe the Health4Life initiative, cluster RCT, and patterns of alcohol use and sleep behaviours of participating students. To date more than 3700 students have completed their baseline assessment, with data collection to be completed in November 2019. Preliminary results based on this initial sample indicate 51.5% of students have had a sip of alcohol, 4.2% have ever had a full standard drink of alcohol and 2.3% have had a full standard drink in the past 6 months. These students scored an average of 18.8 ($SD=6.4$) on the Paediatric daytime sleepiness scale (PDSS), indicating excessive daytime sleepiness in this group. Their scores on the PDSS were also significantly worse than those of students who did not reporting drinking in the last 6 months ($M=13.7$ ($SD=5.9$), $F(1,3520)=58.06$, $p > .001$).

Conclusion: The Health4Life Initiative presents a unique opportunity to gather detailed information about alcohol use and sleep patterns from a large sample of adolescents. Preliminary results indicate alcohol use and poor sleep co-occur within this population. Final results will have the potential to improve our understanding of the ways in which alcohol use and sleep are related in this vulnerable age group and inform the development of effective prevention programs.

Symposium 55

2:00 PM-3:15 PM

2:00 PM-3:15 PM

THE PROCESSES UNDERLYING PHYSICAL ACTIVITY HABIT FORMATION

Jaclyn P. Maher, Ph.D.¹, Amanda L. Rebar, PhD², Kimberly R. More, MSc³, Ryan E. Rhodes, Ph.D.⁴¹University of North Carolina at Greensboro, Greensboro, NC; ²Central Queensland University, Cooe Bay, Queensland, Australia; ³Iowa State University, Ames, IA; ⁴University of Victoria, Victoria, BC, Canada

Contemporary health behavior theories have almost exclusively focused on the role that conscious regulatory processes such as plans, beliefs, and expected value play in regulating physical activity behavior. Although evidence suggests that manipulating these factors can, in part, change behavior, health behaviors are often resistant to attempts to change them. Accumulating evidence suggests that habit, a non-conscious process, plays a role in regulating physical activity behavior even after accounting for more conscious regulatory processes. Habits develop through the repeated pairing of a contextual cue and a behavioral response so that, over time, encountering the cue automatically elicits an impulse to engage in the behavioral response. As a result, habits are well-learned, automatic, and context-dependent influences on behavior. Given that habits are hypothesized to be less resistant to lapses in motivation due to limited reliance on conscious processing, habit formation likely represents an essential part of sustained physical activity engagement. Therefore, understanding the mechanisms underlying physical activity habit formation is critical to effective physical activity promotion efforts. The presentations in this symposium will draw on observational and experimental data to elucidate the processes underlying physical activity habit formation. The first presentation will present intensive data collected through ecological momentary assessment to empirically test the theoretical propositions that habit strength for physical activity and sedentary behavior should be associated with degree of context-stability of those behaviors among older adults. The second presentation will present evidence tracking physical activity habit strength monthly for six months during and following an 8-week exercise rehabilitation program designed for cardiovascular and pulmonary disease patients. The third presentation will present on the relative role of context stability and exercise identity in habit formation within a randomized controlled trial designed to promote brisk walking habits among sedentary women. Overall, these presentations will provide important insights into physical activity habit formation among low active populations. The discussant will address both the specific contributions of these presentations and the broader implications of promoting physical activity habits and the integration of habits in theory refinement.

THE INFLUENCE OF CONTENT STABILITY ON PHYSICAL ACTIVITY AND SEDENTARY BEHAVIOR HABIT STRENGTH AND BEHAVIOR: AN ECOLOGICAL MOMENTARY ASSESSMENT STUDY

Jaclyn P. Maher, Ph.D.¹, Genevieve F. Dunton, PhD, MPH², Amanda L. Rebar, PhD³¹University of North Carolina at Greensboro, Greensboro, NC; ²University of Southern California, Los Angeles, CA; ³Central Queensland University, Cooe Bay, Queensland, Australia

Background: Habits develop through cue-behavior associations learned over time as a result of repeated pairings of a contextual cue (i.e., time of day, physical location, surrounding people) with a rewarding behavioral response. Therefore, the degree of stability in contexts in which physical activity (PA) or sedentary behavior (SB) is engaged may have important motivation implications; yet, research investigating the specific contexts of an individual's PA or SB as it pertains to health behavior habits is lacking. This study used ecological momentary assessment (EMA) to empirically test the theoretical propositions that habit strength for and level of PA and SB should be associated with degree of context-stability of those behaviors.

Methods: Older adults (N=104) completed a 10-day EMA protocol. Participants answered 6 EMA prompts/day to assess current behavior as well as social (e.g., alone, with spouse/partner, with friend) and physical (e.g., at home, park, store) contexts of behavior. Day (weekday, weekend day) and time (e.g., morning, afternoon, evening) stamps of EMA questionnaires provided temporal context data. Behavioral context stability was calculated as the reversed entropy scores of the social, physical, and temporal contexts of PA and SB weighted for total frequency of context prompts. Greater entropy indicated greater heterogeneity of contexts. Habit strength for PA and SB were assessed by questionnaire prior to beginning the EMA protocol. An ActiPal monitor was worn continuously to assess average daily time spent in moderate-vigorous PA (MVPA), light PA, SB, and number of sit-to-stand transitions. Habit strength or behaviors was regressed onto context stability and total frequency scores.

Results: Social context stability was positively associated with MVPA ($\beta = .43$); people engaged in more MVPA if they tend to be around the same types of people when active. Physical context stability was negatively associated with sit-to-stand transitions ($\beta = -.23$); people tended to transition from sitting less often if they sat in more variable locations. No context stability scores predicted light PA, SB or PA or SB habit strength.

Conclusions: Although context stability was related to behavior, this did not appear to be explained by habit, as habit strength did not differ by the degree of context stability surrounding bouts of PA or SB. Further research is necessary to determine the extent to which context stability is associated with the formation and maintenance of health behavior habits.

HOW EXERCISE REHABILITATION PROGRAMS IMPACT PHYSICAL ACTIVITY HABITS AMONGST CARDIOVASCULAR AND PULMONARY DISEASE PATIENTS

Amanda L. Rebar, PhD¹, Kristy-Lee Alfrey, BS², Benjamin Gardner, PhD³, Christopher Askew, PhD⁴, Corneel Vandelaotie, PhD², Jenni Judd, PhD²

¹Central Queensland University, Coocoo Bay, Queensland, Australia; ²Central Queensland University; ³King's College London, London, England, UK; ⁴University of The Sunshine Coast

Heart and lung disease are among the leading causes of death and strain on healthcare resources globally. Physical activity is an instrumental aspect of rehabilitation and relapse prevention. Following hospitalization or diagnosis, some patients are referred to gym- or hospital-based physical activity rehabilitation programs; however, the programs typically only last between 2-3 months. Habits are theorized to form gradually and, once established, persist over time, thereby resulting in long-term behavior change. To increase the number of patients who continue regular activity following rehabilitation, we need to understand how rehabilitation programs impact habit for physical activity, both in terms of rehabilitation exercise and lifestyle physical activity. Habits are automatic behavioral tendencies, or urges to act, activated by learned mental associations of cues and responses. Being physically active out of habit is a different psychological process than being active out of volition and self-control, with habit being more resistant to lapses in motivation and more likely to be sustained long-term. Tracking physical activity habit formation of patients participating in an exercise rehabilitation program will provide important insight into how rehabilitation could be restructured to most effectively help people form long-term physical activity habits.

Habit for both rehabilitation exercise and lifestyle physical activity of 33 rehabilitation patients were tracked monthly for six months during and following an 8-week rehabilitation program. Patients reported strong habit for rehabilitation exercise throughout the program ($M = 5.59$, $SD = 1.40$) and the trajectory of habit formation was flat, which is atypical of habit formation trajectories shown in other studies for lifestyle health behaviors. People's habit for lifestyle physical activity was comparatively much weaker than their habit for rehabilitation exercise ($M \Delta 95\% \text{ CI: } -2.25 \text{ to } -1.62$). Multilevel modelling revealed that people's habit strength for lifestyle physical activity was significantly stronger during the time of the rehabilitation program ($95\% \text{ CI: } 0.21 \text{ to } 1.04$) compared to before the program; but dropped off again following program completion ($95\% \text{ CI: } -0.60 \text{ to } 0.64$).

In-clinic exercise rehabilitation programs may not translate into lifestyle physical activity habits, and therefore long-term behavior change is unlikely. Additionally, these findings call into question habit theory tenets such as how habits form and whether they generalize beyond a specific context. More is needed to understand how habits play out in rehabilitation programs and the theoretical implications of understanding habit in this context before establishing whether integrating habit behavior change techniques within existing exercise rehabilitation programs will be beneficial.

THE ROLE OF CONTEXT STABILITY AND EXERCISE IDENTITY IN HABIT FORMATION

Kimberly R. More, MSc¹, L. Alison Phillips, PhD¹

¹Iowa State University, Ames, IA

Regular exercise prevents chronic illness and is important for disease management, yet few adults are able to maintain a regular regimen. Interventions that target exercise maintenance focus on habit development via action planning which attempts to link cues and behavior until the association becomes automatic (i.e., habit). For complex behaviours (e.g., exercise), which require a substantial amount of time and physical exertion, the effectiveness of planning interventions may be improved upon; that is, having a stable context for exercise may not be sufficient for habit to form. The present study examined the relative role of context stability and exercise identity as factors in habit formation using a novel methodology called Necessary Condition Analysis (NCA).

Data from the present study are from a randomized controlled experiment that tested four strategies (including control) for forming a brisk-walking habit in sedentary young women ($N = 175$; $\text{Mage} = 19.14$, $\text{SDage} = 1.58$). Participants' context stability was measured at baseline and their identity and habit strength for exercising were measured one month post intervention. Physical activity was measured using self-report and FitBits. Across conditions, we tested the hypothesis that both context stability and identity would be necessary-but-not-sufficient conditions for habit development.

The hypothesis was tested using NCA and multiple regression analysis. Participants were removed from analyses if they failed any random response check. Neither daily nor weekly context stability were necessary-but-not-sufficient conditions for habit development, nor did they predict habit using regression ($ps > .05$). Identity was a weak necessary-but-not-sufficient condition for habit development ($d = .026$, $p = .014$). Thus, those with weak identities did not develop strong habits. Additionally, identity predicted habit development using regression ($\beta = .41$, $p < .001$).

Context stability may be less important for habit development than forming a strong exercise identity. However, future research should evaluate these relationships with more in-depth measures of context stability, with objective measures of habit strength, and with additional types of physical activity. That is, identity may be more important for habit formation for other - less commonly practiced - types of physical activity. In conclusion, targeting identity formation may promote habit.

DHC PRESENTS: USING THE DESIGN SPRINT METHODOLOGY TO DEVELOP DIGITAL HEALTH TOOLS--THREE CASE STUDIES

Danielle E. Jake-Schoffman, PhD¹, Valerie Silfee, PhD², Katrina Mateo, MPH, PhD candidate³, Andrew Onda, MBA², Megan A. McVay, PhD¹¹University of Florida, Gainesville, FL; ²UPMC Health Plan, Pittsburgh, PA; ³Healthcare Innovation Technology Lab (HITLAB), New York, NY

The design and implementation of digital tools in the context of multilevel behavioral interventions pose numerous decision points and challenges for development teams. Unfortunately, this process is often full of delays and can sometimes lead to a late start to a program or having to use a digital tool with limited pilot data. The Design Sprint process, designed by the Google Ventures team, provides a framework through which teams undertake a five-day problem solving process, engineered to push the team through roadblocks and stimulate creative thinking. The process has since been used in a variety of settings with success, including both academic and industry teams. In this symposium, we will present three case studies of the use of the Design Sprint methodology to iterate health technology tools, including modifications to the procedures, lessons learned, and the value add of undertaking this ambitious process. We will begin with an overview of the original Design Sprint process as laid out by the Google Ventures team. The first case study is an example of the process as conducted through the digital behavioral unit of an integrated health care delivery system, to build a digital health coaching dashboard prototype. In this example, the team maintained high fidelity to the original Design Sprint methodology, including all steps and timeline as suggested. The second case study is an example of the process as conducted by team of academic researchers in an allied health department, to build a digital patient-facing facilitation guide and an initial implementation plan for a behavioral weight loss study. In this example, the team modified the Design Sprint methodology to accommodate academic schedules and university regulations, including fitting within 2.5 days and conducting formative data collection outside the sprint period. The third case study is an example of the process as conducted at a digital health innovation company to build a design prototype of a digital goal-setting platform for stress management. In this example, the team conducted an accelerated 2-day Design Sprint followed by four rounds of user-testing of the prototype, each including a process of rapid review and prioritization of user feedback and redeployment of the prototype with revisions. Finally, the discussant, an expert in the execution of Design Sprints, will provide a summary of the case studies and lead a conversation about the considerations for using the process to develop and iterate digital health products in a variety of research and practice settings.

USING AN ADAPTED DESIGN SPRINT METHODOLOGY TO INCREASE SPEED AND CREATIVITY DURING DEVELOPMENT OF A WEB-BASED TOOL AND IMPLEMENTATION STRATEGY

Danielle E. Jake-Schoffman, PhD¹, Megan A. McVay, PhD¹, Marissa Donahue, MA²¹University of Florida, Gainesville, FL; ²University of Florida

While obesity is present in nearly 40% of US adults, few people have access to formal weight loss treatment. Freely available weight loss apps that include tracking and social networks have high potential for promoting weight loss. However, few people currently use these tools, and those who use them tend to be healthier than those who do not. The context of a primary care appointment is ideal to encourage the use of freely available tools, as it leverages the heightened interest in making health changes and influence of the primary care provider to encourage initiation of new health behaviors. However, tools to support this initiation of weight loss are not widely available. Thus, the objective of this project was to develop a patient-facing guide ("facilitation guide") to motivate use of freely available online weight loss tools, and an implementation strategy to integrate this guide into the clinical encounters around a primary care appointment.

As part of a systematic intervention development process, team members developed the patient-facing facilitation guide and an initial implementation plan using a modified version of the Design Sprint process (Google Ventures). Team members were the Co-PIs of the project and the research coordinator. The Design Sprint process was modified to accommodate academic schedules and IRB regulations, including shortening to 2.5 days across a week (vs. original 5 days) of group work with additional research conducted after hours; substituting some suggested steps (e.g., "Ask the Experts" conducted through scientific literature reviews); and skipping other steps altogether (e.g., using a "Straw Poll" to inform decisions). Other tasks were implemented with fidelity to the Design Sprint protocol (e.g., "How Might We" note taking procedures to identify key objectives, "Lightening Demos" to learn from existing products, "Crazy 8" sketches to generate/refine intervention ideas). Following the initial sprint week, the team took several additional steps. First, the outline of the tool was further iterated into a full clickable prototype (created in PowerPoint). Second, the prototype and semi-structured interview guides were submitted for IRB approval. Third, with approval secured, the team gathered feedback on the prototype and the implementation plan through a series of qualitative interviews with n=4 primary care providers and n=12 patients with obesity.

Overall, the Design Sprint process fostered creativity and out-of-the-box thinking, leading to innovations in the products designed. It encouraged the team to make difficult decisions about the products in an abbreviated period of time, ultimately eliminating "sticking points" that typically stall progress for days or weeks, thus accelerating the design process. Details of adaptations to the Design Sprint methodology and suggestions for researchers to tailor the process to their projects will be shared.

2:00 PM-3:15 PM

SPRINTING TOWARDS IMPROVED HEALTH: A GOOGLE DESIGN SPRINT PROCESS TO BUILD A HEALTH COACHING DASHBOARD

Valerie Silfee, PhD¹, Nicole Beswick, MS, NBC-HWC², Christianne Johnson, MA², Alexa Pavlick, BA³, Bethany Tillilie, MBA², Fatma Uyar Morency, PhD², Ja-Way Wang, BSBA², Brandon Zepeda, MII-PS², Andrew Onda, MBA¹

¹UPMC Health Plan, Pittsburgh, PA; ²UPMC Health Plan; ³Western Psychiatric Institute

As digital health behavior interventions continue to grow, more and more people are getting access to digital programs and apps they need to prevent and manage chronic conditions. However, research has shown that a digital tool alone is not sufficient to change behavior. Human interaction is critical, and health coaches are an important asset to be able to positively move individuals through the behavior change process. Unfortunately, there are many barriers to health coaching in an applied setting including documentation, scheduling communications, understanding participants' health history, and monitoring progress. Therefore, the goal of this project was to develop a digital coaching dashboard that would eliminate barriers faced by health coaches, in order to improve or maintain Health Plan members' perceived health and well-being.

Members of the UPMC Health Plan Behavioral Unit for Digitally Delivered Interventions (BUDDI) participated in a five-day Design Sprint, following the process developed and perfected by Jake Knapp of Google Ventures. We specifically sought to understand what information is necessary to effectively coach, how to create an intuitive dashboard, and the extent to which health coaches trust suggestions from emerging technology. The Design Sprint process was followed exactly as outlined and facilitated by a separate Experience Strategy team at UPMC. The core team was made up of seven individuals, including behavioral scientists, health coaches, product managers, data analysts, and experience and UX designers. The team followed the five-day process by mapping the problem (Monday), sketching solutions (Tuesday), choosing the strongest sketches (Wednesday), building a realistic prototype (Thursday), and testing the prototype with five UPMC Health Plan behavioral health and lifestyle health coaches (Friday). Protocol activities included but were not limited to "Asking the Experts" to gain insights to the problem, "Lightning Demos" to review solutions from other industries, and a "Structured Critique" of each other's sketches. We also generated a coaching dashboard prototype along with answers to our core questions and key findings and themes from the testing with five UPMC behavioral health and lifestyle health coaches.

Those attending this session will obtain a deeper understanding of the Design Sprint methodology and how this process uses a step-by-step checklist to move a challenge from a problem to a tested solution in five days.

3

2:00 PM-3:15 PM

USING AN ACCELERATED DESIGN SPRINT AND RAPID MODIFICATION/REDEPLOYMENT METHODOLOGY TO DEVELOP A DESIGN PROTOTYPE OF A DIGITAL BEHAVIOR CHANGE TECHNIQUE TOOL FOR STRESS MANAGEMENT

Katrina Mateo, MPH, PhD candidate¹, Frank Fries, MS², Silky Kadakia, MA², Stan Kachnowski, PhD, MPA¹

¹Healthcare Innovation Technology Lab (HITLAB), New York, NY; ²Healthcare Innovation Technology Lab (HITLAB)

Behavior change interventions typically contain multiple behavior change techniques (BCTs) that, if enacted appropriately, are likely to effect a desired change. However, BCT effectiveness can depend on how they are delivered and whether user engagement is sustained, both with the delivery platform (e.g. in-person, digital) and the BCT.

As part of a larger effort to translate optimized prototypes of BCTs into health behavior change products, a design prototype of a digital goal-setting platform for stress management that integrates five key BCTs related to goal setting was developed by: 1) using an accelerated design sprint methodology to create an initial prototype, and 2) conducting iterative user-testing with rapid execution and redeployment of modifications to the user interface/user experience (UI/UX).

A 2-day design sprint (an accelerated design workshop that aims to define goals, validate assumptions, and design the initial UX for a new product) was held with digital health researchers, behavioral scientists, a UX designer, and product developer. Based on workshop outcomes, a sketch concept, user flow framework, and testing calendar was developed (2 weeks). After initial development and internal review/refinement of the design prototype (5 weeks), four rounds of user-testing (navigating clickable UX "flows") with post-interview data collection was conducted with 17 participants (mean age 36.8 years [range 22-64 years], 82% female, English-speaking, interested in behavior change around stress management). Each round was followed by rapid review and prioritization of user feedback, and iterative prototype updates prior to the next testing round. After user-testing (7 weeks), a content analysis of data identified common themes/patterns related to UI/UX preferences, challenges, acceptability, and overall value, which guided final refinements and recommendations for next steps.

Three user "flows" and related content were developed for the design prototype: Flow 1 for a first-time user (i.e. welcome screen, assessment questions, goal setting, creating a plan, main menu options); Flow 2 for an active/regular user (i.e. personal tracking of daily progress); and Flow 3 for a user returning after a hiatus (i.e. problem identification, goal/plan adjustment). Users liked the overall UI/UX describing the design prototype as more comprehensive and easier to use than other digital health tools. Users wanted more goal specificity and personalization, and also suggested a range of improvements to the UI/UX and content, as well as additional features to better guide, support, and engage users.

This project completed in under 5 months demonstrates the utility of using a design sprint and iterative user-testing and modification redeployment methodology to develop design prototypes for digital behavior change platforms.

DESIGNING RESEARCH TO TEST MECHANISMS UNDERLYING BEHAVIOR CHANGE: THE NIH SCIENCE OF BEHAVIOR CHANGE INITIATIVE

Talea Cornelius, PhD, MSW¹, Jun Ma, MD, PHD², Erica Sciolli, Ph.D.³, Bonnie Spring, PhD⁴, Jonathan W. King, PhD⁵¹Columbia University Irving Medical Center, New York, NY; ²University of Illinois at Chicago, Chicago, IL; ³VA Boston Healthcare System, Boston, MA; ⁴Northwestern University Feinberg School of Medicine, CHICAGO, IL; ⁵National Institute on Aging / NIH, Bethesda, MD

Long-term behavior change to promote health and longevity is difficult. Behavior-change interventions are inconsistent; when successful, we rarely know why or how they work. The NIH Common Fund's Science Of Behavior Change (SOBC) program aims to revolutionize behavior change research by using an experimental medicine approach to identify and engage mechanisms of behavior change. This method promotes a unified science to advance the field to create more effective behavioral interventions. In brief, the experimental medicine approach comprises four basic steps: (1) identify a potential mechanism of behavior change, (2) measure the hypothesized mechanism using validated instruments, (3) intervene and demonstrate that the mechanism has been influenced, and (4) observe whether influencing the mechanism results in subsequent behavior change. This is akin to testing a mediation model within a randomized control trial.

The SOBC network began in 2015 with eight teams tasked with identifying, measuring, and influencing a mechanism of behavior change with relevance to health regimen adherence more broadly. Initially, these teams worked to develop and validate assays to measure hypothesized mechanisms underlying behavior across three domains: self-regulation, stress, and interpersonal processes (UH2 phase). Currently, six of these teams are in the process of testing whether mechanism change results in behavior change (UH3 phase). The network has also recently expanded to include 13 R21/R01 revisions applying the experimental medicine approach. This phase of SOBC, in which mechanism change is linked to behavioral outcomes, brings associated challenges regarding measurement and trial design. Results from UH3 studies will ultimately lead to a deeper understanding of why interventions succeed—or, why they do not.

This symposium provides a brief overview of the SOBC steps and history (presented by Dr. Talea Cornelius, a member of the SOBC resource and coordinating center), complemented by a presentation from Dr. Jun Ma, a SOBC network member currently working to validate hypothesized mechanisms of behavior change (i.e., brain circuits implicated in emotion, cognition, and self-focused reflection) underlying weight loss. Dr. Erica Sciolli, a new SOBC member, will discuss the incorporation of neurological mechanisms into her research examining the impact of progressive exercise training on chronic pain, depression, and PTSD. Dr. Bonnie Spring will present a systematic meta-review of interventions targeting self-regulatory mechanisms of change and the association of these techniques with weight loss, eating, and physical activity outcomes, and will discuss some of the challenges associated with designing studies to test mechanisms of behavior change. Finally, Dr. Jonathan King will present the NIH perspective on funding for intervention research informed by the SOBC approach

ENGAGING SELF-REGULATION TARGETS TO UNDERSTAND THE MECHANISMS OF BEHAVIOR CHANGE AND IMPROVE MOOD AND WEIGHT OUTCOMES: THE ENGAGE PROJECT

Jun Ma, MD, PHD¹¹University of Illinois at Chicago, Chicago, IL

Despite new evidence for effective integrated behavior therapy for treating comorbid obesity and depression, the underlying mechanisms remain unknown. This lack of understanding significantly hampers efforts to optimize the efficacy of behavioral interventions and limits their implementation. The 2-phased ENGAGE project innovatively integrates sophisticated mechanistic studies with rigorous investigation of behavioral treatment effects in randomized clinical trials (RCTs) of patients with obesity and depression. Leveraging the latest advances in transdisciplinary basic sciences, the ENGAGE project exemplifies an experimental medicine approach by focusing on changes in large-scale brain circuits (in both phases) and the gut microbiome and proinflammatory cytokines (in phase 2) to elucidate potential mechanisms along the microbiome-gut-brain axis underlying integrated behavior therapy for obesity and depression. This integrated therapy with demonstrated effectiveness in a recently JAMA-published RCT, combines 2 nationally recognized behavioral interventions: problem solving therapy with as-needed intensification of pharmacotherapy for depression and standard behavioral weight loss treatment. Embedded within this RCT, the now completed phase 1 of the ENGAGE project was a discovery study among a subset of the parent trial sample (n=108) to explore whether and how a priori-defined brain circuits—namely, target circuits—subserving emotion, cognition, and self-focused reflection mediated treatment effects on health behavior changes as well as weight loss and depression outcomes. Phase 2 is actively recruiting (target n=105) for a replication study designed to examine the same target brain circuits in a geographically and socioeconomically different sample randomized to receive an enhanced version of the integrated behavior therapy. Additionally, stool and blood specimens are collected for microbiome and cytokine analyses because, based on emerging data, modification of the microbiota-gut-brain axis via the integrated behavior therapy is a plausible, transdiagnostic mechanism affecting treatment adherence and response. In line with the Society of Behavioral Medicine 41st annual meeting theme of “Finding Innovative Solutions for Tomorrow's Health Challenges,” we will present main results from phase 1 and discuss lessons learned from both phases to implement a mechanisms-focused, experimental medicine approach in novel behavior change intervention research.

2

2:00 PM-3:15 PM

NEUROBIOLOGICAL MEDIATORS OF SELF-REGULATORY AND REWARD-BASED MOTIVATIONAL PREDICTORS OF EXERCISE MAINTENANCE IN CHRONIC PAIN AND PTSD: AN EXPLORATORY PILOT STUDY

Erica Scioli, Ph.D.¹, James Whitworth, Ph.D.², Michael Esterman, Ph.D.², Sunny Dutra, Ph.D.³, Kristina Bogdan, BS², Alex Eld, BS⁴, Ann Rasmusson, MD²

¹VA Boston Healthcare System, Boston, MA; ²Boston University School of Medicine; ³William James College; ⁴VA Boston Healthcare System

This study will use the Science of Behavior Change (SOBC) experimental medicine approach to compare the effects of a 3-month, individually prescribed progressive exercise training program on neurobiological and related neuropsychological mechanisms by which our exercise-training paradigm may foster exercise maintenance. More specifically, we will investigate hypothesized relationships between exercise-training associated augmentation of neuropeptide Y (NPY) system function and improvements in putative mechanisms: reward sensitivity and self-regulation, neuropsychological capacities posited to underlie self-efficacy and intrinsic motivation, which have been shown to predict exercise maintenance. This study will focus on Veterans with chronic low back pain (cLBP) and posttraumatic stress disorder (PTSD). It includes a baseline, acute, cardiopulmonary exercise assessment (CPX) that will inform the exercise prescription for a 12-week progressive exercise training program, comprised of three 45-minute aerobic exercise sessions per week (walking or running). All exercise sessions will be supervised by an exercise physiologist in the Clinical Studies Unit at the VA Boston Healthcare System. Intermittent telephone calls by the researchers will provide additional motivational support and problem solving. Implementation of the prescribed exercise regimen will be supported by use of heart rate and actigraph monitors programmed to help the participants achieve their prescribed heart rate range. A “midpoint” (week 6) and “endpoint” (week 13) CPX assessment will track changes in NPY system function and delineate relationships to the putative mechanisms proposed to foster exercise maintenance. All three CPX tests will be performed in accordance with guidelines published by the American College of Cardiology. We hypothesize that the capacity to release NPY in response to vigorous exercise (i.e., during CPX) will be associated with improvements in reward sensitivity and self-regulation, which will in turn be associated with self-efficacy and intrinsic motivation to foster exercise maintenance. To have sufficient power to test these hypotheses, 70 participants will be randomized to either the “active exercise training condition” or to a “wait list symptom monitoring condition”. Data from this R21 will be used to demonstrate feasibility and inform the further development of individually prescribed, motivationally based exercise regimens to reduce the negative consequences of these disorders over the long-term. In addition to a description of how this study illustrates the SOBC’s recommended experimental medicine approach, an update on study progress will be presented along with a discussion of challenges in implementing mechanisms-based research supported by an exploratory R21 award.

2:00 PM-3:15 PM

SELF-REGULATORY BEHAVIOR CHANGE TECHNIQUES TO PROMOTE WEIGHT LOSS, HEALTHY EATING, AND PHYSICAL ACTIVITY: A META-REVIEW

Bonnie Spring, PhD¹, Katrina Champion, PhD², Rebecca Acabchuk, PhD³, Emily Hennessy, PhD⁴

¹Northwestern University Feinberg School of Medicine, CHICAGO, IL; ²University of Sydney; ³University of Connecticut, Storrs, CT; ⁴University of Connecticut, Storrs, CT

Poor quality diet, physical inactivity, and obesity are the most prevalent behavioral risk factors for chronic disease. They are also covariant, suggesting that behavior change techniques (BCTs) that effectively change one risk factor might also improve other diet, activity, and weight outcomes, enhancing intervention efficiency. To examine that question, this registered meta-review, (CRD42019128444), synthesized evidence from 30 meta-analyses published between 2007 and 2017 aggregating data from 409,185 participants to evaluate whether inclusion of 14 self-regulatory BCTs in health promotion interventions was associated with greater improvements in outcomes. Study populations and review quality varied, with minimal overlap among summarized studies. AMSTAR-2 ratings averaged 37.31% ($SD = 16.21\%$; range 8.33-75%). All BCTs were examined in at least one meta-analysis; goal setting and self-monitoring were evaluated in 18 and 20 reviews, respectively. No BCT was consistently related to improved outcomes. Although results might indicate that BCTs fail to benefit diet and activity self-regulation, we suggest that a Type 2 error is more plausible, reflecting methodological limitations: population heterogeneity, insufficient intervention fidelity, and failure to evaluate BCT effects on outcomes experimentally. An understanding of independent and interactive effects of individual BCTs on different health outcomes and populations is needed urgently to ground a cumulative science of behavior change.

2:00 PM-3:15 PM

THE NIH SCIENCE OF BEHAVIOR CHANGE COMMON FUND PROGRAM: WHY, WHAT, AND WHEN?

Jonathan W. King, PhD¹

¹National Institute on Aging / NIH, Bethesda, MD

The goal of the NIH Science of Behavior Change (SOBC) Common Fund Program has been to transform behavioral intervention designs by fostering and encouraging the development of an experimental medicine approach to behavior change research. This experimental medicine approach requires us to focus first on hypothesizing specific intervention targets (mechanisms of change) and demonstrating first that one can measure the activity of the target mechanism; second that one can design a manipulation that changes the level of activity of the target mechanism; and third that a proposed intervention changes both the activity of the target mechanism as well as the behavior in which one is seeking change. In this way, it seeks to unify the basic and translational science approaches to behavior change as well as increasing our understanding of *how* interventions work to change behavior, which could lead us to find ways to optimize those interventions and/or determine what types of people they would be most suitable for and what moderating factors might need to be taken into account. This presentation will give a brief history of SOBC including the rationale for the adoption of the experimental medicine approach to behavior change and a discussion of where there may be the greatest future opportunities for progress using the methods and tools developed by the program.

Symposium 58

2:00 PM-3:15 PM

DREAM OR REALITY: CAN NEW TECHNOLOGIES REALLY DELIVER TAILORED, EFFECTIVE BEHAVIOURAL MEDICINE INTERVENTIONS TO POPULATIONS?

Brian Oldenburg, BSc, MPsychol, PhD¹, Craig B. Taylor, MD², Enying Gong, MSc¹, Andrea K. Graham, PhD³

¹University of Melbourne, Melbourne, Victoria, Australia; ²Stanford/Palo Alto University, Stanford, CA; ³Center for Behavioral Intervention Technologies, Northwestern University, Chicago, IL

With the rapid development of digital technology, this has opened up new opportunities and possibilities for improving health outcomes in populations. However, there are many challenges in optimizing the impact of such interventions at the population level, including the difficulty in reaching vulnerable populations, lack of engagement and suboptimal program use, as well as study design and measurement issues. This requires the application of new user-centered design and research approaches to optimize the delivery of effective digital interventions for defined populations. In this symposium, the presenters will describe recent research trials from different countries, their findings and learnings for advancing the new field of digital public health. Ms Gong will describe how a digitally-enabled intervention was able to reach and impact on vulnerable stroke patients in rural China, thereby demonstrating the effectiveness of the intervention in empowering both providers and patients. Dr. Taylor will describe a new model - Prevalence Reduction Through Outcome Optimization (PRTOO) - that uses prevalence, risk, reach, outcome, uptake, engagement and client/stakeholder input data, all continuously monitored, to inform prevention and intervention decisions. Dr. Oldenburg will describe how recent digital interventions using interactive voice recognition and speech have been able to improve chronic disease self-management by creating high levels of engagement. Each presenter will describe the issues related to intervention reach, engagement and outcomes. The discussant will reflect on the learnings from these three presentations and how the outcomes from digital interventions can be improved in the future.

CORRESPONDING AUTHOR: Brian Oldenburg, BSc, MPsychol, PhD, University of Melbourne, Melbourne, Victoria, Australia; boldenburg@unimelb.edu.au

DIGITAL TECHNOLOGY TO TRANSFORM CURRENT APPROACHES TO CHRONIC DISEASE MANAGEMENT IN POPULATIONS

Brian Oldenburg, BSc, MPsychol, PhD¹, Dominique Bird, PhD², Shaira Baptista, PhD Candidate³, Greg Wadley, PhD⁴, Jane Speight, PhD⁵, Paul Scuffham, PhD⁶

¹University of Melbourne, Melbourne, Victoria, Australia; ²University of Queensland, Woolloongabba, Queensland, Australia; ³Australian Centre for Behavioural Research in Diabetes; ⁴University of Melbourne; ⁵The Australian Centre for Behavioural Research in Diabetes, Diabetes Victoria, Melbourne, Victoria, Australia; ⁶University of Queensland

While many mhealth programs and digital technologies (interactive digital technology, iDT) are now widely available and at least some have been shown to help individuals monitor and improve lifestyle behaviors and improve clinical outcomes relevant to chronic disease management, it is still unclear how iDT can be rigorously optimized to engage large numbers of users in purposeful prevention and/or routine chronic disease management. Critical steps for population-level impact include: (1) optimizing the user experience to significantly increase the long term impact and widespread use of iDT; (2) data linkage, interoperability of platforms and systems integration to enhance their utility and scalability; (3) producing frameworks, guidelines and business models to enable widespread uptake and adoption of safe and effective iDT by consumers, health practitioners and health services. We have been involved with a series of 5 randomized trials published in the last 15 years that have demonstrated high levels of engagement with telehealth and voice-delivered programs as well as effectiveness in terms of clinical, behavioral, quality of life and economic outcomes. (1) The Logan Healthy Living program evaluated a phone-delivered physical activity and dietary behaviour intervention for primary care patients with type 2 diabetes or hypertension. (2) The ProActive Heart Program evaluated a phone-delivered secondary prevention intervention for myocardial infarction patients. (3) The MoodCare Program evaluated a phone-delivered coaching intervention for ACS patients with depression. (4) The TLC Diabetes Program evaluated an automated, interactive telephone intervention to improve type 2 diabetes management. (5) Most recently, the My Diabetes Coach Program has evaluated a mhealth program involving "conversation" with an embodied conversational agent to improve type 2 diabetes management. Good levels of engagement and improved health outcomes and cost effectiveness are comparable between our trials of human-delivered telehealth (Trials 1-3) and automated conversational delivery (Trials 4-5). Recently available smart voice assistants at home or on people's mobile devices can now be used to help people with a variety of chronic conditions with information, guidance and coaching. The advent of this new technology provides tremendous potential to deliver conversational programs at scale with good reach, engagement, effectiveness and cost-effectiveness.

2:00 PM-3:15 PM

USING DIGITAL TECHNOLOGY TO REDUCE THE PREVALENCE OF DISORDERS IN POPULATIONS: TIME FOR A NEW APPROACH

Craig B. Taylor, MD¹, Andrea K. Graham, PhD², Ellen Fitzsimmons-Craft, PhD³, Brian Oldenburg, BSc, MPsychol, PhD⁴

¹Stanford/Palo Alto University, Stanford, CA; ²Center for Behavioral Intervention Technologies, Northwestern University, Chicago, IL; ³Washington University School of Medicine in St. Louis; ⁴University of Melbourne, Melbourne, Victoria, Australia

Advances in digital technology, including the almost ubiquitous access to smart devices, social media and smart wearables, combined with increasing use of artificial intelligence and machine learning and new ways of doing research and analyzing data in this field create the potential to achieve the dream of reducing the prevalence of disorders and improving health in populations. Among the many advantages of digital technology is that preventive and clinical interventions can now be integrated into health care and community delivery systems: both are needed to reduce prevalence. We describe a new model—called Prevalence Reduction Through Outcome Optimization (PRTOO)—that uses prevalence, risk, reach, outcome, uptake, engagement and client/stakeholder input data, all continuously monitored, to inform prevention and intervention decisions. The application of aspects of this model is presented through a series of studies design, in part, to reduce prevalence of eating disorders in populations. The models include the application of PRTOO approaches to: (a) College and university populations of students with eating disorders, where a series of strategies were used to boost initial engagement rates from < 64% to >75% (uptake, engagement and outcome data will also be presented for this study); (b) National eating disorder screening efforts, where treatment options are being developed to increase uptake for the 100K+ individuals who screen positive for eating disorders each year, but who are not in treatment (baseline uptake rates will be presented.); and (c) A state-wide initiative where a combination of universal, targeted and indicated preventive and clinical interventions are offered to all students who screen positive for eating disorders in any of the state colleges or universities. While promising, PRTOO and other models of data-driven intervention improvement, will require further development and new methods of funding.

USING DIGITAL TECHNOLOGY TO IMPROVE ESSENTIAL CARE DELIVERY AMONG THE RURAL POPULATION: THE SINEMA MODEL FOR EMPOWERING BOTH PROVIDERS AND PATIENTS

Enying Gong, MSc¹, Wanbing Gu, Ms², Lijing Yan, PhD, MPH²

¹University of Melbourne, Melbourne, Victoria, Australia; ²Duke Kunshan University

The fast-growing mobile health technology provided a promising tool to address the barriers that hinder the prevention and management of chronic conditions. Most of existing mhealth interventions for chronic disease prevention and control in low- and middle-income countries focused on message-based health education program, while few of the existing solutions provide a system-approach solution to address the barriers at all system, providers' and patients' levels to promote disease management. The system-integrated technology-enabled model of care (SINEMA) is an innovative model designed to improve stroke secondary prevention in rural China with intervention components targeted on both providers and patients. The SINEMA model is supported by a digital health system that seamlessly integrated customized Android-based smartphone App for primary care providers and voice-messages for stroke patients. The SINEMA model was implemented in Nanhe County, rural China and was evaluated through a cluster-randomized controlled trial lasted for 12 months among fifty villages with 1299 stroke patients. The providers' follow-up survey demonstrated that the intervention resulted to an improvement in stroke care-related knowledge ($P=0.09$), more positive attitude on stroke care ($P=0.054$), and stronger confidence in patients' management ($P=0.009$) among village doctors in the intervention arm compared with control arm. Village doctors in the intervention arm also stated in the interviews that the SINEMA model improved their awareness on stroke patients' care, resulted in a better patient-doctor relationship, created new communication channels for provider-provider communication. The SINEMA intervention resulted in a modest but significant intervention effect on systolic blood pressure ($P=0.005$) among patients. The interview among patients revealed that voice-messages play as a reminder to supplement the frequent follow-up visits and improved patients' adherence to treatment, which was consistent with the quantitative findings on medicine use ($P<0.05$ for hypertensive medicine and aspirin) and medication adherence ($P<0.04$ for statin) between the two arms. As proven effective, the SINEMA model provides a solution for resource-limited settings with the potential of empowering existing primary healthcare providers and improving health outcomes among stroke patients.

Symposium 59

2:00 PM-3:15 PM

ENHANCING ACCOUNTABILITY AND REVIEW IN BEHAVIORAL RESEARCH

Valerie Durrant, Ph.D.¹, William T. Riley, Ph.D.¹, Christine M. Hunter, PhD², Kenneth E. Freedland, PhD³

¹National Institutes of Health, Bethesda, MD; ²Office of Behavioral and Social Sciences Research, National Institutes of Health, Bethesda, MD; ³Washington University School of Medicine, Saint Louis, MO

Behavioral research represents nearly \$5 billion of National Institutes of Health (NIH) grant funding each year. The goal of this funding is to produce a substantial and sustained impact on science and public health. This symposium will address areas for enhancement in innovation, accountability, and impact through recent findings on the innovation of behavioral intervention research and on the timely publication of grant-supported research as well as NIH efforts to better balance and align the content and scientific productivity of NIH study sections. Dr. Durrant will present on the Center for Scientific Review ENQUIRE initiative, a new continuous quality improvement effort to balance study sections by content areas and scientific productivity. Dr. Riley will present analyses of the proportion of R01 behavioral research grants that fail to publish in a timely manner and predictors of lag to publication. Dr. Hunter will present analyses of recently NIH funded behavioral clinical trials and the proportion testing novel intervention components or packages vs. adaptations of existing interventions. The discussant, Kenneth Freedland, will discuss potential implications of these initiatives and findings with a focus on opportunities to achieve greater accountability and productivity in future behavioral research.

CORRESPONDING AUTHOR: William T. Riley, Ph.D., National Institutes of Health, Bethesda, MD; wiriley@mail.nih.gov

1 2:00 PM-3:15 PM

CONTINUOUS QUALITY IMPROVEMENT AT THE NIH CENTER FOR SCIENTIFIC REVIEW: ENQUIRE

Valerie Durrant, Ph.D.¹¹National Institutes of Health, Bethesda, MD

The NIH Center for Scientific Review (CSR) reviews 77% of the applications submitted to NIH, including most investigator-initiated research applications, in over 200 chartered or recurring scientific review groups (SRGs). The scientific merit of an application as assessed by study sections is a key consideration in the ultimate funding decision, and CSR and NIH have a keen interest in assessing SRGs and their outcomes. CSR has recently initiated the ENQUIRE (Evaluating Panel Quality in Review) process, a two-stage strategic process involving multiple stakeholders to examine the scientific scope, review outcomes, and procedural effectiveness of scientifically-connected groups of study sections. This presentation will provide an overview of the ENQUIRE process and the results of the process for a cluster of study sections related to health care delivery, patient management, and health behaviors conducted in 2019—highlighting the key considerations, rationale, and timeline for expected changes.

2 2:00 PM-3:15 PM

ZERO PUBLICATIONS FROM R01 BEHAVIORAL RESEARCH

William T. Riley, Ph.D.¹, Sara Hargrave, Ph.D.²¹National Institutes of Health, Bethesda, MD; ²National Cancer Institute

Publishing study results is one of the most established methods for providing research transparency. Despite the importance of reporting or publishing results to research transparency and to a cumulative science that builds on prior research, studies of clinical trials have shown that between a third to a half fail to publish findings of the primary outcome in a timely manner (i.e., 2 to 3 years from the end of the project). Given the increased emphasis of scientific productivity as a criterion for evaluating and enhancing NIH study sections, the Office of Behavioral and Social Sciences Research (OBSSR) analyzed the publication records of R01 and U01 grants to determine the proportion behavioral and social science grants that do not publish in a timely manner. Using all R01 NIH funded grants in the last decade, the months from the end of the project period to the first publication associated with the grant were calculated. Approximately 10% of behavioral R01 grants had not published within 2 years from the end of the project and this percentage was slightly higher than the zero publication rate of grants not coded as behavioral. Survival analyses and Cox Proportional Hazard analyses were used to estimate the lag time to publication and predictors of the lag to publication and failure to publish in a timely manner.

3 2:00 PM-3:15 PM

INTERVENTION INNOVATION IN BEHAVIORAL CLINICAL TRIALS FUNDED BY THE NIH

Christine M. Hunter, Ph.D.¹, William T. Riley, Ph.D.², Farheen Akbar, MPH³¹Office of Behavioral and Social Sciences Research, National Institutes of Health, Bethesda, MD; ²National Institutes of Health, Bethesda, MD; ³National Institutes of Health, Rockville, MD

The NIH has placed considerable emphasis on the translation of basic science findings to new intervention components or packages. This basic to applied translation is a scientific priority of the Office of Behavioral and Social Sciences Research (OBSSR) and is a core principle of the NIH Science of Behavior Change Common Fund initiative. A number of behavioral intervention development frameworks have also been proposed by the NIH. To assess if this focus on innovative intervention development has resulted in grants that evaluate new intervention components or packages, funded behavioral and social science grants from fiscal year 2018 that indicated they were clinical trials were evaluated by subject matter experts. If the grant focused on testing a social or behavioral intervention, the focus of the grants were manually coded as testing: 1) a new intervention component or package, 2) an adaptation of existing intervention components or packages to a new population, setting, mode of delivery, or disease area or 3) an existing intervention (e.g., pragmatic trial, comparative effectiveness, implementation science). Results of this analysis will be presented, and the implications for advancing behavioral intervention science will be discussed.

Symposium 60 2:00 PM-3:15 PM

HOW DOES YOGA INFLUENCE HEALTH AND WELLBEING? A FOCUS ON MECHANISMS OF EFFECT

Lisa A. Uebelacker, Ph.D.¹, Erik Groessl, Ph.D.², Crystal L. Park, Ph.D.³, Suzanne Danhauer, Ph.D.⁴¹Brown University and Butler Hospital, Providence, RI; ²UC San Diego, La Jolla, CA; ³University of Connecticut, Storrs Mansfield, CT; ⁴Wake Forest School of Medicine, Winston Salem, NC

Evidence regarding yoga's beneficial effects on health in myriad populations is rapidly increasing (Gerber, 2018). Yet because most yoga research has focused on evaluating its efficacy or effectiveness for producing positive health outcomes, our understanding of *how* yoga brings about these effects remains quite limited. Identifying the mechanisms through which yoga operates will allow interventionists to optimize the yoga delivered, potentiating its effects. In this symposium, three presenters will describe results of their studies that address yoga's mechanisms of effect. In the first presentation, Lisa Uebelacker will describe qualitative results of a study of people with chronic pain and in medication-assisted treatment for opioid use disorder who participated in the yoga arm of a 12-week pilot RCT. Participants identified multiple potential mediators, including cognitive processes such as an increased ability to focus their thoughts and reduced anxiety and physical tension. Erik Groessl will then describe results of an RCT of military veterans with chronic low back pain (CLBP). Results suggest that yoga reduces disability in veterans with CLBP by reducing fatigue and pain severity. In the last presentation, Crystal Park will describe psychosocial mechanisms of a mindful yoga intervention to reduce stress; particularly notable was mediation of reduced stress through improved spiritual wellbeing and interoceptive awareness, but not mindfulness. Our discussant, Suzanne Danhauer, will integrate these findings on yoga's mechanisms of action and highlight directions for future research.

2:00 PM-3:15 PM

POSSIBLE MECHANISMS OF ACTION OF YOGA FOR PEOPLE WITH CHRONIC PAIN IN MEDIATION-ASSISTED TREATMENT FOR OPIOID USE DISORDER: A QUALITATIVE STUDY

Lisa A. Uebelacker, PhD¹, Donnell Van Noppen, BA², Genie Bailey, MD³, Geoffrey Tremont, PhD⁴, Ana M. Abrantes, PhD⁵, Michael Stein, MD⁶¹Brown University and Butler Hospital, Providence, RI; ²Butler Hospital, Providence, RI; ³Stanley Street Treatment & Resources, Fall River, MA; ⁴Brown University/ Rhode Island Hospital; ⁵Brown University / Butler Hospital, Providence, RI; ⁶Boston University School of Public Health, Boston, MA

Yoga participants may have insights into cognitive, affective, or other mechanisms that explain the impact of yoga on chronic pain. We conducted interviews with people with chronic pain who were in medication-assisted treatment for opioid use disorder, and who participated in a pilot randomized clinical trial of 12 weeks of hatha yoga for chronic pain vs. a health education control group. Eighteen of 20 participants assigned to the yoga arm completed the interview after their final class. Research staff asked participants about what they liked and did not like about the program; how the yoga program helped participants to improve their health or live with pain; what yoga practices they engaged in at home; and what components of yoga were most helpful and why. Research staff audiorecorded and transcribed interviews. We then created a codebook and coded participant quotes. We report key codes related to possible mechanisms of action here. Participants stated that both *asanas (postures)* and *breathing practices* were helpful. Asanas helped to decrease pain or tension in specific parts of the body. Different participants mentioned different asanas; no one asana stood out as most helpful. Participants expressed pride in the fact that they were engaging in a practice that *improved aspects of physical health*, including balance, strength, or posture. Overall, yoga practices, and especially breathing practices, helped participants to *feel less emotionally anxious* and to *decrease physical tension* within their bodies; this is one way in which yoga might lead to decreased pain or decreased pain-related impairment. Participants also talked about *changes in cognitions and cognitive processes*: i.e., an increased ability to focus their thoughts, shift the (negative) way they were thinking, pay attention to and accept their bodies, and feel a sense of accomplishment. These cognitive changes may also lead to decreased pain-related impairment. Notably, whereas many participants said that yoga practices had a positive impact on *pain severity*, a few stated that they were afraid to try or continue yoga because they thought it might increase physical pain. In sum, participants commented on numerous ways in which yoga may decrease pain or pain-related disability, including improved physical health, decreased anxiety, decreased physical tension, and change in cognitions or cognitive processes. Asanas also directly and immediately relieved specific pain for some participants.

2:00 PM-3:15 PM

EXPLORING THE MECHANISMS OF YOGA FOR REDUCING DISABILITY IN VETERANS WITH CLBP

Erik Groessl, PhD¹, Adhana McCarthy, PA-C, MPA², Lin Liu, PhD¹¹UC San Diego, La Jolla, CA; ²UC San Diego

Military veterans have higher rates of chronic low back pain (cLBP) than non-veterans, and treatment options such as opioid medications have limited effectiveness and major side effects. Yoga has improved cLBP in non-veterans, but insufficient prior research exists with military veterans. In 2017, we completed an RCT of yoga with 150 military veterans with cLBP who were randomized to either yoga or a delayed-treatment group. Yoga sessions were provided 2x weekly for 12 weeks and home practice was encouraged. Assessments occurred at baseline, 12-weeks, and 6-months. Participants were a mean of 53.4 years old, 26% female, 51% non-White or Hispanic, 18% homeless in last 5 years, 20% taking opioids, and mean cLBP duration of 15 years. The yoga group reported significantly greater improvements in disability, pain severity and interference, fatigue, and quality of life. Here, we examine the mechanisms by which yoga reduced back pain-related disability (primary outcome).

Disability was measured with the Roland-Morris Disability Questionnaire. Pain was measured with the Brief Pain Inventory. Fatigue was measured with the Fatigue Severity Scale. Physiological measures included grip strength, balance, and flexibility. To examine the potential mechanisms by which yoga improved disability at 24 weeks, we used mediational analyses conducted using R software. First, we selected mediator variables from secondary outcomes that were correlated with disability scores and on which the yoga group had significantly greater change at 12- or 24-weeks. Pain severity and fatigue met the criteria. We then ran parallel and sequential mediational analyses. In the parallel analysis, the mediational effect of yoga through fatigue was significant ($p = 0.038$) and the mediational effect of pain severity trended towards significance ($p = 0.070$). The remaining direct effect of yoga on disability was not significant ($p = 0.116$). In the sequential analysis, the total mediated effect of yoga through pain severity and fatigue was significant ($p = 0.003$) while the direct effect remained unchanged.

In conclusion, data suggest that two mechanisms by which yoga reduces disability in veterans with cLBP are by yoga's effect on fatigue and pain severity while other direct effects of yoga were no longer significant. Physiological pathways were not significant here but may still be important. Pain is an expected mediator but our finding that fatigue was the most important factor measured is novel.

3

2:00 PM-3:15 PM

PSYCHOSOCIAL MECHANISMS OF STRESS REDUCTION IN HIGHLY STRESSED ADULTS IN A 12-WEEK KRIPALU YOGA INTERVENTION

Crystal L. Park, PhD¹, Lucy Finkelstein-Fox, M.S.², Tosca Braun, PhD³, Sara Lazar, PhD⁴¹University of Connecticut, Storrs Mansfield, CT; ²University of Connecticut, Storrs, CT; ³Brown University; ⁴Massachusetts General Hospital

Although many studies have demonstrated that yoga interventions are effective at reducing stress, very little of this work has identified the mechanisms by which stress reduction is brought about. Understanding how yoga works is essential to optimizing yoga interventions. In the present study, we aimed to advance our understanding of yoga's mechanism of effects by testing five potential mediators that have been proposed to explain yoga's impact on stress. These mediators included increased self-control, mindfulness, interoceptive awareness, spiritual well-being, and ability to relate to others.

Methods: 41 participants (70% female; 63% White) who were enrolled in a yoga program to reduce stress at two study sites (one urban, one rural) completed self-reported validated surveys at baseline (T1), 8 weeks (T2), 12 weeks (T3; post-intervention), 16 weeks (T4; follow-up). Paired sample t-tests probed T1-T3 change, T1-T4 change, and T3-T4 maintenance. To assess hypothesized mechanisms, T3/T4 scores were regressed on T1 to generate standardized change residuals, then correlated.

Results: Reduction in stress as measured by the Perceived Stress Scale (PSS; Cohen, 1994) from T1 to T3 (although ns) was significantly associated with increased interoceptive awareness (MAIA; Mehling et al., 2012) and spiritual well-being (FACIT-Sp; Peterman et al., 2002) from T1 to T3 ($p < .05$). None of the potential mechanisms was a significant correlates of change in PSS from T1 to T4 (although this change was statistically significant, $p < .05$). Reduction in stress as measured by the DASS (Lovibond & Lovibond, 1984) from T1 to T3 was significant ($p < .05$) and similarly significantly associated with increase in interoceptive awareness and spiritual well-being from T1 to T3. Reduction in DASS stress from T1 to T4 (also statistically significant, $p < .05$) was significantly associated with increases in spiritual well-being from T1 to T3 and T1 to T4, increase in self-control (BSCS; Tangney, Baumeister, & Boone, 2004) from T1 to T4, and increases in ability to relate to others (Experiences in Close Relationships Scale-avoidance (Fraley et al., 2000) from T1 to T4. Change in mindfulness (FFMQ; Baer et al., 2006) was not significantly related to changes in either stress measure. All significant pre-post changes in psychosocial mechanisms were maintained from T3 to T4.

Conclusion: Results provide inferential support for psychosocial mechanisms through which yoga may reduce stress in highly stressed adults. These mechanisms provide important clues for finetuning interventions; for example, implementing yoga interventions a greater focus on spiritual well-being or interoceptive awareness may show stronger stress reduction effects. Future research should test these hypotheses more rigorously using active controls and larger sample sizes.

Symposium 61

2:00 PM-3:15 PM

TRANSDISCIPLINARY INNOVATIONS TO ASSESS AND CHANGE LOCAL AND GLOBAL FOOD SYSTEMS TO SUPPORT HEALTHY EATING

Kayla de la Haye, PhD¹, Donna Spruijt-Metz, MFA, PhD¹, Abigail L. Horn, PhD¹, Bruce Lee, MD, MBA², Simone A. French, PhD³¹University of Southern California, Los Angeles, CA; ²CUNY, Baltimore, MD; ³School of Public Health University of Minnesota, Minneapolis, MN

The environments and systems in which people acquire and consume food profoundly influence diet and health because they shape food availability and accessibility, and they embody the social and choice architectures that influence eating decisions and habits. Many features of social, built, and macro environments have been associated with unhealthy eating, because they make it difficult to acquire healthy food and regularly cue unhealthy eating. Exposure to these environments has been associated with increased risk for diet-related diseases such as obesity, diabetes, heart disease, and cancer, and this risk is concentrated among communities that are low-income communities and of color, contributing to inequities in nutritional health.

However, our understanding of the ways in which people *interact* with these complex eating and food environments, the *dynamics* of eating behaviors in these systems as they unfold over time, and how these *multi-level processes* occur at a population scale, is nascent. There is now exciting potential to explore these research questions, which grapple with spatio-temporal contexts, system dynamics, and population-level phenomena, by combining behavioral medicine with mobile technology, big data, and novel systems science and data science methods. This knowledge has the potential to inform multiscale, whole-of-system interventions that effectively and sustainably promote healthy eating among priority populations.

In this symposium we present and discuss transdisciplinary team science that draws on innovative data, methods, and technologies to understand and intervene on eating behavior in the context of local and global system dynamics. Presenters with expertise in eating behavior, mobile health, data science, and systems science, present new research on eating behaviors and interventions in the context of dynamic family systems, built food environments, and macro-policy environments. A cross-cutting theme in each project is a focus on priority populations, and how innovations to monitor and modify eating in complex systems can inform efforts to reduce nutritional health disparities. Critically, we discuss the potential for this work to generate new insights and theoretical perspectives of eating behaviors that are embedded in time and context, and the role for this work to inform whole-system interventions and policy that leverage technology, big data, and transdisciplinary science to support healthy eating.

MONITORING AND MODELING FAMILY EATING DYNAMICS IN REAL TIME USING MOBILE HEALTH TECHNOLOGIES

Donna Spruijt-Metz, MFA, PhD¹, Kayla de la Haye, PhD¹, Brooke Bell, BA², Abu Mondal, BS³, Meiji Ma, BS³, Ridwan Alam, n/a⁴, John Lach, PhD³, John Stankovic, PhD⁵

¹University of Southern California, Los Angeles, CA; ²University of Southern California; ³University of Virginia; ⁴University of Virginia, Charlottesville, VA; ⁵University of Virginia, Earlysville, VA

Family eating dynamics have been shown to influence eating behaviors and even impact obesity, but until recently, these dynamics could only be assumed based on in-lab or in-home observation, or snapshots of these processes captured using questionnaires. We developed the Monitoring and Modeling Family Eating Dynamics (M2FED) sensor system to enable ubiquitous, real-time observations of several theoretically-important aspects of family eating dynamics in the home. M2FED captures individual eating behaviors, which family members eat together and when, moods and stress levels of individual family members during eating episodes, and eating in the absence of hunger. To do this the M2FED system includes multiple sensor components: smart watches trained to detect individual eating events; beacons placed in the home to spatially locate family members; and smartphones equipped with the M2FED app that triggers Ecological Momentary Assessments according to a combination of sensed eating events and a timed schedule to evaluate mood and stress. To integrate and analyze this information, the system also includes a CPU placed in participant's homes and a Cloud-based dashboard and storage capability.

M2FED has been deployed in the homes of 15 Latino families in Los Angeles (with 36 adults and 29 children participating), with each deployment lasting approximately two weeks. This talk will provide an overview of the data captured on these 15 families, and how they came together over food, when, with whom, and in what state (i.e. mood, stress), and how that was related to eating in the absence of hunger among family members. We will discuss the advantages and challenges of using new technologies to understand family eating dynamics in real time, including the interactions and trade-offs between the data that is needed to understand dynamic processes, participant burden, and the re-development of theory that can encompass the dynamic nature of eating behaviors within social systems.

2:00 PM-3:15 PM

OBJECTIVE MEASUREMENTS OF FOOD ENVIRONMENT EXPOSURE AND ACCESS IN LOS ANGELES FROM BIG MOBILITY DATA

Abigail L. Horn, PhD¹, Kayla de la Haye, PhD¹, Esteban Moro, PhD², John Wilson, PhD³, Thomas Valente, PhD¹, Burcin Bozkaya, PhD², Moshen Bahrami, PhD², Sandy Pentland, PhD⁴

¹University of Southern California, Los Angeles, CA; ²MIT Media Lab; ³University of Southern California; ⁴MIT Human Dynamics Laboratory

Food environments—the spaces in which people acquire and consume food—profoundly impact diet and related diseases. However, measures of food environments typically focus on assumed exposures within predefined static locations, predominantly neighborhoods, and there is a lack of evidence about where people move around to access food. Big data on human mobility combined with spatiotemporal data science methods represent a new paradigm to provide objective, population-level measurements of the food outlets people are exposed to along their daily routes (activity-space food environments) and the food outlets that they actually visit (food foraging), and to study how these patterns relate to demographics, built environments, and ultimately nutritional health.

Working with an interdisciplinary team of scientists in public health nutrition, food system modeling, and data/computer science, we use a massive data set on individual mobility to characterize patterns of activity-space food environments and food foraging at an unprecedented scale and resolution in both time and space. We use a U.S.-wide dataset of mobility records collected on smartphones and shared by a mobile location service company through a Data for Good Initiative. This study focuses on a subset of these records for a representative sample of around 700,000 adult Los Angeles (L.A.) residents over a six-month period (2016-2017), and which includes geolocation every 5 or so minutes for each person. By combining this granular data with comprehensive “points of interest” databases we can detect billions of visits to geolocated food outlets (e.g., grocery stores, restaurants, corner stores). Although anonymous, the mobility data allows us to determine where each individual lives, works, and carries out routine activities. We use this information to characterize and model the activity-space food environments and food foraging patterns of these L.A. residents, and to explore differences in these patterns based on socio-demographics. We will discuss how these findings can advance our understanding of how diverse populations use food environments, and how mobile food environment exposures and accessibility impact nutritional health. More generally, we will discuss opportunities and limitations of mobility data science approaches as well as technical and ethical considerations in acquiring and using this type of data for health behavior research.

3

2:00 PM-3:15 PM

FOOD SYSTEMS MODELS TO INFORM INTERVENTIONS AND POLICY

Bruce Lee, MD, MBA¹, Sheryl Siegmund, BS, mS², Kelly O'Shea, BSFS², Marie Ferguson, MSPH²¹CUNY, Baltimore, MD; ²CUNY

Dietary behaviors are complex systems and can be affected by complex systems. This includes biological, psychological, social, environmental, economic, and other systems. Unaided, considering all of these different systems and processes when designing policies and interventions can be challenging, if not infeasible. The risks of not considering and addressing these systems include developing band-aids rather than solutions, implementing unsustainable solutions, having unintended consequences, and wasting considerable time, effort, and resources through trial and error. Systems science approaches such as mapping and computational modeling can help better understand and address these systems. We have entered an era where the explosion in information, including Big Data and new ways to collect data, and computational advances have made such systems methods even more powerful. This presentation will review examples of how we have used such systems methods to determine appropriate diet-related policies and interventions, across several multi-scale contexts. One example is simulating and quantifying the resulting impact of changes in body mass index for a person at different ages. Another example is measuring the potential effects of a sugar-sweetened beverage warning label policy, in San Francisco, Baltimore, and Philadelphia. A third is a simulation study that uses agent-based models to demonstrate how current infant feeding recommendations could lead to unhealthy child weight trajectories, because they may not be taking into account variations in infant and family circumstances. Together, these examples highlight the immense potential for multidisciplinary teams using innovations in systems thinking and modeling to develop more effective and sustainable system-oriented interventions for nutrition.

Symposium 62

2:00 PM-3:15 PM

VACCINE HESITANCY AND SOCIAL MEDIA: LOOKING TOWARD A PUBLIC HEALTH AGENDA

Sherry Pagoto, PhD¹, Jasmin Tiro, PhD², Jeanine D. Guidry, PhD³, Beth L. Hoffman, MPH⁴, Bernard F. Fuemmeler, PhD, MPH³¹University of Connecticut, Storrs, CT; ²University of Texas Southwestern Medical Center, Dallas, TX; ³Virginia Commonwealth University, Richmond, VA; ⁴University of Pittsburgh, Pittsburgh, PA

In 2011, The Center for Disease Control listed vaccines as one of the 10 biggest public health achievements of the 20th century. Over the next few years, myriad infectious disease outbreaks occurred as a result of vaccination rates dipping below herd immunity thresholds. In 2019, the World Health Organization listed vaccine hesitancy among the top public health threats of the year. Despite widespread consensus within the medical community on the effectiveness and safety of vaccines, Web 2.0 technologies have allowed vaccine myths to spread as widely as the viruses they were designed to eradicate. This is not the first emergence of vaccine myths, such phenomena have been observed as far back as when the earliest vaccines were introduced in the 1700's. The goal of this symposium is to feature cutting edge research about vaccine myths and social media and to place it into historical context so as to generate a discussion about messaging strategies and policy approaches that leverage the new media environment to increase vaccine uptake. The first presenter will discuss her data on how vaccine hesitancy is actually a heterogeneous phenomenon. In an elegant latent class analysis, she portrays six shades of hesitancy among 1,193 parents in Texas and then explores the degree to which each is associated with beliefs in anti-vaccine content on social media. The second speaker will present a quantitative analysis of 500 HPV vaccine-related posts on the social media platform, Pinterest, prior to their recently imposed restriction on vaccine-related content. Unfortunately, only 3% of HPV vaccine-related posts were from official medical entities and none from government organizations. As such, nearly two-thirds of posts portrayed HPV vaccines as a threat to human health. This points to a dire need for public health organizations to take a more proactive role in leading the public narrative about vaccines. Finally, the third speaker will present her work exploring the historical context of the anti-vaccination movement. Her research reveals that as far back as the year 1721 anti-vaccine messages were being disseminated via the media. Given the reach of social media, such anti-vaccine messaging now has the ability to disseminate further and more quickly. The discussant and chair will synthesize this innovative blend of mixed methods research to put forth a research and public health agenda on vaccine hesitancy on social media. Given the modern nature of this problem and the need for modern solutions, this symposium is squarely in line with the Society of Behavioral Medicine Presidential Annual Meeting theme of discovering innovative solutions to tomorrow's health problems.

ATTITUDES DRIVING VACCINE HESITANT BEHAVIOR AMONG PARENTS: A LATENT CLASS ANALYSIS

Jasmin Tiro, PhD¹, Serena Rodriguez, PhD, MPH², James Michael Blackwell, MPH³, Sharice Preston, PhD⁴, David Monticalvo, MPH², Erika Thompson, PhD, MPH, CPH⁵, Jenny Francis, MD, MPH⁶, Sandi Pruitt, PhD²

¹University of Texas Southwestern Medical Center, Dallas, TX; ²University of Texas Southwestern Medical Center; ³University of Texas southwestern medical center; ⁴University of Texas Health Science Center at Houston, Houston, TX; ⁵University of North Texas Health Science Center; ⁶University of Texas Southwestern Medical Center; Children's Medical Center

Vaccine-hesitant parents are a heterogeneous group, and may be susceptible to misinformation on social media. We used scales measuring different aspects of vaccine hesitancy (general vaccine attitudes, conspiracy beliefs, and social media misinformation attitudes) to: (1) identify subtypes of vaccine hesitant attitudes, and (2) examine which subtypes are associated with hesitant behavior.

Methods: Via mail and email, we invited parents of adolescents living in North Texas to complete an online survey between April-Jun 2019. Items assessed vaccine hesitant behavior: (1) "ever delayed having," and (2) "ever decided not to have" your child get a vaccine (Yes/no/don't know). We measured beliefs with: (a) Opel's general vaccine attitudes scale; (b) Shapiro's vaccine conspiracy beliefs scale (Shapiro); and (c) credibility of HPV vaccine information on social media. Trust in provider was also measured. Latent class analysis and logistic regression were used for data analysis.

Results: 1,193 responded, most were mothers (65.6%), non-Hispanic white (60.0%), and college graduates (62.6%). About half (55.3%) reported their adolescent had not started the HPV vaccine series. Of the 660 parents of HPV-unvaccinated children, 25.8% reported delaying/refusing a vaccine at least once. In the total sample, we identified six classes of parents along the hesitancy continuum— (1) Very hesitant: endorses conspiracies; believes social media misinformation [7.9%]; (2) Very hesitant: endorses conspiracies especially about pharmaceutical companies, mixed beliefs about social media misinformation [13.7%]; (3) Moderately hesitant: endorses conspiracies [5.6%]; (4) Neutral about vaccines, conspiracies, and social media misinformation [10.5%]; (5) Not hesitant: does not endorse conspiracies, has mixed beliefs about social media misinformation [23.8%]; (6) Not hesitant: does not endorse conspiracies or believe social media misinformation [38.6%]. Despite these hesitant attitudes, a sizeable proportion of adolescents within each class were vaccinated (25.6% -73.4%). Trust in provider was lowest among parents in Class #2 ($P < 0.001$). Among the parents of unvaccinated children when compared to the neutral class #4, the very hesitant groups (Classes #1-2) were more likely to report hesitant behavior (aOR 3.30 and 4.98), while non-hesitant groups (Classes #5-6) were less likely to report hesitant behavior (aORs 0.72 and 0.29, respectively).

Conclusions: About 27% of parents were classified into a vaccine hesitant group that endorsed conspiracy beliefs; this population was mixed in whether they believed information on social media was credible. Social media campaigns targeted to parents in each of these six classes are needed. Messages addressing provider mistrust and pharmaceutical conspiracy beliefs should be developed to help parents manage vaccine misinformation found on social media.

VACCINE (MIS)INFORMATION AMONG RECIPES: A COMPARATIVE ANALYSIS OF HPV VACCINE POSTS ON PINTEREST BEFORE AND AFTER SEARCH TERM BLOCKING AND REINSTATEMENT

Jeanine D. Guidry, PhD¹, Emily Vraga, PhD², Linnea Laestadius, PhD³, Hannah Ming, MPH⁴, Yan Qin, MS⁵, Xiaoli Nan, PhD⁵, Carrie Miller, PhD⁶, Aurora Occa, PhD⁷, Bernard F. Fuemmeler, PhD, MPH¹, Kellie Carlyle, Ph. D.¹

¹Virginia Commonwealth University, Richmond, VA; ²University of Minnesota; ³University of Wisconsin; ⁴Virginia Commonwealth University; ⁵University of Maryland; ⁶Virginia Commonwealth University, Glen Allen, VA; ⁷University of Kentucky

Background: Despite widespread consensus within the medical community on the effectiveness and safety of vaccines, vaccine myths are prevalent on social networking sites. Recent studies have primarily focused on factual misinformation in the text of posts shared on social media. However, visual-based social media platforms, such as Pinterest, may produce unique insights into how misinformation about vaccines is spread. This study investigates (mis)information regarding human papillomavirus (HPV) vaccine on Pinterest, comparing HPV vaccine (mis)information on Pinterest prior to and after the platform took action to limit vaccine misinformation.

Method: A quantitative content analysis of 500 HPV-vaccine-related Pinterest posts was conducted using keywords "HPV vaccine" and "HPV vaccination" (both n=250) in late 2018. A follow-up analysis of a 250-post sample collected using keyword HPV vaccination in August of 2019 is ongoing, to assess differences between this newly collected sample and HPV vaccination posts from the first sample (n=250).

Results: Among the 500 visual posts of the first sample, most originated with individuals, with only 3% from official medical entities and none from government entities such as the CDC. Moreover, misinformation was prevalent among the posts, with 65.4% portraying the HPV vaccine as a threat and 13.9% discussing conspiracy theories related to the HPV vaccine. Additionally, 56.1% referred to adverse reactions to the vaccine, including death. Finally, 32.5% contained potentially fear-inducing material such as a large needle. Mann Whitney U tests showed that pins containing the threat of the HPV vaccine, photos/names of presumed HPV vaccine victims, HPV vaccine adverse reactions, and fear visuals produced significantly more engagement than pins that did not contain these elements.

Conclusion: In the first sample, HPV vaccine skepticism was prevalent and associated with higher engagement on Pinterest. This portrayal of the HPV vaccine is concerning and may have accelerated the spread of misinformation. This portrayal helps justify Pinterest's actions to limit public exposure to this content. In the second sample, early findings suggest that searches for "HPV vaccine" are still disabled and that hits from the search "HPV vaccination" are trending toward the health benefits of vaccination. Early results suggest that platform-based interventions may be able to help reduce the spread of health-related misinformation. Public health professionals should add the Pinterest platform to their social media toolkit to help combat the spread of HPV vaccine misinformation.

2:00 PM-3:15 PM

VACCINE MISINFORMATION ON SOCIAL MEDIA: HISTORICAL CONTEXTS, LESSONS LEARNED, AND PATHS FORWARD

Beth L. Hoffman, MPH¹, Elizabeth Felter, DrPH, MPH, MCHES², Kar-Hai Chu, PhD¹, Chad Hermann, PhD³, Todd Wolynn, MD³, Jessica G. Burke, PhD¹, Jason Colditz, MEd¹, Riley B. Wolynn, n/a¹, Brian A. Primack, MD, PhD⁴

¹University of Pittsburgh, Pittsburgh, PA; ²University of Pittsburgh; ³Kids Plus Pediatrics; ⁴University of Arkansas, Fayetteville, AR

Introduction: While the presence of vaccine misinformation on social media is well-documented, less is known about the historical context of the anti-vaccine movement and strategies to effectively counter the spread of this misinformation. The purpose of this presentation is to (1) integrate findings from a previous study on vaccine misinformation on Facebook into a broader historical framework, and (2) discuss three approaches to counter the impact and spread of this misinformation.

Methods: A literature review was conducted for the historical overview, and results were synthesized with findings from a 2019 research study of 197 individuals who posted anti-vaccination comments on a Pittsburgh pediatric practice's Facebook page. These findings are influencing an ongoing collaboration between public health researchers and pediatricians to develop and pilot test interventions aimed at reducing the spread and influence of vaccine misinformation.

Results: Throughout history, the anti-vaccination movement has consistently used fear-evoking images, distortion of data, and personal narratives to spread misinformation; these same techniques are used today in Facebook posts containing vaccine misinformation. Facebook posts that were shared on multiple profiles in our sample (i.e., went “viral”) bore a striking resemblance to 1721 anti-vaccination headlines in the *New England Courant* and 19th century anti-vaccine newspaper cartoons. In September 2019, a rapid-response, pro-science social media network—the “Shots Heard” initiative—was launched to aid and support practices that sustain an anti-vaccine attack. It currently has over 230 members has already been activated to assist health professionals on both Facebook and Twitter.

Conclusions: Social media outlets facilitate anti-vaccination connection and organization, thus assisting in the amplification and diffusion of centuries-old arguments and techniques. These findings suggest the importance of understanding the history of the anti-vaccination movement when developing tools to counter vaccine misinformation on social media. Current efforts to curb the spread this misinformation include media literacy education and entertainment education interventions, as well as online practitioner collaborations.

Symposium 63

2:00 PM-3:15 PM

NEGATIVE AFFECT, QUALITY OF LIFE, AND IMMUNE FUNCTION IN CAREGIVERS OF CHILDREN WITH SPECIAL HEALTHCARE NEEDS

Mandy Bamber, PhD¹, Ross May, PhD², Isela Valera, PhD²

¹Florida State University College of Nursing, Tallahassee, FL; ²Florida State University, Tallahassee, FL

Objective: The primary aim of this study was to explore relationships between trait mindfulness, negative affect, caregiver burden, burnout, quality of life (QOL), and resiliency in informal caregivers of children with special healthcare needs (CSHCN). We also examined the effects of caregiver burden on immune, cytokine, and aortic function, and compared results to informal caregivers of typically developing children.

Background: Children with special health care needs have chronic physical, mental, behavioral, or developmental condition and require more health-related services. This population account for 18% of children and are typically cared for by family (informal caregivers). Informal caregivers neglect their own health and wellbeing, resulting in severe stress, illness, depression, and anxiety. Caregiver burnout leads to increased work absenteeism, social isolation, and increased hospital admissions for their loved one. The number of informal caregivers is growing exponentially, which substantially impacts our healthcare system. Informal caregivers can improve the wellbeing, QOL, and health outcomes of their loved ones and reduce healthcare costs through decreased hospital readmissions and long-term care in the home. However, the considerable risk to informal caregivers' psychological and physical health can be detrimental.

Methods: Fifty-six informal caregivers of typically developing and CSHCN were recruited to participate. Data was collected in a single time point. Participants completed measures for: negative affect, quality of life, caregiver burden, burnout, trait mindfulness, and resiliency. Aortic hemodynamics was collected using the Arteriograph24. A venous blood sample was collected to examine immune (IgG1, IgG2, IgG3, IgG4, IgA, IgM) and cytokine function (IL-4, IL-2, CXCL10 IL-1β, TNF-α, MCP-1, IL-17A, IL-6, IL-10, IFN-γ, IL-12p70, CXCL8, TGF-β1).

Results: There were no significant correlations or differences between groups on trait mindfulness and aortic hemodynamics. Significant correlations were present between trait mindfulness subscales: nonjudging with negative affect, QOL, resiliency, self-esteem, burnout, and burden; nonreactivity with self-esteem, negative affect, burnout, and burden; awareness with QOL, burden, & burnout; observing with QOL. Informal caregivers of CSHCN had greater negative affect, caregiver burden, physical burnout, increased IgG1, and decreased cytokine function (IL-1, TNF-α, IFN-γ, TGF-β, IL-2) compared to caregivers of typically developing children.

Conclusions: Caregiving significantly impacts physical and psychological health of caregivers. We plan to examine intracellular immune and inflammatory function to fully describe the effects of caregiving on these systems. Future studies should compare effects of self-help interventions on psychological and physical caregiver health.

NIH-DOD-VA PAIN MANAGEMENT COLLABORATORY: PRAGMATIC CLINICAL TRIALS OF NONPHARMACOLOGICAL APPROACHES TO PAIN MANAGEMENT

Robert Kerns, PhD¹, Julie M. Fritz, PT, PhD², Susan N. Hastings, M.D., M.H.S.³, Steven George, PT, PhD, FAPTA⁴, Wendy Weber, ND, PhD, MPH⁵, Daniel Rhon, DSc⁶

¹Yale, New Haven, CT; ²University of Utah, Salt Lake City, UT; ³Durham VA Center of Innovation, Durham, NC; ⁴Duke University, Durham, NC; ⁵National Center for Complementary and Integrative Health, Bethesda, MD; ⁶Brooke Army Medical Center, JBSA Fort Sam Houston, TX

Pain management is a high priority for the Departments of Health and Human Services, Defense (DoD) and Veterans Affairs (VA). Prevalence of pain and chronic pain are higher among veterans and military service members than civilians. High rates of medical and mental health comorbidities increase the complexity of the pain experience in these populations and add to the challenges of effective pain management. To address these challenges, DoD and VA have adopted the stepped care model of pain management and other guidelines and care pathways that emphasize timely and equitable access to integrated, patient-centered, evidence-based, multimodal and interdisciplinary pain care emphasizing nonpharmacological approaches and promotion of adaptive pain self-management. In 2017, these agencies partnered with the National Institutes of Health (NIH), especially the National Center for Complementary and Integrative Health (NCCIH), to fund the NIH-DoD-VA Pain Management Collaboratory (PMC) that supports design optimization and conduct of 11 pragmatic clinical trials of nonpharmacological approaches for managing pain and comorbidities in Veteran and Military Health Systems. This approximately \$81 million initiative addresses key scientific knowledge and practice gaps and supports DoD and VA pain strategic initiatives. Dr. Robert Kerns, one of 3 program directors for the PMC Coordinating Center, will chair the symposium and present the aims, structure and functioning of the Collaboratory and introduce the concepts of pragmatic clinical trials and their relevance for addressing the gap between evidence for nonpharmacological approaches and limited integration of these approaches into routine clinical care. Progress on multiple issues related to study design and biostatistics, phenotyping and outcomes, optimizing use of electronic health records, data sharing, ethical and regulatory challenges, stakeholder engagement and implementation science will be presented. Principal investigators from two trials being implemented in either VA (Drs. Susan Hastings and Steven George) and DoD (Drs. Julie Fritz and Daniel Rhon) will follow this overview and (1) describe their trials highlighting their key scientific knowledge gaps and aims to address them and innovative pragmatic design and methodological features and (2) present preliminary stakeholder data that informed modification of their trials to optimize successful trial implementation and impact. Dr. Wendy Weber, Project Scientist for the PMC and Clinical Research Branch Chief, Division of Extramural Research at NCCIH, will serve as discussant. She will provide additional background and context for the PMC initiative, highlighting important differences between explanatory and pragmatic clinical trials and the potential significance and innovation of the initiative.

SMART STEPPED CARE MANAGEMENT FOR LOW BACK PAIN IN MILITARY HEALTH SYSTEM

Julie M. Fritz, PT, PhD¹, Dan Rhon, PT, DSc²¹University of Utah, Salt Lake City, UT; ²Physical Performance Service Line, Office of the Surgeon General

Background: Chronic pain is a ubiquitous concern in civilian and military populations. Incident rates for chronic pain among active duty military members increased more than 3-fold from 2007 – 2014. More than half of veterans who served in recent deployments report chronic pain. The most common chronic pain diagnosis in the Military Health System (MHS) is low back pain (LBP). For active duty military, LBP has been the most common reason for a medical encounter every year since 2011, accounting for over 1 million encounters in 2015 at a cost of nearly \$1 billion in medical expenditures. LBP is also the leading cause of medical discharge across military services and is one of the leading causes of seeking healthcare or being evacuated from a combat theater. These factors along with the contribution of chronic LBP to the opioid crisis make the condition a priority for improvement in the MHS. The 2010 U.S. Army Pain Management Task Force report recommended a stepped care approach that begins with lower cost, readily available interventions followed by more intensive treatments for individuals who do not respond. A key challenge in implementing stepped care for LBP comes from the large number of interventions encompassed by each Step and a lack of information on comparative effectiveness, treatment tailoring and sequencing within Steps. Lack of guidance on what treatments to choose for a particular patient is a primary motivation for this project.

Aims and Objective: We will conduct a sequential multiple assignment randomized trial (SMART) trial comparing the effectiveness and cost-effectiveness of initial and follow-up treatments based on a stepped care model for patients with chronic LBP in the MHS using patient-centered outcomes and healthcare utilization including opioid use. Sub-aims will compare main effects of initial and follow-up treatment options and the sequencing effects of different treatment combinations.

Design & Methods: We will recruit active duty military members, family members, or Tricare beneficiaries receiving care for chronic LBP in an MHS facility. Participants will first receive 6 weeks of Phase I care with either physical therapy (PT) or Move to Health (M2H) interventions. The M2H intervention is a holistic well-being approach using motivational interviewing and goal setting to address lifestyle factors impacting chronic pain. After Phase I we will assess response to initial treatment strategy. Phase I responders will be receive up to 2 additional sessions of treatment to facilitate a transition to self-management. Phase I non-responders will be randomly assigned to a more intensive Phase II treatment of either mindfulness or a combined PT+M2H intervention. Phase II will last for 8 weeks with follow-up assessments at 18 weeks (conclusion of Phase II), 6 months and 12 months after enrollment. Outcomes include patient-reported measures and healthcare utilization and costs.

2

2:00 PM-3:15 PM

IMPROVING VETERAN ACCESS TO INTEGRATED MANAGEMENT OF BACK PAIN (AIM-BACK): A PRAGMATIC, CLUSTER RANDOMIZED TRIAL

Susan N. Hastings, M.D., M.H.S.¹¹Durham VA Center of Innovation, Durham, NC

Background: Low back pain (LBP) is among the most prevalent and disabling medical conditions experienced by Veterans. Improving patient care for LBP is a high priority for many federal agencies and recent clinical practice guidelines emphasize the importance of non-pharmacological management of LBP. However, optimal care pathways to enhance access to non-pharmacological treatments have not been well-established.

Aims: The primary study aim is to examine the effectiveness of two different guideline-concordant, clinical care pathways that emphasize the delivery of non-pharmacological treatment options for LBP. A secondary aim is to determine participant characteristics associated with greater improvements in pain interference and function, and better adherence to each care pathway.

Methods: A key activity during the study planning phase was stakeholder engagement. We conducted semi-structured individual telephone interviews (n=13) with health care professionals involved in LBP care, and a focus group (n=6) among patient-representatives and caregivers. Stakeholders were positive about the focus on multimodal non-pharmacological care and enthusiastic about a telehealth delivery approach. Key insights included framing of the mental health aspect in a non-stigmatizing manner and emphasis on communication skills among individuals delivering the care pathways. Based on stakeholder input care pathways were finalized into 1) Integrated Care Pathway characterized by early physical therapy/pain modulation, home based activity, risk stratification, and behavioral treatment (if indicated) and 2) Coordinated Care Pathway characterized by pain navigator coordinated care that includes shared decision-making and facilitated guideline-adherent referrals. During the next phase, we will conduct a 4-year embedded pragmatic trial in the VA health care system to compare the effectiveness of the two care pathways for LBP. Sixteen VA clinics will be randomized 1:1 to the Integrated Care or Coordinated Care Pathway. Veterans (n = 1680) will be followed for primary outcomes (PROMIS Short Form scores for pain interference and function) captured from the electronic health record and a subset (n = 840) will complete telephone interviews for additional patient-reported outcomes to augment electronic health record data.

Conclusions: A phased pragmatic clinical trial design allowed for early stakeholder engagement that enhanced development of multimodal non-pharmacologic treatment pathways. Future trials should account for the need to engage stakeholders early in the planning stages of studies that will be embedded within health systems. Trial results will provide critically needed information on best methods for improving LBP care for Veteran populations as well as inform the potential for matching Veteran subgroup characteristics to a specific care strategy for better outcomes.

Symposium 65

THE PROMISE OF PRAGMATIC TRIALS TO IMPROVE WOMEN'S HEALTH: CLOSING RESEARCH-TO-PRACTICE GAPS IN OBESITY & DIABETES PREVENTION

Susan D. Brown, PhD¹, Obidiugwu K. Duru, MD, MS², Monique Hedderson, MPH, PhD¹, Leanne Redman, PhD, FTOS³, Cheryl L. Albright, PhD, MPH⁴, Assiamira Ferrara, MD, PhD⁵

¹Kaiser Permanente Northern California, Oakland, CA; ²UCLA, Los Angeles, CA; ³Pennington Biomedical Research Center, Baton Rouge, LA; ⁴University of Hawaii at Manoa, Honolulu, HI; ⁵Division of Research, Oakland, CA

Certain risk factors for obesity and diabetes are unique to women, such as excess weight gain during pregnancy and gestational diabetes mellitus (GDM). Women also have unique interactions with healthcare systems and community programs across the life span. These touchpoints present opportunities to embed pragmatic trials of interventions with potential for broad reach and population health impact. Such trials may help close gaps between research and practice by testing scalable interventions designed with implementation in mind.

The goal of this symposium is to advance pragmatic research in women's health by discussing the design and methods of behavioral intervention trials in health care and community settings that target women's unique risk factors for obesity and diabetes. The symposium will begin by highlighting features of pragmatic trials and investigator resources that reflect the growing interest in pragmatic designs. Presenter 1 will discuss successes and challenges in the conceptualization and conduct of pragmatic research among women with GDM, including collaborations with health system leaders. Presenter 2 will describe how a cluster-randomized trial on shared decision-making in primary care clinics informed research to promote diabetes prevention health services among women with GDM. Presenter 3 will describe the rationale and methods for a pragmatic trial testing a mobile health (mHealth) weight management intervention among pregnant women with overweight or obesity in an integrated health system. Presenter 4 will describe engagement with community partners and stakeholders to develop a pragmatic, scalable, and patient-centered weight management intervention for pregnant women in the Louisiana Women's, Infants and Children (WIC) program, which is being evaluated in a state-wide randomized controlled trial. Finally, the Discussant will summarize lessons learned across trials and identify future opportunities for pragmatic prevention research in women's health.

SHARED DECISION MAKING IN DIABETES PREVENTION: HELPING WOMEN AT HIGH RISK CONSIDER BOTH LIFESTYLE CHANGE AND METFORMIN

Obidiugwu K. Duru, MD, MS¹, Tannaz Moin, MD, MBA, MSHS¹, Norman Turk, MS², Amanda Vu, PharmD², Dominick Frosch, PhD³, Kia Skrine Jeffers, PhD, RN⁴, Yelba Castellon-Lopez, MD⁵, Chi-Hong Tseng, PhD², Keith Norris, MD, PhD², Carol Mangione, MD, MSPH²

¹UCLA, Los Angeles, CA; ²UCLA Division of General Internal Medicine/Health Services Research; ³Palo Alto Medical Foundation Research Institute; ⁴UCLA School of Nursing; ⁵UCLA Department of Family medicine

More than 84 million Americans are at risk for diabetes. Few are receiving treatment to prevent it, and many are not aware they are at risk. The Diabetes Prevention Program (DPP) showed that both metformin and lifestyle change can help prevent diabetes, so it is important that patients and healthcare providers work together in a shared decision making (SDM) approach to decide which approach best matches the patient's diabetes risk as well as patient's needs and preferences. This is particularly true for women with a history of gestational diabetes mellitus (GDM), who are at particular risk of developing diabetes and for whom metformin and lifestyle change have similar effectiveness. Our research team recently conducted a cluster-randomized trial of SDM led by clinical pharmacists in 20 primary care practices in a large healthcare system. The study enrolled overweight/obese adults with prediabetes (BMI >24 kg/m² and HbA1c 5.7-6.4%) were enrolled from 10 intervention clinics. Propensity score matching was used to identify control patients from 10 usual care clinics. In the intervention, pharmacists engaged patients in a face-to-face SDM visit using a decision aid (DA) to describe prediabetes and four possible options for diabetes prevention; in-person DPP, in-person DPP +/- metformin, metformin only, or usual care. We found that among female participants who initiated diabetes prevention, 67% attended the DPP lifestyle change program while 44% started metformin, underscoring the importance of presenting both options to this population. We also found that in an intention-to-treat design, the mean weight loss at 12 month follow-up for women who participated in SDM, regardless of what strategy they chose, was -4.9 lbs. Based on these results, our team conducted a new follow-up pilot study specifically among a women with a history of GDM, who were at least 12 months post-partum. In this study, pharmacists shared the DPP and DPP Outcome Study data specific to the GDM subpopulation during the SDM sessions. The pilot study also included online DPP in addition to in-person DPP as lifestyle change options. The 29 study participants self-reported their race and ethnicity in separate categories: 13 were white, 11 Asian, 10 Latino and 2 African American. At the time of the SDM consult, 24 (83%) chose DPP, and 9 (31%) chose metformin, while only 2 (7%) declined starting either option. The great majority of the women who chose DPP selected the online option, as many said this best fit their schedule. We have also surveyed an additional 111 women with a GDM history, to better understand their perspectives on diabetes prevention and shared decision making. Based on these findings, our team is planning a larger SDM intervention for women with a GDM history, to help them understand the relative benefits of lifestyle change and metformin and make the personal decision they feel is best.

2

2:00 PM-3:15 PM

DEVELOPMENT AND TESTING OF AN ADAPTIVE INTERVENTION AMONG PREGNANT WOMEN WITH OVERWEIGHT OR OBESITY: A PRAGMATIC RANDOMIZED CONTROLLED TRIAL IN AN INTEGRATED HEALTH SYSTEM

Monique Hedderson, MPH, PhD¹, Assiamira Ferrara, MD, PhD², Susan D. Brown, PhD¹, Cheryl L. Albright, PhD, MPH³

¹Kaiser Permanente Northern California, Oakland, CA; ²Division of Research, Oakland, CA; ³University of Hawaii at Manoa, Honolulu, HI

Pregnant women with overweight or obesity are at high risk of perinatal complications. More than half of women with overweight or obesity exceed the Institute of Medicine (IOM) GWG guidelines, which further exacerbates their elevated risk of perinatal complications. Thus, there is an urgent need to help pregnant women with overweight and obesity achieve appropriate GWG. Traditional high-intensity interventions to improve GWG among overweight and obese women have achieved success but are too time intensive for some women. Emerging evidence and our pilot study suggest that mobile health (mHealth) interventions for weight management can be effective in pregnancy, but a large-scale randomized trial in the real-world clinical setting is needed. We will discuss the design and implementation of an ongoing pragmatic randomized controlled trial of pregnant women with overweight or obese women randomized to usual care or usual care plus an mHealth intervention. Here we describe the rationale and design of the intervention, developed in partnership with clinical leaders in a large integrated health system, to promote appropriate gestational weight gain. To increase scalability, an adaptive intervention that begins with an effective, yet low resource-intensive treatment and then provides incremental support and resources only to patients who need them will be discussed. Technology-based tools—including a mobile app, wireless “smart” scale, wearable activity tracker, and diet tracking app—will enable convenient self-monitoring, feedback, and goal setting. mHealth interventions offer a promising scalable solution to overcome patients’ and clinicians’ barriers to GWG management. If this mHealth intervention is proven effective, it could become a complementary part of clinical care, leading to better outcomes for mothers and their infants.

3

2:00 PM-3:15 PM

DEVELOPMENT OF A PRAGMATIC, SCALABLE, AND PATIENT-CENTERED WEIGHT MANAGEMENT INTERVENTION FOR PREGNANT WOMEN IN THE LOUISIANA WOMEN’S, INFANTS AND CHILDREN (WIC) PROGRAM

Leanne Redman, PhD, FTOS¹, L. Anne Gilmore, PhD, RD, LDN², Abby Altazan, MS², Emily Flanagan, PhD²

¹Pennington Biomedical Research Center, Baton Rouge, LA; ²Pennington Biomedical Research Center

Low income and minority women are the most vulnerable to maternal obesity, to excessive weight gain during pregnancy and poor birth outcomes and their children have the highest prevalence of childhood obesity. Evidence suggests that risks of maternal and childhood obesity and chronic disease can be attenuated by interventions in pregnancy that promote healthy gestational weight gain. Effective and scalable healthcare services developed specifically for under-served women during pregnancy is urgently needed to impact the health of future generations. The USDA Special Supplemental Nutritional Program for Women, Infants and Children (WIC), a vital service provider to approximately 15% of U.S. pregnancies per year, has an unprecedented opportunity to positively impact the inter-generational influences of poor nutrition during pregnancy and early childhood. In our previously funded research we developed and tested the efficacy of SmartMoms®, a novel e-Health intensive lifestyle intervention that relies on behavior change theory to promote healthy rates of gestational weight gain through a smartphone application. In a randomized controlled pilot trial, SmartMoms® significantly reduced the proportion of overweight/obese pregnant women with excess gestational weight gain by more than 30% according to the 2009 Institute of Medicine recommendations. Compared to an identical intervention delivered in-person, SmartMoms® fostered greater adherence and the cost to the participant was 3.5 times cheaper. SmartMoms® is scalable. Since participants are “mobile”, SmartMoms® has the potential to overcome many of the barriers to intensive lifestyle interventions reported in under-served women such as lack of transportation and time. With input from community and peer groups, SmartMoms® was adapted for under-served women by considering health literacy, cultural beliefs, behavior patterns and value systems in the design. Using formative research and systematic consultations with a Community Advisory Board and a WIC Peer Advisory Group we adapted SmartMoms® for low-income women. The stakeholder groups informed production of the SmartMoms® curriculum; a gamification component to incentivize participation; and helped to ensure cultural sensitivities and health literacy was incorporated in the intervention. An adapted SmartMoms® offers an innovative, cost-effective and scalable solution for gestational weight gain management in women served by WIC which is now being tested in a pragmatic, community-based randomized, clinical trial.

DIABETES PREVENTION AMONG WOMEN WITH GDM: DEVELOPING AND TESTING INTERVENTIONS AT THE HEALTH SYSTEM LEVEL

Assiamira Ferrara, MD, PhD¹

¹Division of Research, Oakland, CA

Women with obesity face increased risk for gestational diabetes mellitus (GDM), or diabetes first diagnosed during pregnancy. In turn, GDM markedly increases women’s risk for developing type 2 diabetes later in life. This presentation will discuss strategies for designing and implementing health system-based interventions aimed at breaking the cycle of obesity, gestational diabetes, and type 2 diabetes. Behavioral interventions that leverage electronic health records and care delivery via telemedicine will be discussed. Examples include health communication interventions to promote appropriate weight gain during pregnancy and telephone-based interventions adapted from the Diabetes Prevention Program curriculum. In particular, this presentation will focus on partnerships with clinical and operational leaders that are essential to the successful development and conduct of pragmatic trials in health system settings. This presentation will also highlight needs for future research, including the need for sustainable models of care that maximize patient and health provider satisfaction while minimizing cost.

STRESS FROM WITHIN: SEXUAL MINORITY MEN'S COMMUNITY AND ROMANTIC ATTACHMENTS AND HEALTH-RELATED RISKS

Ilan Meyer, Ph.D.¹, Brock Grecco, Master of Social Science², Bianca D. Wilson, Ph.D.³, Phillip Hammack, Ph.D.⁴, John Pachankis, Ph.D.⁵, Kirsty A. Clark, Ph.D., MPH⁶, Charles Burton, Ph.D.⁷, Tyrel J. Starks, Ph.D.⁸, Gabriel Robles, Ph.D.⁹

¹The Williams Institute, Los Angeles, CA; ²UCLA, West Hollywood, CA; ³The Williams Institute, CA; ⁴University of California, Santa Cruz, Santa Cruz, CA; ⁵Yale University, New Haven, CT; ⁶Yale University, New York, NY; ⁷Yale School of Public Health, New Haven, CT; ⁸Hunter College, CUNY, Brooklyn, NY; ⁹Hunter College, New York, NY, NY

Validated across hundreds of studies, minority stress theory has emerged as the predominant explanation for the substantial disparities in sexual minority mental (e.g., depression) and behavioral (e.g., HIV-related risk behavior) health. At the same time, careful examination of many of these studies suggests that minority stress does completely account for this disparity, leaving open the possibility that other less examined phenomena are at play. This panel presents emerging evidence that sexual minority men's experiences of mental and behavioral health challenges might at least partially be explained by stressors existing within sexual minority men's own communities and relationships.

First, we will review qualitative data showing that young sexual minority men today largely experience their community in terms of sex apps. Although the gay community has historically been a source of support and protection for its most vulnerable members, today's young sexual minority men's use of these apps imbues the gay community with intersectional sources of marginalization leaving many young sexual minority men vulnerable to rejection concerns and related health risks within their own community.

Second, a series of eight multimethod studies will show that sexual minority men are particularly stressed by their perceptions that the gay community is focused on sex, status, competition, and exclusion of diversity. We show that gay community stress, in fact, better predicts sexual minority men's mental health than minority stress. Three experiments locate the origin of this stress in the unique, status-based competitive pressures faced by sexual minority men, who by virtue of the fact that their social and sexual relationships often occur with other men might be particularly likely to compete with each other for social and sexual gain.

Third, we will show that sexual minority men's experiences of gay community stress also predict their HIV-risk behavior. We will present experimental evidence showing that sexual minority men's rejection by other sexual minority men leave them prone to risk-taking behavior.

Finally, we will examine stressors emerging from young sexual minority men's romantic relationships. Stigma-related histories leave this population vulnerable to attachment-related difficulties, which are potentially exacerbated within couples' relationships. We will show that attachment anxiety and avoidance within young sexual minority male couples can leave these couples vulnerable to substance use, with implications for couples' intervention.

Ilan Meyer, developer of minority stress theory, will discuss ways that the emerging evidence presented here for *within*-community stress complements and extends minority stress theory to offer a more comprehensive portrait of the social determinants of sexual minority men's mental and behavioral health than previously recognized.

“WHITE, TALL, TOP, MASCULINE, MUSCULAR”: INTRA-COMMUNITY MARGINALIZATION AMONG YOUNG GAY AND BISEXUAL MEN

Brock Grecco, Master of Social Science¹, Phillip Hammack, Ph.D.², Ilan Meyer, Ph.D.³, Bianca D. Wilson, Ph.D.⁴

¹UCLA, West Hollywood, CA; ²University of California, Santa Cruz, Santa Cruz, CA; ³The Williams Institute, Los Angeles, CA; ⁴The Williams Institute, CA

The LGBT community has been a source of support and resilience to LGBT people, but LGBT people are also susceptible to intra-community rejection and marginalization. LGBT people may find themselves stigmatized by norms governing sexuality, gender, gender expression, race/ethnicity, and social class. We present results of research that aimed to understand how young gay and bisexual men experience intra-community marginalization. We adopted an intersectional approach that attends to the effects of multiple stigmatization. Based on existing literature we hypothesized that the following themes may impact young gay/bisexual men: body type, race/ethnicity, substance use, gender expression, sexuality, HIV/AIDS status, and socioeconomic status.

Method: Data was collected as part of the *Generations* qualitative study in 5 regions in the United States using advertising and in-person recruitment in LGBT venues. Comprehensive interviews were conducted in person by trained interviewers with 191 men and women of all ages. Interviews were transcribed verbatim and analyzed using Dedoose software. In this paper we report on all young (18 – 25 years-old) gay/bisexual men (including those identified in similar sexual minority terms, like pansexual, N = 32). Interviews were coded for use of intra-community stigmas reported in the literature with the objective of describing themes in the narratives that would support or disconfirm the hypothesized themes.

Results: Social apps played a central role in the young men's understanding and experience of community. Many respondents perceived intra-community marginalization related to body, race, gender expression and sexuality. Stigma related to HIV/AIDS status, substance use and social class were minimally present. When stigmas were present, they tended to be experienced interactionally, particularly regarding racialized stereotypes expectations (e.g., Asian men are twinks, effeminate). If an individual was not perceived to meet stereotypical idealized traits for their race, then they felt rejection from and marginalization in the community.

Conclusion: While research has shown that connection to the LGBT community can have a positive health impact, even ameliorating the negative impact of minority stress, the young men in our study had a sense of community that was tied in with use of social (in particular, sex) apps that may be damaging to health and counteract other positive impacts of connections with the LGBT community. As the primary means of connection to the LGBT community for many in this cohort, sex apps have the potential to negatively impact their identities, health, and well-being with perceptions of rejection leading to feelings of isolation, low self-esteem, and rejection-related stress.

SEX, STATUS, COMPETITION, AND EXCLUSION: INTRA-MINORITY STRESS FROM WITHIN THE GAY COMMUNITY AND SEXUAL MINORITY MEN'S MENTAL AND BEHAVIORAL HEALTH

John Pachankis, PhD¹, Charles Burton, PhD², Kirsty A. Clark, PhD, MPH³

¹Yale University, New Haven, CT; ²Yale School of Public Health, New Haven, CT; ³Yale University, New York, NY

Sexual minority men might face unique, status-based competitive pressures given that their social and sexual relationships often occur with other men, who are known to compete for social and sexual gain. In a multistage study, we tested a novel theory of intra-minority gay community stress suggesting that status-focused elements of the gay community contribute to sexual minority men's mental health problems and associated behavioral risks. We first created a measure of gay community stress with items derived from qualitative interviewing ($n = 49$); calculated its psychometric properties, including one-year temporal stability ($n = 937$); and confirmed its structural stability in samples of US ($n = 96$) and Swedish ($n = 1,413$) sexual minority men. Being stressed by perceiving the gay community's focus on sex, focus on status, focus on competition, and exclusion of diversity predicted sexual minority men's mental health over-and-above a comprehensive battery of traditional minority stressors ($\beta = .17$, $p < .01$) and mediated the influence of gay community status on mental health. To examine the impact of status concerns (i.e., about masculinity, attractiveness, and wealth) on sexual minority men's feelings of exclusion in interactions with other sexual minority men, a series of experiments manipulated 1) the sexual orientation of rejecters (i.e., heterosexual vs. gay; $n = 103$), 2) the social status of sexual minority rejecters (i.e., high vs. low; $n = 84$), and 3) whether the type of rejection from sexual minority rejecters (i.e., status-based vs. non-status-based; $n = 252$). Overall, these experiments provide partial support for the possibility that sexual minority men's status concerns underlie their experience of gay community stress. Together, these studies advance psychological and sociological accounts of sexual minority men's mental and behavioral health beyond minority stress theory, with implications for interventions.

2:00 PM-3:15 PM

RISK FROM WITHIN: GAY COMMUNITY STRESS AND SEXUAL RISK-TAKING AMONG SEXUAL MINORITY MEN

Kirsty A. Clark, PhD, MPH¹, Charles Burton, PhD², John Pachankis, PhD³

¹Yale University, New York, NY; ²Yale School of Public Health, New Haven, CT; ³Yale University, New Haven, CT

Background: Sexual minority men remain highly impacted by the human immunodeficiency virus (HIV) with social stress being a clear predictor of their risk for infection. The past several decades of research regarding sexual minority men's HIV-risk behaviors has almost exclusively focused on the influence of social stress emanating from outside the gay community (e.g., heterosexist discrimination). However, converging lines of evidence have more recently suggested that sexual minority men also face stress from within their own communities.

Purpose: We sought to examine whether social stress from within the gay community (i.e., gay community stress) might influence sexual minority men's risk behaviors, including HIV-risk behaviors, over-and-above more commonly examined social stressors affecting this risk.

Methods: We tested whether gay community stress was associated with sexual minority men's HIV-risk behaviors in a large national survey of sexual minority men (Study 1), and experimentally tested gay community stress's impact on behavioral risk-taking and attitudes towards condom use (Study 2).

Results: Self-reported exposure to gay community stress was positively associated with HIV-risk behaviors when accounting for the effects of heterosexist discrimination, minority stress, and general life stress (Study 1). Participants who were rejected from an online group of other sexual minority men evidenced greater risk-taking in a subsequent risk-taking task and reported fewer perceived benefits of condom use when accounting for state affect than participants who were accepted by their online group (Study 2).

Conclusions: Sexual minority men's experiences of stress and rejection stemming from members of their own community may be an important and overlooked predictor of HIV infection and transmission.

4

2:00 PM-3:15 PM

INTIMATE RELATIONSHIP QUALITY AS A MECHANISM LINKING ADULT ATTACHMENT AND INDIVIDUAL HEALTH AMONG YOUNG SEXUAL MINORITY MALE COUPLES: A TEST OF THE RELATIONSHIP PROCESS FRAMEWORK

Tyrel J. Starks, PhD¹, Gabriel Robles, PhD²

¹Hunter College, CUNY, Brooklyn, NY; ²Hunter College, New York, NY, NY

Background: Younger sexual minority men (YSMM, aged 18 – 29) face unique challenges in enacting intimate relationships. Experiences of stigma may lead to expectancies – or the anticipation – of rejection from romantic partners, with implications for both relationship functioning and health. Generally, relationships characterized by low levels of satisfaction, commitment and investment are associated with negative health outcomes. The Relationship Process Framework (RPF; Pietromonaco et al, 2013) suggests that Attachment-related beliefs (about the desirability of the self and the reliability of others) are associated with health through the mechanism of relationship functioning. The purpose of the current study was to test a model implied by RPF to predict drug use, a well-established correlate of HIV risk, among YSMM.

Methods: Baseline data were analyzed from 70 YSMM couples ($n_{\text{individuals}} = 140$) enrolled in a larger trial. Eligible couples were sexually active with relationship length ≥ 3 months. Both partners were aged 18 or over, identified as cis-gender male, and were able to communicate in English. At least one partner in each couple was 18-29 years old, reported drug use in the past 30 days, and was HIV-negative. The mean age was 27.01 years ($SD = 5.79$). Most YSMM identified as a racial minority (53.4%). Participants reported the number of days in the past 30 on which they used drugs. They also completed the Experiences with Close Relationships questionnaire and the Multiple Determinants of Relationship Commitment Inventory.

Results: Participants' perception of relationship rewards, costs, and barriers to leaving the relationship were positively associated with the use of drugs excluding marijuana; meanwhile, comparisons, alternatives, and investments were negatively associated with this outcome. Relationship functioning was unrelated to marijuana use. Attachment avoidance was negatively associated with positive dimensions of relationship functioning (rewards, comparison to ideal, and investment) and positively associated with negative dimensions (costs, alternatives, and barriers to leaving the relationship). In contrast, attachment anxiety predicted only negative aspects of relationship functioning (costs and barriers to leaving). All possible indirect pathways between adult attachment and the use of drugs other than marijuana (implied by significant observed direct effects) were statistically significant.

Conclusions: These findings support the RPF premise that attachment is associated with diminished satisfaction, commitment, and investment in relationships and predict the use of drugs other than marijuana through this mechanism. Findings support the development of behavioral interventions – particularly for drug use – that enhance relationship functioning and target cognitions within sexual minority men's close relationships.

Symposium 67

2:00 PM-3:15 PM

INNOVATIVE TECHNOLOGY-BASED APPROACHES FOR ADDRESSING THE SEXUAL HEALTH NEEDS OF YOUNG SEXUAL MINORITY MEN

Mary A. Gerend, Ph.D.¹, Brian Mustanski, Ph.D.², Michael Newcomb, Ph.D.², Cynthia Cabral, Ph.D.³¹Florida State University College of Medicine, Tallahassee, FL; ²Northwestern University, Chicago, IL; ³PRIDE Research Consortium, New York, NY

Young gay, bisexual and other sexual minority men (YMSM) experience vast sexual health inequities relative to their heterosexual counterparts. Indeed, YMSM experience a disproportionate burden of the HIV epidemic in the United States, and YMSM of color have the highest rates of new infections compared to all other groups. Unfortunately, efforts to address the HIV epidemic have too often ignored the broader sexual health needs of YMSM, which has contributed to documented HIV prevention fatigue in this population. In addition to HIV prevention, YMSM express a need for information about developing a positive sexual self-image, finding and building healthy romantic relationships, having satisfying sexual relationships, and preventing other sexually transmitted infections. Furthermore, most sexual health interventions that have been developed to date do not consider the unique developmental contexts of adolescence, emerging adulthood, and young adulthood; YMSM in each of these developmental periods have differing needs that are not fully met by interventions developed for adult sexual minority men. Finally, most sexual health promotion programs for YMSM are available only to those who live in the largest urban centers in the United States, leaving vast disparities in sexual healthcare access across the country. The goal of this symposium is to highlight four innovative technology-based interventions that aim to address multiple facets of YMSM sexual health and have the potential to extend the reach of sexual health programs across the United States.

First, Dr. Mary Gerend will present data from a pilot randomized controlled trial assessing the feasibility, acceptability and preliminary efficacy of a text-message-based mHealth intervention that aims to promote sexual health and increase human papilloma virus vaccine uptake among YMSM. Second, Dr. Brian Mustanski with describe implementation strategies for eHealth interventions by presenting data related to the execution of a hybrid effectiveness-implementation trial of the Keep it Up! HIV prevention and sexual health promotion intervention for YMSM. Third, Dr. Michael Newcomb will use data from a pilot feasibility and ongoing randomized controlled trial to describe facilitators and barriers to the successful use of videoconferencing technology to deliver a relationship education and sexual health promotion program to young male couples across the United States. Finally, Dr. Cynthia Cabral will discuss the use of videoconferencing for a motivational interviewing intervention that aims to reduce HIV risk in adolescent sexual minority men, as well as the unique considerations in using this technology with adolescents. Together, these talks represent four novel and innovative strategies for extending the reach of sexual health interventions to YMSM across the United States.

USING TEXT MESSAGING TO INCREASE HPV VACCINATION AMONG YOUNG SEXUAL MINORITY MEN: RESULTS FROM A PILOT RANDOMIZED CONTROLLED TRIAL

Mary A. Gerend, Ph.D.¹, Krystal Madkins, MPH², Shariell Crosby, B.A.², Aaron K. Korpak, B.A.³, Gregory L. Phillips II, Ph.D.³, Michael Bass, Ph.D.², Magda Houlberg, MD⁴, Brian Mustanski, Ph.D.²¹Florida State University College of Medicine, Tallahassee, FL; ²Northwestern University, Chicago, IL; ³Northwestern University; ⁴Howard Brown Health Center, Chicago, IL

Background: Men who have sex with men (MSM) are at high risk for cancers caused by human papillomavirus (HPV), such as anal cancer. A safe and effective vaccine is available to prevent HPV infection, yet vaccine uptake among young MSM remains low. Guided by theory and formative research, we developed a mobile health (mHealth) intervention called txt2protect to increase HPV vaccination among young gay and bisexual men. This study assessed the acceptability, feasibility, and preliminary efficacy of the intervention in a pilot randomized controlled trial.

Methods: Young MSM aged 18-25 were recruited from the Chicago area via social media and a local registry to participate in a 9-month sexual health program delivered via text messaging. After completing the baseline assessment, participants were randomly assigned to the treatment (n = 72) or control condition (n = 76). The treatment condition focused primarily on HPV vaccination, with only brief mention of other sexual health practices (e.g., condom use, PrEP, HIV testing), whereas the control condition focused on a variety of sexual health practices with only brief mention of HPV vaccination. Participants received daily text messages for the first three weeks and monthly text messages for the remaining ~8 months of the trial. Primary outcome measures included acceptability (satisfaction with the intervention), feasibility (recruitment and retention), and efficacy as determined by HPV vaccine initiation (i.e., receipt of the first dose of the 3-dose series) by the end of the trial.

Results: Participants in the treatment and control condition reported high levels of satisfaction with the program (scores > 4 on a 5-point scale) and scores were similar across conditions. Although retention in the trial was high with over 87% of participants completing the final 9-month assessment, some challenges related to participant recruitment were encountered. Rates of HPV vaccine series initiation were significantly higher among participants in the treatment condition (19.4%) relative to the control condition (6.6%), OR = 3.43 (95% CI: 1.17, 10.08).

Discussion: Findings suggest that txt2protect is a highly acceptable and potentially promising mHealth intervention for increasing HPV vaccination among young gay and bisexual men. Future research is needed to refine and strengthen the intervention and explore additional recruitment methods for extending its reach.

2:00 PM-3:15 PM

ACCELERATING EHEALTH BEHAVIORAL INTERVENTIONS INTO PRACTICE: THE KEEP IT UP! HYBRID EFFECTIVENESS-IMPLEMENTATION TRIAL

Brian Mustanski, PhD¹, Nanette Benbow, M.A.², Kathryn Macapagal, PhD¹, C. Hendricks Brown, Ph.D.², Justin Smith, Ph.D.¹, Bruce R. Shackman, Ph.D.³, Benjamin P. Linas, MD⁴, Patrick Janulis, Ph.D.²

¹Northwestern University, Chicago, IL; ²Northwestern University; ³Weill Cornell Medicine; ⁴Boston University

Background: Despite substantial NIH investment in developing eHealth HIV interventions, little implementation research has examined strategies to effectively scale up these programs. To advance eHealth intervention implementation, we are conducting a county-randomized comparative implementation trial of two delivery approaches for Keep It Up! (KIU!), an online, CDC-best-evidence HIV prevention program for young men who have sex with men (YMSM) that just tested HIV negative. Strategy 1 is a traditional approach of community-based organizations (CBOs) integrating the program into their ongoing HIV testing operations. Strategy 2 is direct-to-consumer (DTC) strategy with home-based HIV/STI testing. This presentation describes the protocol for target county selection and outcome measures in the trial as an illustration of implementation research for behavioral interventions.

Methods: We reviewed geographic clustering of counties with 1,500+ YMSM. Standalone counties were automatically selected for inclusion. Among clustered counties, we selected the one with the most Black and Latino 18–29-year-olds and removed those directly adjacent, repeating this procedure until 64 counties were selected. Two adjacent counties were added based on topography.

Selected counties were stratified and randomized 2:1 to receive KIU! via the CBO or DTC strategy. Funding proposals were solicited from CBOs in the 44 CBO-strategy counties. Counties with successful CBO applicants were checked against the DTC counties to ensure balance. Outcomes for this type III hybrid trial follow RE-AIM, with the primary outcomes being impact (reach x effectiveness) and cost per infection averted. We also capture various metrics of adoption and implementation from YMSM self-report, KIU! meta-data, and CBO and DTC staff reports and interviews.

Findings: The CBO-strategy arm selected 14 CBOs for funding in the first round. A second funding announcement was released Fall 2019, with the goal of selecting another 8 CBOs, resulting in 22 counties per arm. The subsequent panel presentations will discuss the pragmatic design of each arm as well as the refreshing of the intervention technology to meet the demands of scalability.

Implications for Behavioral Interventions: Given the national urgency to end the HIV epidemic, understanding the best strategies to implement eHealth HIV interventions to reach the most people is critical to realizing the cost-effective scalability promised by such interventions. Careful selection of research targets and unobtrusive measures is critical to maintaining scientific rigor while remaining pragmatic in these studies.

2:00 PM-3:15 PM

USING VIDEOCONFERENCING TO EXTEND THE REACH OF RELATIONSHIP EDUCATION AND HIV PREVENTION FOR YOUNG MALE COUPLES

Michael Newcomb, PhD¹, Jim Carey, MPH²

¹Northwestern University, Chicago, IL; ²Northwestern University

Background: Young men who have sex with men (YMSM) bear a disproportionate burden of the HIV epidemic, and many new infections occur in the context of serious romantic relationships. Relationships also provide myriad benefits that promote mental and physical health. Thus, our team developed 2GETHER, an innovative relationship education and HIV prevention program for young male couples. This presentation will describe the adaptation of 2GETHER for remote administration via videoconferencing as part of a national randomized controlled trial, as well as barriers and facilitators to the use of this medium for intervention.

Methods: We adapted 2GETHER in two phases. Phase 1 included researching videoconferencing platforms, refining intervention content for online delivery based on literature review and expert consultation, and internal testing. In Phase 2, we conducted a pilot trial of the adapted intervention with 10 dyads (N = 20). Participants were diverse in terms of race/ethnicity, HIV status, and geographic location. After completing a baseline assessment, couples completed group skill building sessions, followed by individualized couple sessions for skill implementation. Upon completion, participants completed a 2-week posttest and exit interview.

Results: During Phase 1, we made several alterations to the group sessions to address participant fatigue. First, we split the 2 group sessions into 3 sessions to minimize loss of attention. Second, we pre-recorded videos of narrated PowerPoint slides of intervention content and sent them to participants 1 week prior to group sessions to facilitate briefer, more focused group discussions. The content and format of the individualized sessions were not altered. All group and individual sessions were conducted via BlueJeans videoconference, which we selected for its usability, ability to conduct group meetings with ease, and security features. During the Phase 2 pilot feasibility/acceptability trial, all participants completed all study components and reported few concerns with the format or content. In this pilot trial and the ongoing randomized controlled trial of this adapted intervention, we have identified several barriers to successful implementation of this approach, including difficulty conveying affect and building rapport via videoconference, distractions and loss of privacy in participants' home setting, and variations in access to sexual healthcare services by area of participant residence.

Discussion: Results support the feasibility and acceptability of delivering 2GETHER online via videoconferencing; we have been able to reach couples throughout the country with diverse relationship and sexual health experiences. Together with evidence of preliminary efficacy from the original pilot trial, 2GETHER shows strong promise of efficacy in addressing the health needs of young male couples across the U.S.

2:00 PM-3:15 PM

VIDEOCONFERENCE MOTIVATIONAL INTERVIEWING WITH YOUNG SEXUAL MINORITY MEN (YSMM): OPPORTUNITIES AND CHALLENGES

Cynthia Cabral, PhD¹, Carly Wolfer, BA², Ore Shalhav, MPH³, Ali Talan, DrPH⁴, H. Jonathon Rendina, PhD, MPH⁵, Tyrel J. Starks, PhD⁶, Kathryn Macapagal, PhD⁷, David Moskowitz, PhD⁸, Michael Newcomb, PhD⁷, Brian Mustanski, PhD⁷

¹PRIDE Research Consortium, New York, NY; ²PRIDE Health Research Consortium at Hunter College, New York, NY; ³PRIDE Health Research Consortium, Hunter College, CUNY, NEW YORK, NY; ⁴Hunter College, New York, NY; ⁵Hunter College and The Graduate Center, CUNY, New York, NY; ⁶Hunter College, CUNY, Brooklyn, NY; ⁷Northwestern University, Chicago, IL; ⁸Northwestern University

Background: Younger sexual minority men (YSMM, aged 14-20) frequently do not have access to sexual health education that meets their unique needs, and report that any sexual health education they receive centers on the experiences of their cis heterosexual counterparts. YSMM are also at an increased risk for HIV transmission.

Methods: The Northwestern University SMART Project aims to address this concern by providing a comprehensive interactive online sexual health education program for YSMM intended to reduce participants' HIV and STI risk. If participants are not responsive to the online education component of the SMART program, they have the opportunity to be randomized to a brief Motivational Interviewing intervention delivered via videoconference (e.g., Facetime, Skype) delivered by Masters and PhD level e-coaches with mental health training. This discussion will focus on "lessons learned" for delivering a motivational interviewing intervention remotely with this population.

Results: To date, 185 participants have been randomized to the SMART e-coaching condition. Of these, 89 have engaged in at least one session of e-coaching and 75 have completed the e-coaching sessions. Unique challenges with this intervention strategy include negotiating boundaries during e-coaching calls, discussing and clarifying limits to confidentiality, managing inquiries from parents and guardians, and ensuring flexibility around scheduling e-coaching calls. Participants who have completed the e-coaching calls report a positive experience overall, stating that it was helpful to talk to the e-coaches about sex, safe sex practices, and their sexual identity as a YSMM.

Conclusions: Continued engagement and flexibility with YSMM are vital factors in the remote delivery of a motivational interviewing based intervention intended to reduce HIV/STI transmission. These findings support the continued development of such interventions for YSMM.

Symposium 68

2:00 PM-3:15 PM

TRANSLATIONAL RESEARCH ON GENDER AFFIRMATION AND HEALTH WITH TRANSGENDER COMMUNITIES TO INFORM PRACTICE AND POLICY

Jae M. Sevelius, PhD¹, Kristi Gamarel, PhD², Luz Venegas, BFA¹, Wesley King, MPH², JoAnne Keatley, MSW³, Racquelle Trammell²

¹University of California, San Francisco, San Francisco, CA; ²University of Michigan, Ann Arbor, MI; ³CoE for Transgender Health, UCSF, OAKLAND, CA

In the past two decades, there has been a notable rise in societal recognition of the experiences of transgender and gender diverse people. Researchers, clinicians, and policy makers are increasingly recognizing stigma and violence as drivers of health inequities. The Model of Gender Affirmation proposed by Co-Chair Dr. Sevelius has gained traction as a means of identifying avenues for intervention. The Model of Gender Affirmation proposes that unmet need for gender affirmation poses substantial health risks for transgender and gender diverse people. To inform efforts to address health inequities among transgender and gender diverse people, it is critical to build a stronger understanding of gender affirmation and its relationship to health and well-being. This symposium brings together cutting-edge empirical research all led by transgender and gender non-binary researchers to foster stronger understandings of gender affirmation in different health domains, as well as identify ways that this research can be translated to improve the provision of health promotion interventions. The presentations included in this symposium consider different types of gender affirmation (e.g., social, medical), experiences of gender affirmation (e.g., partner stigma, migration to urban enclaves), represent diverse transgender and gender diverse communities throughout the lifespan, and have implications for individual- to structural-level interventions. The first talk presents findings on Latina transgender women's experiences of gender affirmation as part of an ongoing pre-exposure prophylaxis (PrEP) demonstration project. The second talk characterizes the ways in which stigma within relationship contexts can undermine gender affirmation and serves as a precipitant to violence and avoidance of self-care among transgender women of color. The final talk presents qualitative data illustrating transgender young adults' migration stories to San Francisco for gender affirmation at the price of structural vulnerabilities. The discussion will be led by Ms. Joanne Keatley, a world-renowned leader in the field of global transgender health, with extensive expertise in community-engaged research with, for, and by transgender and gender diverse communities, and will focus on future directions for addressing gender affirmation across multiple levels in the field of behavioral medicine globally.

“APOYO ENTRE NOSOTRAS” (SUPPORTING EACH OTHER): TRIUNFO, A PEER-NAVIGATION BASED MODEL TO PROVIDE INTERSECTIONAL GENDER AFFIRMING CARE TO TRANSGENDER LATINX

Luz Venegas, BFA¹, Luis Gutierrez-Mock, PhD², Arianna Salinas², Cinthya Herrera², Sophia Zamudio-Haas, DrPH², Kim Koester, PhD², Jae M. Sevelius, PhD¹

¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco

Purpose: Transgender women continue to have the highest rate of new HIV infections of any population group in the US, due in large part to a lack of adequate services. When designing programs for Latinx transgender individuals, we must assess and address social and structural barriers to care. For transgender Latinx immigrants, these barriers may include language, legal documentation, employment, and transportation. *Triunfo*, a pre-exposure prophylaxis (PrEP) demonstration project located at La Clínica de la Raza in Oakland, California, uses a peer-navigation model to deliver gender affirming care in combination with immigrant specific services.

Methods: We nested an ethnographic study within a larger mixed methods evaluation to qualitatively assess the implementation and outcomes of *Triunfo*. We conducted participant observation of group medical appointments, social events, and support groups over the course of six months. We also conducted in-depth interviews with 15 participants and 3 key informants (physician, coordinator, and peer navigator). A Framework Approach guided analysis. We developed a structured codebook and used Dedoose to organize and code data.

Results: *Triunfo* has successfully enrolled 67 participants, many of who had never before received formal medical care. Most participants are immigrants and recent arrivals who sought asylum in the US. Peer navigators connect participants with a range of services relevant to the intersectional needs of immigrant trans Latinx communities. At La Clínica, clinicians provide sexual health prevention and treatment services, hormone replacement therapy, and referrals for gender affirming surgeries. Peer navigators schedule and escort participants to obtain identification, name changes, legal-status support, and other services as needed outside of the clinic. Social support is provided through monthly groups, social events, and casual dinners. The social, structural, and clinical aspects of *Triunfo* are woven together in a way that feels seamless to participants.

Conclusions: *Triunfo* redefines and broadens the meaning of healthcare to include the social, mental, and overall wellbeing of participants. By providing care that is compassionate and culturally competent, this intervention successfully served a group of Spanish speaking transgender women and connected them with crucial services, including PrEP.

2:00 PM-3:15 PM

A “QUEER TAX” ON HEALTH AND INCLUSION: THE COSTS OF MIGRATION FOR TRANSGENDER PEOPLE SEEKING INCLUSIVE SERVICES AND COMMUNITY SUPPORT IN THE SAN FRANCISCO BAY AREA

Wesley King, MPH¹, Kristi Gamarel, PhD¹, Don Operario, PhD², Raha Mouzoon, MPH³, Victorine Stanislaus, MD⁴, Mariko Iwamoto, MA⁴, Sabrina Suico, BA⁴, Tooru Nemoto, PhD⁴

¹University of Michigan, Ann Arbor, MI; ²Brown University, Providence, RI; ³University of Michigan; ⁴Public Health Institute

Purpose: Transgender (trans) refers to individuals whose gender identity differs from culturally prescribed expectations associated with their assigned sex at birth. Many trans people seek gender affirmation across different domains. Evidence documents unmet gender affirmation needs place trans young adults at risk for a myriad of adverse health outcomes including HIV, non-prescribed hormone use and substance use. As a result, trans young adults may migrate to urban enclaves to fulfill their gender affirmation needs such as obtaining trans-inclusive healthcare and community support. This study explored the experiences and consequences of migration on trans young adults who migrated to San Francisco (SF) Bay Area to access gender affirmative health services and support.

Methods: A convenience sample of 60 trans young adults ages 18 to 29 (32% non-binary, 28% trans women, and 40% trans men) participated in a one-time qualitative interview as part of a larger study of hormone use and substance use. Qualitative interviews were audio-recorded and transcribed. We used thematic analysis to develop and refine the codes and themes.

Results: Two themes emerged regarding migration and gender affirmation needs: (1) gender affirmation experiences and (2) the price or “queer tax” for gender affirmation. Participants described how gender affirmation needs across healthcare and social domains were met upon moving to SF. However, migration placed many participants at risk for other structural vulnerabilities, including homelessness, employment discrimination, and racial discrimination in healthcare settings. Despite these vulnerabilities, participants were willing to “pay” this price in order to gain trans-related safety and affirmation.

Conclusions: Our findings underscore the importance of understanding how unmet gender affirmation needs and urban migration may place trans young adults at greater risk for adverse structural conditions that can determine health outcomes. Future research and interventions are needed to address gender affirmation needs beyond urban enclaves and reduce health disparities among trans populations.

2:00 PM-3:15 PM

THE MANIFESTATIONS OF STIGMA WITHIN THE RELATIONSHIPS OF TRANSGENDER WOMEN OF COLOR: IMPLICATIONS FOR GENDER-AFFIRMING HIV PREVENTION INTERVENTIONS

Racquelle Trammell¹, Lilianna Reyes, MPA², Laura Jadwin-Cakmak, MPH³, Cierra Burks², Bré Rivera, BA², Gary W. Harper, PhD, MPH⁴, Emily Arnold, PhD⁵, Kristi Gamarel, PhD¹

¹University of Michigan, Ann Arbor, MI; ²Trans Sistat of Color Project; ³University of Michigan; ⁴University of Michigan, School of Public Health, Ann Arbor, MI; ⁵University of California, San Francisco

Purpose: Transgender women of color are disproportionately affected by the HIV epidemic. One of the most consistently reported contexts for HIV transmission and acquisition among transgender women is within romantic partnerships. Transgender women experience intersectional stigma across all areas of their lives, including within romantic partnerships. Relationship stigma –the anticipation of negative treatment based on being in a relationship with a member of a stigmatized group –has been linked to adverse HIV and other health outcomes; however, there has been limited research to document the nuances of the relationship stigma experienced by transgender women of color. The current study sought to understand how transgender women of color experience relationship stigma and its impact on their health.

Methods: We conducted 5 focus groups (n=33) between January and March 2019 with transgender women of color as part of the Love Her Collective – a community-academic partnership. The overall goal of the study was to identify the HIV-related health needs of transgender women of color in Detroit, Michigan. Qualitative interviews were audio-recorded and transcribed. We employed a phenomenological analytic approach to develop and refine emerging themes related to relationship stigma.

Results: Participants ranged in age from 18 to 66 (M=31, SD=13); 79% identified as Black, and 18% identified as Multiracial. In total, 63% identified as living with HIV and 29% did not know their HIV status. Four overarching themes emerged: 1) Forms of enacted relationship stigma that undermine gender affirmation needs; 2) Complex association between enacted relationship stigma and internalized intersectional stigma; 3) Enacted relationship stigma as an antecedent to intimate partner violence, and 4) Enacted relationship stigma undermining health-promoting behaviors, including healthcare seeking.

Conclusions: Findings support the importance of gender-affirming approaches to health promotion and HIV prevention that account for the various ways that transgender women of color experience stigma. Approaches that account for the nuanced ways that relationship stigma undermine women's self-care, including linkage to and engagement in HIV prevention services are needed. Future research on gender-affirming intervention approaches to target the manifestations of relationship stigma in order and increase the use of HIV prevention strategies among transgender women of color will be discussed.

3:30 PM-3:45 PM

INOCULATING AGAINST FLU VACCINE MISINFORMATION: A TEST OF 3 INTERVENTIONS

Niraj Patel, PhD¹, Laura D. Scherer, PhD²

¹none, Boston, MA; ²University of Colorado, Aurora, CO

Purpose: Many people believe that the influenza vaccine can cause the flu, and this myth may be one reason for low flu vaccination rates. Correcting this misperception is important, but misinformation corrections are rarely completely effective at changing beliefs because they can be less memorable than misinformation, or leave people with incomplete mental models (e.g., fail to explain how a person could become sick with flu-like illness after receiving the vaccine). We therefore tested three interventions to reduce beliefs in this vaccine myth: a didactic message, an explanatory message, and a narrative message.

Methods: 1119 men and women age 18-73 (M=32, SD=12; 73% White, 11% African American) completed an online survey. Participants first reported their belief that the flu vaccine causes the flu. Then they were randomized to one of four conditions: Control (no correction), basic CDC statement that the flu vaccine does not cause the flu, a more thorough explanation of why a person might get sick after the vaccine, and 4. a narrative that contained all of the aforementioned information. After the intervention, participants reported their belief in the myth and their vaccination intentions. Next, participants read a short stories suggesting that the flu vaccine does cause the flu, and then stated their beliefs and intentions again.

Results: A 4 (Condition) × 2 (Time: Time 1 vs. Time 2) ANOVA on belief in the myth revealed a 2-way interaction, (F(3, 1036)=5.50, p< .001, =.04. All of the interventions increased rejection of the myth to the same degree (ps< .001) whereas there was no change in the control condition (p=.10; see Figure below). A 2-way interaction also emerged comparing Time 2 vs. Time 3 (F(3, 1037)=3.42, p=.017, =.01); all conditions showed a decrease in myth rejection at Time 3, but the thorough correction and narrative conditions showed greater resistance to the biasing stories. No intervention affected vaccination intentions.

Conclusions: Didactic corrections (“the flu vaccine does not cause the flu”) reduced beliefs in the myth, but more thorough explanatory corrections may be more effective at inoculating against further misinformation. Vaccination intentions were unaffected by the interventions, which points to other concerns or perceived barriers that may prevent vaccination.

Paper Session 34

3:45 PM-4:00 PM

COUNTERING ANTIVAX MISINFORMATION VIA SOCIAL MEDIA PLATFORMS: MESSAGE-TESTING EXPERIMENTS FOR HPV VACCINATION UPTAKE

Sunny Jung Kim, Ph.D., M.S., M.A.¹, Jenna E. Schiffelbein, MPH, CHES², Inger Inset, NBC-HWC³, Ardis L. Olson, MD⁴¹Virginia Commonwealth University School of Medicine, Richmond, VA; ²Dartmouth College Geisel School of Medicine, Lebanon, NH; ³Dartmouth College, Lebanon, NH; ⁴Norris Cotton Cancer Center, Dartmouth Geisel School of Medicine, Hanover, NH

Background: Myths and negative attitudes toward the human papillomavirus (HPV) vaccine are common, in part, due to the prevalence of misinformation. We sought to test the relative effectiveness of various messages about HPV vaccination, with the goal of identifying a set of messages that can be used on social media to change parents' attitudes toward the vaccine and their intentions to vaccinate their child(ren).

Methods: We generated two cohorts for the message-testing experiments: 1) a local sample of residents from NH and VT and 2) a national sample (total n = 1,672). Eligible participants were parents who had at least one child (n = 1,040). Based on the results from our virtual focus groups, we identified five campaign themes to target (distrust of the healthcare system, safety concerns, effectiveness concerns, connection to sexual activity, and misinformation about the vaccine). We developed five experimental messages for each of the themes, and six control messages about e-cigarettes. After completing pre-test measures, participants were randomly assigned to one message, which was presented in a simulated social media environment. After message exposure, participants completed post-test questions to measure changes in their attitudes toward the vaccine and behavioral intentions to vaccinate their child(ren) against HPV.

Results: The experimental messages significantly increased positive attitudes toward HPV vaccination, compared to the control messages ($t = 3.03$, $p = .003$). Parents' behavioral intention to vaccinate their child(ren) against HPV was significantly associated with the increase in positive attitudes toward HPV vaccination ($Pearson\ r = 1.14$, $p = .05$). According to the structural equation modeling, messages countering such themes as—distrust of the healthcare system, effectiveness concerns, connection to sexual activity, and misinformation about the HPV vaccine—were likely to increase behavioral intention, in part, due to the increased positive attitudes toward the vaccine (RMSEA = .014, CFI = .91, SRMR = .031). Among the messages focused on correcting misinformation about the vaccine, those addressing the effects of the HPV vaccine for cancer prevention and messages directly countering misinformation (e.g., the vaccine causes death) were effective in increasing parents' behavioral intention to vaccinate.

Conclusion: Social media can offer the opportunity to change attitudes and behavioral intentions toward HPV vaccination, rather than just facilitating the spread of misinformation. Messages about HPV vaccination were tested in a controlled setting simulating social media, and we identified messages and themes that were effective in changing attitudes and behavioral intention to vaccinate against the HPV. Given how ubiquitous social media is today, promoting tested messages—such as ours—on social media may play an important role in cancer prevention.

Paper Session 34

4:00 PM-4:15 PM

SAFER \neq SAFE: DEVELOPING AN ANTI-VAPE MESSAGE FROM THE TRUTH ANTI-TOBACCO CAMPAIGNElizabeth C. Hair, PhD¹, Jessica M. Rath, PhD, MPH, CHES¹, Erin J. Miller Lo, MPH¹, Alexis A. Barton, PhD, MS¹, Siobhan N. Perks, MPH¹, Donna Vallone, PhD, MPH¹¹Truth Initiative, Washington, DC

When **truth**, a national, mass-media, youth-smoking prevention campaign launched in 2000, nearly a quarter of all U.S. youth smoked cigarettes. Today, the rate of vaping among youth has been rising, up to 21% in 2018, putting **truth** back where it started. Using the lessons learned from almost 20 years of communicating to youth and young adults about tobacco, **truth** launched their first anti-vaping campaign, Safer \neq Safe, in October 2018. This study outlines the formative research strategies that informed the content of the campaign and the ongoing methods of evaluating its impact among young people. The campaign's strategy draws from the behavior change literature, which theorizes that knowledge, attitudes, and beliefs towards tobacco use can influence intentions, which in turn influence behavior.

First, substantiated e-cigarette-related facts were tested through surveys and focus groups for their ability to capture the attention of young people, while informing and motivating them. Second, mobile ethnographies, focus groups, and in-home interviews were used to understand how the audience thinks about tobacco and vaping. Using these results, ads were developed and copy-tested for their impact (percent of anti-vape attitudinal change); message comprehension; emotional response profile (positive passion, disgust, outrage); and **truth** brand equity attributes. Finally, the ads' in-market performance was evaluated by continuously monitoring target audience feedback via a media tracking study, assessing ad awareness, receptivity, and vape knowledge and attitudes among a sample of 240 youth and young adults per week.

Qualitative research indicated that vaping represents a gray area for youth and young adults. They believe it is better than smoking, but aside from a conscious desire to be part of this latest trend, their vape knowledge is lacking. Thus, facts that increased knowledge about nicotine content and health consequences were perceived as motivating and informative. Copy-testing showed that the ads had high likeability, strong perceived relevancy, and clear communication of the "safer is not the same as safe" message. The in-market testing showed increases in important vape knowledge; notably, a 23% decrease in agreement that "vaping/using e-cigarettes including JUUL is safe." As tobacco use patterns shift and new products emerge, evidence-based public education campaigns can play a key role in changing tobacco related knowledge among young people.

4:15 PM-4:30 PM

MEETING JUULERS WHERE THEY ARE: USING ETHNOGRAPHY AS A TOOL TO ASSESS ATTITUDES AND MOTIVATIONS

Jessica M. Rath, PhD, MPH, CHES¹, Erin J. Miller Lo, MPH¹, Siobhan N. Perks, MPH¹, Alexis A. Barton, PhD, MS¹, Donna Vallone, PhD, MPH¹, Elizabeth C. Hair, PhD¹

¹Truth Initiative, Washington, DC

For mass-media prevention messaging to be an effective tool at the population level, it is crucial to understand the target audience. While there are now decades of literature and knowledge surrounding the use of cigarettes among youth, there remains a dearth of much needed qualitative research exploring the knowledge, attitudes, and habits of youth and young adult e-cigarette users, including JUUL users. Given the meteoric rise of JUUL in the e-cigarette marketplace, it is critically important to reach out to youth and young adults to understand the motivations of the young people for whom JUUL and other similar products have been so appealing. To that end, Truth Initiative conducted qualitative ethnographic studies with vapers, primarily JUULers, with the goal of successfully messaging to these young people in truth's® future prevention messaging campaigns.

Taking a multi-faceted approach, Truth Initiative incorporated mobile surveys, in-home ethnographies, and qualitative focus groups as part of a systematic study of young JUULers. Trained facilitators spoke with 38 current or potential JUUL users aged 15 to 24 across the country who were high school students, college students, or recently graduated. Topics discussed were key to understanding this demographic, from tastes, lifestyles, and habits, to attitudes and behaviors, and how young people in this generation see themselves and their roles in society. Finally, Truth Initiative explored how these young people use e-cigarettes and JUUL, the benefits, both social and emotional, that they receive from their e-cigarette use, and the motivations behind product use.

The findings were revealing: while young people generally believe that vaping is less harmful compared to smoking, their understanding of the risks associated with vaping tend to be minimal. JUULing is ubiquitous, so much so that the activity is a verb on its own – and most participants expressed the desire to be part of the trend. Participants indicated that the product also serves as a security blanket of sorts, much like a drink or phone in one's hand, and is a conversation starter at parties and in groups.

Understanding the appeal of JUUL and the role it serves in the lives of youth and young adults is critical to making progress toward changing young peoples' attitudes and behaviors, and in taking steps to curb the epidemic of youth vaping and JUULing.

4:30 PM-4:45 PM

MISINFORMATION AND OTHER ELEMENTS IN HPV VACCINE TWEETS: AN EXPERIMENTAL COMPARISON

Noel T. Brewer, PhD¹, William A. Calo, PhD, JD, MPH²

¹University of North Carolina, Chapel Hill, NC; ²Penn State College of Medicine, Hershey, PA

Background: Misinformation about HPV vaccination posted on social media has the potential to discourage vaccination by increasing vaccine hesitancy. We sought to examine how four key messaging elements of social media affect parents' motivation to get the HPV vaccine for their children, trust in social media content, and perceived risk about HPV-related diseases.

Methods: In 2017-2018, we surveyed a national sample of 1,206 U.S. parents of children aged 9 to 17 years. We developed 16 experimental tweets that varied in four messaging elements: sentiment (accurate or misinformation), source (person or organization), narrative style (storytelling or scientific data), and topic (effectiveness or safety). Content was slightly modified from real tweets posted in June and July 2017 (median reading level was grade 7). We randomly assigned parents to one tweet using a 2 x 2 x 2 x 2 between-subjects factorial experiment. After viewing the tweet, the survey assessed parent's motivation (main outcome) as well as parent's trust in the tweet and perceived risk (secondary outcomes).

Results: Accurate tweets elicited higher HPV vaccine motivation than tweets with misinformation (25% vs. 5%, OR=6.23, 95% CI: 4.15, 9.33). Similarly, motivation was highest for tweets from organizations versus persons (20% vs. 10%, OR=2.41, 95% CI:1.70, 3.41) and about effectiveness versus safety (20% vs. 10%, OR=2.52, 95% CI:1.77, 3.57). No interactions among sentiment, source, narrative style, or topic were statistically significant for motivation. The impact of the manipulations on motivation was mediated by perceived risk and trust.

Conclusions: Tweets with misinformation may undermine parents' motivation to get HPV vaccine for their children in our national online experiment. Social media campaigns may help to increase public trust in vaccination.

SUCCESS STORIES: NIH'S ROLE IN CLOSING EVIDENCE GAPS AND INFORMING USPSTF CLINICAL PRACTICE RECOMMENDATIONS

Erin M. Ellis, MPH, PhD¹, Elizabeth Neilson, PhD, MPH, MSN¹, Quyen Ngo-Metzger, MD, MPH², Kat Schwartz, MS¹, Jennifer Villani, PhD, MPH³, Elizabeth A. Vogt, MPH⁴, Carrie Klabunde, Ph.D., MBA, MHS⁵

¹NIH, Rockville, MD; ²Kaiser Permanente School of Medicine, Pasadena, CA; ³NIH/NIDA, Rockville, MD; ⁴The Scientific Consulting Group, Inc., Annapolis, MD; ⁵National Institutes of Health/Office of Disease Prevention, Rockville, MD

Background: Although NIH-funded breakthroughs have undoubtedly contributed to improvements in health, knowledge accumulates slowly and unpredictably, making it challenging to quantify NIH's real-world impact. To this end, we examined the extent to which NIH-funded research has informed U.S. Preventive Services Task Force (USPSTF) recommendations about preventive health care services. USPSTF recommendations shape primary care delivery and health insurance coverage policies, two factors critical to disease prevention.

Methods: When the USPSTF deems the evidence insufficient to issue a recommendation for or against providing a service, they issue an "I" (insufficient evidence) statement and outline evidence gaps that need attention in future research. Periodically, the USPSTF reassesses the evidence base to determine if a recommendation can be made. We identified 7 I Statements that were upgraded to definitive recommendations based on new evidence ("Success Stories") between 2012 and 2018. All relevant citations in the systematic evidence review that informed the USPSTF upgraded recommendation were identified. For each citation, study design characteristics, funding information, and bibliometric measures were captured.

Results: Up to 67 ($M = 33$) articles were cited in each systematic review; one-half of the studies reported in the articles were conducted in the U.S. Fourteen NIH Institutes collectively funded 37% (range: 17-79%) of the articles cited. R- and U-series grants were the most common, but intramural, contract, and other funding mechanisms were also used. Although most (84.5%) reported randomized trial results, cohort, cross-sectional, and case-control designs were also employed. Using relative citation ratios, study impact was higher for NIH-funded ($M = 12.77$) than non-NIH funded ($M = 7.04$) research. There was considerable diversity across Success Stories in study design characteristics, funding sources, and clinical reach via citations in guidelines issued by professional organizations.

Conclusions: NIH played an important role in supporting research needed to fill USPSTF evidence gaps. Given the diversity of funding mechanisms and study designs represented, fostering the science needed to fill remaining evidence gaps may likewise require creative and pragmatic study designs and funding opportunities. Successfully addressing USPSTF evidence gaps can contribute to meaningful improvements in population health.

A SCOPING REVIEW OF THE STATE OF STRENGTH TRAINING BEHAVIOUR CHANGE INTERVENTIONS

Jasmin K. Ma, PhD, R.Kin¹, Jennifer Leese, MA², Stephanie Therrien, BA², Alison A. Hoens, MSc, BScPT³, Karen Tsui, MScPT, ACPAC⁴, Linda C. Li, PT, PhD⁵

¹University of British Columbia/Arthritis Research Canada, Vancouver, BC, Canada; ²Arthritis Research Canada, Richmond, BC, Canada; ³University of British Columbia Department of Physical Therapy, Vancouver, BC, Canada; ⁴Trillium Health Partners, Toronto, ON, Canada; ⁵University of British Columbia, Vancouver, BC, Canada

Background: Despite the benefits to muscle strength, physical function/independence, and cardiometabolic health, as little as 6% of the population are meeting the guidelines for strength training (ST) twice a week. Barriers to ST (e.g., knowledge of technique and prescription parameters, perceived complexity, and need for equipment) suggest interventions targeting this behaviour are unique from general physical activity or aerobic activity. The objective of this scoping review is to comprehensively summarize the current state of behaviour change interventions for promoting ST participation.

Method: Using the scoping review methodology by Arksey and O'Malley (2005), we searched electronic databases (Medline, Embase, PsychINFO, and PubMed), reference lists, and consulted experts in the field. Articles were included if they i) employed an intervention to promote ST and ii) ST participation was an outcome. Article screening was conducted by two independent reviewers and data extraction was performed by one reviewer and verified by a second reviewer. Study characteristics and interventions factors were extracted. Interventions were coded using the BCT Taxonomy v1.

Results: We identified 32 articles reporting on 24 unique interventions. Studies were primarily randomized controlled trials (75%), conducted amongst older adults (38%) and/or a wide range of populations with chronic disease or disability (67%). Among interventions that are theory-based ($n = 11$), 82% used social cognitive theory (SCT) and the rest used the transtheoretical model (TTM). The majority of interventions were delivered face-to-face (96%), by an exercise specialist (63%), in community or home settings (83%) with a variety of exercise prescriptions used across studies. A median of 9 BCTs were used (minimum: 4, maximum: 19). The most common BCTs included adding objects to the environment ($n=20$), instructions on how to perform the behaviour ($n=20$), graded tasks ($n=18$), and behavioural practice/rehearsal ($n=18$).

Conclusion: Several research questions remain unanswered in the field of strength training behaviour change. Research that addresses the lack of diversity in theory and intervention factors employed may benefit from examining theories outside of SCT and TTM, alternatives to exercise specialist intervention deliverers and the face-to-face mode of delivery, testing of optimal exercise prescription parameters for promoting adherence, and underexplored BCTs that address ST-specific barriers.

DHC PRESENTS: THE ROLE OF BEHAVIOR MEDICINE IN THE EVOLVING WORLD OF DIGITAL HEALTH.

Madalina L. Sucala, PhD¹, Heather Cole-Lewis, PhD, MPH², Danielle Arigo, Ph.D. in Clinical Psychology³, Stephanie P. Goldstein, PhD⁴, Megan Oser, PhD⁵, Eric B. Hekler, PhD⁶, Michael A. Diefenbach, Ph.D.⁷

¹Johnson and Johnson, New York, NY; ²Johnson and Johnson, Westfield, NJ; ³Rowan University, Glassboro, NJ; ⁴Alpert Brown Medical School/The Miriam Hospital Weight Control and Diabetes Center, Providence, RI; ⁵Mahana Therapeutics, SF, CA; ⁶UC San Diego, San Diego, CA; ⁷Northwell Health, Manhasset, NY

Background: The Society of Behavioral Medicine (SBM) has established its Digital Health Council (DHC) in 2014. The DHC's mission is to envision what the digital health field will look like in the future and prepare SBM and its membership to be at the forefront of the field. Towards this end, a 2019 DHC initiative was to develop a digital health roadmap, highlighting its impact on the field of behavioral science. The project aimed to assess current digital health needs and interests within SBM, and to gather expert insights on the evolution of the field.

Methodology: SBM Survey: 346 SBM members completed a survey on their digital health needs and interests.

Stakeholders Interviews: 15 digital health experts were interviewed on their perspective of the anticipated evolution of the digital health field, as well its implications for behavior science.

Results: SBM Survey: 77% reported experience with digital health projects, and 65% of those with no experience expressed interest to engage with digital health. Current barriers and difficulties reported included collaboration or communication difficulties, finding the right partners, and institutional support difficulties. Respondents reported needing SBM's support for their digital health endeavors, through: webinars, networking opportunities, or collaboration platforms.

Stakeholders Interviews: Experts anticipated the following changes: 1) Digital healthcare landscape will be shaped by payment/reimbursement models; 2) Digital health solutions will have an increasingly recognized impact and will widen access to care; 3) Technology will usher in precision behavioral medicine; 4) Technology will be seamlessly integrated into daily life and into the process of receiving care; and 5) Models of behavior change will evolve. The following implications and recommendations for behavior science emerged from the interviews: 1) Set up cross-sector partnerships and multi-disciplinary collaborations; 2) Ensure that digital health solutions are indeed set up to widen access to care for everyone; 3) Develop digital health solutions that will meet the rigors of digital therapeutics; 4) Advance new methodologies and more refined theories of behavior change.

Implications: SBM is uniquely positioned to meet the digital health field's evolution and to prepare its members to meaningfully contribute to it by utilizing the infrastructure, talent development and collaboration opportunities that it provides. Further necessary initiatives and efforts will be highlighted.

Paper Session 35

4:15 PM-4:30 PM

PILOT STUDIES PRESENTED AT THE SOCIETY OF BEHAVIORAL MEDICINE

Lauren E. von Klingraeff, MPH¹, Ethan T. Hunt, MPH¹, Roddrick Dugger, MPH², Alexis Oliveira, n/a¹, Sarah Burkart, MPH, PhD¹, Bridget Armstrong, PhD¹, R G. Weaver, Ph.D.¹, Michael Beets, M.Ed, MPH, PhD¹

¹University of South Carolina, Columbia, SC; ²University of South Carolina Arnold School of Public Health, Columbia, SC

Introduction: Among all published intervention articles, the proportion of those identified as pilot studies has increased from < 2% in 1974 to 9.7% of in 2018. This proliferation of pilot studies may still underestimate the actual count of all pilot studies conducted potentially due to common pilot study attributes (e.g. small sample size, varying methodological rigor). The extent to which publication bias occurs within pilot studies is unknown yet can prove useful when evaluating published pilot studies to determine whether those appearing in peer-reviewed journals are fundamentally different than those that go unpublished.

Methods: Annual Meeting Supplements containing the abstracts presented at the Society of Behavioral Medicine (SBM) were obtained for years between 2006 and 2017. Each year was systematically searched using the terms "pilot" or "feasibility" or "preliminary" or "exploratory" to identify all pilot studies presenting on a behavioral intervention. Behavioral interventions were defined as studies designed to test the feasibility of a behavioral intervention and/or provide evidence of a preliminary effect(s). Abstracts which reported pilot protocols, mechanistic studies conducted in laboratories or clinical settings as well as scale, tool or device development were not retained. The title, body, authors on each abstract was used to link it to published studies by searching publication databases, author's curriculum vitae, ResearchGate, and Google Scholar. Publications were matched to SBM abstracts if the publication reported identical intervention components including duration, location, and target population though they could vary on reported sample population by +/- five participants. Publications which later published presented abstracts findings as single arms of multi-arm trials were excluded.

Results: Of the 12,915 abstracts from the Annual Meeting Supplements, 500 (3.9%) were pilots. In 2006, 1.7% of all abstracts published for SBM were pilot behavioral interventions; that rate increased to 4.8% in 2017. The number of total abstracts presented at SBM increased 132% from 2006 to 2017 (747 to 1734) while pilot abstracts increased by 538% (13 to 83). Slightly less than half (45%) of all presented pilot behavioral interventions were published. Characteristics differentiating published vs. non-published pilot behavioral interventions are currently being compared and results will be presented.

Conclusion: Pilot studies are often endorsed as a necessary step in the development of large-scale behavioral intervention. The proportion of pilot behavioral interventions that go unpublished is large, suggesting clear publication bias with those that eventually appear in the peer-reviewed literature. The analysis of the pilot abstract characteristics and their association with publication will shed light on potential biases in published pilot studies.

Paper Session 35

4:30 PM-4:45 PM

PERSPECTIVES ON THE VALIDATION OF BEHAVIOR CHANGE INTERVENTIONS

Sonali R. Mishra, MSI¹, Shefali Haldar, PhD², Predrag Klasnja, PhD³, Wanda Pratt, PhD¹¹University of Washington, Seattle, WA; ²Northwestern University, Chicago, IL; ³University of Michigan, Ann Arbor, MI

Background: Because behavior change is complex and interventions fail for many reasons, researchers have called to evaluate behavior change interventions not just based on whether they effect behavior change, but also on whether they successfully affect the *mechanism* they target (i.e., how the intervention is supposed to work). For example, interventions designed to work by enhancing self-efficacy can be evaluated both on whether users change their behavior and on whether users' self-efficacy increases. Such calls have focused on evaluating interventions based on how researchers intend them to work. But before evaluating whether an intervention works, how can we tell if it successfully implemented intended mechanisms in the first place—i.e., how can we validate the intervention?

Purpose: We explored issues surrounding validation in a multi-step study to design interventions to encourage hospitalized patients to prevent medical errors.

Methods: We designed several low-fidelity behavior change intervention prototypes for hospitalized patients, aimed at encouraging them to speak up regarding concerns about their care. Each prototype targeted a particular mechanism of change in the Integrated Behavioral Model (IBM). We conducted a small-scale validation study (n=7) of these prototypes, asking researchers specializing in health behavior change interventions ("experts") to map prototypes onto mechanisms in the IBM, and interviewed experts (n=4) about their attitudes towards the creation and evaluation of theory-based interventions. We conducted semi-structured interviews with hospitalized patients (n=15), probing for their responses to validated prototypes, and coded their responses for mechanisms of change named in the IBM.

Findings: End users (hospitalized patients) and experts at times diverged in their interpretations of what mechanisms an intervention targeted. Experts themselves often disagreed about how interventions were supposed to work: only 6 of 24 prototypes achieved an average Cohen's kappa of .41 or more. Disagreement about the mechanism of interventions resulted both from the design of interventions and from differing ideas about the inherent relationships between mechanisms.

Conclusion: Individuals respond differently even to targeted interventions. Researchers should employ methods such as user interviews or measurement of multiple possible mechanisms to understand why behavior change interventions succeed or fail, and to contribute to knowledge about interrelationships between mechanisms and design.

Paper Session 36

3:30 PM-3:45 PM

BASELINE LEVELS OF HABITUAL PHYSICAL ACTIVITY PREDICT WEIGHT LOSS DURING A 24-WEEK SUPERVISED AEROBIC EXERCISE INTERVENTION

Christoph Höchsmann, PhD¹, James L. Dorling, PhD¹, John W. Apolzan, PhD¹, Neil M. Joannsen, PhD¹, Daniel S. Hsia, MD¹, Corby K. Martin, PhD²¹Pennington Biomedical Research Center, Baton Rouge, LA; ²Pennington Biomedical, Baton Rouge, LA

Background: Exercise is recommended for weight management; however, exercise-induced weight loss often is less than expected based on measured energy expenditure. This discrepancy is called weight compensation and results primarily from exercise-induced increases in energy intake. It is unknown if factors pertaining to one's lifestyle prior to starting an exercise program affect weight compensation and its mechanism. The purpose of this analysis was to determine if habitual physical activity (PA) levels at baseline predict weight change, weight compensation, and changes in energy intake during a 24-week supervised, controlled aerobic exercise intervention.

Methods: Data from 108 participants [48.7 (SD 11.6) years, 31.4 (SD 4.6) kg/m²], randomized to either the moderate-dose exercise group (8 kcal/kg body weight/week; KKW) or the high-dose exercise group (20 KKW) of the E-MECHANIC trial, were analyzed. Baseline habitual PA was measured with SenseWear arm-bands over a 2-week period with a minimum of 95% required wear time for a valid day (22h and 48 min). Energy intake was measured with doubly labeled water over 2 weeks, before and after the intervention. Multiple linear regression models, adjusted for sex, exercise group, and baseline value of the outcome were used to estimate the effect of baseline habitual PA on weight change, weight compensation, and change in energy intake.

Results: At baseline, participants spent a median of 44 (IQR 31-73) min/day in moderate-to-vigorous PA (≥ 3 METs). We found negative associations between baseline habitual PA levels and weight change ($\beta = -0.28$; $p = 0.02$), weight compensation ($\beta = -0.24$; $p = 0.04$), and change in energy intake ($\beta = -0.32$; $p < 0.01$). For every 15 min/day decrease in habitual PA at baseline, participants lost 0.23 kg less weight, compensated 0.20 kg more, and increased daily energy intake from to baseline to follow-up by 21.5 kcal/day more.

Conclusions: Habitual PA levels before the start of exercise predicted weight change, compensation, and energy intake changes. Participants with lower baseline habitual PA levels lost less weight from exercise, had higher compensation, and increased energy intake. These results indicate that less active people, who are in the most need of the health benefits of exercise, fail to fully realize these benefits when engaging in an exercise program. Research is needed to understand why this occurs and to develop strategies to mitigate this detrimental effect.

WEIGHT DISCRIMINATION EXPERIENCED PRIOR TO ENROLLING IN A BEHAVIORAL OBESITY INTERVENTION REDUCES TREATMENT RESPONSE

Alena C. Borgatti, B.A.¹, Fei Tan, PhD², Gareth Dutton, PhD¹, Kaylee B. Crockett, PhD³, Ziting Tang, MS⁴¹University of Alabama at Birmingham, Birmingham, AL; ²IUPUI, Indianapolis, IN; ³University of Alabama at Birmingham, Birmingham, AL; ⁴Indiana University - Purdue University Indianapolis, Indianapolis, IN

Background: Weight discrimination is associated with a host of negative outcomes, including depression, unhealthy and disordered eating behaviors, and reluctance to engage in weight-control behaviors. Less is known about the impact of weight discrimination on weight loss, especially in the context of behavioral obesity interventions. Prior research suggests that weight stigma may reduce weight loss in behavioral interventions, but the small and predominantly Caucasian samples limit generalizability of previous findings. Moreover, few studies have considered whether body mass index (BMI) may account for the relationship between weight discrimination and weight loss. The current study evaluated the impact of weight discrimination on program attendance and weight loss among a cohort seeking treatment for obesity. Associations between weight discrimination and depressive symptoms were also examined.

Methods: Participants (N=304; BMI=35.9 kg/m²; 55% African American; 95% women) were enrolled in a 16-week, evidence-based weight loss program that included weekly group sessions. At baseline, participants reported on their experiences of weight discrimination across different settings. Depressive symptoms were measured using the CES-D at baseline. All analyses adjusted for race and baseline BMI.

Results: Participants who experienced weight discrimination reported greater depression at baseline (B=3.59, 95%CI: [1.76, 5.42], p< 0.001). Weight discrimination was not associated with session attendance during the 16-week program (B=-0.64, 95%CI: [-1.97, 0.69], p=0.35), but it was associated with lower weight loss percentage post-intervention (B=0.02, 95%CI: [0.01, 0.04], p=0.001). Specifically, those reporting weight discrimination prior to starting the program lost 2.4% less weight compared to individuals without a history of weight discrimination.

Conclusions: Prior experiences of weight discrimination were associated with diminished weight loss in this behavioral obesity intervention, despite similar attendance rates. This suggests weight discrimination may not deter motivation to attend weight loss interventions. Given the observed associations between discrimination and increased depressive symptoms, future research is needed to explore whether the presence of depressive symptoms may account for the potential impact of perceived discrimination on treatment response.

BEHAVIORAL WEIGHT-LOSS PROGRAMS WITH EXTENDED CARE LEAD TO LONG-TERM IMPROVEMENTS IN GLYCEMIC CONTROL

Vivian Bauman, M.S.¹, Michael Perri, PhD², Meena N. Shankar, MS, RD, CCRC¹, Kathryn M. Ross, Ph.D., M.P.H.¹, Abraham J. Eastman, M.S.¹, Brittney N. Dixon, MPH¹, Umelo A. Ugwoaba, B.S.¹, Andrea N. Brockmann, M.A.¹, Charlayne A. Scarlett, M.P.H.¹¹University of Florida, Gainesville, FL; ²University of Florida, College of Public Health and Health Professions, Gainesville, FL

Introduction: Behavioral weight-loss programs produce weight changes associated with reduced diabetes risk, however, weight regain remains a substantial challenge. Continued contact via extended care programs has demonstrated promise for improving weight-loss maintenance; however, it remains unclear what effect these programs have on glycemic control. Thus, we compared the effect of three extended care programs (delivered via group telephone counseling, individual phone counseling, or email) on long-term changes in glycated hemoglobin (A1c) among adults with obesity and poor glycemic control.

Methods: The study included 267 adults with obesity (female=83.9%, white=77.2%; M±SD: age= 55.9± 9.8 years; BMI=36.5±3.4 kg/m²) and baseline A1c levels in the abnormal range (5.7% and higher; M±SD: A1c=6.0±0.3%). Following completion of the 4-month behavioral weight-loss program, participants were randomized to one of three extended care conditions: email-only (n=95), individual phone calls (n=83), or group phone calls (n=89). A1c and weight were measured at baseline, month 4, and month 22. Effect of extended care condition on A1c and weight was assessed using repeated measures ANOVAs with Bonferroni post-hoc testing.

Results: Participants maintained a mean (SE) weight loss of 5.8% (0.6%) initial body weight and A1c reduction of 0.26% (0.03%) from baseline to month 22 (p< .001). Weight change during this time was positively associated with A1c change, such that larger reductions in weight were associated with greater A1c improvements (r=.27, p=.001). Participants achieved the following mean (SE) reductions in A1c over 22-months: email, 0.27% (0.05%), p< .001; individual phone calls, 0.30% (0.06%), p< .001; group phone calls 0.22% (0.06%), p=.001. There were no significant differences in 22-month weight and A1c reductions between groups (ps >.05).

Discussion: Results demonstrated that a behavioral weight-loss program with extended care delivered via individual phone calls, group phone calls, or email, produced significant changes in weight and HbA1c over a 22-month period. These findings suggest that behavioral weight-loss treatment programs with telephone and email-based extended care can improve blood-glucose control in both the short-and-long-term. Future studies should consider cost-effectiveness of these various treatment options.

Paper Session 36

4:15 PM-4:30 PM

FACTORS CONTRIBUTING TO RE-HOSPITALIZATION AFTER BARIATRIC SURGERY

Ryan Foley, BA¹, Afton Koball, PhD, ABPP², Sarah Domoff, PhD³¹Central Michigan University, Ypsilanti, MI; ²Gundersen Health System, La Crosse, WI; ³Central Michigan University, Mount Pleasant, MI

Obesity is a major health concern in the United States, with 41.2% of men and 38.1% of women meeting criteria for obesity in 2016 (National Center for Health Statistics, 2018). Currently, bariatric surgery is the most successful treatment for morbid obesity (Adams, 2007; Cardoso, 2017; Sjostrom, 2007). While there is promising research indicating the benefits of bariatric surgery, concerns surrounding post-operative psychiatric destabilization and alcohol misuse have emerged. Multiple studies have revealed a link between Roux-en-Y gastric bypass surgery (RYGB) and alcohol use disorders post-surgery (Cuellar-Barboza, 2015; King, 2012; Steffen, 2015; Suzuki, 2012). While research has initiated the process of identifying outcome risks associated with bariatric surgery, less is known regarding when or why psychiatric hospitalizations occur postoperatively. Therefore, the goal of the current study was to examine the incidence of, and contributing factors to, psychiatric hospitalization post-surgery. The sample consisted of patients (N = 93) from a Midwest hospital who received RYGB surgery and had been readmitted post-surgery at least once.

Participants (83.7% female) in this study were, on average, 45.0 (SD = 9.86) years of age at first readmission. The majority of the sample (53%) had one readmission post-bariatric surgery; 24% had two readmissions, 7% had three readmissions, 4% had four readmissions, and 10% of patients had five or more readmissions. Across 267 post-surgery re-admissions, 42.4% of all re-admissions were due to alcohol-related problems, including 39.6% of readmissions with acute alcohol intoxication. Patients being readmitted for the first time after bariatric surgery, who were presenting with alcohol related problems, were readmitted after a mean of 1942 days (approximately 5.3 years; SD = 1217 days). Patients being readmitted for psychiatric concerns (41.3% of readmissions) were readmitted an average of 1278 days (3.5 years; SD = 1056 days) post-surgery. Results indicate that a significant percentage of patients readmitted after RYGB surgery are experiencing alcohol-related problems, indicating a unique relationship between RYGB and postoperative alcohol problems. Psychologists on bariatric surgery teams should prioritize ongoing assessments of alcohol misuse in RYGB patients (for years after surgery) and provide psycho-education around alcohol use long-term.

Paper Session 36

4:30 PM-4:45 PM

CONSISTENCY OF SELF-WEIGHING, RATHER THAN FREQUENCY, MAY BE KEY FOR PROMOTING WEIGHT LOSS MAINTENANCE

Andrea N. Brockmann, M.A.¹, Abraham J. Eastman, M.S.¹, Brittney N. Dixon, MPH¹, Umelo A. Ugwoaba, B.S.¹, Charlayne A. Scarlett, M.P.H.¹, Vivian Bauman, M.S.¹, Meena N. Shankar, MS, RD, CCRC¹, Michael Perri, PhD², Kathryn M. Ross, Ph.D., M.P.H.¹

¹University of Florida, Gainesville, FL; ²University of Florida, College of Public Health and Health Professions, Gainesville, FL

Background: Greater adherence to self-monitoring of weight, typically defined as total frequency of self-weighing over a specific time period, has been shown to promote greater success at both weight loss and longer-term weight loss maintenance. For dietary self-monitoring, however, research has shown that greater *consistency* of self-monitoring (the number of weeks that a participant monitored intake ≥ 3 days) may be more important than total frequency for promoting weight loss maintenance. Less is known regarding the relative importance of consistency in self-weighing, and a threshold for defining consistency of self-weighing has not been established. Thus, the current study aimed to 1) develop this threshold and 2) investigate the contributions of frequency and consistency of self-weighing to weight loss maintenance during a 9-month period following a 12-week weight-loss program.

Methods: Participants were 74 adults with overweight/obesity, (mean \pm SD) age = 50.7 \pm 10.4 years, BMI = 31.2 \pm 4.5 kg/m², 84% White, 69% Female. Weight was assessed at in-person assessments at Month 3 (post-intervention) and Month 12 (end of the maintenance period). *Frequency* of self-weighing was defined as the number of days that participants self-weighed during the maintenance period via a study-provided smart scale. A threshold for *consistency* was defined as the minimum number of days per week of self-weighing that was significantly associated with weight change, with 7 potential options ranging from ≥ 1 to all 7 days each week. Next, three hierarchical regressions were used to assess associations between frequency, three levels of consistency (the minimum and maximum clinical recommendations of ≥ 1 day and all 7 days, along with the identified threshold) and weight change during the maintenance period.

Results: Significant associations were observed between consistency of self-weighing and percent weight loss when consistency was defined as self-weighing ≥ 6 or all 7 days/week, $r_s = -.27$ and $-.32$, $p_s = .019$ and $.005$, respectively. These associations remained significant after controlling for frequency, $p_s = .025$ and $.013$, respectively; however, there was not a significant association observed between frequency and weight change, and no interaction was observed between frequency and consistency, $p_s > .05$.

Conclusion: Results demonstrate that consistency of self-weighing may be more important than total frequency for preventing weight regain after the end of a weight-loss program. Further, results suggest that a high level of consistency (self-weighing ≥ 6 days/week) may be necessary to promote successful weight loss maintenance. Taken together with previous findings, our results support the emerging clinical recommendation of daily self-weighing to promote weight loss maintenance.

Paper Session 37

3:30 PM-3:45 PM

CHANGES IN SMOKING PREVALENCE AND PERCEPTION OF SMOKING ON CAMPUS BEFORE AND AFTER A SMOKE-FREE UNIVERSITY CAMPUS POLICY

Christopher J. Rogers, M.P.H.¹, Jessica Barrington-Trimis, PhD², Jennifer B. Unger, Ph.D.³, Myriam Forster, BA;MPH;PhD⁴¹Keck School of Medicine University of Southern California, Castaic, CA;²USC, Los Angeles, CA; ³University of Southern California, Los Angeles, CA;⁴California State University, Northridge, Santa Monica, CA

Background: Smoke-free policies can decrease the prevalence of smoking and denormalize smoking behaviors; however, there is limited research into whether policies that prohibit all smoking on college campuses significantly impacts smoking behavior – and the perception of the prevalence of peer smoking – among college students.

Methods: This study compares college campus smoking prevalence and perceptions of smoking prevalence before and after a complete smoking ban was enacted in the fall of 2015. Logistic regression models evaluated the trends in prevalence across repeated cross-sectional survey waves administered in a large, ethnically diverse public university in 2011 (n=1,548), 2013 (n=3,657), 2015 (n=3,456), 2016 (n=2,575), and 2018 (n=4,600). A spline term was included in regression models to evaluate whether the trend in prevalence or perceptions differed after (vs. before) the smoking ban was implemented.

Results: In 2011, 21.1% of students reported smoking any tobacco product, 13.2% reported cigarette use, and students thought that 41.4% of the students on campus smoked cigarettes in the past 30 days. On average, the prevalence of nicotine product use decreased over the study period. Prior to the ban, the prevalence of smoking any tobacco product decreased on average 27.9% (AOR=0.89, 95%CI: 0.85, 0.97) every year; after the ban, a significantly greater decline was observed, where smoking prevalence decreased by 37.8% (AOR=0.787, 95%CI: (0.78,0.98). Similar patterns were observed for specific tobacco products (i.e., cigarette use). The perceptions of prevalence of student smoking on campus decreased by about 4.3% per year prior to the ban ($\beta=-2.29$; 95%CI:-2.89,-1.69), and by about 6.5% every year after the ban ($\beta=-6.11$, 95%CI:-8.26,-3.96). For both prevalence of use and perceptions of use on campus, the greatest changes after implementation of the ban were observed among 18-21 year old students (p-interaction < 0.05). Stratified analysis identified that the pre/post decline in past 30-day nicotine product and perceived prevalence was largest in the youngest age category (18-21 years old).

Discussion: These results suggest campus-based anti-smoking policies are an effective tool. Over time, campus-based smoking bans may contribute to a reduction in use of all nicotine delivery systems and may strengthen anti-smoking normative beliefs particularly among younger cohorts who enroll after a ban has established a smoke-free campus.

3:45 PM-4:00 PM

LONGITUDINAL STUDY OF DUAL USE OF COMBUSTIBLE CIGARETTES AND THE NICOTINE SALT POD SYSTEM (NSPS) IN ADULT CURRENT SMOKERS

Yining Z. Malloch, n/a¹, Gem M. Le, n/a², Joshua Vose, MD, MBA², Erik Augustson, PhD, MPH²¹JUUL Lab Inc., San Francisco, CA; ²JUUL Labs, Inc., San Francisco, CA

Objective: Use of the nicotine salt pod system (NSPS) has increased among adults; however there is limited data on NSPS use patterns and dual use with combustible cigarettes (CC) over time. This study examined changes in dual use and switching to NSPS-only over a 6-month period among new NSPS users who were current smokers.

Methods: Longitudinal survey data of U.S. adults (age 21 or older) who recently purchased a NSPS (JUUL Labs, Inc.) starter kit was analyzed as part of an IRB approved behavioral study. Current smokers were defined as having smoked > 100 lifetime cigarettes and reported smoking some days/every day at baseline. To specifically characterize dual use of NSPS and cigarettes, participants that reported use of other brand vapor products were excluded from analysis. Follow-up assessments of past 30-day NSPS use and CC were completed (n = 9903). Dual use was defined as reporting any use of NSPS and CC in the past 30 days. NSPS-only was defined as no concomitant CC use at all. To further understand dual use and dropouts, an intention-to-treat (ITT) sample was created by treating all dropouts as having returned to CC-only use. Dual and NSPS-only use rates were summarized for the ITT sample (n=9955) and compared to the efficacy sample (n=9903).

Results: Most current smokers were white (73.8%) males (53.9%) with mean age of 32.7 (SD = 11) years. At each follow-up, dual use rates decreased, from 67.3% at 1-month, 57.4% at 2-months, 52.5% at 3-months to 45.4% at 6-months. Dual use rates declined an average of 3.7% each month, whereas NSPS-only use rates increased an average of 2.9% each month. NSPS-only use rates increased from 31.2% at 1-month, 39.6% at 2-months, 43.4% at 3-months to 48.8% at 6-months. As late as 6-months, NSPS-only became more common than dual use. The increase of NSPS-only use rates was largely derived from the decrease of dual use rates. In the ITT sample, dual and NSPS-only use rates at each follow-up had less than 1% difference compared to the efficacy sample.

Conclusions: Although a sizeable number of current smokers fully switched from CC after 1 month of NSPS use (31.2%), rates of dual use of NSPS and CC continued to decline sharply over 6-months of follow-up. This suggests that many dual users may be in a transition period before completely switching from CC to NSPS. Longer follow-up research is needed to assess this pattern over time.

Paper Session 37

4:00 PM-4:15 PM

CORRELATES OF CIGARETTE-ONLY AND E-CIGARETTE TOBACCO USE AMONG LOW-INCOME, URBAN VULNERABLE POPULATIONS

Arturo Durazo, PhD¹, Janice Y. Tsoh, PhD¹, Natalie Rivadeneira, MPH², Urmimala Sarkar, MD²¹University of California, San Francisco, San Francisco, CA; ²UCSF, San Francisco, CA

Smoking prevalence among low-income or unstably housed individuals remains disproportionately high. Unstably housed smokers may use alternate tobacco products as an aid to reduce or quit conventional cigarette smoking due to financial restraint in respond to increased cigarette tax and smoke-free policy. Concurrent use of multiple tobacco products is associated with negative health consequences. Self-regulation theory describes thoughts and emotions that drive health-protective behavior to manage future illness threat. Of particular interest is having more understanding of tobacco use and cancer beliefs among racial/ethnic minority, low-income, and unstably housed groups. The aims of this analysis were to describe conventional cigarette and/or e-cigarette use, particularly in racial/ethnic and unstably housed groups in the City of San Francisco using data from an adaption of the San Francisco Health Information National Trends Survey (N=1,027). Survey oversampled disadvantaged populations and was administered in English (50%), Chinese (25%) and Spanish (25%).

Overall, 26% reported tobacco use in the past 30 days (18% cigarettes, 2% e-cigarettes, 6% dual use). Compared to White participants, Asian and Latinx respondents were less likely to use any tobacco product (OR 0.24, 95% CI: 0.11, 0.52 and OR 0.41, 95% CI: 0.20, 0.84, respectively). Limited English proficient respondents were less likely to use (OR 0.31, 95% CI: 0.19, 0.51). Related to socioeconomic position (SEP) related factors, housing instability was positively associated with use (OR 2.42, 95% CI: 1.72, 3.40) and those earning \$35,000-\$50,000 yearly, compared to higher income group, were less likely to use (OR 0.48, 95% CI: 0.24, 0.95). Respondents who believed there was little to prevent cancer were more likely to use (OR 1.60, 95% CI: 1.03, 2.51). Those who reported lower risk perception were less likely to use (OR 0.56, 95% CI: 0.36, 0.88). In racially and SEP diverse urban regions, with high levels of tobacco use and poor health outcomes, development of informed health communication and interventions designed to increase awareness of the links between tobacco use and cancer risk may help to dispute incorrect illness beliefs, and promote tobacco cessation.

4:15 PM-4:30 PM

EFFECTS OF AN ONLINE RESPONSIBLE VENDOR TRAINING FOR RECREATIONAL MARIJUANA STORES ON SALES TO PSEUDO-UNDERAGE CUSTOMERS

David B. Buller, PhD¹, Gill Woodall, PhD², Robert F. Saltz, Ph.D.³, Andrew M. Grayson, PhD¹, Mary K. Buller, M.A.¹, Sierra N. Svendsen, BS⁴, Lucia Liu, M.S.⁴, Gary R. Cutter, PhD⁵¹Klein Buendel, Inc., Golden, CO; ²Klein Buendel, Inc., Albuquerque, NM; ³Pacific Institute for Research & Evaluation, Berkeley, CA; ⁴Klein Buendel, Golden, CO; ⁵University of Alabama at Birmingham, Birmingham, AL

Recreational marijuana sales in the United States debuted in Colorado and Washington State in 2014. Initial regulations were designed in part to ensure that marijuana products were sold only to adults over age 21 who provided a state-approved identification (ID). Training store personnel in responsible sales practices, an intervention that has reduced alcohol sales to under-age youth, was evaluated in the recreational marijuana markets in these two states in 2016-18. An online responsible marijuana vendor (RMV) training was developed with input from state regulators and recreational marijuana store personnel. The five modules contained interactive learning elements that covered state laws, ID checking, health effects of marijuana, driving under the influence, refusal of sales to intoxicated customers, and store processes such as product tracking and labeling. A sample of n=175 recreational cannabis stores in Colorado and Washington State were selected for a randomized controlled trial, with sales to pseudo-underage patrons measured at baseline and two follow-ups post-randomization (2 visits per store at each measurement round). After baseline, 75 stores were assigned to a usual and customary training (control) condition; the remaining 100 stores were invited to use the RMV training (40% of stores used it). At baseline, sales of marijuana to pseudo-underage buyers were refused at 93% of 349 visits to the stores across the 2 states. Adjusting for store characteristics, there was no difference in change in refusal rates between treatment groups from baseline (intervention: 94%, control: 95%) to 3-month posttest (intervention: 96%, control: 98%) or 9-month posttest (intervention: 98%, control: 98%, treatment x assessment round: p=0.672). In the intervention group, training uptake was not related to refusal rate (training x assessment round: p=0.382). Nearly all recreational marijuana stores refused sales to young customers who did not present a state-approved ID. Training in responsible sales practices alone did not appear to affect refusals. State regulations and industry concerns over federal priority for preventing diversion to youth appeared to create very high deterrence of sales to underage-appearing customers from the outset of the markets. This ceiling effect in the refusal measure may have made it difficult to achieve a training effect. The RMV training may have simply reinforced this high compliance with regulations on ID checking and underage sales.

UNDERSTANDING THE RELATION BETWEEN TOBACCO OUTLET DENSITY AND TOBACCO USE IN AFRICAN AMERICAN YOUNG ADULTS

Daniel Rodriguez, Ph.D.¹, Anna M. Adachi-Mejia, PhD², Heather A. Carlos, MS³, Jennifer Ratmanský¹La Salle University, Philadelphia, PA; ²Geisel School of Medicine at Dartmouth, Lebanon, NH; ³Norris Cotton Cancer Center, Dartmouth College, Lebanon, NH

Researchers have assessed the relation between tobacco outlet density (TOD) and various sociodemographic factors such as urban/rural neighborhood status, and the percentage of people living in poverty or the percentage of African Americans and Hispanics living in a census tract. The results of these studies have revealed striking TOD disparities, with the greatest density in areas where ethnic minorities and the poor live. Researchers have found relations between TOD and smoking behavior, including the inception, progression, and cessation of use, although the results are mixed, with some researchers finding no relations at all. This suggests that the TOD-tobacco use relation is not homogeneous, and that more research is critically needed to better understand how TOD affects use, particularly in ethnic minorities who have the greatest exposure to tobacco outlets. We therefore proposed to assess the relation between TOD and tobacco use (combustible cigarettes and chew tobacco) behavior in a sample of 694 African American young adults (18-22 years old) taking part in the Panel Study of Income Dynamics (PSID) Transition to Adulthood (TA) 2015 supplement. Using binary logistic regression analysis and controlling for urban/rural status, education, participation in risky behaviors (e.g., fighting, drinking and driving), and biological sex, we assessed all main effects, and two and three-way interactions involving TOD and urban/rural status. There were two significant two-way interactions. There was a positive relation between TOD and use of a tobacco product for males but a negative TOD/tobacco use relation for females ($p=0.031$). There was also a significant education by TOD interaction ($p=0.036$) with TOD positively related to tobacco use for participants with a high school education or less but a negative TOD/tobacco use relation for participants with greater than a high school education. There was also a significant TOD by urban/rural neighborhood by risky behavior three-way interaction ($p=0.037$). For participants living in a rural neighborhood, the relation between TOD and tobacco use was positive for those engaging in risky behavior but negative for those not engaging in risky behavior. In urban settings, the relation was almost reverse, with those engaging in risky behavior having a negative relation between TOD and tobacco use. These findings suggest the relation between TOD and tobacco use is not straight forward. Researchers should assess how TOD impacts use in different populations of young adults, particularly ethnic minorities, using methods that permit for greater assessment of heterogeneity of effects.

RURAL RESIDENTS' PERSPECTIVES ON A MHEALTH/PERSONALIZED HEALTH COACHING INTERVENTION

Nancy E. Schoenberg, Ph.D.¹, Madeline Dunfee, M.Ed., MPH¹, Matthew H. Rutledge, n/a¹, Hannah J. Yeager, n/a², Bonnie Spring, PhD³¹University of Kentucky, Lexington, KY; ²University of Rochester, Georgetown, KY; ³Northwestern University Feinberg School of Medicine, CHICAGO, IL

Rural Appalachian residents experience elevated prevalence of cardiovascular disease, cancer, diabetes, and obesity, leading to some of the highest rates of premature mortality in the US. Sparse personal (e.g., low socioeconomic status) and community resources (e.g., health care professional shortages, food deserts, inadequate recreational facilities) contribute to and compound these disparities. However, new opportunities, including increasing personal technology use and connectivity, may help overcome health disparities and resource scarcity. We convened four focus groups (N=38) and sixteen key informant interviews to assess perspectives on an evidence-based diet and physical activity intervention, Make Better Choices 2 (MBC2). A multicomponent lifestyle intervention, MBC2 consists of personalized coaching, personal technology (app), accelerometer, and financial incentives. Focus group and key informant participants were recruited through snowball and purposive sampling. Two experienced focus group conveners and two trained local interviewers collected the data. All sessions were, with participants' permission, tape recorded and later transcribed. Three researchers content analyzed the transcripts. Consistent with qualitative research standards, rigor was enhanced through member checks with a Community Advisory Board and peer debriefing. Findings indicate extensive enthusiasm for the mHealth/personalized coaching approach, with minimal need for program modification. Specifically; 1) Appalachian residents overwhelmingly believe in the viability and support the use of personal technology to deliver health interventions, particularly with personalized health coaching; 2) though abating, intertwined circumstances persist that must be addressed to improve the likelihood of the success of mHealth lifestyle interventions in Appalachian communities; 3) successful technology-oriented interventions would benefit from leveraging personal connections, using local coaches, and enhancing participants' educational opportunities. Other recommendations included expanding the upper age inclusion; using social media for recruitment and retention; providing community resource guides to direct participants to local healthy food and activity opportunities; and hosting quarterly events to highlight success stories. We conclude that blending personal coaching and new technologies not only is feasible, but may be essential to reach vulnerable rural residents.

DEVELOPMENT AND FEASIBILITY OF PAM: A VERY BRIEF FACE-TO-FACE INTERVENTION FOLLOWED BY A TEXT MESSAGE AND/OR SMARTPHONE APP

Katerina Kassavou, PhD¹¹The University of Cambridge, Cambridge, England, UK

Objectives: This paper describes the development and feasibility of a very brief face-to-face intervention (VBI) followed by a text message and/or smartphone app to support treatment adherence to patients with hypertension in primary care.

Primary and secondary outcome: The primary outcome of the intervention development was the development and operationalisation of the three-component intervention: the VBI, the text message, and the smartphone app. The primary outcome of the intervention feasibility was to assess intervention uptake and retention rates, explore process of behavioural change, and obtain outcome values (means and CI) to inform an effectiveness and cost effectiveness trial. Medication adherence was assessed using urine analysis, refill prescription data and self-reports. Clinical outcomes were assessed using systolic blood pressure, HbA1c and full lipid profile.

Participants and Methods: Intervention development was informed by (a) a pilot one-month study with 23 patients, (b) in-depth interviews with patients and practice nurses, (c) PPI/E input, (d) stakeholders' consultations, and (e) systematic reviews of empirical evidence. Intervention feasibility is assessed in an RCT with 100 patients (n=60 intervention group and n=40 control group).

Results: Intervention piloting suggested high intervention engagement with, and fidelity of, the text message and app intervention; which included a combination of behaviour change techniques and strategies highly tailored to patients' beliefs and prescription plan. The intervention has a good uptake (5.6% response to invitation) and attrition (5% drop out) rate at three months follow up. Patients and nurses end-of-intervention interviews informed the process by which intervention impacted on medication adherence and made recommendations to optimise intervention uptake, attrition and implementation.

Conclusion: PAM is a feasible adjunct to primary care. A larger RCT of 764 patients (382 per group) from 50 primary care practices is recruited to provide robust evidence about its effectiveness and cost-effectiveness.

PATIENT CHARACTERISTICS ASSOCIATED WITH MOBILE APPLICATION ENGAGEMENT FOR ASTHMA AND COPD SELF-MANAGEMENT

Rahul Gondalia, PhD, MPH¹, Esther Rimmelink, PhD neuroscience¹, Leanne Kaye, PhD, MPH, RD¹, Shivani Parikh, n/a², Kelly Henderson, MPH¹, Alesha Thompson, MPH³, Meredith Barrett, PhD¹

¹Propeller Health, San Francisco, CA; ²Propeller Health, Palo Alto, CA; ³Council of State and Territorial Epidemiologists (CSTE), Atlanta, GA

Introduction: Digital health interventions that include a mobile application ("app") have been shown to benefit patients with respiratory disease, likely due to improved self-management (e.g. greater daily medication adherence). However, engagement with apps may vary by patient, resulting in differential exposure to the intervention. The objective of this study was to identify characteristics associated with higher app engagement in patients with asthma or COPD.

Methods: Adult patients (≥ 18 years of age) with self-reported asthma or COPD and enrolled in a digital health platform (Propeller Health, Madison, WI), consisting of electronic medication monitors (EMMs) and a companion mobile application ("app"), were considered. EMMs captured the date, time and location of each inhaler actuation that was then delivered to the app via Bluetooth to give patients insights on their inhaler use. Patients reported data on their education and income via electronic surveys. Multivariable, linear regressions were used to identify patient characteristics associated with engagement metrics, including mean daily app opens and mean daily app session duration (seconds), for asthma and COPD separately. The engagement metrics were right-skewed, therefore were log-transformed prior to modeling. Patient-level characteristics included age, gender, household income (< vs. ≥ \$50,000 annually), education level (≤ vs. > high school), and the number of days on the platform. The threshold for statistical significance was 0.05.

Results: The patient population (n = 617) with asthma (n = 433) and COPD (n = 184) were on average 38 and 60 years of age and 17% and 40% male, respectively. Mean daily app opens were 0.34 and 0.57, and session duration was 13.3 and 23.4 seconds, for asthma and COPD, respectively. Multivariable linear regressions found that older age was associated with more frequent app opens and longer session duration in both asthma and COPD (all $P < 0.01$). Male gender was positively associated with app opens ($P < 0.001$) and session duration ($P < 0.01$) in COPD, but not asthma. Lower annual income was associated with shorter session duration in asthma only ($P = 0.04$).

Conclusion: Results suggest that socio-demographic characteristics, such as age, gender and income, are associated with engagement with an asthma and COPD mobile app. These characteristics can be used for targeting interventions to increase app engagement, thereby improving awareness and self-management of disease.

4:15 PM-4:30 PM

USER ENGAGEMENT AND ADAPTATION OF A SMARTPHONE-BASED APPLICATION FOR LATINA WOMEN WITH BREAST CANCER

Sharon H. Baik, PhD¹, Laura B. Oswald, PhD², Joanna Buscemi, PhD³, Diana Buitrago, BA⁴, Francisco Iacobelli, Ph.D.⁵, Alejandra Perez-Tamayo, MD⁶, Judith Guiltman, n/a⁷, Frank Penedo, PhD⁸, Betina Yanez, PhD⁴

¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²Moffitt Cancer Center, Tampa, FL; ³DePaul University, Chicago, IL; ⁴Northwestern University, Chicago, IL; ⁵Northeastern Illinois University, Chicago, IL; ⁶University of Illinois, Chicago, IL; ⁷ALAS-Wings, Chicago, IL; ⁸Sylvester Comprehensive Cancer Center, Miami, FL

Background: Latina women often experience disparities in breast cancer survivorship, including poorer health-related quality of life (HRQOL) and greater psychosocial needs compared to their white counterparts. Our team developed the *My Guide* application to improve HRQOL and the *My Health* active-control application to promote overall health among Latina breast cancer survivors (BCS). This presentation describes user engagement of these smartphone applications.

Methods: Latina BCS (N=78) were randomized to use *My Guide* or *My Health* for six weeks, after which they completed exit surveys to report levels of satisfaction with their assigned application. Individual application usage was tracked and quantified using click-level data.

Results: On average, participants used the applications for 478.15 minutes (7.97 hours) across six weeks (M=79.69 minutes/week, SD=64.31, range 0-269). Overall usage did not differ between conditions ($p > .05$). In total, 97% and 92% of participants were satisfied with the *My Guide* and *My Health* application, respectively, and 92% of *My Guide* and 84% of *My Health* participants wanted to continue using the applications. *My Guide* and *My Health* had a total of 6,516 and 7,923 clicks within the applications, respectively. Within *My Guide*, most clicks were on topics related to psychosocial aspects of the cancer experience (27%) followed by physical symptoms (15%) and general breast cancer knowledge (13%). Within *My Health*, the majority of clicks were on topics related to nutrition (43%) and exercise (19%). In semi-structured exit interviews, many *My Guide* participants expressed a desire for additional content regarding general health and lifestyle behaviors, whereas many *My Health* participants desired more content specific to breast cancer and coping strategies. In addition, participants reported wishing they had access to the applications during cancer treatment as opposed to following treatment.

Conclusions: As *My Guide* and *My Health* had similar application usage, were acceptable to participants, and collectively included relevant breast cancer survivorship concerns, we adapted and merged the applications to develop a new application for Latina women in active treatment for breast cancer, *My Guide for Breast Cancer Treatment*. User engagement findings from these trials have implications for the cancer-related needs of Latina breast cancer patients.

Paper Session 38

4:30 PM-4:45 PM

GAMIFICATION OF A DAILY, NEUROCOGNITIVE TRAINING PROGRAM ENHANCES WEIGHT LOSS FOR MEN BUT NOT FOR WOMEN

Evan M. Forman, PhD¹, Stephanie Manasse, Ph.D.¹, Diane H. Dallal, BA¹, Rebecca J. Crochiere, B.A.², Meghan L. Butryn, PhD¹, Adrienne S. Juarascio, Ph.D.¹

¹Drexel University, Philadelphia, PA; ²WELL Center, Drexel University, Philadelphia, PA

Inhibitory control (IC) is a basic brain capacity to inhibit prepotent responses in order to adaptively restrain intrinsic drives. IC exerts a strong influence on hedonically-driven behavior such as the consumption of high-calorie food. As such, the ability to improve IC holds promise as a means of enhancing the impact of conventional weight loss programs. Computerized inhibitory control trainings (ICT), which involve repeated practice at inhibiting response to a relevant stimulus, have shown mixed results in impacting real-world behavioral change. One determinant of success appears to be whether participants are willing to repeat trainings frequently over an extended duration. Gamification represents a method of increasing engagement with ICT. We previously reported that gamification, surprisingly, reduced the effects of ICT on weight loss. In this follow-on study, we explored the moderating effect of gender on gamification.

Overweight participants who were habitual sweets consumers (N=76) were put on a non-sweets diet for 8 weeks, and were asked to complete 42 daily and 2 weekly home computer-based 10-minute ICTs personalized to each person's most-frequently-consumed sweets. Participants were randomized to receive either a non-gamified ICT or a gamified ICT (involving quickly moving down supermarket aisles, grabbing food to place in a shopping cart, and featuring animation, sound, points, levels and badges). In line with hypotheses, gamification improved engagement with daily ICT in men only: For example, gamification increased compliance 9.1% in men, but decreased compliance by 3.2% in women ($F=1.60$, $p=.20$), although overall compliance with daily trainings was higher for women compared to men (89.8% vs. 81.1%, $t(74)=2.24$, $p=.03$). Most notably, the gamification effect was significantly moderated by gender; specifically, gamification enhanced 8-week weight loss for men (4.2% vs 2.5%), but attenuated weight loss for women (1.7% vs 3.1%; $F=.547$, $p=.02$).

Overall results suggest that gender profoundly moderates the effects of gamification on daily, neurocognitive training paradigms designed to impact health behavior. Most notably, gamification enhanced the effects of ICT on weight loss for men, perhaps because of intrinsic enjoyment of gamification; yet, gamification attenuated the effects for women, perhaps because gamification elements were distracting. Further work is needed to understand the underlying reasons for, and scope of, gender's moderating effect. Further work is also needed to identify gamification strategies that enhance effects for women.

Paper Session 39

3:30 PM-3:45 PM

MEDIATORS OF ACCEPTANCE AND COMMITMENT THERAPY FOR FEAR OF CANCER RECURRENCE

Ekin Secinti, M.S.¹, Catherine E. Mosher, Ph.D.², Wei Wu, PhD³, Patrick V. Stutz, B.A.⁴, Shelley A. Johns, PsyD⁴¹Indiana University Purdue University Indianapolis, Indianapolis, IN; ²Indiana University-Purdue University Indianapolis, Indianapolis, IN; ³Indiana University Purdue University Indianapolis, Carmel, IN; ⁴Indiana University School of Medicine, Indianapolis, IN

Growing research supports the efficacy of Acceptance and Commitment Therapy (ACT) for improving psychological well-being in cancer survivors, but less is known regarding mechanisms underlying ACT's effects. According to the ACT model, the central mechanism of ACT is increased psychological flexibility, which refers to being fully engaged in the present moment (mindfulness/acceptance) while acting consistently with one's values (commitment/action). In this study, we conducted secondary analyses examining psychological flexibility and mindfulness facets as potential mediators of ACT's effect on fear of cancer recurrence and other psychological outcomes.

Female breast cancer survivors ($N = 91$, stages 0-III) with clinically-elevated fear of cancer recurrence were recruited from academic oncology clinics in the mid-western United States. Most participants were Caucasian (84%) with an average age of 59 years ($SD = 11$). Participants were randomly assigned to ACT ($n = 33$), survivorship education ($n = 32$), or enhanced usual care ($n = 26$). ACT and survivorship education participants completed six weekly 2-hour group sessions, while enhanced usual care participants received written materials on managing life after cancer treatment in one brief meeting. Participants completed self-report measures at baseline, post-intervention, and one and six months post-intervention. Prior analyses indicated that ACT significantly improved fear of cancer recurrence, depressive symptoms, and anxiety.

Latent growth mediation models showed that change in psychological flexibility mediated ACT's effect on change in fear of cancer recurrence ($B = -0.42$, 95% CI $[-3.14, -0.04]$), depressive symptoms ($B = -3.95$, 95% CI $[-7.18, -0.04]$), and anxiety ($B = -6.73$, 95% CI $[-8.85, -0.02]$). However, change in mindfulness facets (nonjudging and nonreactivity) did not predict change in study outcomes.

Consistent with the ACT model, these preliminary findings suggest that change in psychological flexibility may underlie the effects of ACT on psychological outcomes. Conversely, change in mindfulness facets did not mediate ACT's effects. Only ACT participants received mindfulness training, and, thus, null findings may be related to an inaccurate understanding of mindfulness. Next steps include determining which specific aspects of psychological flexibility (e.g., mindfulness/acceptance vs. commitment/action) help explain the impact of ACT on psychological outcomes in large, diverse samples of cancer survivors.

Paper Session 39

3:45 PM-4:00 PM

GROUP VERSUS INDIVIDUAL ACUPUNCTURE (AP) FOR CANCER PAIN: A RANDOMIZED NON-INFERIORITY TRIAL

Linda E. Carlson, PhD¹, Erica N. Reed, BSc(Hons)¹, Jessa Landmann, B.Sc., ND², Devesh Oberoi, n/a¹, Katherine-Ann L. Piedaloe, BA³, Peter D. Faris, PhD⁴¹University of Calgary, Calgary, AB, Canada; ²Vive Integrative Health Group, Calgary, AB, Canada; ³Cumming School of Medicine, Calgary, AB, Canada; ⁴Alberta Health Services, Calgary, AB, Canada

Background: A service delivery model using group acupuncture (AP) may be more cost-effective than individual AP in general, but there is little evidence to assess whether group AP is a comparable treatment in terms of efficacy to standard individual AP. The study aimed to compare group vs. individual delivery of 6-week AP among cancer patients with pain.

Methods: The study design was a randomized non-inferiority trial of the individual (gold-standard treatment) vs. group AP for cancer pain. The primary outcome was pain interference and severity, measured through the Brief Pain Inventory (BPI). Secondary outcomes included measures of mood, sleep, fatigue, and social support. Changes in outcomes from pre to post-intervention were examined using linear mixed effects modeling and non-inferiority was inferred using a non-inferiority margin, a difference of change between the two arms and 95% CIs. Pain interference was tested with a non-inferiority margin of 1 on the BPI, while pain severity and secondary outcomes were compared using conventional statistical methods.

Results: The trial included 74 participants randomly allocated to group (35) or individual (39) AP. The non-inferiority hypothesis was supported for pain interference [$\Theta -1$, $\Delta 1.03$, 95%CI: .15-2.20] and severity [$\Theta -.81$, $\Delta .52$, 95%CI: .33-1.38] as well as for mood [$\Theta -7.52$, $\Delta 9.86$, 95%CI: .85-18.86], sleep [$\Theta -1.65$, $\Delta 2.60$, 95%CI: .33-4.88], fatigue [$\Theta 8.54$, $\Delta -15.57$, 95%CI: 25.60-5.54] and social support [$\Theta .26$, $\Delta -.15$, 95%CI: -.42-.13], meaning that group AP was not inferior to individual AP treatment. Both arms evidenced statistically significant improvements across all symptoms pre-post intervention. Effect sizes for group vs. individual AP on outcomes of pain, sleep, mood and social support ranged from small to very large, and were consistently larger in the group condition. The total average cost-per-person for group AP (\$221.25) was almost half that of individual AP (\$420).

Conclusions: This is the first study to examine the non-inferiority of group AP with the gold standard individual AP. Group AP was non inferior to individual AP for treating cancer pain, and was superior on many health outcomes. Group AP is more cost-effective for alleviating cancer pain and should be considered for implementation trials.

Paper Session 39

4:00 PM-4:15 PM

THE SEAMLESS STUDY: A RANDOMIZED CONTROLLED TRIAL OF A SMARTPHONE APP-BASED MINDFULNESS INTERVENTION FOR CANCER SURVIVORS

Linda E. Carlson, PhD¹, Utkarsh Subnis, PhD², Norman A. Farb, PhD³, Mark G. Thoburn, n/a⁴, Bechara J. Saab, PhD⁵¹University of Calgary, Calgary, AB, Canada; ²University of Calgary Cumming School of Medicine, Calgary, AB, Canada; ³University of Toronto, Mississauga, ON, Canada; ⁴Mobio Interactive Inc., Toronto, ON, Canada; ⁵Mobio Interactive, Zurich, Zurich, Switzerland

Background: Cancer patients transitioning to survivorship after completing cancer treatments need psychosocial interventions to manage stressors such as anxiety, depression, and fear of cancer recurrence. Mindfulness-based interventions (MBIs) are effective for treating these symptoms; however, cancer survivors are often unable to participate in face-to-face interventions because of difficulties such as work and family commitments, treatment-related side-effects, scheduling conflicts and geography. Smartphone app-based MBIs are an innovative way to deliver psychosocial cancer-care, and can overcome several such difficulties. However, while hundreds of mindfulness training apps are commercially available, none have been developed specifically for and rigorously evaluated in cancer survivors.

Objective: The SEAMLESS study aims to evaluate the efficacy of a tailored app-based mindfulness intervention for cancer survivors on: 1) symptoms of stress (primary outcome), as well as; 2) fear of cancer recurrence, anxiety, depression, fatigue, and overall physical functioning (secondary outcomes). Additionally, the study aims to assess associations between psycho-biometric data collected by the smartphone app with self-reported outcome data from validated psychometric scales.

Methods: The study is a randomized wait-list controlled trial evaluating the effectiveness of the *Am MBCS app* for impacting the primary and secondary outcomes in cancer survivors who have completed all treatments for a minimum of 2 weeks. Outcomes were assessed online using validated psychometric instruments delivered through the Research Electronic Data Capture (REDCap) survey software at: 1) baseline; 2) mid-intervention (2 weeks later); 3) immediately post-intervention (4 weeks); 4, 5 & 6) at 3, 6 and 12 months' post-baseline. The waitlist group crossed over to the intervention condition after the 3-month assessment. Additionally, data will be obtained by the smartphone app itself, which includes users' engagement with the app-based intervention, their emotional state (e.g. angry, elated) from a user-inputted digital emotion-mapping board, and heart-rate data through algorithms that analyze facial bio-signals using photoplethysmography technology.

Results: 83 participants enrolled with primarily breast (44/83, 53%) or colorectal (17/83, 20%) cancers, although many other cancer types are also represented. Data collection for analysis of the primary outcome will be complete by September 2019, and follow-up data will be complete by May 2020. Data will be analyzed to determine group differences using and Linear Mixed Modelling statistical techniques.

Discussion: This study will provide rigorously evaluated efficacy data for an app-based mindfulness intervention for cancer survivors, which if helpful could be made available for psychosocial care at cancer centers worldwide.

Paper Session 39

4:15 PM-4:30 PM

SOCIAL MEDIA RECRUITMENT OF YOUNG ADULT CANCER SURVIVORS INTO A RANDOMIZED TRIAL OF AN MHEALTH PHYSICAL ACTIVITY INTERVENTION

Carmina G. Valle, PhD, MPH¹, Lindsey N. Horrell, PhD, MPH, RN¹, Molly A. Diamond, MPH¹, Erin M. Coffman, MA², Bernardine M. Pinto, Ph.D.³, Brooke T. Nezami, PhD, MA¹, Kristen Polzien, Ph.D.⁴, Karen E. Hatley, MPH⁵, Deborah F. Tate, PhD⁴¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²UNC Chapel Hill Gillings School of Public Health, Durham, NC; ³University of South Carolina, Columbia, SC; ⁴University of North Carolina, Chapel Hill, NC; ⁵UNC Chapel Hill, Chapel Hill, NC

Background: While increasing physical activity is beneficial for cancer survivors, about 60% of young adult cancer survivors (YACS, ages 18-39) are not meeting physical activity guidelines. To date, few studies have recruited YACS from around the United States to promote physical activity using digital and distance-based intervention approaches. This study describes the recruitment strategies used in the Improving Physical Activity after Cancer Treatment (IMPACT) study, a 12-month randomized controlled trial of a theory-based, mobile physical activity intervention designed specifically for YACS.

Methods: We used a variety of methods and channels to recruit YACS who were diagnosed with cancer between the ages of 18-39 and within the last 10 years, had completed active therapy, could read, write and speak English, participated in less than 150 minutes/week of moderate-to-vigorous intensity activity, and had Internet access, a mobile phone, and a text messaging plan. We used phone calls and direct mailings to potentially eligible individuals identified through tumor registries, targeted social media advertisements, list serves, and clinical referrals. We also asked community organizations to share study information on social media and advertised at a national conference for YACS.

Results: The current sample of 273 participants (21% minority, 18% male, mean age 33.4±4.8 years, 98% of planned sample) was recruited over a 13-month period at a rate of 21 participants/month. Of 860 online screening surveys initiated, 693 were completed (80.6%). Of 492 individuals who were initially eligible, 392 completed additional phone screening, and 370 were eligible. Among eligible individuals, 328 (88.6%) consented to participate and 273 (73.8%) have been randomized. The top recruitment approach was social media, with 46.5% (322 of 693) of completed screeners initiated through Facebook, of which 94.7% (305 of 322) were recruited through posts by cancer organizations, friends or family, while just 5.3% (17 of 322) were through paid advertisements. Almost half of randomized participants (131 of 273, 48.0%) were recruited via Facebook posts (45.8% posts by organizations/friends, 2.2% from paid advertisements), while direct mail yielded 40% of participants. Other forms of social media (Instagram and Twitter), email, list serves, clinic referrals, and conference advertisements each yielded 3% or fewer participants.

Conclusion: Facebook was the most successful strategy to recruit YACS to the IMPACT trial. These findings could provide useful guidance for recruiting sedentary YACS and for distance-based mobile physical activity intervention trials.

MERITORIOUS AWARD WINNER**Paper Session 39****4:30 PM-4:45 PM****DEVELOPMENT AND PRELIMINARY FEASIBILITY STUDY OF A COMMUNITY-BASED WELLNESS COACHING FOR CANCER SURVIVORS PROGRAM**

Nicole J. Berzins, n/a¹, Michael J. Mackenzie, PhD², Nicole T. Pickles, BA Psychology Emory University³, Tara Leonard, MS Health Promotion, National Board Certified Health and Wellness Coach², Diane O. Beneck, BSN, National Board Certified Health & Wellness Coach², Mary Lou Galantino, PT, MS, PhD, MSCE, FNAP, FAPTA⁴

¹University of Delaware, Bear, DE; ²University of Delaware, Newark, DE; ³Cancer Support Community Delaware, Wilmington, DE; ⁴Stockton University, Galloway, NJ

In the United States alone, there are more than 15 million cancer survivors, with that number estimated to reach 20 million by 2026. Cancer survivors tend to have poorer health outcomes and are at increased risk for developing a second cancer and other chronic illnesses. Evidence suggests a substantial cancer burden may be prevented through lifestyle modification. The purpose of this preliminary feasibility study was to determine the viability of health coaching for the improvement of health, fitness, and overall well-being of cancer survivors in a community setting. Participants were recruited from Cancer Support Community locations across the state of Delaware. Health coaching was provided to people diagnosed with cancer anywhere along the cancer continuum, from early diagnosis to long-term cancer survivorship. The program provided six individual coaching sessions to each participant: one 90-minute initial in-person session and five 30-minute follow-up sessions, either in-person, by phone, or videoconference, as designated by participant preference. A total of 48 participants completed an average of 85% of coaching sessions. Surveys were sent to participants pre- and post-intervention on a variety of health topics including fitness, eating habits, perceived stress, anxiety, depression, and quality of life. Results were analyzed using repeated measures multilevel modeling. Moderately significant reductions were found in perceived stress ($p < .001$, $d = -0.53$) and anxiety ($p < .001$, $d = -0.57$), with small but significant decreases in depression ($p = 0.10$, $d = -0.35$). Coaching participants also noted significant improvements in weekly physical activity, including weekly moderate-vigorous physical activity ($p = .007$, $d = 0.48$; $p = .034$, $d = 0.37$). Small significant increases were found in healthy eating behavior ($p = .009$, $d = 0.40$). Participants reported moderate change in the quality of their sleep and small but significant changes in the duration of their sleep and sleep efficiency ($p = .006$, $d = -0.46$; $p = 0.05$, $d = -0.35$; $p = 0.035$, $d = -0.27$). Importantly, participants reported improved quality of life particularly in areas of physical and emotional well-being ($p < .001$, $d = 0.46$; $p < .002$, $d = 0.56$). Smaller increases were found in functional and total well-being ($p = 0.011$, $d = 0.36$; $p = 0.002$, $d = 0.39$). Preliminary findings indicate real behavior change in the measured outcomes and suggests that health coaching may be an important tool for cancer survivorship.

CITATION AWARD WINNER**Paper Session 40****3:30 PM-3:45 PM****EFFECTS OF RELATIONSHIP AND COMMUNICATION FACTORS ON AMBULATORY BLOOD PRESSURE IN CAREGIVERS OF ADVANCED CANCER PATIENTS**

Amy K. Otto, PhD¹, Emily C. Soriano, M.A.², Wendy C. Birmingham, Doctoral³, Susan Vadaparampil, PhD¹, Richard E. Heyman, Ph.D.⁴, Lee Ellington, PhD⁵, Maija Reblin, PhD¹

¹Moffitt Cancer Center, Tampa, FL; ²University of Delaware, Newark, DE; ³Brigham Young University, Provo, UT; ⁴New York University, New York, NY; ⁵University of Utah, Salt Lake City, UT

Background: Cancer impacts both patients and their family caregivers. Evidence suggests that caregiving stress, including the strain of taking on a new role, can elevate the risk of numerous medical conditions, including high blood pressure (BP). However, the caregiver's psychosocial experiences, including their interpersonal relationship with the patient, may buffer some of the negative physiological consequences of caregiving. The goal of this study was to examine the influence of psychosocial contextual variables on caregiver ambulatory BP.

Method: Participants were 81 spouse caregivers of patients with advanced GI or thoracic cancer. For an entire day at home with the patient, caregivers wore an ambulatory BP cuff, which measured momentary BP at random intervals ($M = 20$ minutes). Immediately after each BP reading, caregivers reported on physical circumstances (e.g., posture, activity) and psychosocial experiences since the last BP measurement, including affect, caregiver and patient self-disclosure, and role perceptions (i.e., degree to which the caregiver felt more like a spouse vs. caregiver). Multilevel modeling was used to examine concurrent and lagged effects of psychosocial variables on systolic and diastolic BP, controlling for momentary posture, activity, time, and negative affect.

Results: Feeling more like a caregiver (vs. spouse) was significantly associated with lower systolic BP at the same time point, controlling for posture, activity, time, and negative affect. Patient disclosure to the caregiver since the previous BP reading was significantly associated with higher diastolic BP at the same time point. No lagged effects were statistically significant.

Discussion: Our results indicate that caregivers' psychosocial experiences can have immediate physiological effects. Future research should examine possible cognitive and behavioral mechanisms of these effects. For example, feeling more like a caregiver may lower stress by allowing caregivers to focus more on the practical tasks of caregiving; conversely, feeling more like a spouse may increase stress by causing caregivers to focus more on their spouse's potential suffering. Patient disclosure may also serve to increase the caregiver's awareness of the patient's stress, thus increasing the caregiver's own stress and diastolic BP. Future work should also explore longer-term effects of caregiver role perceptions and patient disclosure on caregiver psychological and physical health.

Paper Session 40

3:45 PM-4:00 PM

INVESTIGATING NONVERBAL SYNCHRONY AS A MARKER OF RELATIONSHIP QUALITY IN ONCOLOGY INTERACTIONS WITH WHITE AND BLACK PATIENTS

Lauren M. Hamel, PhD¹, Robert G. Moulder, MA², Susan Eggly, PhD¹, Terrance L. Albrecht, PhD¹, Steven Boker, PhD², David W. Dougherty, MD, MBA³, Louis A. Penner, PhD¹

¹Wayne State University/Karmanos Cancer Institute, Detroit, MI; ²University of Virginia, Charlottesville, VA; ³Dana-Farber Cancer Institute, Boston, MA

Background: Communication in racially discordant (Black patient, non-Black physician) oncology interactions, which constitute about 80% of Black patients' interactions, is generally poorer than in racially concordant interactions, and likely contributes to treatment disparities. However, the nonverbal behaviors that contribute to this problem are largely unknown. We examined nonverbal synchrony, or the nonconscious coordination of movement, which can reflect relationship quality. We hypothesized that racially discordant interactions will have lower levels of nonverbal synchrony.

Methods: Data include video recordings of 68 Black patients and 163 White patients discussing treatment with their non-Black oncologists. Recordings were submitted to motion detection software to measure nonverbal synchrony. This software measures global synchrony (all correlated motion), peak synchrony (all positively correlated motion), who is leading the interaction (similar to who is leading in ballroom dancing), and how much synchrony occurs based on who is leading the interaction. Using multi-level models, we investigated whether nonverbal synchrony differed in racially concordant and racially discordant dyads.

Results: Findings showed greater levels of global synchrony ($p < .05$) and greater peak synchrony ($p < .05$) in racially discordant interactions compared to racially concordant interactions. Global synchrony was the same in racially concordant interactions regardless of who was leading, but greater global synchrony occurred in racially discordant interactions when the patient was leading ($p < .05$).

Conclusions: This is the first study to use a dynamic jointly determined measure of behavior to assess oncology interactions. Contrary to our hypothesis, nonverbal synchrony was greater in racially discordant interactions than in racially concordant interactions. It appears patients are driving more of the synchrony in racially discordant interactions. This may suggest that physicians in racially discordant interactions adapt to their patients to bridge racial differences. Findings could contribute to physician training to enhance coordination and outcomes in oncology interactions.

Paper Session 40

4:00 PM-4:15 PM

IMPLICATIONS OF ENROLLING A RURAL, COMMUNITY PHARMACY AS A VACCINES FOR CHILDREN PROVIDER ON HPV VACCINATION UPTAKE

Casey L. Daniel, PhD, MPH¹, Chelsea L. Green, MPH², Katherine Anderson, n/a³, Shelby L. Bradley, n/a⁴, Anna R. Wright, BS⁵, Frances G. Lawson, n/a⁶

¹University of South Alabama, Mobile, AL; ²University of South Alabama College of Medicine, Spanish Fort, AL; ³University of South Alabama Mitchell Cancer Institute, Mobile, AL; ⁴Mitchell Cancer Institute, Auburn, AL; ⁵University of South Alabama College of Medicine, Mobile, AL; ⁶University of Mississippi Medical Center, Biloxi, MS

Background: Human papillomavirus (HPV) currently infects almost 80 million people in the U.S. High-risk HPV strains are associated with 6 types of cancers in men and women. Despite a safe, effective vaccine against high risk strains, HPV immunization rates remain low, particularly in the southeast. Disparities are a significant concern for rural areas where limited access and low socioeconomic status are major barriers, prompting the suggestion of pharmacies as alternative vaccination sites. In Alabama (AL), 45% of the population lives in rural areas; 22 of the 67 counties lack a pediatrician. Clarke County has the lowest HPV vaccine initiation rate in AL (28.2%), lacks a pediatrician, and 68.9% of adolescents are Medicaid-eligible. This study sought to determine the feasibility of enrolling a community pharmacy in Clarke County as a Vaccines for Children (VFC) provider and assess its potential impact on HPV vaccination.

Methods: We worked with a community pharmacy in Clarke County to enroll as a VFC provider, train in the state immunization registry, and develop internal vaccination and documentation protocols. We designed educational/promotional materials, a social media campaign, and quantitative surveys for parents and the pharmacist to measure baseline knowledge and intervention reach. Program evaluation of intervention efficacy, feasibility, and scalability is ongoing.

Results: From July 24-September 4, 2019, the pharmacy administered 37 HPV vaccines (32 VFC). Among parents, 56.7% reported physician referral to the pharmacy for HPV vaccination. While 53.3% reported attending specifically for the HPV vaccine, 63.3% received at least one other vaccine while there; 36.7% of parents noted convenience and speed as reasons for vaccinating their child at the pharmacy.

Conclusions: Community pharmacies address a significant need as alternative HPV vaccination settings among rural, medically underserved populations and can be feasibly achieved through productive partnerships. Physician referrals to pharmacy indicate growing acceptance of expanding the medical neighborhood. Positive parental response indicates feasibility for pharmacies as alternative settings. Uptake of 37 HPV vaccinations in 6 weeks in a town with population < 1500 is impressive, indicating high demand for more VFC providers in these areas. These findings are promising for expansion of these efforts with the ultimate goal of increasing HPV vaccination and reducing HPV-associated cancers.

4:15 PM-4:30 PM

EXPLORING PATIENT-PROVIDER COMMUNICATION AND EDUCATION ABOUT OPIOID USE FOR CANCER-RELATED PAIN AMONG CANCER SURVIVORS

Paige W. Lake, MPH¹, Melody Chavez, MPH¹, Ana Gutierrez, BA¹, Khary Rigg, PhD¹, Barbara Lubrano, MD², Sahana Rajasekhara, MD², Smitha Pabbathi, MD², Dinorah (Dina) Martinez Tyson, PhD, MA, MPH¹

¹University of South Florida, Tampa, FL; ²Moffitt Cancer Center, Tampa, FL

Background: Prescription opioids are a common and effective method to manage cancer-related pain. However, cancer patients often receive little information from providers about prescription opioids they take. Effective provider communication and education are critical aspects of pain management which may help mitigate fear surrounding opioids and deter nonmedical use in the cancer survivorship context. We aimed to understand health care provider, cancer survivor, and community level stakeholder perceptions of and experiences with patient-provider communication regarding prescription opioids.

Methods: Healthcare providers (n=25), stakeholders (n=6), and cancer survivors (n=25) participated in interviews that assessed patient-provider discussions about pain, perceptions of opioid use, education about pain management, and psychosocial aspects of pain and cancer survivorship. Interviews were audio-recorded, transcribed, and coded. Inductive applied thematic analysis was employed to identify emergent themes.

Results: Participants from all three groups felt that the stigma associated with opioids (i.e., patients fear of being labeled “drug-seeking”), fear of addiction to opioids, and lack of a relationship with providers contributed to patients’ reluctance to discuss and report pain or pain concerns, resulting in poorly managed pain. Several providers also indicated that psychological issues of anxiety/depression could be exacerbated by poor pain management. Conversely, providers and stakeholders indicated that patients often take opioids as a method of coping with anxiety/depression. We also identified that education provided to cancer patients about opioids is inconsistent across providers and that the many different specialties involved in patients’ care team often resulted in a lack of inter-provider communication.

Conclusions: Findings suggest that inter-provider communication could improve and that there is a need for patient-centered communication, which emphasizes fostering relationships with patients, focuses on addressing patient concerns, responding to psychosocial issues, and promotes shared decision-making. These are critical components of cancer care among survivors who may require opioids to manage pain. Multi-level interventions that target patients and providers such as oncologists, primary care providers, psychiatrists, and psychologists should be developed to ensure patients are better informed on prescription opioids and non-opioid options for pain and how to communicate effectively with providers, and to better prepare providers to discuss these issues with patients, as provider education is key to addressing some of the misconceptions surrounding opioid use among patients.

4:30 PM-4:45 PM

ONCOLOGIST CONFIDENCE IN GENOMIC TESTING AND IMPLICATIONS FOR TEST USE TO GUIDE PATIENT CARE

Janet S. de Moor, PhD, MPH¹, Stacy Gray, MD, AM², Andrew N. Freedman, PhD³, Carrie Klabunde, Ph.D., MBA, MHS⁴, Sandra A. Mitchell, PhD, CRNP¹

¹National Cancer Institute, Rockville, MD; ²City of Hope, Duarte, CA; ³NCI, Rockville, MD; ⁴National Institutes of Health/Office of Disease Prevention, Rockville, MD

Background: The rapid evolution of tools for precision oncology has accelerated the inclusion of genomic-based treatment planning as standard care. Yet, there is limited data about the extent to which oncologists are confident that they have the knowledge and resources to use genomic test results to guide treatment. We characterized oncologists’ confidence in using somatic genomic testing to guide treatment decisions and examined predictors of confidence and recent genomic test use.

Methods: Using data from the 2017 National Survey of Precision Medicine in Cancer Treatment, we characterized confidence in using genomic testing in a nationally representative sample of 1,281 medical oncologists, hematologists, and hematologist-oncologists practicing in the United States. Genomic confidence was examined among four types of test users: next generation sequencing (NGS) users, gene expression (GE) users, both NGS and GE users, and non-users. Associations between individual- and practice-level characteristics and confidence were modelled with multinomial logistic regression. The association between confidence and test use was examined with multivariable linear regression.

Results: Over 75% of genomic test users reported they were moderately or very confident using results from somatic panel tests to guide patient care. Confidence was highest among both NGS and GE users (60.1% very confident using test results) and lowest among NGS only users (38.2% very confident using test results). Even among test non-users, 27.1% were very confident and 37.8% were moderately confident using results to guide patient care. Oncologists were most confident using single-gene tests and least confident using whole exome or genome sequencing to guide decisions. NGS and GE users who were not at all or a little confident were least likely to use the results from somatic panel tests to inform care ($p < 0.01$). The association between confidence and test use was similar for NGS only users. Training in genomics, higher patient volume, and treating solid tumors were associated with higher confidence; on-site pathology and electronic health record alerts for genomic testing were associated with lower confidence (p -values < 0.05).

Conclusion: Oncologists’ confidence varies by genomic testing platform, patient volume, genomic training, and practice infrastructure. Research is needed to identify modifiable factors that can be targeted to enhance provider confidence with genomic testing.

Paper Session 41

3:30 PM-3:45 PM

PERCEIVED ENVIRONMENT, PARENT SUPPORTIVE BEHAVIORS AND CHANGES IN PRE-SCHOOL CHILDREN'S PHYSICAL ACTIVITY OVER THREE YEARS

Simone A. French, PhD¹, Nancy E. Sherwood, PhD¹, Yingling Fan, PhD², Alicia Kunin-Batson, PhD³, Jerica M. Berge, PhD, MPH³¹School of Public Health University of Minnesota, Minneapolis, MN; ²Humphrey School of Public Affairs University of Minnesota, Minneapolis, MN; ³University of Minnesota, Minneapolis, MN

Low-income children who live in poor neighborhoods with high crime and fewer safe play areas may be at risk for low PA. Parent supportive behaviors, such as doing PA with their child, modeling PA, verbal encouragement and taking the child to places for PA are consistently associated with higher child PA. Parent supportive behaviors for child physical activity have largely been examined separately from neighborhood factors, and have rarely been examined over time in relationship to changes in child physical activity.

The present study examined the influence of neighborhood environment and parent supportive behaviors for physical activity on changes in child physical activity over a three-year period. The study is a secondary data analysis from the NET-Works randomized controlled trial (2010-2018) involving 534 ethnically/racially diverse (56% Hispanic) preschool-aged children. Measurements were conducted on a rolling basis that included all seasons at baseline and 36 months. Accelerometry data were collected at each measurement time point on both the child and the parent. Details are reported elsewhere. Cohort retention in the parent study was 92% at 36 months.

Multivariate regression models were used to separately examine associations between neighborhood environment and parent supportive behaviors, and change at 36 months in child physical activity. Separate models were run for change in child moderate/vigorous PA (MVPA) and sedentary activity. Baseline value of the respective physical activity variable was included as a covariate in each model.

In adjusted multivariate regression models, parent supportive behaviors ($B = 3.2$ [se 1.4], $p < .03$) and perceived neighborhood environment (presence of lighting, street crossings, playgrounds) ($B = 1.1$ [se .40], $p < .01$) were statistically significant positive predictors of increases in child MVPA over three years. Decreases in child sedentary behavior were significantly associated with greater perception of positive neighborhood environment ($B = -2.5$ [se .81], $p < .002$), and marginally significantly associated with parent supportive behaviors ($B = -5.3$ [se 2.9], $p < .06$).

These results suggest that interventions that target both neighborhood traffic and lighting environment and the parents' supportive behaviors could be effective to promote child physical activity over time.

3:45 PM-4:00 PM

OBJECTIVELY ASSESSED PHYSICAL ACTIVITY AND REWARD RESPONDING IN PRESCHOOLERS

Diana J. Whalen, PhD¹, Joan Luby, MD¹, Greg Hajcak, PhD²¹Washington University in St. Louis, St. Louis, MO; ²Florida State University, Tallahassee, FL

Physical activity is crucial to mental health and wellbeing. Yet, relatively little work has focused on psychophysiological indices that may clarify relations between physical activity and mental health in young children. Using event-related potentials (ERPs), several studies demonstrate physical fitness and physical activity related improvements in cognitive and executive functioning among older children and adolescents. Whether alterations in reward circuit functioning implicated in the pathophysiology of depression can also be detected remains unexplored. The purpose of the present study was to quantify the impact of physical activity on affective neural responding assessed using the reward positivity (RewP) ERP component in preschoolers. This marker is of particular interest given known associations with the onset of mood disorders and alterations in reward circuit functioning. We hypothesized that objectively-assessed physical activity would predict RewP amplitudes, such that preschoolers with more physical activity across one week would evidence higher RewP amplitudes. Participants included 53 preschool children ages 3-5 years enrolled in a multi-wave study of physical activity and mental health recruited from the general community. Caregivers completed questionnaires about their child as well as a clinical interview assessing symptoms of psychopathology. Preschoolers were fitted with an accelerometer that was worn for one week, obtaining objective counts of physical activity and sedentary behavior. Preschoolers also completed an age-appropriate version of the Doors Guessing Task, where points can be won or lost on each trial while ERPs were recorded. The RewP was calculated as a difference score between the averaged neural responses to wins minus responses to loss in electrode site Fz from 200-350 ms. Overall, preschoolers were engaged in moderate-to-vigorous physical activity for approximately 1.4 hours per day and engaged in sedentary behavior for approximately 4 hours per day, after adjusting for nighttime sleep and napping. 17% ($n=9$) of the sample failed to meet the minimum recommended daily guidelines (less than 60 minutes) for physical activity in this age range. Linear regressions were conducted to determine whether physical activity and/or sedentary behavior were significant predictors of the RewP. After accounting for child age, sex, and negative affectivity, weekly moderate-to-vigorous physical activity was positively related to RewP amplitude [$\beta = 0.36$, 95% CI = (0.08, 0.76), $p = 0.02$]. Further, higher amounts of time spent in sedentary behavior predicted a more blunted RewP amplitude [$\beta = -0.34$, 95% CI = (-0.64, -0.06), $p = 0.02$]. Alterations in reward responding are evident among preschoolers with higher sedentary behavior and offer the first evidence for reductions in reward responding as a function of low physical activity in this young age group.

Paper Session 41

4:00 PM-4:15 PM

PREDICTING PERSONAL PHYSICAL ACTIVITY OF PARENTS DURING PARTICIPATION IN A FAMILY INTERVENTION TARGETING THEIR CHILDREN

Ryan E. Rhodes, Ph.D.¹, Alison Quinlan, BSc, MSc¹, Patti-Jean Naylor, PhD¹, Darren Warburton, PhD², Chris Blanchard, PhD³¹University of Victoria, Victoria, BC, Canada; ²University of British Columbia, Vancouver, BC, Canada; ³Dalhousie University, Halifax, NS, Canada

Background: Parents volunteering to participate in family interventions focused on child MVPA may also be positioned to improve their own MVPA. The purpose of this study was to examine the “spillover” effect of two family interventions targeting inactive children on their parents’ MVPA over 26 weeks. The primary outcome was MVPA via accelerometry with a secondary assessment of MVPA via self-report and putative mediators. Correlates of MVPA across the trial in the form of theory of planned behavior and multi-process action control were examined as exploratory outcomes.

Methods: One hundred and two parents (of children aged 6 to 12 yr), were recruited through advertisements and randomized to either a planning + education condition (n = 52) or an education only condition (n = 50) designed to improve child MVPA. Parental MVPA was assessed via accelerometry and self-report at baseline, six-week, 13-week, and 26-week time-periods as well as assessments of the proposed correlates.

Results: The two family interventions had an increase in parental MVPA from baseline to 26 weeks ($p < .05$), but no group differences on MVPA or the putative mediators using multi-level modeling ($p > .05$). The theory of planned behavior was unable to predict MVPA across the study ($p > .05$). Application of multi-process action control showed this was likely because nearly all participants possessed the intention to be physically active. The predictor of successful-compared to unsuccessful-intenders was a stronger habit in four of the six tests employed ($p < .05$).

Conclusions: The results suggest that parent MVPA may benefit during a family-based intervention but the putative mediators of this increase are unclear. Engaging habit to assist in action control (i.e., translation of intentions into behavior) is recommended for future research in this population.

Paper Session 41

4:15 PM-4:30 PM

EFFECTIVENESS OF SUSTAINABILITY VIA ACTIVE GARDEN EDUCATION (SAGE) ON YOUNG CHILDREN'S LOCOMOTOR SKILLS

Jacob Szeszulski, PhD¹, Elizabeth Lorenzo, BSN², Rebecca E. Lee, PhD²¹University of Texas Health Science Center at Houston, Houston, TX; ²Arizona State University, Phoenix, AZ

Introduction: Early care and education center (ECEC) physical activity programs are important for promoting health benefits in young children, including developmental outcomes such as locomotor skills. This study examined the effects of a garden-based, physical activity intervention on preschool-aged children's locomotor skill development using quantitative and qualitative outcome measures.

Methods: Sustainability via Active Garden Education (SAGE) is a garden-based program for preschool-aged children designed to improve physical activity and fruit and vegetable consumption in ECECs. SAGE engages children in structured physical activities (e.g., gardening, relay races, dancing) that promote learning, but may also enhance locomotor development. We used a cluster-randomized controlled trial to evaluate SAGE's effectiveness on children's quantitative (progressive cardiovascular endurance run [PACER]; n=104) and qualitative (CHAMPS Motor Skill Protocol [CMSP]; n=48) locomotor skills. ECEC (N=15) were block randomized to receive SAGE or a child safety comparison condition. Intervention children that completed the PACER (52.9±4.2 months; 73.4% Hispanic; 50% male) and CMSP (52.7± months; 68.8% male; 68.8% Hispanic) were not significantly different by age, ethnicity, or sex from control children that completed the PACER (54.5±4.8 months; 84.4% Hispanic; 51.5% male) and CMSP (54.6±5.0 months; 56.3% male; 85.7% Hispanic), respectively ($ps > .05$). We evaluated intervention outcomes using mixed effects linear regression models.

Results: Overall, children's average PACER laps (3.7±2.3 to 4.0±2.0) and CMSP criterion (20.0±5.0 to 22.1±5.0) increased from baseline to post-intervention. At post-intervention, both conditions (SAGE and control) increased their number of PACER laps completed. Children in the SAGE condition (0.3±2.1 laps) did not significantly improve by more laps than children in the control condition (0.4±2.1 laps). For the CMSP, children in the SAGE condition had a substantial increase in the number of criterion met (2.9±4.3), compared to children in the control condition (0.5±4.3). Mixed linear regression models, controlling for school level clustering, baseline locomotor score, and sex, revealed that the SAGE intervention was not significant for improving quantitative PACER scores ($b = -0.2 \pm 0.6$; $p = 0.723$), but was marginally significant for qualitative CMSP outcomes ($b = 2.3 \pm 1.2$; $p = 0.051$).

Discussion: Locomotor skills are a critical component of ECEC teacher's evaluation standards for children's development. To address these standards, ECEC teachers need programs that engage children in physical activity throughout the school day. SAGE offers a promising, structured program that ECEC teachers can apply during the school day, which meets national accreditation guidelines for development and engage children in a unique learning experience.

ENHANCING YOUTH'S PHYSICAL ACTIVITY IN URBAN NEIGHBORHOODS VIA GREEN SCHOOLYARD TRANSFORMATIONS

Amy M. Bohnert, Ph.D.¹, Laura Nicholson, MA², Laurel Mertz, BS in Psychology, BA in Spanish³, Carolyn R. Bates, Ph.D.⁴, Dana Gerstein, MPH, RD⁵

¹Loyola University Chicago, Evanston, IL; ²Loyola University Chicago, Forest Park, IL; ³Loyola University Chicago, Chicago, IL; ⁴Children's Mercy Kansas City/University of Kansas Medical Center, Chicago, IL; ⁵University of California, Nutrition Policy Institute, Evanston, IL

Background: Urban communities often have less access to nature and safe outdoor spaces, limiting opportunities for youth to engage in physical activity (PA). Transforming existing schoolyards into vibrant green spaces with developmentally appropriate play structures may be one way to overcome this challenge. Although prior work suggests that transformed green schoolyards demonstrate improvements in utilization and PA over time (Bates, Bohnert & Gerstein, 2018), the current study is the first to analyze changes in utilization and PA prior to and following a green schoolyard transformation among youth living in urban areas.

Methods: Using a multi-method evaluation strategy based on the RE-AIM framework, data were collected at two schoolyards in the city of Chicago prior to (T1) and following (T2) the transformation. Participants included children pre-k through 8th grade (51.9% male), and majority of children observed were African American (47.1%) or Latino/Hispanic (49.9%). Behavioral mapping techniques (Cosco, Moore, & Islam, 2012) were employed to capture both utilization and ratings of PA on the schoolyard (Child Activity Rating Scale; Durant et al., 1993). In addition, caregivers, teachers, and community members completed surveys assessing levels of schoolyard utilization and opportunities for PA (T1n = 178; T2n = 204).

Results: Several analyses, including t-tests, ANOVAs, and chi-square were used to examine changes in utilization and PA from T1 to T2. Behavioral maps indicated greater utilization of the schoolyard following the renovation, most notably prior to school (T1n = 295; T2n = 364) and afterschool (T1n = 85; T2n = 450). Caregivers and teachers also reported that the schoolyard was better utilized at T2 as compared to T1 during before and after school periods [$t(99) = -5.136$, $p < .001$; $t(142) = -3.489$, $p < .01$; $t(95) = -.3728$, $p < .001$; $t(133) = -3.860$, $p < .001$]. Levels of moderate-to-vigorous PA (MVPA) increased significantly from T1 to T2 at one school, $X^2 = 7.90$, $p < .01$, but not the other. Finally, caregivers and community members indicated that they used the schoolyard more for their children to play [$t(164) = -5.536$, $p < .001$; $t(33) = -2.175$, $p < .05$] and they felt the neighborhood was safer for children to play outside during the day [$t(153) = -2.587$, $p < .05$; $t(32) = -2.53$, $p < .05$] at T2 as compared to T1.

Conclusions: These findings suggest that green schoolyards may offer safe spaces for children to be physical active within high-crime urban neighborhoods.

PREMATURE MORTALITY ASSOCIATED WITH BEHAVIORAL HEALTH CONDITIONS DESPITE ACCESS TO COMPREHENSIVE HEALTH CARE SERVICES

Esti Iturralde, PhD¹, Natalie Slama, MPH¹, Andrea Kline-Simon, MS², Kelly Young-Wolff, PhD, MPH³, Don Mordecai, MD⁴, Stacy A. Sterling, DrPH, MSW¹

¹Kaiser Permanente Northern California, Oakland, CA; ²Kaiser Permanente Division of Research, Oakland, CA; ³Kaiser Permanente Northern California, Oakland, CA; ⁴Kaiser Permanente, Oakland, CA

Background: Individuals with severe mental illness (SMI), including psychotic, bipolar, and other affective disorders, die earlier than peers in the general population, usually of physical health conditions. Studies of U.S. public mental health service consumers attribute 15-30 years of reduced lifespan to SMI. However, most studies have not examined this mortality risk among a broader socioeconomic spectrum of insured individuals with access to comprehensive medical and behavioral health care, nor has research closely assessed the role of substance use disorders (SUDs), a common behavioral health comorbidity.

Purpose: Using 2010-2017 death records and electronic health records, we examined all-cause and cause-specific mortality, age of death, and health care use patterns associated with SMI and SUDs among members of an integrated healthcare delivery system in the U.S.

Method: Participants included 285,966 adult health system members with a documented SMI or SUD diagnosis in 2010 (behavioral health [BH] group) and 285,966 individuals with no BH diagnosis in 2010 matched on age, gender, and medical facility (comparison group). Multivariable models assessed BH diagnosis-specific mortality risk adjusting for race/ethnicity, socioeconomic status, health status, and smoking history.

Results: Physical health conditions (e.g., heart disease) accounted for 92.6% and 95.7% of deaths in the BH and comparison groups, respectively. Of the SMI conditions, psychotic disorders were associated with the highest all-cause mortality risk (adjusted OR [aOR] = 3.49; 95% confidence interval [CI]: 3.03-4.02), followed by bipolar disorders (aOR = 2.07; 95% CI: 1.81-2.38) and other affective disorders (aOR = 1.71; 95% CI: 1.67-1.76) relative to comparison individuals. Having a SUD (regardless of SMI diagnosis) conferred equivalent all-cause mortality risk as having a psychotic disorder, relative to comparison individuals (aOR = 3.48; 95% CI: 3.27-3.70). Cause-specific mortality risk results showed similar patterns. Of participants who died, individuals in the BH group died on average 6 years earlier than comparison individuals. The BH group used health services, including primary care, at higher rates than the comparison group. (All comparisons significant at $p < 0.001$.)

Conclusions: Even in an insured population, with broad access to medical and mental health services, and accounting for other confounding factors, SMI and SUDs were associated with significant excess mortality, often due to physical health conditions. Health care system approaches that integrate care for physical and behavioral health conditions are needed for this vulnerable population.

MESSAGE RECALL AND EYE TRACKING OF TEXT AND IMAGES IN SKIN CANCER PREVENTION PSAS

Karen Glanz, PhD, MPH¹, Amy Bleakley, PhD, MPH², Andrew Strasser, PhD¹, Amy Jordan, PhD³, Caroline LaRochelle, BA¹, DeAnn Lazovich, PhD, MPH⁴

¹University of Pennsylvania, Philadelphia, PA; ²University of Delaware, Newark, DE; ³Rutgers the State University of New Jersey, New Brunswick, NJ; ⁴University of Minnesota, Minneapolis, MN

Skin cancer in its various forms is the most commonly diagnosed cancer in the United States. Prevention guidelines recommend the practice of sun protection behaviors (e.g., using sunscreen) and avoiding indoor tanning. PSA videos are frequently used in health communication efforts to persuade and inform audiences. The videos are often a combination of images and text, and eye tracking analyses allow researchers to discern what features or design elements in the composition of a message/video hold an audiences' gaze, if not attention. Attention has been observed to be positively associated with recall and knowledge. We conducted two lab experiments using PSAs to encourage the recommended sun protection behaviors (Study 1; n=126) and to promote quitting indoor tanning (Study 2; n=44). Eye tracking recorded participants' gaze on objects of interest (AOIs), either text or images, that were identified a priori by the research team as central to the PSA. Recall of the AOIs after a two week follow-up was assessed. T-tests and Chi-square statistics were used to determine the relationship between recall (3 categories- none, some, all) and the percent total average fixed duration (i.e., amount of time eyes were fixed to each object). Results demonstrated that participants were more likely to correctly recall images associated with the videos compared to text. The more time spent fixed on images, the better the recall compared to those who recalled no images ($F(2)=4.78$, $p < .01$). Recall also improved as initial engagement (i.e., fixation on the first video image) increased ($F(2)=3.33$, $p < .05$). Implications for the development of effective health care messaging will be discussed.

POLICY EVALUATION OF A STATEWIDE LAW MANDATING SCHOOL-BASED FITNESS AND BODY MASS INDEX MEASUREMENT AND REPORTING

Phaedra Corso, PhD¹, Justin Ingels, MPH, MS², Janani Rajbhandari-Thapa, n/a², Marsha Davis, n/a²

¹Kennesaw State University, Kennesaw, GA; ²University of Georgia, Athens, GA

Introduction: To combat the childhood obesity epidemic, many states have passed legislation requiring schools to measure fitness and body mass index (BMI) in children (surveillance), with or without the additional requirement to report results to parents (screening). Evidence on effectiveness and cost-effectiveness of these policies are mixed and therefore so are recommendations from leading medical/public health organizations. In this study, we evaluate a statewide school-based fitness and BMI surveillance and screening law that has been fully implemented in Georgia since 2012, based on four attributes of policy implementation: 1) parental awareness of the policy; 2) parental awareness of his/her child's own fitness assessment results; 3) usage of fitness results in modifying behavior and seeking medical care, if applicable; and 4) perceptions of fitness assessments in schools.

Methods: State-wide survey data were collected from random-digit dial and online (Qualtrics Online Sample) from April to December 2018, for a total sample of N=1683 respondents. All respondents were 18 years and older, a parent/legal guardian of a child in 5th through 8th grade attending a public school in Georgia, able to respond in English or Spanish, and not employed as a teacher or administrator in the public-school system.

Results: Although most parents (92%) had never heard of the specific fitness and BMI assessment legislation, more than half

(>52%) of all parents reported that their child participated in one component of the mandatory fitness assessment. However, only 31% of parents reported receiving fitness and BMI results. For these parents, 65% reported talking to their child about the report, while less than half (43.7%) reported talking to the child's doctor. The majority of all parents were in favor of nutrition education (80%) and physical activity opportunities (94%) for their children in schools; but fewer parents were in favor of mandatory BMI screening as a state policy (45%).

Discussion: Overall this study shows that a state-level law mandating fitness and BMI assessment for children may be successful in school-based surveillance of physical activity and obesity levels, but fails in terms of public awareness, individual receipt of screening information and behavior change, and public perception of the appropriateness of the policy.

Paper Session 42

4:15 PM-4:30 PM

EFFECT OF CALIFORNIA “COMPETITIVE” FOOD AND BEVERAGE POLICIES ON WEIGHT STATUS AMONG HIGH SCHOOL STUDENTS

Emma V. Sanchez-Vaznaugh, ScD, MPH¹, Brisa N. Sanchez, PhD², Maria E. Acosta, MPH³, Mika Matsuzaki, PhD⁴¹San Francisco State University, San Francisco, CA; ²Drexel University, Philadelphia, PA; ³San Francisco State University, Alameda, CA; ⁴SFSU, Seattle, WA

Background: Competitive food and beverage policies (“CF&B policies”) have been adopted to help prevent childhood obesity. However, few studies have examined their influence on obesity and obesity disparities among high school students.

Objective: To investigate whether the association between California’s CF&B policies and overweight/obesity varies by race/ethnicity among high school students.

Methods: Using statewide California data from 9th Grade students in public schools along with a quasi-experimental design, gender-stratified multilevel logistic models estimated trends in overweight/obesity between the periods before 2002-2007 and after 2008-2012 enactment of CF&B policies and assessed whether those trends differed significantly by race/ethnicity. Models were adjusted for student-level variables (age, race/ethnicity, physical fitness) and school-level socioeconomic factors.

Results: Before the policies were enacted (2002-2007), overweight/obesity was significantly increasing among both boys and girls and across all race/ethnic groups. In the post-policy period (2008-2012), overweight/obesity declined over time among boys of all racial/ethnic groups though the decline was not significant among Asian students. Overweight/obesity prevalence was no longer significantly increasing for Asian, African American and White girls, and showed slight, though non-significant, annual declines among Latina girls. The association between the policies and overweight/obesity varied significantly by race/ethnicity. Asian girls experienced the largest change in the overweight/obesity trends, followed by Latinx, White and African American girls. Among boys, Latino children saw the largest change in overweight/obesity trends, followed by African Americans, Asians and Whites.

Conclusion: Within California’s overall positive policy environment to halt the obesity epidemic, the CF&B policies are associated with improvements in population-level overweight/obesity prevalence among students in high schools, with differences in the magnitude of those improvements by race/ethnicity.

Implications for Practice and Policy: Policies to regulate junk food and sugary drinks in schools may be an effective strategy to prevent obesity among students in high schools and achieve health equity. Examining the joint role of policies to modify the food environment within and outside schools may provide additional strategies to fully reverse the obesity epidemic.

Support/Funding Source: NHLBI and RWJF.

THE POTENTIAL PUBLIC HEALTH IMPACT OF A DEPRESSION AND WEIGHT MANAGEMENT INTERVENTION: LESSONS FROM THE RAINBOW TRIAL

Megan A. Lewis, PhD¹, Lisa Goldman Rosas, PhD, MPH², Nan Ly, PhD³, Laura K. Wagner, MPH⁴, Valerie Etta, BA⁴, Olivia Burrus, MPH⁴, Mark Snowden, MD MPH⁵, Elizabeth M. Venditti, PhD⁶, Jeremy Goldhaber-Fiebert, PhD⁷, Jun Ma, MD, PHD³¹RTI International, Seattle, WA; ²Stanford University, Palo Alto, CA; ³University of Illinois at Chicago, Chicago, IL; ⁴RTI International, Research Triangle Park, NC; ⁵University of Washington, Seattle, WA; ⁶University of Pittsburgh School of Medicine, Pittsburgh, PA; ⁷Stanford University, Stanford, CA

Background: The Research Aimed at Improving Both Mood and Weight (RAINBOW) trial demonstrated that an integrated and collaborative care intervention significantly improved obesity and depression. We used an effectiveness-implementation hybrid type 1 approach employing the RE-AIM framework to study stakeholder perspectives of the intervention’s implementation and potential public health impact.

Methods: We conducted 185 semi-structured interviews with 148 patient participants (out of 409 total) and 37 clinical stakeholders (e.g., physicians, medical directors, and clinical managers) at primary care practices where the trial was conducted. The interviews included 74 at baseline, 32 at 6 months (end of intensive treatment), 36 at 12 months (end of maintenance treatment), and 43 at 24 months (end of post-treatment follow-up). Interviews were recorded, transcribed, coded and analyzed with NVivo using a Framework Analysis approach to identify themes in the data. Coders’ Kappa scores were .53-1.00 across codes which is considered moderate to excellent agreement. Here we present findings related to RE-AIM’s effectiveness dimension.

Results: At baseline, both stakeholder groups saw the promise of an integrated and collaborative approach to addressing obesity and depression. Stakeholders voiced concerns about the time, resource intensity, and challenges of changing multiple weight/lifestyle behaviors and managing mood at the same time. Clinical stakeholders expressed skepticism that this approach could work for different patient subgroups (e.g., older vs younger ages). Over time, patient stakeholders reported benefit from improved problem solving skills and greater social support, but desired more individual tailoring and accountability for making changes. Over time, clinical stakeholders stated that the expertise provided from a team-based collaborative approach was effective across diverse patient groups (e.g., age and other SES factors). They continued to voice concerns about how this approach could be implemented as standard practice and incentivized due to the additional time required to deliver collaborative care.

Conclusion: Stakeholders’ perceptions of an integrated and collaborative approach to managing obesity and depression suggest that effectiveness at scale could hinge on providing patients with tailored content and greater accountability while clinical stakeholders viewed resources and incentives in a primary care context as the linchpin for wider uptake and implementation of the approach to impact public health.

Paper Session 43

3:30 PM-3:45 PM

EXAMINING ASSOCIATIONS BETWEEN UNMET SOCIAL NEEDS AND HEALTH AMONG MEDICAID BENEFICIARIES

Amy McQueen, PhD¹, Linda C. Li, PT, PhD², C. Deepak Baddam, M.S³, Rachel E. Smith, MSN, RN, CCM⁴, Matthew W. Kreuter, PhD, MPH⁵¹Washington University School of Medicine, St. Louis, MO; ²University of British Columbia, Vancouver, BC, Canada; ³Centene Corporation, Baton Rouge, LA; ⁴Louisiana Healthcare Connections, Baton Rouge, LA; ⁵Washington University in St. Louis, St. Louis, MO

Background: Having unmet social needs such as housing or transportation impedes disease management and health behavior change that could increase negative health outcomes and costly healthcare utilization. Most research to date has examined associations between a single social need (e.g., food insecurity) and a few health-related outcomes in a specific population subgroup (e.g., parents with young children). To extend this work, we examined a larger set of social needs and health-related outcomes in a sample of adult Medicaid beneficiaries in Louisiana.

Methods: Members (n=10,267) of the Louisiana Healthcare Connections (LHCC) Medicaid health plan completed a 10-item social needs assessment by phone July 10, 2018 to June 28, 2019 as part of standard service. Questions assessed members' expectations for having enough food, housing (2), physical safety (2), childcare, transportation, ability to pay for utilities, necessities, and unexpected expenses in the next month. Sum scores were created; higher scores reflect a greater number of unmet needs. Social needs data were linked to member's medical and pharmacy claims data and other LHCC interviewer-administered assessments for general health risk, depression (PHQ-2), and substance abuse (CAGE-AID) completed within the 12 months prior to the social needs assessment. Descriptive statistics and bivariate associations are reported.

Results: Most members were female (72%), African American (45%) or White (32%), and had Medicaid through SSI (22%), TANF (20%) or expansion (55%) programs. Most (55%) reported at least one unmet need (M=1.1, SD=1.4) including not having enough money for unexpected expenses (47%) or necessities like food, shelter and clothing (14%), and utilities (12%). Of the subset who had children and needed childcare, 43% had problems finding or paying for it. Having a greater number of unmet needs was associated with greater health care utilization: PCP ($F=16.55$, $p<.0001$), ER ($F=21.43$, $p<.0001$), and inpatient ($F=3.89$, $p=.021$) visits. Having a greater number of unmet needs was associated with having a chronic condition, a vision, hearing or mobility problem, nicotine dependence, depressive symptoms, and problems taking medications as directed ($p<.001$).

Conclusions: While the direction of causality is not known, our findings support associations between social needs and diverse health-related outcomes. This study is novel in its state-wide representation, linking of self-report and claims data, and study of multiple unmet needs and health outcomes. Future analyses will include additional outcomes and examine differences by type and cluster of social needs and for different chronic conditions and combinations. These results support efforts to integrate systematic screening and interventions to address unmet needs into healthcare systems to improve health outcomes.

ADDITIVE EFFECTS OF GLOBAL STRESS AND DAILY GENERAL AND TYPE 1 DIABETES STRESSORS DURING EMERGING ADULTHOOD

Cynthia A. Berg, Ph.D.¹, Eunjin L. Tracy, Ph.D.², Jonathan E. Butner, Ph.D.³, Maria D. Ramirez Loyola, M.A.⁴, Deborah J. Wiebe, PhD, MPH⁴¹University of Utah, Salt Lake City, UT; ²University of Utah, SALT LAKE CITY, UT; ³University of Utah, Salt Lake City, UT; ⁴University of California, Merced, Merced, CA

Emerging adulthood is described as a high-risk time due to the transitional nature of this time period and the additional new contexts that emerging adults must navigate (work, college, new friends). We know that daily diabetes stressors are associated with poorer well-being (affect) and diabetes management in adolescents (Lansing et al., 2016). However, little is known about how stressors of daily life—outside of diabetes—and more global stress may contribute to daily well-being and diabetes outcomes. Furthermore, it is unclear if and how global stress may amplify the effects of daily diabetes and general stressors on well-being. Two-hundred and twelve emerging adults (aged 18.81, 66% female) with type 1 diabetes (length of diagnosis 8.47 years; mean HbA1c of 8.93) completed the Perceived Stress Scale (Cohen & Williamson, 1998) to measure global stress. In addition, individuals completed a brief checklist (1 = *yes*, 0 = *no*) for 14 consecutive days indicating their experience of 5 daily diabetes stressors (e.g., taking wrong insulin dose) and 6 daily general stressors (e.g., problem with work or chores, argument with someone). To assess daily affect, individuals rated a total of 18 daily emotion words (1 = *not at all*, 5 = *extremely*) with 9 words each reflecting positive (PA) and negative affect (NA). To assess daily diabetes outcomes, individuals rated self-care behaviors and reported their daily blood glucose (BG). Results from multi-level analyses with global stress, general and diabetes stressors (both within- and between effects) indicated that global stress was associated with greater NA and lower PA. In addition, on days in which individuals experienced more general and diabetes stressors than their average (within-person effects) they also experienced more daily NA and less daily PA. Global stress amplified the effect of daily diabetes and general stressors on mood, such that disruptions to NA were greater for those experiencing more global stress. For diabetes outcomes, global stress was associated with lower self-care behaviors and higher BG mean. Both within- and between-effects of diabetes stressors revealed that higher diabetes stressors were associated with lower self-care behaviors and higher BG mean. Emerging adults' global stress is associated with their well-being and diabetes outcomes above and beyond the experience of daily diabetes stressors.

Paper Session 43

4:00 PM-4:15 PM

THE ROLE OF DIFFICULTIES IN EMOTION REGULATION AND DEPRESSIVE SYMPTOMS IN INSULIN OMISSION TO LOSE WEIGHT

Aislinn B. Beam, B.A.¹, Deborah J. Wiebe, PhD, MPH¹, Cynthia A. Berg, Ph.D.²¹University of California, Merced, Merced, CA; ²University of Utah, Salt Lake City, UT

Insulin omission to lose weight (IOLW) is a serious concern for those with type 1 diabetes (T1D), predicting subsequent complications and mortality. It is, thus, imperative to understand factors that may elevate IOLW, especially during late adolescence when risk behaviors are increasing and T1D management is low. We examined mediation and moderation models to understand how two interrelated factors – depressive symptoms and difficulties in emotional regulation – are related to IOLW during late adolescence. Seniors in high school with T1D longer than one year ($N = 247$) completed measures of depressive symptoms (CESD), difficulties in emotion regulation (DERS), and diabetes self-management behaviors, as well as a one-item measure of insulin omission for the purpose of losing weight, and a home assay kit to assess HbA1c. Analyses were run using the PROCESS macro, binary logistic regressions, t -tests, and correlations in SPSS. Consistent with prior research, most participants reported they never skip insulin to lose weight but 39 (17%) reported they skip insulin for the specific purpose of losing weight at least some of the time. Individuals who indicated they sometimes skip insulin to lose weight had higher (poorer) HbA1c than those who never skip insulin, $t(232) = -2.852, p = .005, (M = 8.94$ vs 8.14% , which is a clinically meaningful difference). IOLW groups did not differ on self-management behaviors, $t(225) = 1.541, p = .125$, suggesting IOLW is a risk behavior rather than simply an indicator of poor self-management. Each of the five DERS subscales and depressive symptoms were individually correlated with greater IOLW (r values $> .14, p < .03$). When depressive symptoms and DERS subscales were examined simultaneously in logistic regressions, however, only depressive symptoms were consistently and uniquely associated with IOLW ($B > .04, p < .05$). Tests of moderation revealed no significant interactions between depressive symptoms and DERS subscales (p values $> .70$), suggesting that depressive symptoms pose risks for IOLW even among those with good emotion regulation skills. Tests of mediation indicated each DERS subscale scores was associated with IOLW indirectly through greater depressive symptoms. Programs to develop emotion regulation skills and screening for IOLW especially among those with difficulties in emotion regulation or elevated depressive symptoms may be helpful at this high-risk time of development.

4:15 PM-4:30 PM

DIABETES DISTRESS MEDIATES THE RELATIONSHIP BETWEEN DEPRESSIVE SYMPTOMS AND GLYCEMIC CONTROL AMONG PEOPLE WITH TYPE 2 DIABETES

Yiqing Qian, M.P.H.¹, Edwin B. Fisher, PhD², Dane Emmerling, MPH³¹University of North Carolina-Chapel Hill Gillings School of Global Public Health, Chapel Hill, NC; ²Gillings School of Global Public Health, University of North Carolina-Chapel Hill, Chapel Hill, NC; ³University of North Carolina at Chapel Hill, Carrboro, NC

The relationships among depressive symptoms, diabetes distress and glycemic control are complex. The co-occurrence of depressive symptoms with diabetes is associated with poorer glycemic control, more severe functional impairments, and poorer self-management behaviors. Distress regarding the demands of diabetes care and threats of its complications, called “diabetes distress,” is correlated with depression but a distinct construct. People can be depressed without distress about their diabetes, while others may be distressed by the demands of diabetes in the absence of depression. Previous studies show that diabetes distress is significantly associated with poor glycemic control, poor self-care behaviors, and poor quality of life among those with type 2 diabetes, even after controlling for depression. Moreover, diabetes distress has been proposed as a mediator between depressive symptoms and diabetes self-care and clinical outcomes such as blood glucose. However, this hypothesis has not been widely tested.

Using data from five collaborating US sites studying peer support for diabetes management among underserved populations ($n = 917$), this study examined the relationships of depressive symptoms (PHQ-8), diabetes distress (brief, 4-item scale adapted from Diabetes Distress Scale), and HbA1c (measure of blood glucose level over previous three months) from baseline to post-intervention. Post-intervention follow-up varied across sites from 6 to 12 months following baseline and so was controlled, along with demographics and intervention group assignment in all analyses. Diabetes distress, depressive symptoms, and HbA1c each decreased over time ($ps < .05$). Depressive symptoms, diabetes distress, HbA1c were all correlated with each other both cross-sectionally and from baseline to post-intervention (rs from $.10$ to $.57; ps < .05$). Structural equation modeling showed that post-intervention diabetes distress mediated the relation between baseline depressive symptoms and post-intervention HbA1c (indirect effect: $b = .013, p < .001$), controlling for baseline HbA1c. In parallel analyses, however, depressive symptoms did not mediate the relation between diabetes distress and HbA1c. These findings add support for the role of diabetes distress as a mediator of the effects of depression. Generalized attention to depression without attending to the reasons for diabetes distress may account for reports of failure of treatment of depression to benefit diabetes management.

ASSESSING QUALITY OF LIFE AND BIOCHEMICAL PARAMETERS AMONG ADULTS WITH DIABETES

Rachel Stackhouse, B.A.¹, Andrew Nicholson, MSPH², Stephanie Rettig, MPH³, Jackie Ridgley, BA⁴, Binhuan Wang, PhD⁵, Sundar Natarajan, MD, MSc⁵¹NYU Medicine/Veterans Affairs New York Harbor Healthcare System, New York, NY; ²VA NY Harbor Healthcare System, New York City, NY; ³VA New York Harbor Healthcare System, New York, NY; ⁴NYU Langone / VA NY Harbor Healthcare, New York, NY; ⁵NYU School of Medicine, New York, NY**Background:** Diabetic foot ulcer (DFU) is a common complication of diabetes mellitus and may lead to other serious complications such as infection, amputation, and death. Risk factors for a DFU include neuropathy and a prior DFU. While a history of a DFU can lead to a lower quality of life and impaired kidney function, it is unknown how these factors compare in at-risk patients with neuropathy but with no history of a DFU.**Objective:** To compare quality of life, kidney function, and sociodemographic information among individuals with history of a DFU and those without a previous DFU.**Methods:** We used data from two behavioral intervention trials, one that targets preventing recurrent DFU (secondary prevention) while the other targets preventing the first DFU (primary prevention). Assessments included the Foot and Ankle Ability Measure (FAAM) for foot-specific quality of life; the Veterans RAND 12-Item Health Survey (VR-12) and European Quality of Life (EQ-5D) instrument for general quality of life; number of adverse events; urinary sodium to creatinine ratio (UNa/UCr) to determine sodium intake; urinary protein to creatinine ratio (UPr/UCr) and estimated glomerular filtration rate (eGFR) for kidney function. Comparisons were made using Fisher's exact test for categorical variables and Wilcoxon-Mann-Whitney tests for continuous variables.**Results:** Data were from 236 participants with previous DFU and 406 participants without. Compared to Veterans without a prior DFU, Veterans with a history of a DFU were younger (68.6 vs. 70.3 years, $p = 0.0232$), had a lower body fat percentage (25.0 vs. 29.0, $p = 0.0004$), and were less likely to be married or with a partner (36.0 % vs. 43.5%, $p = 0.080$). Those with a history of a DFU also had lower eGFR (73.12 vs. 79.96 mL/min, $p = 0.0006$), higher UNa/UCr (9.45 vs. 8.73, $p = 0.5180$), and a higher UPr/UCr (0.54 vs. 0.34, $p = 0.0273$). Interestingly, no significant differences were found between the two groups for general quality of life, disease-specific quality of life, or the percentage of participants experiencing an adverse event.**Conclusion:** Adults with a previous DFU had higher sodium intake and poorer kidney function compared to those without a prior DFU but with neuropathy. However, we found no difference in either disease-specific or general quality of life for patients with history of a DFU compared to patients without.**CORRESPONDING AUTHOR:** Rachel Stackhouse, B.A., NYU Medicine/Veterans Affairs New York Harbor Healthcare System, New York, NY; rachelstackhouse@gmail.com

TARGETING SELF-REGULATION SKILLS IN CHILDREN TO PROMOTE HEALTH BEHAVIORS: CLINICAL TRIAL RESULTS

Sharon L. Lo, PhD¹, Ashley Gearhardt, PhD¹, Benjamin Katz, PhD², Niko Kaciroti, Ph.D¹, Richard Gonzalez, PhD¹, Christine M. Hunter, PhD³, Kiren Chaudhry, B.A.⁴, Alison L. Miller, PhD⁵, Julie Lumeng, MD¹¹University of Michigan, Ann Arbor, MI; ²Virginia Tech, Blacksburg, VA; ³Office of Behavioral and Social Sciences Research, National Institutes of Health, Bethesda, MD; ⁴University of Michigan School of Public Health, Canton, MI; ⁵University of Michigan, School of Public Health, Ann Arbor, MI

Self-regulation is implicated in the development of physical and mental health conditions that have detrimental personal and societal costs. Self-regulation challenges are linked to difficulties harnessing cognitive, emotional, and motivational resources to achieve goals and may contribute to unhealthy behaviors. Enhancing self-regulation skills early in life has the potential to increase positive health outcomes. During school-age years, children's self-regulation skills undergo rapid development due to maturation of brain areas that support these skills, as well as increasing autonomy related to health behaviors and increasing environmental demands (e.g., social, academic) that require self-regulation.

This paper presents results from a clinical trial using a Multiphase Optimization Strategy study design and Science of Behavior Change experimental medicine approach (Nielsen et al., 2018) to test different behavioral interventions to enhance self-regulation in children. Research has identified several important components to self-regulation including executive functions, emotion regulation skills, future-thinking, and approach bias. Interventions targeted each of these self-regulation domains and were further evaluated to determine the most effective combinations. Participants were 118 children (ages 9-12 years; $M = 10.2$) from low-income families who were randomized to receive up to four interventions. Interventions were delivered via home visits and implementation fidelity and dosage were assessed. Self-regulation targets were assessed using behavioral tasks, interviews, parent- and child-reported surveys.Results indicated that self-regulation targets could be reliably assessed in a low-income sample of children and that interventions were delivered with high fidelity. Intervention effects were small-to-moderate ($.03 < d < .65$), and effect sizes varied somewhat by assessment method. Intervention effects were strongest for emotion regulation and future-thinking skills and reached statistical significance. Tests of combined interventions revealed that reduction in anger dysregulation was strongest for emotion regulation intervention alone, and moderate for children who completed a combination of emotion regulation, executive function, and future-thinking interventions. Improvement in future-thinking was driven by the future-thinking intervention alone, rather than a combination of different interventions. Smaller effects on executive functions and approach biases have important implications for future interventions to consider the role of cognitive development and evaluate the optimal age period to promote self-regulation. Implications of self-regulation focused interventions for health promotion among low-income children who are at high risk for poor self-regulation and health disparities will be discussed.**CORRESPONDING AUTHOR:** Sharon L. Lo, PhD, University of Michigan, Ann Arbor, MI; sharlo@umich.edu

Paper Session 44

3:45 PM-4:00 PM

THE RELATIONSHIP BETWEEN PARENT HEALTH LITERACY, CHILD HEALTH LITERACY, AND CHILD EATING BEHAVIORS

Sasha A. Fleary, PhD¹, Patrece Joseph, M.A.², Pauline Dimaano, B.S.³, Carolina Goncalves, B.A.⁴¹Tufts University, Medford, MA; ²Child Health Equity Research Lab, Medford, MA; ³Child Health Equity Research Lab in the Eliot-Pearson Department of Child Study and Human Development at Tufts University, Cambridge, MA; ⁴Tufts University, Boston, MA

Background: Health literacy (HL) affects the uptake of health behavior interventions and is implicated in health disparities. Children develop HL via parents' scaffolding, modeling, and providing opportunities for practice of the skills. In adults, HL is positively related to health behaviors and health decision-making, however little is known about the relationship between parent and child HL and children's behavior outcomes. Dietary behaviors are poor among children despite its impact on long-term chronic disease risk. Understanding the relationship between parent and child HL and children's dietary behaviors will inform intervention strategies to improve behaviors. We are particularly interested in pre-adolescent children given that their dietary decision-making is complicated by their increased autonomy for dietary behaviors while simultaneously being reliant on parents for food availability and subjected to some parental rules about food. We expect parent HL to be positively related to child HL, and parent and child HL to be related to dietary behaviors.

Method: Data were collected from parents and children 9-12-years-old (N = 71, 51% girls, 45% Black/African American, 34% low income). Parents completed a HL measure. Children completed measures of HL and dietary behaviors. Child dietary behaviors were categorized into daily servings of fruits and vegetables, junk foods, and number fast food restaurant visits. Regression analyses were computed to predict: (1) child HL from parent HL and; (2) child dietary behaviors from child and parent HL.

Results: After accounting for children's age and gender, parent HL was positively related to child HL ($R^2=.37$; $\beta=.029$, $p=.02$). Children's HL and dietary behaviors were unrelated. However, parent HL was negatively related to children's fast food intake ($R^2=.42$; $\beta=-0.41$, $p=.001$) and approached significance for junk food.

Discussion: HL, a type of cultural health capital, has long-term impact on health. The positive relationship between parent and child HL supports HL as intergenerational; thus, targeting parent HL likely improves the long-term health and reduces health disparities of multiple generations. Despite increased autonomy, preadolescent children are still primarily reliant on parents for their dietary options and this likely explains the nonsignificant results for child HL and dietary behaviors. Parent HL likely impacts parents' decision-making for food availability and food parenting practices, hence the negative relationship between parent HL and children's fast food intake. Future studies should explore the temporal relationship between child HL and dietary behaviors as well as the trajectory for the development of child HL to determine the most opportune time for intervening on children's HL skills to affect behavior change.

Paper Session 44

4:00 PM-4:15 PM

HOW MOTHERS' BEHAVIORS IN A STRUCTURED EATING TASK ALIGN WITH PARENT CHILD INTERACTION THERAPY SKILLS & IMPACT CHILDREN'S EATING

Tiffany M. Rybak, PhD¹, Kristoffer Berlin, PhD², Robert Cohen, PhD², Alison L. Miller, PhD³, Katherine L. Rosenblum, PhD⁴, Julie Lumeng, MD⁴¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH; ²The University of Memphis, Memphis, TN; ³University of Michigan, School of Public Health, Ann Arbor, MI; ⁴University of Michigan, Ann Arbor, MI

Early childhood is a critical period for the development of healthy eating behavior. We aimed to examine how mothers' behaviors during an eating scenario align with evidence-based parenting skills (e.g., Parent-Child Interaction Therapy (PCIT)) and to determine how these skills impact children's eating. We observationally coded videos of dyadic parent-child interactions for 50 mothers and 50 children (ages 4 to 7 years old) from a primarily low-income population. We examined interactions during a structured eating task [e.g., taste-testing of 4 different foods: green beans (familiar, vegetable) cupcake, (familiar, sweet), artichoke (novel, vegetable), and halva (novel, sweet)] by first, applying the PCIT coding scheme [measured in two phases: 1) Child-Directed Interaction (CDI) phase, which uses a particular skillset to strengthen the parent-child bond, and 2) the Describe, Approach, Direct command, and Selectively attend (DADS) phase, which capitalizes on the bond strengthened by CDI and encourages children to approach novel or anxiety-provoking stimuli by incorporating direct commands and selective attention], to determine if these skills are applicable during an eating situation. Applying and coding PCIT skills in an eating scenario and obtaining adequate reliability established feasibility (average reliability: 83% agreement and 0.77 kappa for the frequency/sequence-based method). Second, using multilevel lag sequential analysis, we assessed how the use of CDI and DADS "Do" and "Don't" skills related as an antecedent to children's eating behavior. When examining all antecedent-consequences of interest overall, a CDI and DADS "Do" was more likely to be followed by child eating ($p=.03$; $p < .01$, respectively). Examining bites of food specifically, children were more likely to eat in response to a CDI and DADS "Do" rather than a "Don't" (CDI $p < .01$; DADS $p < .01$). Lastly, when examining how children respond to a "Do", children were more likely to eat following a DADS "Do", rather than engage in other behavior ($p=.02$); however, this was not significant for the CDI model ($p=.87$), suggesting that the unique features of DADS skills are more effective at encouraging eating relative to other behavior when compared to CDI skills. This study used novel methodology and expands prior work around dyadic interactions during eating scenarios. Findings demonstrate that PCIT "Do" skills encourage eating and may help children overcome food neophobia and increase consumption of a variety of healthy foods.

OMEGA-3 FATTY ACID COMPOSITION OF HUMAN MILK IS ASSOCIATED WITH INFANT TEMPERAMENT

Adi Fish, MA¹, Jennifer Hahn-Holbrook, PhD², Laura Glynn, PhD³¹University of California, Merced, san jose, CA; ²University of California, Merced, Merced, CA; ³Chapman University, Orange, CA

Background: There is growing evidence that omega-3 fatty-acids are important for brain development in childhood and are necessary for optimal health in adults. Yet, there have been no studies examining how the fatty-acid composition of human milk influences infant behavior or temperament. The aim of this study was to determine the relation between human milk fatty acid composition and temperament in the breastfed infant.

Methods: 52 breastfeeding mothers provided milk samples at 3 months postpartum and completed the Infant Behavior Questionnaire (IBQ), a widely used parent-report measure of infant temperament. Milk was assessed for omega-3 fatty-acids (linolenic acid-ALA, eicosapentaenoic acid-EPA, docosahexaenoic acid-DHA, Eicosatrienoic Acid) and omega-6 fatty-acids (linoleic acid, arachidic acid, linoleic acid, linolenic acid, Dihomo-gamma-linolenic acid-DGLA, Arachidonic acid-AA, Eicosadienoic acid). Total milk fat and the ratio of omega-6/omega-3 fatty acids were also examined.

Results: Regression models revealed that babies whose mothers' milk was richer in omega-3 fatty acids displayed lower scores on the negative affectivity dimension of the IBQ ($\beta = -.335$, $p = .015$). Repeating the analyses with each of the negative affectivity subscales revealed similar negative associations for sadness ($\beta = -.028$, $p = .048$), and distress to limitations ($\beta = -.037$, $p = .006$). These associations remained significant after statistically adjusting for maternal age and education level, which were both positively correlated with omega-3 fatty acids levels in milk. Omega-6 fatty acids and total fat concentrations of milk were also negatively related to infant distress to limitations, although these associations were not long statistically significant after maternal age and education level were included in the model. Omega-6/ omega-3 fatty acid ratio was not related to infant temperament.

Conclusions: These results support the idea that omega-3 fatty acids may be beneficial for the developing infant brain. Further, the results suggest that mothers may have the ability to shape the behavior of their offspring by adjusting the fatty acid composition of their milk.

Paper Session 44

4:30 PM-4:45 PM

EXAMINING FOOD PREFERENCES AND CONSUMPTION FOR SUGAR SWEETENED BEVERAGES AND FRUITS AND VEGETABLES IN PARENT-ADOLESCENT DYADS

Kara Wiseman, MPH, PhD¹, Laura Dwyer, PhD², April Oh, PhD, MPH³, Linda Nebeling, PhD, MPH, RD⁴¹University of Virginia, Charlottesville, VA; ²Cape Fox Facilities Services, Dupont, WA; ³NIN/NIC/BRP/HCIRB, Rockville, MD; ⁴NIH/NCI/BRP, Rockville, MI

Food preferences are associated with consumption but this association has been underexplored in dyads. Further, the degree to which access to foods, based on area-level socioeconomic status (SES), moderates these associations is unknown. The purpose of this study was to estimate dyadic associations between preferences and consumption of sugar sweetened beverages (SSB) and fruits/vegetables (FV) and to explore moderation by area-level SES. Data came from the Family Life Activity Sun Health and Eating (FLASHE) study among 1303 parent-adolescent dyads. Preferences for SSB and FV each included two items. Outcomes were predicted daily teaspoons of sugar intake from SSBs and predicted daily cups of FV. An Actor-Partner Interdependence Model (APIM) determined the dyadic association between preferences for SSB/FV and consumption, adjusted for parent and adolescent sex, age, race/ethnicity, and BMI, and parent education. Models were then stratified by area-level SES within a 1200 meter circular distance from dyads' home, which was categorized into tertiles. For SSB, the APIM revealed actor effects for parents (e.g., parent preferences predicting parent consumption, $\beta = 0.43$, $p < 0.01$) and adolescents ($\beta = 0.22$, $p < 0.01$), and a parent partner effect, such that increasing parent preferences for SSB was associated with increasing adolescent consumption ($\beta = 0.13$, $p < 0.01$). In stratified analyses, the parent actor effect was higher among parents in the lowest ($\beta = 0.46$, $p < 0.01$) vs. highest SES tertile ($\beta = 0.37$, $p < 0.01$). For FV, the APIM revealed actor effects for parents ($\beta = 0.22$, $p < 0.01$) and adolescents ($\beta = 0.34$, $p < 0.01$), and an adolescent partner effect such that increasing adolescent FV preferences were associated with increasing parent consumption ($\beta = 0.12$, $p < 0.01$). The correlation of FV preferences between parents and adolescents decreased as SES increased ($r = 0.37$ for the lowest vs. $r = 0.15$ for highest tertile). We found evidence of dyadic associations for SSB and FV preferences and consumption in parent/adolescent dyads, with partner effects differing by type of food. Specifically, parent SSB preferences could negatively impact adolescents by increasing their SSB consumption, while adolescent FV preference is potentially beneficial, as it was associated with increased FV consumption in the parent. Combined with the presence of effect modification by area-level SES, these results highlight the potential role of the neighborhood and family in interventions to modify eating behaviors.

A WEB-BASED EXECUTIVE FUNCTIONING INTERVENTION FOR ADOLESCENTS WITH EPILEPSY: EPILEPSY JOURNEY

Avani C. Modi, Ph.D.¹, Shari L. Wade, Ph.D.², Matthew M. Schmidt, PhD³, Aimee W. Smith, Ph.D. LP-HSP⁴¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH; ²Cincinnati Children's Hospital Medical Center/University of Cincinnati, Cincinnati, OH; ³University of Florida, Gainesville, FL; ⁴East Carolina University, Greenville, NC

Introduction: Executive functioning (EF) includes skills necessary for goal-directed and complex activities such as problem-solving, initiating, monitoring, organizing, planning, self-regulating, and using working memory. One-third to half of youth with epilepsy exhibit significant deficits in EF. Epilepsy Journey is a web-based problem-solving intervention that improves executive functioning skills in youth with epilepsy. However, examining the impact of Epilepsy Journey on additional secondary outcomes, including emotional/behavioral functioning, health-related quality of life (HRQOL), and sleep, is also of interest and an aim of the current study.

Methods: Thirty-nine adolescents, ages 13 to 17, were recruited (Mage=15.3 ± 31.3; 56% female). To be eligible for the open trial, participants were required to have at least two subclinical (>1 SD) or one clinically-elevated subscale on the caregiver version of the Behavior Rating Inventory of Executive Function. The 12-week online program (Epilepsy Journey) consisted of 10 self-directed online modules and synchronous Skype sessions with a coach. Content was organized around a journey theme in which different "lands," or learning modules, targeted EF domains in the context of a problem-solving framework. Participants and their caregivers completed the following questionnaires of interest from pre- to post-intervention to 2 and 5-month follow-up: Behavior Assessment Schedule for Children (BASC), PedsQL Epilepsy Module (HRQOL measure), and The Children's Report of Sleep Patterns.

Results: Significant improvements were reported on the parent-reported BASC Externalizing symptoms ($b=-6.13$, $p<0.01$), Behavioral Symptom Index ($b=-6.23$, $p<0.01$), and Adaptive Skills ($b=4.65$, $p<0.01$). No significant improvements were noted on the adolescent-reported BASC. For HRQOL, parent-reported Mood/Behavior Scale ($b=9.91$, $p<0.05$) and adolescent-reported Epilepsy Impact ($b=10.17$, $p<0.01$), Cognitive functioning ($b=3.95$, $p<0.001$), Executive functioning ($b=4.15$, $p<0.001$), and Sleep ($b=14.74$, $p<0.05$) subscales improved significantly over time. Finally, significant improvements were noted for several sleep scales, including parent-reported bedtime fears/worries ($b=-1.32$, $p<0.01$) and sleep location index ($b=-0.48$, $p<0.001$) and adolescent-reported sleep location index ($b=-0.34$, $p<0.05$), restless legs symptoms ($b=-1.49$, $p<0.05$), parasomnia symptoms ($b=-0.18$, $p<0.05$), and sleep indicator items ($b=-0.19$, $p<0.05$).

Conclusions: Findings suggest that Epilepsy Journey can lead to improvements in key secondary outcomes, including parent-reported behavioral and emotional functioning, parent and adolescent-reported HRQOL, and sleep patterns. An important next step is to test Epilepsy Journey in a robust Phase 3 trial.

IMPACT OF NEIGHBORHOOD FOOD ENVIRONMENT ON DIETARY AND WEIGHT CHANGE AMONG CHILDREN IN WEIGHT CONTROL TREATMENT

Lauren A. Fowler, PhD¹, Jackie Hayes, PhD², Richard I. Stein, Ph.D.³, Anne Claire Grammer, BA⁴, Rachel Conlon, PhD⁵, Katherine N. Balantekin, PhD, RD⁶, Robinson Welch, Ph.D.⁷, Brian Saelens, Ph.D.⁸, Michael Perri, PhD⁹, Leonard Epstein, PhD⁶, Denise E. Wilfley, PhD¹¹Washington University in St Louis, St Louis, MO; ²Miriam Hospital/Brown University, San Francisco, CA; ³Washington University School of Medicine, Saint, MO; ⁴Washington University in St. Louis, St. Louis, MO; ⁵University of Pittsburgh School of Medicine, Pittsburgh, PA; ⁶University at Buffalo, Buffalo, NY; ⁷Washington University in St. Louis, Clayton, MO; ⁸University of Washington / Seattle Children's Research Institute, Seattle, WA; ⁹University of Florida, College of Public Health and Health Professions, Gainesville, FL

Introduction: Some cross-sectional studies link neighborhood food environment with child weight, but whether neighborhood food environment influences weight control efforts in children is under-studied.

Method: Parent-child dyads ($n=106$; child demographics: mean age=9.4 ± 1.3y; 68% female; 67% white; mean percent over median body mass index for age and sex [%OW]=61.6 ± 24.8 [baseline] and 49.7 ± 25.4 [month 4]) completed 4 months of family-based behavioral obesity treatment (FBT) and were subsequently randomized to one of three 8-month weight control conditions: social facilitation high dose (SFM+ HIGH), social facilitation low dose (SFM+ LOW), or an educational control (CONTROL). Anthropometric and dietary assessments were completed pre-FBT (month 0), post-FBT (month 4), and post-maintenance intervention (month 12). The neighborhood food environment around each dyad's residence was characterized once at baseline and operationalized through a geographic information system as counts of different types of food stores within a 1-mile radius. Store types included general/convenience stores, quick service food chains and non-chains, grocery stores, supermarkets, and restaurants. Diet quality was operationalized using healthy eating index 2015 (HEI) scores from three 24-hour dietary recalls. Hierarchical linear regression was used to examine if maintenance condition moderated the relationship between the neighborhood food environment and month 12 child outcomes, controlling for child age, household socioeconomic status, and month 4 %OW and HEI score.

Results: Across conditions, having more nearby general/convenience stores significantly predicted greater increases in %OW ($B=-.418$, $SE=.18$, $p=.031$). Condition moderated the relationship between the number of nearby non-chain quick service food outlets (e.g., local sub shop) and child's diet quality at 12 months, such that more non-chain quick service food outlets was related to poorer diet quality among children in CONTROL ($B=-1.69$, $SE=.68$, $p=.016$), but not among children in the more active SFM+ HIGH or LOW. Condition did not significantly moderate the relationship between counts of other types of food outlets and child diet quality or weight change.

Conclusion: SFM, which helps families navigate socio-environmental contexts, including macro environments, buffers against the negative effects of some unhealthy food service outlets to promote diet quality during weight control, although convenience/general stores may prove particularly detrimental to weight loss maintenance, even with more intense intervention.

Paper Session 45

4:00 PM-4:15 PM

MATERNAL DEPRESSIVE SYMPTOMS, PARENTAL INVOLVEMENT AND TYPE 1 DIABETES MANAGEMENT DURING LATE ADOLESCENCE

Deborah J. Wiebe, PhD, MPH¹, Cynthia A. Berg, Ph.D.², Daniel Mello, Ph.D.¹, MaryJane S. Campbell, MS³, Maria D. Ramirez Loyola, M.A.¹, Aislinn B. Beam, B.A.¹

¹University of California, Merced, Merced, CA; ²University of Utah, Salt Lake City, UT; ³University of Utah, SALT LAKE CITY, UT

Late adolescence is challenging for type 1 diabetes (T1D) management as parental involvement declines, and young people manage a complex illness more independently from parents. Yet, parents remain a trusted resource during late adolescence, and parental involvement predicts T1D outcomes well into emerging adulthood. Mothers' depressive symptoms have been found to undermine her ability to be an effective caregiver for early adolescents with T1D. We examined whether maternal depressive symptoms also pose risks for T1D management during late adolescence. Seniors in high school ($N = 192$; 63% female; 87% non-Latino White) completed surveys reporting on mothers' and fathers' involvement in T1D management, self-management behaviors and depressive symptoms, and an assay kit to measure HbA1c. Mothers completed surveys to indicate levels of depressive symptoms. Mothers reported high levels of depressive symptoms with 22% above the CESD cutoff of 16 and 13% above the more conservative cutoff of 21. Mothers' depressive symptoms were correlated with teens' reports of lower self-management ($r = -.262, p = .001$) and higher depressive symptoms ($r = .186, p = .008$), but were unrelated to HbA1c. Although maternal depressive symptoms were generally unrelated to maternal and paternal involvement, teens reported being more likely to keep secrets about T1D management from mothers when mothers were more depressed ($r = .145, p = .040$) and keeping secrets was associated with higher (poorer) HbA1c ($r = .198, p = .002$). Multiple regressions revealed that some aspects of maternal involvement were less associated with T1D management when mothers reported more depressive symptoms. For example, maternal depressive symptoms moderated the association of mothers' knowledge of her adolescent's T1D management with HbA1c, indicating knowledge was associated with better HbA1c only when mothers were less depressed ($B = -.032, p = .032$). Findings also revealed teens are more likely to turn to and benefit from fathers' involvement when mothers were more depressed. For example, mothers' depressive symptoms moderated associations between relationship quality with fathers and HbA1c ($B = -.029, p = .023$), and between keeping diabetes-related secrets from fathers and HbA1c ($B = .029, p = .007$). In each case, positive aspects of fathers' involvement were associated with better T1D management when mothers were more depressed. Taken together, these findings demonstrate the importance of maternal depressive symptoms in the dynamics of family management of T1D during late adolescence.

ADVERSE CHILDHOOD EXPERIENCES AND HEALTH PROMOTING BEHAVIORS AMONG YOUNG ADULTS: ANOTHER PERSPECTIVE ON TRAUMA AND HEALTH

Timothy J. Grigsby, PhD¹, Christopher J. Rogers, M.P.H.², Larisa Albers, n/a³, Krupa Jiva, n/a¹, Stephanie M. Benjamin, PhD³, Myriam Forster, BA;MPH;PhD⁴

¹University of Texas at San Antonio, San Antonio, TX; ²Keck School of Medicine University of Southern California, Castaic, CA; ³California State University, Northridge, Northridge, CA; ⁴California State University, Northridge, Santa Monica, CA

Background: A robust literature has demonstrated a strong, graded relationship between exposure to childhood abuse and household dysfunction with negative health outcomes throughout the lifespan. Considerably less research has examined the relationship between adverse childhood experiences (ACE) with positive health behaviors, a gap filled by the present study.

Methods: During 2017-2018, a general health questionnaire that included items on ACE was administered to young adults (ages 18-29) at universities in California ($n=3,862$) and Texas ($n=451$). Seven categories of ACE were included: psychological, physical, or sexual abuse; violence between parents; and living with household members who were substance misusers, mentally ill, or ever imprisoned. Protective and preventive health behaviors in young adulthood were regressed on the number of endorsed items (range: 0-7), categorized as 0 (referent), 1, 2, 3, 4, or more ACE, using logistic regression controlling for age, gender, race/ethnicity, and site.

Results: Approximately 41.9% of the sample reported ACE exposure with a significantly higher rate among Texas participants ($p < 0.001$). The seven ACE were strongly interrelated ($p < 0.001$) and tended to cluster. ACE exposed participants were as likely to be interested in receiving physical and mental health information as non-ACE exposed participants, but consistently and significantly less likely to receive health information from their university (p 's < 0.01). There was no dose-response relationships between cumulative ACE and protective health behaviors (seatbelt/helmet use, condom use, or daily fruit/vegetable intake) though participants reporting higher ACE levels had greater odds of compromised health promoting behaviors. There was a graded relationship between ACE exposure and increased odds of ever being tested for HIV, but this pattern did not show up for other preventive health behaviors including self-exams or sunscreen use. Among alcohol users, reporting more ACE was related to decreased use of certain protective behavioral strategies (e.g., pacing drinks, having a friend let you know when you've had enough).

Conclusions: This study contributes to extant literature on ACE and health by demonstrating the impact of ACE on health education, protective health behaviors, and preventive health behaviors. Interventions to improve health promotion activities in ACE exposed populations can improve quantity and quality of life for this vulnerable population.

4:30 PM-4:45 PM

RECONSIDERING MEDIA USE AND SUICIDE: GENDER AND RACIAL/ETHNIC DISPARITIES IN THE 10-YEAR TRENDS AMONG A NATIONAL SAMPLE

Yunyu Xiao, MPhil¹, Chengbo Zeng, MPH²¹New York University, JERSEY CITY, NJ; ²University of South Carolina, Columbia, SC

Background: Suicide is the second leading cause of death for adolescents. Recent studies increasingly showed significant associations between high media use and adolescent suicidal behaviors. Yet, results have been inconsistent and based on short-period cross-sectional designs. While girls were suggested to be more susceptible to social media, little is known about differences by gender and race/ethnicity in the link between long-duration media use and trends in suicidal behaviors over time. Such information is imperative to inform tailored suicide intervention targeting at-risk adolescents using media excessively. This study aims to examine gender and racial/ethnic disparities in associations between high media use and trends of adolescent suicidal behaviors.

Methods: A nationally representative sample of 147,929 students in grades 9-12 (50.5% female) was derived from the 1999-2017 National Youth Risk Behavior Survey, a school-based survey conducted biannually. High media use were two dichotomized variables measuring whether students had over 3 hours/day of 1) watching TV and 2) using computers for non-school work (e.g., videogames, YouTube, Instagram, Facebook). Suicidal behaviors (ideation, plan, attempts, injury by attempts) were self-reported. Logistic regression analyses were used to examine associations between high media use and trends of each suicidal behaviors by sex and racial/ethnic groups, adjusting for grade levels. Linear and quadratic trends were examined.

Results: Male adolescents with high media use were associated with different changes in suicidal behaviors by race/ethnicity. High TV use was associated with increasing trends of injury by attempts among Hispanic (OR=1.69, $p < .05$) and other-race (OR=3.28, $p < .05$) males. Black males with high internet and social media use showed an increasing trend of suicide plan (OR=1.42, $p < .05$). However, high internet use was associated with decreasing trend of suicidal ideation among Asian male (OR=0.60, $p < .05$) with faster rates in the later period ($p < .05$), suicide attempts (OR=0.65, $p < .05$) and injury by attempts (OR=0.66, $p < .05$) among White males. No significant results were revealed among females.

Conclusions: Only male adolescents with high media use showed significant associations with trends in suicidal behaviors in the past 10 years. Racial/ethnic disparities among male subgroups were uncovered. Black males with high computer use and Hispanic and other-race adolescents watching TV for more than 3 hours showed higher risks in suicide trends. Health practitioners are suggested to screen different types of high media use to detect at-risk adolescents from different racial/ethnic background. Suicide interventions incorporating media use may be effective. Future investigation is needed to explain mechanisms associated with racial/ethnic disparities in the effects of media use on trends of suicide.

LONG-TERM IMPACT OF ADOLESCENT CHRONIC PAIN ON YOUNG ADULT EDUCATIONAL, VOCATIONAL, AND SOCIAL OUTCOMES

Caitlin B. Murray, PhD¹, Cornelius B. Groenewald, MB ChB², Rocio de la Vega, PhD¹, Tonya M. Palermo, PhD³¹Seattle Children's Research Institute, Seattle, WA; ²University of Washington School of Medicine, Seattle, WA; ³University of Washington School of Medicine; Seattle Children's Research Institute, Seattle, WA

Introduction: Chronic pain often begins in adolescence and results in negative consequences including missed school, withdrawal from social activities, and over-dependency on parents. While research has advanced understanding of the initial impact of chronic pain during childhood, surprisingly little is known about its long-term consequences as youth transition to adulthood. This is the first nationally representative study to characterize the impact of chronic pain in adolescence on key educational, vocational, and social outcomes in young adulthood (12 years later).

Methods: Data from the National Longitudinal Study of Adolescent to Adult Health was used, including 3,174 youth with chronic pain and 11,610 without chronic pain who completed Wave I at ages 11-17 (adolescence) and Wave IV at ages 24-32 (young adulthood). We conducted multivariate regression analyses to examine the main effect of adolescent chronic pain status (Wave I) in predicting young adult educational, vocational, and social outcomes (Wave IV) while controlling for sociodemographic variables (i.e., Wave I sex, race/ethnicity, and parent income and Wave IV age) and adolescent depressive symptoms.

Results: Adolescent chronic pain was associated with decreased odds of attaining a high school diploma (OR = 0.66, 95% CI: 0.57 – 0.82) and attaining a bachelor's degree (OR = 0.83, 95% CI: 0.71 – 0.96) in young adulthood. Adolescent chronic pain was also associated with decreased odds of receiving employer-provided insurance benefits (OR = 0.80, 95% CI: 0.68, 0.92) and increased odds of receiving public assistance (OR = 1.31, 95% CI: 1.16, 1.48). Finally, adolescent chronic pain was associated with earlier pregnancy/increased rate of having biological children (OR = 1.28, 95% CI: 1.13, 1.45) as well as lower romantic relationship quality ($b = -0.08$, SE = .02) in young adulthood.

Conclusion: Chronic pain in adolescence is associated with risk for educational, vocational, and social impairments in young adulthood, indicative of socioeconomic disparities. Our findings contribute to the limited knowledge base of the scope of adverse long-term outcomes in young adults with a history of adolescent chronic pain, informing the need for more focused screening and intervention efforts. Increased research attention is needed to understand the life course impact of pediatric chronic pain, including early risk factors and underlying mechanisms that influence adverse outcomes.

EXERCISE AND DIETARY RECOMMENDATIONS FOR WOMEN WITH CHRONIC PAIN: WHAT'S WEIGHT AND RACE GOT TO DO WITH IT?

Lauren E. Mehok, M.S.¹, Kaitlyn Walsh, B.S.², Megan M. Miller, PhD³, Adam T. Hirsh, PhD¹

¹Indiana University - Purdue University Indianapolis, Indianapolis, IN; ²Texas A&M University, College Station, TX; ³Indiana University Purdue University Indianapolis, Indianapolis, IN

Although treatment guidelines indicate that providers should recommend exercise for chronic pain, there is variability in the types of exercises that are recommended. Emerging research also suggests that diet modifications improve pain; however, little is known about clinical practice patterns for this treatment. We have found that patient weight and race, analyzed separately, elicit different recommendations for various pain treatments, including lifestyle modifications. To better understand the nuances of these effects, the current study explored the impact of patient weight and race on recommendations for specific types of exercise and dietary change. Medical students (N=90; 60% female) viewed vignettes and videos of middle-aged women with chronic back pain performing a sit-to-stand task. Patient weight (overweight/obese) and race (Black/White) varied across videos. For each patient, participants rated how likely they were to recommend aerobic, strength, and flexibility exercises, as well as dietary changes. Repeated measures ANOVAs identified significant main effects of patient weight on recommendations for aerobic ($F(1,89)=29.85$, $p<.01$) and strength ($F(1,89)=6.08$, $p=.02$) exercise, such that patients with obesity were more likely to be recommended both. Results indicated a significant main effect of patient race on recommendations for flexibility exercise ($F(1,89)=4.92$, $p=.03$), such that White patients were more likely to receive this recommendation. Lastly, there was a significant weight-by-race interaction for dietary changes ($F(1,89)=40.53$, $p<.01$). Black patients with obesity were more likely to be recommended dietary changes than Black patients with overweight, but this effect was reversed for White patients. Although most patients with chronic pain would benefit from aerobic and strength exercise, patients with obesity may be perceived as deriving particular benefit (for both pain and weight management) and, thus, be more likely to elicit these recommendations. The race difference in flexibility recommendations mirrors findings that programs such as yoga are underutilized by racial/ethnic minorities. Finally, although speculative, the dietary finding may be driven by perceptions of race differences in receptivity to diet and weight loss advice. Future studies are needed to identify the mechanisms underlying these weight and race effects so that all patients with chronic pain may benefit from evidence-based multidisciplinary care.

Paper Session 46

4:00 PM-4:15 PM

DISABILITY IN PEOPLE WITH CHRONIC SPINAL PAIN IS MORE STRONGLY ASSOCIATED WITH PAIN BEHAVIOR THAN PHYSICAL PERFORMANCE

Nicholas Karayannis, MPT, PhD¹

¹Stanford University, Oakland, CA

Objective: Disability is a highly contextual and broad dimension for people with chronic low back pain (CLBP) predominantly assessed through patient-reported outcome measures. Few studies have examined the patient's perception and physical capacity. The primary aim was to determine correlates between body function and activity limitations from a patient's perspective with sensory-motor performance. The secondary aim was to investigate the association between pain beliefs and behaviors with disability outcomes.

Design, participants, and setting: An observational, cross-sectional study of 328 people with CLBP, recruited from an academic medical center (Stanford, CA) as part of a three-armed randomized control trial of mind-body therapies.

Methods: We collected patient-reported outcomes (PROs) and sensory-motor performance and sensitivity measures using a global and local (lumbar region) physical performance test battery. PROs included disability (Roland Morris Disability Questionnaire), physical health (PROMIS® Physical Function, Pain Interference, and Pain Behavior), mental health (PROMIS® Anxiety and Depression), and pain beliefs (Fear-Avoidance Beliefs Questionnaire, Pain Catastrophizing, Chronic Pain Acceptance Questionnaire). The 4-component physical performance test battery included an assessment of 1) Walking speed and endurance (Ten-meter walk, Two-minute walk); 2) Global balance and functional lower extremity strength (Single-limb stand, Five times sit-to-stand tests); 3) Lumbar flexibility (Forward bend test) and extensor endurance (Ito test); and 4) Lumbar two-point sensory discrimination (2PD_{Lumb}), and pressure-pain threshold (PPT_{Lumb}). Locally-weighted polynomial regression, principal component analysis, and Pearson correlations visualized through heat-maps were used to assess the relationship between body function and activity limitations from a patient's perspective (PROs) with sensory-motor performance recorded by the clinician (Aim 1). Pearson correlations visualized through heat-maps were used to assess the relationship between pain behaviors and beliefs (Aim 2).

Results: A moderate relationship emerged between patient-reported physical function ($r=0.28$), disability ($r=-0.27$), pain behavior ($r=-0.27$), and pain interference ($r=-0.23$) with clinician-measured walking speed and endurance, and lower extremity strength. A strong relationship emerged between disability and pain behavior ($r=0.53$).

Conclusions: External manifestations of back pain as expressed through PROMIS® Pain Behavior elucidated body function and activity limitation more strongly than a physical and sensory-motor performance test battery.

Clinical Relevance: The patient's communication of their experience with pain and movement may help to provide a deeper context to the broad dimension of disability in people living with CLBP.

PERCEIVED RACIAL/ETHNIC DISCRIMINATION AND CONDITIONED PAIN MODULATION IN AFRICAN AMERICAN ADULTS

Matthew C. Morris, PhD¹, Ernesto Ruiz, PhD², Stephen Bruehl, PhD³, Hector F. Myers, PhD⁴, Burel R. Goodin, PhD⁵, Uma Rao, MBBS⁶, Edward Lannon, M.S.⁷, Subodh Nag, PhD²

¹University of Mississippi Medical Center, Department of Psychiatry and Human Behavior, Jackson, MS; ²Meharry Medical College, Nashville, TN; ³Vanderbilt University Medical Center, Nashville, TN; ⁴Vanderbilt University, Nashville, TN; ⁵The University of Alabama at Birmingham (UAB), Department of Psychology, Birmingham, AL; ⁶University of California, Irvine, Irvine, CA; ⁷University of Mississippi Medical Center, Jackson, MS

Background: African Americans (AA) report higher pain severity and disability compared to Non-Hispanic Whites with similar pain conditions. Racial differences in exposure to stressful and traumatic life events may account, in part, for such disparities. Perceived racial/ethnic discrimination is associated with greater daily pain complaints and lower pain tolerance. The present study sought to address one important gap in this literature: is discrimination associated with conditioned pain modulation (CPM) after controlling for other types of stressors? CPM refers to changes in perceived pain intensity for a test stimulus during application of a conditioning stimulus. Impaired CPM has been implicated as a risk factor for chronic pain.

Methods: Participants were 62 pain-free AA (mean age = 27.2 years; 42 females) who completed a heat stimulation protocol and self-report measures on lifetime adversity. CPM was determined by changes in pain ratings (0 = “no pain” and 100 = “worst imaginable pain”) from a preconditioning phase (test stimulus = 30x30mm thermode) to a conditioning phase (conditioning stimulus = 46.5°C hot water bath). Weaker CPM (i.e. lesser reduction in pain ratings) is believed to reflect dysfunction of descending endogenous pain modulatory systems.

Results: Multilevel models examined within-person associations of adversity measures with changes in pain ratings from preconditioning to conditioning. Perceived discrimination ($b=3.35$, $SE=0.87$, $p<.001$) was associated with changes in pain ratings over and above the influence of age, sex, childhood trauma exposure, family adversity, acute and chronic stress levels. Simple slope analyses revealed that individuals reporting lower levels (-1 SD) of discrimination showed evidence of CPM ($b=-7.31$, $SE=3.60$, $p=.044$); in contrast, those reporting higher levels (+1 SD) of lifetime discrimination did not exhibit CPM.

Conclusion: Pain-free AA adults who reported greater lifetime racial/ethnic discrimination exhibited reduced CPM. These findings implicate discrimination as a risk factor for acute and chronic pain via reduced CPM. Importantly, discrimination was associated with reduced CPM even after controlling for the effects of other types of stressful and traumatic life events across the lifespan. Future research on the developmental and contextual features of stressors that alter pain sensitivity could help to address disparities in prevalence, severity and treatment of pain impacting AA adults.

FEELING AND BODY INVESTIGATORS: A RANDOMIZED CONTROLLED TRIAL OF A TREATMENT FOR YOUNG CHILDREN WITH FUNCTIONAL ABDOMINAL PAIN

Nancy Zucker, PhD¹, Alannah Rivera-Cancel, BA¹, Nandini Datta, PhD², Savannah Erwin, BS¹, Julia Nicholas, BS¹, Kristen A. Caldwell, BA¹, Lindsay Ives, MA¹, Adrienne Romer, PhD³, Samuel Marsan, BA¹, Madeline Farber, BA¹, Gary Maslow, MD, MPH¹

¹Duke University, Durham, NC; ²Stanford University, Durham, NC; ³McLean Hospital, Durham, NC

Persistent abdominal pain is one of the most frequent somatic symptoms among children, signaling increased vulnerability to anxiety, depression, and chronic pain symptoms. The term Functional Abdominal Pain – Not Otherwise Specified (FAP-NOS) is used for pain that cannot be entirely attributed to a disease process. No interventions for FAP-NOS have been developed specifically for young children, who are just learning to decode bodily sensations as signals of their needs and emotions. Prior interventions have successfully treated FAP-NOS by equipping parents with strategies for de-catastrophizing their child's pain. However, interventions focused on avoiding pain may be missing a key opportunity to help young children develop emotion awareness and regulation skills, a learning process particularly important in children at increased risk of developing anxiety and mood disorders. The Feeling and Body Investigators (FBI) intervention for FAP-NOS directly focuses on pain: using playful characters to learn about body sensations (e.g., Gassy Gus), using exposures to evoke uncomfortable sensations to discern how smart the body is, and mapping these sensations to interpretations and actions. In a randomized design, we compared FBI in 5- to 9-year-old children to the Caregivers in Action (CIA) intervention, the current standard of care. It was hypothesized that while both interventions would reduce pain, the FBI intervention would be more effective at improving emotion regulation. FBI resulted in a 68.7% reduction in pain frequency as assessed via interviews comparing 3-month pre-treatment with 3-month post-treatment. Reductions in pain intensity ($d = .59-.85$, child; $d = .65-.70$, parent report, $p < .05$); pain distress ($d = .85-1.05$, $p < .001$), and pain interference ($d = -.68$, $p = .001$) were statistically significant and of medium to large effect size. Two-way mixed-measures ANOVA revealed that FBI was as effective as CIA in reducing pain. In regard to negative affect, the analyses partially supported the hypotheses. FBI improved positive affect ($d = .49$, $p < .01$) and decreased negative affect ($d = -.62$ to $-.68$, $p < .01$). Improvement in emotion regulation was reported by 85% of parents in FBI, a frequency that approached significance relative to CIA ($\chi^2(2) = 5.8$, $p = .056$). Findings suggest that approaching pain and other sensations with playfulness and curiosity can help children be less fearful of their bodies while developing emotion awareness and regulation.

ASSOCIATIONS BETWEEN CHILDHOOD FOOD NEGLECT AND DSM-5 EATING DISORDERS IN A NATIONAL SAMPLE OF U.S. ADULTS

Jaime A. Coffino, MA, MPH¹, Tomoko Udo, PhD², Carlos Grilo, Ph.D.³¹University at Albany, SUNY, Providence, RI; ²School of Public Health, University at Albany, Rensselaer, NY; ³Yale University School of Medicine, New Haven, CT

Adverse childhood experiences (ACEs) have been associated with increased risk for eating disorders (EDs). It has also been suggested that restricted access to food, such as experiencing food insecurity, may increase risk for disordered-eating behaviors, such as binge eating. Childhood food neglect represents early experiences with restricted access to food and maltreatment. This study examined the relationship between childhood food neglect and *DSM-5*-defined EDs in a nationally representative sample of U.S. adults, with a particular focus on whether the relationship persists even after adjusting for other ACEs and family financial difficulties during childhood.

Methods: The study included respondents from the National Epidemiological Survey on Alcohol and Related Conditions III (NESARC-III) who answered a question regarding childhood food neglect ($n = 36,145$). First, the prevalence of lifetime anorexia nervosa (AN), bulimia nervosa (BN), and binge-eating disorder (BED) was determined by a history of childhood food neglect. Analyses then compared the odds of each ED diagnosis after adjusting for sociodemographic characteristics (Model 1) and additionally adjusting for history of other ACEs and governmental support during childhood (Model 2).

Results: Prevalence estimates for AN, BN, and BED with a history of childhood food neglect were 2.80% ($SE = 0.81$), 0.60% ($SE = 0.21$), and 3.50% ($SE = 0.82$), respectively and 0.80% ($SE = 0.07$), 0.30% ($SE = 0.03$), and 0.80% ($SE = 0.05$) for those without a history (all significantly different at $p < .05$). In the fully-adjusted model, odds of having an eating-disorder diagnosis were significantly higher for AN (AOR = 2.98 [95% CI = 1.56–5.71]) and BED (AOR = 2.95 [95% CI = 1.73–5.03]) in respondents with history of childhood food neglect compared with those without the history; AORs were not significant for BN.

Discussion: The findings suggest that individuals with a history of childhood food neglect may be at significantly increased odds of meeting lifetime diagnoses of AN and BED and that these elevated rates persist after adjusting for other adverse experiences and financial difficulties during childhood. Thus, identifying and addressing food neglect during childhood may perhaps help to prevent the development of EDs.

Mason, PhD⁶¹The Virginia Consortium Program in Clinical Psychology, Norfolk, VA; ²Old Dominion University, Norfolk, VA; ³The Virginia Consortium Program, Norfolk, VA; ⁴Virginia Consortium Program in Clinical Psychology, Newport News, VA; ⁵Virginia Consortium Program in Clinical Psychology, Norfolk, VA; ⁶University of Southern California, Los Angeles, CA

Purpose: Disordered eating behavior (DEB) is associated with physical and mental health concerns in both eating disorder (ED) and non-clinical (NC) samples. Past reviews and meta-analyses have examined longitudinal changes in global ED pathology, but none have assessed variations in the use of particular DEBs over extended periods. To address this gap, a meta-analysis was conducted to examine longitudinal changes in DEB use in ED and NC samples.

Method: Prospective studies assessing changes in DEBs via at least two assessments with a time lag of ≥ 10 years were included. Risk ratios (*RR*) were calculated for both baseline to 10-14.9-year and baseline to ≥ 15 -year follow-up changes in the use of binge eating, multiple purging, self-induced vomiting, laxatives, diuretics, diet pills, compensatory exercising, fasting/dieting, and multiple DEBs. Subgroup analyses tested whether ED vs. NC samples and female vs. male sex/gender influence overall effect magnitude for analyses with sufficient data.

Results: In total, 17 studies (44 articles; 26 unique [sub]samples) were included that provided data for 31 to 9,031 participants per sample (baseline *M*age=18.63, *SD*=5.49; range=11.59–29.30). There were nine ED and 17 NC (sub)samples. Over 10-year follow-up, significant decreases were found in the use of vomiting ($RR=0.60$), laxatives ($RR=0.66$), compensatory exercising ($RR=0.80$), and fasting/dieting ($RR=0.60$). Over 15+ year follow-up, significant decreases were found in the use of laxatives ($RR=0.37$), diuretics ($RR=0.42$), diet pills ($RR=0.25$), and compensatory exercising (0.75). ED vs. NC status moderated 10-year changes in binge eating (ED: $RR=0.53$; NC: $RR=0.99$), multiple purging (ED: $RR=0.55$; NC: $RR=2.09$), and laxatives use (ED: $RR=0.34$; NC: $RR=1.30$). Sex/gender did not moderate changes in DEB use.

Conclusions: The present results suggest changes in DEB use vary based on DEB type and whether participants comprise clinical ED or NC samples. Use of purging DEBs generally decreased over time across all studies. Moderation analyses showed that NC samples had increases in the use of multiple purging and laxatives whereas ED samples' use decreased. Also, binge eating only decreased in ED samples. Increased clinical attention should be given to DEB prevention in NC populations to preclude the development of clinical EDs, and potential physiological (e.g., cardiovascular, gastrointestinal, neurobiological) and psychological morbidity associated with long-term DEB use.

Paper Session 47

4:00 PM-4:15 PM

WEIGHT BIAS INTERNALIZATION MEDIATES THE RELATIONSHIP BETWEEN FOOD ADDICTION AND OVERVALUATION OF SHAPE AND WEIGHT

Jaime A. Coffino, MA, MPH¹, JoAnna Elmquist, n/a², Carlos Grilo, Ph.D.³¹University at Albany, SUNY, Providence, RI; ²n/a, New Haven, CT; ³Yale University School of Medicine, New Haven, CT

Introduction: Food addiction, a form of disordered eating posited to occur in the presence of highly palatable foods and resembling behaviors common in substance use and other behavioral addictions, is associated with obesity and binge-eating disorder (BED). BED is associated with weight bias internalization (WBI) and body-image concerns including the overvaluation of shape and weight. Although overvaluation of shape and weight and WBI are associated with BED, the relationship between food addiction, overvaluation of shape and weight, and WBI is yet to be explored. The current study examined the mediating effect of WBI on the relationship between overvaluation of shape and weight and food addiction in BED patients.

Methods: Participants included 246 treatment-seeking adults with obesity who met *DSM-IV-TR* criteria for BED. Overvaluation of shape and weight were assessed using both the Eating Disorder Examination (i.e., semi-structured interview) and the Eating Disorder Examination Questionnaire (i.e., self-report measure). Food addiction was assessed with the Yale Food Addiction Scale and WBI was assessed using the Weight Bias Internalization Scale.

Results: Results from the correlation analysis indicated that WBI was positively and significantly related to overvaluation of shape and weight and food addiction (all p 's < .001). Results from the mediation analyses indicated that WBI fully mediated the relationship between overvaluation of shape and food addiction (self-reported: 95% CI = .08-.24; interview: 95% CI = .09-.23) and overvaluation of weight and food addiction (self-reported: 95% CI = .10-.26; interview: 95% CI = .07-.18).

Discussion: This is the first study to examine the mediating effect of WBI on the relationship between overvaluation of shape and weight and food addiction in adults with BED. Findings suggest that overvaluation of shape and weight and WBI are important correlates of food addiction in this patient group with BED with comorbid obesity. Specifically, participants with BED who report high levels of overvaluation of shape and weight are more likely to perceive themselves as addicted to food because of the statistically-mediating influence of WBI. The findings should be tested in prospective repeated-measures longitudinal designs and using experimental methods; if replicated, findings could ultimately inform treatment refinement.

GUT HYPERVIGILANCE IN ANOREXIA NERVOSA: IMPLICATIONS FOR TREATMENT

Alannah Rivera-Cancel, BA¹, Julia Nicholas, BS¹, Samuel Marsan, BA¹, Beate M. Herbert, Associate Professor², Cynthia Bulik, PhD³, Katharine L. Loeb, PhD⁴, Nancy Zucker, PhD¹¹Duke University, Durham, NC; ²University of Tuebingen, Ulm, Baden-Wuerttemberg, Germany; ³University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁴Fairleigh Dickinson University, Teaneck, NJ

Introduction: Gastrointestinal symptoms are common during the acute phase of anorexia nervosa (AN), challenge treatment retention, and often persist after recovery. These symptoms are typically seen as normative and expected sequelae of malnutrition and re-nourishment and thus not systematically addressed in treatment. Yet, aversive visceral experiences may impair the process of re-nourishment and contribute to potent visceral memories that increase preoccupation with the gut and the risk of relapse. We explore emotional reactions and preoccupation to gut sensations, body sensations that constitute anxious arousal, and eating disorder symptoms in adolescents with AN or a history of AN relative to healthy controls (HC) and in their mothers. We hypothesized that gut sensations, specifically, rather than somatic symptoms generally, would be elevated in individuals with AN and their mothers—suggesting gut hypervigilance as a vulnerability factor that may be exacerbated by the starvation of AN.

Methods: Twenty-two female adolescents with AN or a history of AN and 31 healthy female adolescents completed online questionnaires including the Visceral Sensitivity Index (VSI), the Childhood Anxiety Sensitivity Index (CASI), and the Eating Disorder Inventory-3 Drive for Thinness and Body Dissatisfaction subscales. The parents of both groups of participants also completed an online battery that included the VSI and the Anxiety Sensitivity Index (ASI). Independent samples t -tests were used to assess differences between groups. Parents of AN and HC adolescents were matched based on child age, and paired sample t -tests with 16 pairs of parents were used to compare parents' VSI and ASI.

Results: Independent samples t -tests revealed significantly higher VSI in AN relative to HC ($M_{AN} = 39.00$, $SD_{AN} = 14.18$, $M_{HC} = 26.9$, $SD_{HC} = 8.8$, $t = 3.6$, $p = .001$, $d = 1.1$) and no significant differences in CASI ($t = .25$, $p = .8$, $d = .08$). VSI, but not ASI, was significantly correlated with body dissatisfaction ($r = .62$, $p < .01$) and drive for thinness ($r = .64$, $p < .01$). VSI was positively correlated with age of onset ($r = .45$, $p < .05$). Paired sample t -tests found no statistically significant differences in VSI ($t = 1.48$, $p = .16$, $d = .54$) or ASI ($t = -1.38$, $p = .19$, $d = -.50$) between AN-parents and HC-parents, though effect sizes were medium.

Conclusions: When individuals have had painful and/or uncomfortable visceral sensations, vulnerable individuals may become hypervigilant to body experiences in an attempt to avoid future aversive sensations. In AN, the task of renourishment is painful and uncomfortable. In a condition already marked by body preoccupation, the challenge of renourishment may worsen this preoccupation. There is an urgent need to develop strategies for renourishment that minimize this discomfort, a focus that may improve outcomes and help lessen risk for relapse.

Paper Session 47

4:30 PM-4:45 PM

AN INITIAL TEST OF FEASIBILITY, ACCEPTABILITY, AND EFFICACY OF A VIRTUAL REALITY INHIBITORY CONTROL TRAINING FOR BINGE EATING

Stephanie Manasse, Ph.D.¹, Elizabeth Lampe, B.A.¹, Adam Payne-Reichert, B.S.², Adrienne S. Juarascio, Ph.D.¹, Evan M. Forman, PhD¹¹Drexel University, Philadelphia, PA; ²Drexel University, Newtown, PA

Treatments for binge eating (a key problematic behavior across eating disorders and obesity) have suboptimal outcomes. One reason for suboptimal outcomes is that treatments do not sufficiently address deficits in inhibitory control (i.e., the ability to withhold a prepotent response), which are known to maintain binge eating. Enhancing inhibitory control through computerized inhibitory control trainings (ICTs) has the potential to reduce binge eating and be highly disseminable, but the literature is mixed as to whether ICTs can produce real-world behavioral changes. A virtual reality (VR)-based ICT has the potential to yield improved outcomes over traditional computer-based ICTs due to (1) more realistic imagery of foods encountered in everyday life; and (2) realistic motor movements (e.g., reaching for food versus a keypress). Additionally, recent technological advancements allow for regular at-home use of a VR ICT, increasing disseminability and the potential for repeated practice. As such, we developed the first-ever VR ICT for reducing binge eating (*TakeControlVR*) and evaluated its feasibility, acceptability, and initial efficacy. We recruited participants with clinically significant binge eating ($n=13$) to complete a daily VR ICT in their own homes for two weeks. Binge eating was measured at pre-treatment, post-treatment, and after a 2-week follow-up period. A subset of participants ($n=7$) completed a 4-week waitlist baseline period prior to the training period. On a 5-point Likert scale, participants rated *TakeControlVR* as easy to use ($M=4.23\pm.83$) and fun ($M=4.23\pm.93$). Participants also reported that they looked forward to using it ($M=4.15\pm.99$), and that completing trainings became part of their daily routine ($M=4.31\pm 1.61$). Mean compliance with daily trainings was 85.7%. Moreover, *TakeControlVR* resulted in an 81.1% decrease in binge episodes from pre-treatment to follow-up ($M_{pre}=10.17\pm 2.21$, $M_{post}=1.92\pm.90$), compared to the waitlist control period, during which binge eating decreased 34.8% ($M_{pre}=13.50\pm 5.4$, $M_{post}=8.8\pm 2.96$). Results indicate that a daily, at-home virtual reality ICT can be feasible, acceptable and result in reductions in binge eating. Future research should examine whether (1) VR ICTs are feasible, acceptable, and efficacious over a longer training period, (2) whether VR ICTs show relative efficacy over and above computerized non-VR trainings, and (3) whether VR ICTs add incremental value as an adjunct to standard treatments.

Paper Session 48

3:30 PM-3:45 PM

PILOT TRIAL OF COGNITIVE BEHAVIORAL THERAPY INTERVENTION TO IMPROVE CONTRACEPTION USE IN WOMEN AT RISK FOR UNINTENDED PREGNANCY

Stephen J. Lepore, PhD¹, Collins N. Bradley, PhD¹, David W. Sosnowski, PhD², Melissa Godfrey, MPH¹¹Temple University, Philadelphia, PA; ²Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD

Over one-half of pregnancies are unintended (UP) and UP has been linked to poorer maternal and child health. UP risk is greatest in low-income and minority women, particularly if they suffer from depression and low self-esteem. We tested an innovative behavioral intervention aimed at lowering risk for UP via improved contraception use in high-risk women. The intervention consisted of telebased, peer-led contraception education and cognitive behavioral therapy (CBT). There is evidence that using peers in the delivery of CBT is acceptable and beneficial among low-income and minority women. Eligibility included: not sterilized; not pregnant or planning to be; sexual intercourse past 3 months; inconsistent or no birth control; 18-45 years old, own smartphone, and have elevated depressive symptoms. Baseline data were collected before women ($N = 133$) were randomized to Intervention or a treatment as usual control group. The intervention included 8 telephone sessions with a peer specialist, a mobile app to monitor mood and activities, and a workbook. Data were collected via telephone interviews pre-intervention and at 4-, 10-, and 14-week follow-ups. The main outcomes at 14-weeks were consistent birth control use, distress symptoms and self-esteem. Mediators included sexual/contraceptive self-efficacy, coping, and mattering to others at 10-weeks. Missing data were handled using multivariate imputation by chained equations. Contraception consistency was only analyzed in women having intercourse with a male partner at 14-week follow-up. Participants were mostly (82.0%) non-White; 60.2% lived in poverty; 51.1% had history of UP. Participants completed a median of 6 phone sessions; 88.7% rated the CBT workbooks as somewhat or very helpful; 81.5% rated the Daylio app as somewhat or very helpful. Results suggested that being in the CBT group may have increased the odds of consistently using contraception relative to controls: odds ratio = 1.98 (95% CI = .86 – 4.54), $p = .05$. Sensitivity analyses using original data were similar: odds ratio = 2.28 (95% CI = 1.01-5.27), $p = .02$. There was no statistically significant effect of the intervention on distress symptoms or self-esteem at 14-weeks. Among the mediators, there was a significant positive effect of intervention on 10-week sense of mattering to others ($p < .05$ imputed and original data), but this was unrelated to subsequent contraception use. In sum, using peer specialists to deliver CBT targeting psychological risk factors to improve contraception use is theoretically compelling, but as an innovation it is risky. Women in the intervention appeared to have improved contraception use but may need treatments that are more intensive to realize improved psychological functioning (e.g., more homework, more sessions). Given the generally high adherence to and positive ratings of treatment, more intensive treatment may be feasible.

MERITORIOUS AWARD WINNER**Paper Session 48****3:45 PM-4:00 PM****MILITARY SEXUAL TRAUMA HISTORY AND IMPAIRED ROMANTIC RELATIONSHIP FUNCTIONING AMONG US ARMY RESERVE/NATIONAL GUARD SOLDIERS**Jennifer Fillo, Ph.D.¹, D. Lynn Homish, M.S.², Gregory Homish, Ph.D.²¹University at Buffalo, The State University of New York, BUFFALO, NY;²University at Buffalo, The State University of New York, Buffalo, NY

There has been growing attention to the alarming prevalence of military sexual trauma (MST) in the US Military, as well as its physical, mental, and behavioral health consequences. However, far less attention has been paid to the toll MST can take on service members' romantic relationships. In the civilian literature, sexual trauma history is directly linked to impaired relationship functioning. Undermining these relationships may be especially harmful in military populations because partners are a critical source of support, often playing a vital role in aiding recovery from service-connected conditions. To shed light on this important issue, this research examined relations between MST history and multiple indicators of current romantic relationship functioning among male and female service members and veterans. Data were drawn ($N = 356$) from Operation: SAFETY, an ongoing longitudinal study examining health and well-being among U.S. Army Reserve and National Guard soldiers and their partners. OLS regression analyses examined associations between participants' MST history and multiple indicators of current romantic relationship functioning (i.e., marital satisfaction, intimacy, negative social exchange), as well as potential differences by sex. MST history predicted lower current romantic relationship satisfaction ($b = -9.44, p = .012$). MST history also predicted lower emotional intimacy ($b = -1.46, p = .027$) and recreational intimacy ($b = -1.11, p = .038$), but was unrelated to sexual intimacy ($b = -0.08, p = .253$). Interactions with participant sex revealed that the detrimental effect of MST history on social intimacy was greater for females than males, and the effect of MST history on intellectual intimacy only held for females. Further, MST history predicted more negative social exchange in current romantic relationships (total score: $b = 3.95, p = .010$). Specifically, those with a history of MST reported greater insensitivity ($b = 1.34, p = .020$) and interference ($b = 1.04, p = .004$) in their relationships. Results revealed that the consequences of MST extend beyond service members to also impair functioning in their romantic relationships. Soldiers with MST history were less satisfied, had lower intimacy, and had greater negative social exchange in their current romantic relationships. Findings demonstrate the far-reaching consequences of MST and underscore the need for interventions aimed at preserving this important source of support for service members.

Paper Session 48**4:00 PM-4:15 PM****"HIV MADE ME STRONGER:" CONCEPTIONS OF SUCCESSFUL AGING AMONG OLDER WOMEN LIVING WITH HIV**Anna A. Rubtsova, PhD¹, Tonya N. Taylor, PhD², Gina Wingood, ScD³, Deborah Gustafson, PhD⁴, Marcia Holstad, PhD, FNP-BC, FAANP, FAAN⁵

¹Emory University Rollins School of Public Health, Atlanta, GA; ²SUNY Downstate Medical Center, Brooklyn, NY; ³Columbia University Mailman School of Public Health, New York, NY; ⁴State University of New York Downstate Medical Center, Brooklyn, NY; ⁵Nell Hodgson Woodruff School of Nursing at Emory University, Atlanta, GA

Older (age 50+) women living with HIV (OWLH) face multiple challenges related to the intersection of HIV infection and aging, e.g. multimorbidity and polypharmacy, as well as HIV- and gender-related stigma and discrimination. However, in our previous quantitative study we found a high prevalence of self-rated Successful Aging (SA) among OWLH enrolled in the Women's Interagency HIV Study (WIHS). In the sample of 386 OWLH, 84% rated their SA to be 7 or higher on a scale from "1" (least successful) to "10" (most successful). Little is known about what accounts for this high prevalence and exactly how OWLH understand SA. To date, several studies examined SA among predominantly white male HIV-seropositive adults but not among OWLH. Therefore, the purpose of this qualitative study was to examine subjective understandings of SA among OWLH. The study used purposive sampling to recruit OWLH enrolled in WIHS and, as a comparison group, OWLH who were not enrolled in WIHS but received clinical care. The sample for these analyses included 19 OWLH who participated in semi-structured interviews - 10 in Atlanta, GA (3 WIHS and 7 non-WIHS) and 9 in Brooklyn, NY (5 WIHS and 4 non-WIHS). The interviews were conducted between October 2018 and March 2019 and ranged from 30 to 120 minutes. Transcribed interviews were analyzed using qualitative content analysis methodology within the grounded theory approach. Several themes emerged in participants' definitions of SA, such as self-care, taking HIV medications, and being resilient ("HIV made me stronger"). Both WIHS and non-WIHS participants emphasized life course perspective in their definitions of SA, i.e. women viewed their aging successful as a more stable phase of life in contrast to hardships they experienced while being younger (e.g., drug use, incarceration). Taking together with our earlier quantitative findings, these results suggest that SA is achievable among OWLH. Interventions enhancing resilience should be considered to promote SA in OWLH.

Paper Session 48

4:15 PM-4:30 PM

WHAT ARE BREAST CANCER PATIENTS' BELIEFS ABOUT DISCUSSING SEXUAL HEALTH WITH THEIR PROVIDERS?

Lauren A. Zimmaro, PhD¹, Mary Catherine Beach, MD, MPH², Stephen J. Lepore, PhD³, Jennifer B. Reese, PhD⁴¹Fox Chase Cancer Center, Harleysville, PA; ²Johns Hopkins School of Medicine, Baltimore, MD; ³Temple University, Philadelphia, PA; ⁴Fox Chase Cancer Center, Philadelphia, PA

Objectives: Women with breast cancer (BC) experience sexual concerns and often avoid discussing them with their healthcare providers (HCP). Little quantitative research has investigated the beliefs BC patients hold in relation to discussing sexual issues. We aimed to (1) characterize the beliefs patients report regarding discussing sexual concerns with HCP, (2) categorize patients according to the extent to which they report certain beliefs, and (3) compare these patient groups on communication self-efficacy and sexual concerns.

Methods: 141 BC patients (M age=56, 33% minority) provided baseline self-report data as part of a sexual health communication intervention trial. Standard measures assessed beliefs about sexual health communication that could interfere with women's likelihood of discussing such issues (e.g., "I might become embarrassed;" "I worry about offending my provider"), self-efficacy for clinical communication about sexual concerns, and level of sexual concerns. Exploratory factor analysis identified underlying types of beliefs. Hierarchical cluster analysis detected groups of patients with similar response patterns based on the factors. Chi-square tests and ANOVAs compared patient groups on level of sexual concerns and communication self-efficacy.

Results: Two factors within the communication belief items emerged: (1) items reflecting *patients' own beliefs about or perceived inability* to discuss sexual concerns (self-beliefs; e.g. "I wouldn't know where to start"), and (2) items reflecting *patients' perceptions of providers' feelings* that might limit discussing sexual concerns (provider-beliefs; e.g. "My provider might become embarrassed"). Patients endorsed self-beliefs to a greater extent than provider-beliefs (M=2.5 vs. 2.0, range 1-5), $t(143)=7.86$, $p<.001$. Three patient clusters emerged: (1) high self/high provider-beliefs (high/high; $n=19$; 13%), (2) high self/low provider-beliefs (high/low; $n=95$; 66%), and (3) low self/low provider-beliefs (low/low; $n=30$; 21%). The clusters differed from one another on sexual communication self-efficacy in the expected direction, $F(2)=10.57$, $p<.001$, with the high/high cluster having the lowest self-efficacy, followed by the high/low cluster, and then the low/low cluster. Mean sexual concerns were moderate ($M=4.7$, range 0-10) and did not differ among patient clusters ($p=.867$).

Conclusions: When asked about beliefs on sexual health clinical communication, BC patients most often and most highly endorsed beliefs reflecting their own level of confidence and comfort with discussing this topic, as opposed to their providers'. Next steps include assessing whether patient beliefs relate to actual clinical communication and whether interventions are effective at enhancing not only patients' their beliefs and skills but also their communication with providers.

4:30 PM-4:45 PM

SEXUAL SATISFACTION AND SEXUAL AGENCY IS ASSOCIATED WITH WELL-BEING FOR WOMEN REGARDLESS OF AGE OR RELATIONSHIP STATUS

Christine M. Curley, M.A.; J.D.¹¹University of Connecticut, North Kingstown, RI

Health psychology has focused primarily on nutrition, exercise, and smoking cessation to improve wellness, largely failing to discuss the health benefits of sexual satisfaction. This study found a significant association between sexual satisfaction, relationship satisfaction, and sexual agency, and well-being for women of varying ages.

Studies have found a strong association between sexual satisfaction and overall well-being, but have not directly examined whether this differs for women of varying ages or depends upon relationship status. This study recruited women to examine: (1) that there will be an association between age, sexual agency, relationship satisfaction and sexual satisfaction; (2) that higher levels of sexual satisfaction will be associated with higher levels of overall well-being; (3) which factors are more strongly predictive of sexual satisfaction; and (4) the extent to which relationship status impacts the association between the variables examined.

Methods: The survey sample consisted of 347 women aged 18-76; ($M=34.29$; $SD=14.19$); 79.9 % White; and 63% heterosexual (of participants reporting their sexual orientation).

Participants answered a series of survey questions about their overall well-being, sexual satisfaction, sexual agency, relationship satisfaction, and sociosexual orientation using established validated measures, as well as demographic questions including relationship status and socioeconomic status.

Discussion: For all women, regardless of age, higher sexual satisfaction was correlated with higher overall well-being; this finding is important as it counters the misconception that sexual satisfaction matters less for women as they grow older.

Higher sexual agency scores were associated with higher sexual satisfaction scores. Particularly striking was the strength of the correlation between sexual agency and sexual satisfaction, and that sexual agency was a stronger predictor of sexual satisfaction than relationship satisfaction.

Regression analyses revealed that the strongest predictor of sexual satisfaction was sexual agency, followed by relationship satisfaction, with neither age nor sociosexual orientation being significant predictors.

Partial correlations indicated that relationship status does not alter the association (1) between age and overall well-being; (2) between sexual satisfaction and overall well-being; (3) between sexual agency and overall well-being; and (4) between sexual agency and sexual satisfaction.

AN OBSERVATIONAL ASSESSMENT OF THE SLEEP ENVIRONMENT IN FAMILY CHILD CARE HOMES

Tayla Ash, ScD, MPH¹, Kim M. Gans, PhD, MPH², Alison Tovar, PhD, MPH³, Patricia M. Risica, DrPH⁴¹Brown University, Providence, RI; ²UConn, Storrs, CT; ³URI, Kingston, RI; ⁴Brown School of Public Health, Providence, RI**Objective:** To conduct in-person observations of the sleep environment in Family Child Care Homes (FCCHs), which has never before been studied.**Methods:** We observed the childcare sleep environment in 24 FCCHs.**Results:** Children napped on a variety of sleep surfaces (e.g. cot/mat, playpen, crib, bed, couch, floor) and with a variety of items (e.g. blanket, pillow, stuffed animal, pacifier, book, sippy cup or bottle, multiple items, no items). Providers commonly engaged in environmental changes such as altering the light (69% dimmed or shut off the lights) or noise level of the room (41% played music) during naptime. The overall noise level during naptime was rated as very quiet in 53% of FCCHs, somewhat quiet in 35%, and not quiet in 12%. Disruptive noises while children were sleeping were observed in 35% of FCCHs. Electronics (e.g. television, tablets) were used during naptime in 27% of FCCHs, and variability with regards to the proximity in which children slept to one another was observed, whether or not providers helped children fall asleep, and flexibility as to when and for how long children napped.**Conclusions:** Nap environments vary widely across FCCHs. Further research is needed to understand how the childcare nap environment influences child sleep and other behaviors.

NIGHTLY SLEEP QUALITY, DAILY AFFECT, AND PERCEIVED SAFETY AMONG YOUNG ADULTS EXPERIENCING HOMELESSNESS

Brian W. Redline, BA¹, Eldin Dzubur, PhD¹, Danielle R. Madden, PhD¹, Benjamin F. Henwood, PhD, MSW¹¹University of Southern California, Los Angeles, CA**Introduction:** Young adults who are homeless experience daily adversities and high rates of emotional disturbances that may be related to poor sleep, but the directionality of such associations is unclear. This study examines the effects of daily affect and perceived safety on nightly sleep quality, and of sleep quality on next-day affect, among young adults who are homeless.**Methods:** Young adults (n=107, ages 18-25) recruited from homeless shelters and drop-in centers completed a baseline survey and seven days of smart-phone surveys including daily retrospective surveys and ecological momentary assessments (EMA) at 2-hour intervals during waking hours. Daily surveys assessed prior night sleep quality and EMA assessed current affect and perceived safety on 5-point scales that were collapsed to daily means. Separate mixed-effects logistic regressions evaluated the between-subject (BS) and within-subject (WS) effects of positive affect (i.e., happy, calm, excited), negative affect (i.e., sad, stressed, irritated), and perceived safety on nightly sleep quality, and of sleep quality on next-day affect. Covariates included age, sex, race, and depression score (PHQ-9).**Results:** Participants (age: 21.8±2.0, 69% male, 55% Black) were followed for an average of 5.9±1.4 days. Those who on average reported feeling less negative affect, more positive affect, or safer during the day than others were more likely to have better sleep quality in general (ORs=0.88, 1.14, 1.24; p'<.001), and the likelihood of an individual reporting better sleep on a given night was associated with feeling more positive (OR=1.13, p<.01), less negative (OR=0.92, p<.05), or safer (OR=1.20, p<.001) than their average that day. Sleep quality was also associated with next-day affect: Those who slept better on average were generally more likely to have less negative (OR=0.87, p<.01) and more positive affect (OR=1.21, p<.001), and sleeping better than one's average was associated with higher odds of less negative (OR=0.96, p<.01) and more positive affect (OR=1.02, p<.05) the next day.**Conclusions:** We found bidirectional effects between sleep quality and waking affect within and between subjects, with relatively stronger effects in the direction from affect to nightly sleep quality. The strongest BS and WS effects were between daytime perceived safety and sleep quality that night, emphasizing the importance of not only providing access to shelters at night, but also safe spaces during waking hours.

USING SLEEP TREATMENT ADVERTISED ON WEB-BASED SOCIAL MEDIA TO RECRUIT HEAVY-DRINKING YOUNG ADULTS FOR ALCOHOL TREATMENT

Garrett I. Ash, PhD¹, Momoko Ishii, B.S.², Brian Pittman, MS², Kelly DeMartini, PhD³, Stephanie O'Malley, Ph.D.³, Nancy S. Redeker, Ph.D.⁴, David S. Robledo, BS Public Health⁵, Lisa Fucito, PhD²

¹Veterans Affairs Medical Center, New Haven, CT; ²Yale University School of Medicine, New Haven, CT; ³Yale University, New Haven, CT; ⁴Yale University, West Haven, CT; ⁵Yale University, Norwalk, CT

Background: Alcohol use disorder onset peaks during young adulthood, but young adults rarely self-identify for specialized alcohol treatment. Thus, more work is needed to identify novel treatment engagement strategies to reduce this substantial public health burden. Heavy alcohol use may disrupt sleep, and we have previously shown that young adults are interested in the connection between sleep and alcohol and are open to getting help for their sleep. Therefore, we have started a novel program focused on using sleep treatment as a way to engage heavy-drinking young adults.

Objective: This study examined utility of social media advertisements for our sleep treatment research study to recruit heavy-drinking young adults and evaluated sleep and alcohol use and current treatment goals among those who responded to the web-based survey.

Methods: Using Facebook's and Snapchat's advertising programs, 3 separate advertising slogans ran for 5 months targeting young adults who either had sleep concerns or were open to participating in a sleep program. Advertisements were shown to young adult (18-25yr), English-speaking Facebook and Snapchat users in the greater New Haven, Connecticut, area. Participants were invited to complete a Web-based survey to determine initial eligibility for a sleep treatment study.

Results: Advertisements generated 6,983 clicks and 823 valid, completed surveys in 5 months. Fees averaged \$0.35 per click, \$2.97 per completed survey, \$6.73 per participant meeting initial screening eligibility, and \$62.78 per participant enrolling in the study. On average, those who completed the web-based survey were $X \pm SD$ 21.2 \pm 2.3 yrs of age, and 68.6% (630/919) were female. Most reported sleep concerns (78.6%) and interest in the connection between sleep and alcohol (65.0%) but few concerns about alcohol (5.9%). A large fraction (39.6%) met the inclusion criteria of being high-risk drinkers (Alcohol Use Disorders Identification Test (AUDIT-C) ≥ 5 women, ≥ 7 men). Those not meeting the drinking criteria had better subjective sleep quality (2.9 \pm 0.9 out of 5) compared with those who met the criteria but did not enroll (2.7 \pm 0.8) and those who enrolled (2.5 \pm 0.9) ($p < 0.01$). In addition, those who met criteria but did not enroll had less severe drinking than those enrolled (AUDIT-C 6.6 \pm 1.6 vs 8.1 \pm 1.7, $p < 0.01$). Of those meeting drinking criteria, 12.0% (39/325) enrolled.

Conclusion: Social media advertisements designed to target young adults who had sleep concerns reached those who also drank alcohol heavily. Few were concerned about alcohol, but heavier drinking was associated with greater likelihood of enrolling in the sleep treatment. Using social media advertising for sleep treatment appears effective to engage heavy-drinking young adults, although costs were 2x-5x higher per enrolled participant than previous reports. Further work should target making the approach more cost effective.

TIME FOR BED! EARLIER SLEEP ONSET IS ASSOCIATED WITH LONGER NIGHT SLEEP DURATION DURING INFANCY

Elizabeth L. Adams, PhD¹, Lindsay Master, MAS², Orfeu M. Buxton, PhD³, Jennifer S. Savage, PhD⁴

¹Virginia Commonwealth University, Richmond, VA; ²Pennsylvania State University, Philadelphia, PA; ³Pennsylvania State University, University Park, PA; ⁴Penn State University, University Park, PA

Background: Shorter sleep duration during infancy is associated with adverse health outcomes such as obesity. Clinical recommendations suggest putting infants to bed using short, consistent bedtime routines at an appropriate hour to promote longer nighttime sleep duration; yet, there is a lack of data examining bedtime routines and objective measures of infant sleep. We used actigraphy to explore how bedtime routines were associated with nighttime total sleep time and sleep quality across the first 6 months of life.

Methods: Infants ($n = 23$; ~80% White) wore actigraph (Actiwatch Spectrum) devices on their right ankle for three, 1-week periods at 6, 15 and 24 weeks of age. Data were scored using a SAS-based validated algorithm and corrected using visual assessment. Nighttime total sleep time (TST) and sleep efficiency (i.e., quality) were quantified. Sleep onset was the start of actigraphy-defined nighttime sleep periods. Bedtime routine length, number of activities, feeding as the last activity, and frequency of the doing the same routine were reported by mothers using the Brief Infant Sleep Questionnaire at each age. Multilevel models examined between- and within-person associations between sleep onset, aspects of bedtime routines, and subsequent TST/quality.

Results: As infants aged, sleep onset got earlier (6 weeks: ~9:30PM; 15 weeks: ~8:40PM; 24 weeks: ~8:20PM; $p < 0.01$) and bedtime routines got shorter (6 weeks: 53.9 \pm 5.4 min; 15 weeks: 47.4 \pm 5.4 min; 24 weeks: 35.7 \pm 5.4 min; $p = 0.03$). On average, 6.7 \pm 2.1 activities were done during bedtime routines, and feeding was the last activity for 25% of infants, which did not differ by infant age (p 's > 0.05). Between-person analyses indicated that across all ages, earlier sleep onset was associated with longer TST (22 \pm 10.0 min longer for each 1 hr earlier; $p = 0.03$), and not associated with nighttime sleep efficiency ($p = 0.49$). Within-person analyses showed that when infants' sleep onset was earlier than usual, TST was longer and less efficient that night (34.4 \pm 2.7 min longer; 1.2 \pm 0.3% less efficient for each 1 hr earlier). Bedtime routine length, number of activities, feeding as the last activity, and frequency of doing the same routine were not associated with TST or efficiency at any age (p 's > 0.05).

Conclusion: Infants who went to sleep earlier, also slept more at night. Keeping infants up later in hopes of them sleeping longer may be counterproductive. Our findings align with pediatric recommendations for older children exhibiting mood or behavioral problems, where insufficient sleep may be a contributing factor, and earlier bedtimes are recommended.

Paper Session 49

4:30 PM-4:45 PM

EXAMINING THE ASSOCIATION BETWEEN HOME ENVIRONMENTAL FACTORS AND ADOLESCENT SLEEP HEALTH BY GENDER

Marissa M. Shams-White, PhD, MSTOM, MS, MPH¹, Richard P. Moser, PhD², Todd Horowitz, Ph.D.³, April Oh, PhD, MPH⁴¹National Cancer Institute, National Institutes of Health, Bethesda, MD;²National Cancer Institute/Behavioral Research Program, Rockville, MD;³National Cancer Institute, Rockville, MD; ⁴NIN/NIC/BRP/HCIRB, Rockville, MD

Introduction: Tackling adolescent obesity rates requires an understanding of modifiable risk factors, such as sleep health. Following behavioral approaches (e.g., the social ecologic model) that recognize the role of social and environmental context on behaviors, we hypothesize that adolescent sleep is influenced by home environmental factors. We examined the association of two factors- adolescent screen time and parental sleep quantity- with adolescent sleep quantity and quality by gender (male/female) in the National Cancer Institute's Family Life, Activity, Sun, Health, and Eating (FLASHE) study.

Materials and Methods: FLASHE measured correlates of cancer preventive behaviors in a national sample of parent and adolescent child dyads in 2014. Dyads with adolescents in middle or high school at survey time were included; dyads with missing data or unrealistic total sleep values (< 2h or >16h) were excluded. Adolescent total screen time was defined as total time reported watching television, playing videogames, and using computers, tablets and cell phones. Total average sleep quantity was calculated based on reported sleep and wake times on a typical weekday and weekend day. Sleep quantity and quality were dichotomized based on meeting American Academy of Sleep Medicine's age-specific sleep guidelines and if participants report trouble staying asleep at night, respectively. Sex-stratified, logistic regression models were fit to examine if 1) adolescent screen time and 2) parental sleep quantity were associated with adolescent sleep quantity. The association between adolescent sleep quantity, screen time, and parental sleep quantity together with sleep quality was explored. Models controlled for socio-demographics: adolescent age and race/ethnicity, total household income, and parent marital status.

Results: Of the 1,202 dyads, 51.2% included female adolescents. More females than males reported trouble staying asleep (60.4% vs. 39.6%, $p = 0.016$). Screen time was inversely associated with adolescent sleep quantity in males (odds ratio (OR) (95% CI) = 0.91 (0.85-0.97) but not females (OR = 0.98 (95%CI: 0.92-1.05). Parental sleep quantity was also positively associated with adolescent sleep quantity in males (OR = 1.24 (95%CI: 1.06-1.45) but not females (OR = 1.08 (95%CI: 0.93-1.26)). Adolescent sleep quantity was not associated with sleep quality; in the exploratory model, only screen time was associated with sleep quality in both males (OR: 0.89 (95%CI: 0.81-0.98)) and females (OR: 0.86 (95%CI: 0.79-0.94)).

Conclusion: Our study highlights the importance of the home sleep environment, for adolescent sleep health. Though we cannot infer causality, we suggest that parental sleep quantity, adolescent screen time, and sex differences be considered in future sleep behavior interventions among adolescent populations.

Paper Session 50

3:30 PM-3:45 PM

THE STRUCTURE OF HIV RISK AND PROTECTION IN A FACEBOOK GROUP AFFILIATION NETWORK AMONG YOUNG BLACK MEN WHO HAVE SEX WITH MEN

Lindsay Young, PhD¹, Kayo Fujimoto, PhD², John Schneider, MD, MPH³¹University of Chicago, Los Angeles, CA; ²University of Texas, Health Science Center at Houston, Houston, TX; ³University of Chicago, Chicago, IL

The social networks of young sexual and racial minorities are critical in determining the HIV protections and risks they experience. Increasingly, their interactions occur via social networking sites (SNS) like Facebook, making online networks critical prevention engagement frontiers. Here, we underscore the intermediary role played by Facebook groups in an online HIV risk network among young Black men who have sex with men (YBMSM). Although HIV risks and protections are thought to emerge from the organization of individual behaviors in a network, Facebook group memberships could supplement such organization by virtue of the topics discussed in those spaces. As such, we investigate how Facebook group topics directly related to HIV vulnerability (e.g., LGBTQ Identity) and indirectly related (e.g., Professional Development) work in combination with HIV-related traits of YBMSM as mechanisms of online interaction.

We draw on data from a longitudinal cohort study of YBMSM in Chicago. Demographic, behavioral, and network data, including Facebook group affiliations, were collected from consenting respondents (N=347). We conceptualize YBMSMs' Facebook group affiliations as a network comprised of two node sets — YBMSM and Facebook groups — with ties between YBMSM and groups representing their group affiliation. Then, using a class of statistical models called exponential random graph models, we estimate the likelihood of group affiliation ties being present as a function of group topics and YBMSMs' HIV-related characteristics.

The main component of the Facebook group affiliation network included 82 groups and 221 YBMSM, with 1,260 affiliation ties between them. Topically, the 82 groups were categorized as focusing on *LGBTQ Identity*, *Personal/Professional Development*, *General Chat*, *Nightlife*, *Sexual Attraction*, or *Other*. Results show that individuals were less likely to belong to LGBTQ Identity, Sexual Attraction, and Chat groups and more likely to belong to Personal/Professional Development groups. Meanwhile, YBMSM who were members of at least one LGBTQ Identity, Sexual Attraction, and/or Nightlife group were more likely to cluster around pairs of these groups, respectively. Finally, group topic preferences were significantly associated with specific HIV-related characteristics. YBMSM who engaged in condomless sex tended to affiliate with LGBTQ Identity groups, those who knew about PrEP tended to affiliate with Chat groups, and regular testers tended to belong to LGBTQ Identity and Nightlife groups.

As SNS are now mainstreamed, it behooves researchers to understand their role in forging sexual norms in high-risk populations. Developing interventions that leverage the Facebook group network of YBMSM and, by extension, the topics they discuss, may prove more effective than off-the-shelf interventions that remain agnostic to the needs and interests of this population.

POOR SLEEP AND TIREDNESS PREDICT DAILY SELF-EFFICACY FOR MEDICATION ADHERENCE IN OLDER SEXUAL MINORITY MEN LIVING WITH HIV

Brett M. Millar, PhD¹, Mathilde Ghislain, MSc¹, Nicola Forbes, BA², Juan P. Castiblanco Bustos, n/a¹, Carly Wolfer, BA³, H. Jonathon Rendina, PhD, MPH⁴

¹Hunter College, New York, NY; ²Fordham University, New York City, NY;

³PRIDE Health Research Consortium at Hunter College, New York, NY;

⁴Hunter College and The Graduate Center, CUNY, New York, NY

Background: Given the myriad health benefits of achieving and maintaining an undetectable viral load for people living with HIV, we need to better understand the complex factors that can compromise medication adherence on a given day. Existing research, however, has rarely considered the role of sleep, even though the evidence base for poor sleep's deleterious impact on cognition, emotion, and self-regulation, is vast and growing. Our study explores how last night's sleep quality and today's current tiredness each predict today's self-efficacy for medication adherence, emotion dysregulation, and perceived ability to handle challenges, among a sample of older sexual minority men living with HIV.

Method: Our EMA study involves a 21-day diary design. Participants are NYC-based older (50+) sexual minority men (SMM) living with HIV, reporting suboptimal antiretroviral (ART) adherence. As well as other mood and behavior items, the daily diary asks about: last night's sleep quality (A), current tiredness (B), medication adherence self-efficacy (C), emotion dysregulation (D), and perceived ability to handle today's challenges (E). Multilevel linear modeling tested six models: the influence of within-person A on C-E, and the influence of within-person B on C-E separately, adjusting for between-person A and B, respectively.

Results: Analyzing 845 days of data from 46 participants (mean completion of 18.4 diaries, out of 21), worse-than-usual sleep quality and greater-than-usual tiredness each predicted: lower self-efficacy for medication adherence ($B=0.01$, $p<.05$; $B=-0.29$, $p<.001$), greater emotion dysregulation ($B=-0.01$, $p<.01$; $B=0.60$, $p<.001$), and lower perceived ability to handle the day's challenges ($B=0.01$, $p<.01$; $B=-0.13$, $p<.01$).

Discussion: We found that last night's poor sleep and current tiredness predicted each outcome in a sample of older SMM living with HIV. This highlights the relatively under-studied importance of sleep for factors likely affecting medication adherence. Interventions to improve sleep health thus have the potential to improve ART medication adherence, as well as general physical and mental health. These are especially needed for older people living with HIV given that rates of sleep disturbance associated with normative aging are particularly elevated in the context of HIV, as well as other comorbid chronic conditions. This much-needed focus on sleep represents an innovative opportunity for behavioral medicine research and practice to utilize a broader, whole-person framework in addressing the factors that can either promote or compromise health.

4:00 PM-4:15 PM

PREDICTORS OF SUICIDAL IDEATION AND SUICIDE ATTEMPTS AMONG A NATIONWIDE COHORT OF SEXUAL MINORITY MEN (SMM)

Ali Talan, DrPH¹, K. Marie M. Sizemore, PhD¹, Nicola F. Tavella, MPH, CPH², Aria Tilove, BA³, H. Jonathon Rendina, PhD, MPH⁴, Raymond L. Moody, M.A.⁵

¹Hunter College, New York, NY; ²PRIDE Health Research Consortium, Hunter College, CUNY, New York, NY; ³PRIDE Health Research Consortium at Hunter College, New York, NY; ⁴Hunter College and The Graduate Center, CUNY, New York, NY; ⁵The Graduate Center of The City University of New York, New York, NY

Background: Research has documented significant associations between minority stress processes and negative health outcomes, including suicidality (i.e. suicidal ideation and suicide attempts). Consistent with the minority stress theory, suicidality among SMM is associated with discrimination, harassment, and other victimization, emanating from diverse sources (e.g., family, peers, schools, and communities). While much of the literature has focused on interpersonal discrimination, little is known about how structural discrimination, represented by state-level policies regarding LGBT populations, influence risk of suicide among GBM individuals. We hypothesize that stigma at the structural level shape prejudiced policy, facilitate marginalization, and increase risk of suicidality.

Methods: Data are from UNITE, a cohort study of HIV-negative SMM from across the United States ($N=7952$; $\text{Mage}=32.7$; $\text{SD}=11.4$). Suicidality was assessed using the NIMH Ask Suicide-Screening Questions Toolkit. We conducted chi-square analyses to examine group difference on suicidality. We also conducted a binary logistic regression to examine the association between structural discrimination and suicidality, adjusting for sociodemographic characteristics, interpersonal discrimination, internalized homophobia, and mental health factors known to influence suicidality risk. We adjusted for resiliency (e.g., perceived social support, gay community attachment, "outness"). Structural discrimination was assessed by the State Equality Index (SEI), measuring LGBT-related legislation (e.g., parenting, religious refusal and relationship recognition, non-discrimination, hate crimes, health/safety, and youth-related laws and policies).

Results: We found that 20.7% of the sample reported a suicide attempt in their lifetime. In the past few weeks, 17.6% reported experiencing suicidal ideation, with 9.1% reporting thoughts of killing themselves in the past 7 days. Significant differences by sociodemographic characteristics, interpersonal discrimination, internalized homophobia, resiliency and mental health factors, were identified. Our regression analysis indicated that individuals living in states with the most comprehensive equality measures had significantly lower odds of both suicidal ideation ($\text{AOR}=.84$, $p=.03$) and suicide attempts ($\text{AOR}=.85$, $p<.001$).

Conclusion: Limited research on minority stress includes measures of stigma at both the individual and structural level to determine whether these factors independently predict adverse health outcomes. This study demonstrated that structural discrimination, in addition to known individual and interpersonal risk factors, increase risk of suicidality among GBM. These results suggest that identifying structural interventions may help to reduce sexual orientation-related disparities in suicide attempts.

SYNDEMICS, SELF-REGULATION, AND HIV TRANSMISSION RISK AMONG GAY AND BISEXUAL MEN

Raymond L. Moody, M.A.¹, Christian Grov, PhD, MPH², H. Jonathon Rendina, PhD, MPH³

¹The Graduate Center of The City University of New York, New York, NY;

²CUNY School of Public Health, New York, NY; ³Hunter College and The Graduate Center, CUNY, New York, NY

Background: Research has identified multiple epidemics that disproportionately affect gay and bisexual men (GBM), have high levels of comorbidity, and work synergistically to increase HIV transmission risk behavior (TRB). The syndemic framework has been useful in identifying GBM at increased risk of TRB but less is known about potential mechanisms that link the epidemics that are part of the HIV syndemic. The present study is a longitudinal analysis of executive attention and emotion dysregulation as mediators of the effects of childhood sexual abuse and intimate partner violence on depression, sexual compulsivity, polydrug use, and TRB.

Methods: Data are from One Thousand Strong, a cohort of HIV-negative GBM from across the United States (M_{age}=40.33, SD=13.67). Childhood sexual abuse and intimate partner violence were assessed at baseline and 12-month follow-up. Executive attention, emotion dysregulation, depression, sexual compulsivity, and polydrug use were assessed at 24-month follow-up. TRB (i.e., condomless anal sex with male casual partner) was assessed at 36-month follow-up. A negative binomial logistic regression model was estimated using Mplus with executive attention and emotion dysregulation as mediators of the associations between childhood sexual abuse and intimate partner violence on depression, sexual compulsivity, polydrug use, and TRB.

Results: The analytic sample included 922 GBM. In our path model, adjusting for sociodemographic characteristics, childhood sexual abuse was directly associated with greater emotion dysregulation and poorer executive attention, and was positively associated with depression and sexual compulsivity through these difficulties with self-regulation. Intimate partner violence was associated with greater emotion dysregulation but not with executive attention, and was positively associated with depression and sexual compulsivity through these self-regulation difficulties. Childhood sexual abuse and intimate partner violence were both associated with TRB through the combined indirect effects of self-regulation difficulties, depression, sexual compulsivity, and polydrug use.

Conclusions: The results from this study provide supporting evidence that executive attention and emotion dysregulation mediate associations between several epidemics considered part of the HIV syndemic among GBM. Interventions that target executive attention and emotion dysregulation may have a significant impact on TRB among GBM by reducing the syndemic burden in this population.

MINORITY STRESS AND THE HPA AXIS: DAILY INTERNALIZED HIV STIGMA AND CORTISOL REACTIVITY AMONG SEXUAL MINORITY MEN WITH HIV

H. Jonathon Rendina, PhD, MPH¹, Ali Talan, DrPH², Aria Tilove, BA³, Ore Shalhav, MPH⁴, Laurel Weaver, MA⁵, Joseph A. Carter, MA⁶, Hyejin Park, BA⁷

¹Hunter College and The Graduate Center, CUNY, New York, NY; ²Hunter College, New York, NY; ³PRIDE Health Research Consortium at Hunter College, New York, NY; ⁴PRIDE Health Research Consortium, Hunter College, CUNY, NEW YORK, NY; ⁵Graduate Center of the City University of New York, New York, NY; ⁶The Graduate Center, City University of New York (CUNY), New York, NY; ⁷PRIDE Research Consortium, Palisades Park, NJ

Background: The minority stress literature has established both between-person and within-person effects of internalized HIV stigma—a common stressor for people living with HIV—on a range of affective and behavioral health outcomes. However, little published work to date has examined the extent to which minority stress activates a hypothalamic-pituitary-adrenal (HPA) axis response, which may help to elucidate one mechanism through which stigma leads to health disparities.

Method: We collected ecological momentary assessment data on stigma paired with three salivary collections (i.e., at waking, around noon, and around 9pm) for ten days from sexual minority men (SMM) living with HIV in New York City. Daily data on internalized HIV stigma were disaggregated into between- and within-person effects based on standard procedures for variance decomposition. In addition to log cortisol values for each time point, we also calculated an area under the curve (AUC) value for each day. We conducted three mixed models to examine how disaggregated effects of afternoon reports of internalized HIV stigma were associated with daily AUC and the afternoon and evening cortisol levels adjusted for morning levels. Across models, we adjusted for daily caffeine use, nicotine use, and exercise.

Results: We analyzed 252 days' worth of data across a diverse sample of 46 SMM. Across models, results were consistent—we found a significant and positive effect of between-person internalized HIV stigma on cortisol AUC ($B = 0.79, p < .001$) as well as afternoon ($B = 0.04, p = .02$) and evening ($B = 0.10, p < .001$) log cortisol levels. In other words, people who tend to experience higher levels of internalized HIV stigma across days also experience higher cortisol on a given day. In contrast, we did not identify within-person effects ($B = 0.79, p = .94$; $B = -0.03, p = .47$; $B = 0.06, p = .14$), suggesting unique daily experiences of internalized HIV stigma did not co-occur with increased cortisol.

Conclusions: This study provides support for a biopsychosocial model of minority stress and health, suggesting that SMM prone to experiencing internalized HIV stigma have higher daily levels of cortisol. Surprisingly, we did not find increases in cortisol during specific event-level occurrences of higher internalized HIV stigma. Given the immune-suppressing effect of cortisol, particularly if chronically activated, this suggests the importance of stigma reduction interventions to improve health for SMM living with HIV.

PHYSICAL ACTIVITY ADVISING BY HUMANS VS. COMPUTERS IN UNDERSERVED POPULATIONS: THE COMPASS2 TRIAL MAJOR RESULTS

Abby C. King, PhD¹, Ines Campero, BA², Jylana L. Sheats, PhD, MPH³, Cynthia M. Castro Sweet, PhD⁴, Michelle E. Hauser, MD, MS, MPA¹, Jorge A. Banda, PhD⁵, David K. Ahn, PhD², Timothy Bickmore, PhD⁶

¹Stanford University School of Medicine, Stanford, CA; ²Stanford University School of Medicine, Palo Alto, CA; ³Johnson & Johnson, New Brunswick, NJ; ⁴Omada Health, San Francisco, CA; ⁵Purdue University, West Lafayette, IN; ⁶Northeastern University, Boston, MA

While current physical activity (PA) guidelines emphasize convenient aerobic activities such as walking, less than half of U.S. adults meet these guidelines. Older, low-income, and ethnic minority adults are at particular risk for inactivity due to factors such as reduced access to convenient, customized programs. Technology-enabled delivery channels represent a potentially cost-efficient and practical means for providing customized PA guidance to diverse groups, but most people targeted by eHealth are well-educated, < 50 years old, and non-Hispanic white. This cluster-randomized noninferiority trial tested whether PA advising by a computer-based virtual advisor (Virtual; N=123) was no worse than advising by trained human advisors (Human; N=122) in increasing 12-month walking levels among older inactive Latino adults. The Virtual advisor ("Carmen") was an animated computer agent that simulated face-to-face counseling using simple speech (synthetic English or Spanish) and nonverbal behaviors. The bilingual Human advisors were trained peers—an effective and resource-efficient approach that is well accepted by Latino adults and other diverse groups, but may be less scalable than computer-based programs. Each program was delivered individually at local community centers and followed a similar protocol. 12-month change in weekly walking minutes was measured using a validated interview instrument and corroborated with accelerometry. Intent-to-treat methods were applied. The study retention rate was 94.3% for the sample (ages 50–87 years; 79% women; 44% with < high school education; mean BMI [SD]=32.8 [6.8]). Mean 12-month change in total weekly walking minutes (SE) was 153.9 (18.5) for Virtual and 131.9 (16.6) for Human (difference=22.0, with the lower limit of the 1-sided 95% confidence interval [-0.10] to the right of the noninferiority margin [-.30]; P=0.66), supporting noninferiority. While no participants initially met the nationally recommended PA target range, ~30% in both programs achieved this level at 12 months. Significant improvements emerged in both arms for relevant clinical risk factors (BMI, resting blood pressure), sedentary behavior, and well-being measures (Ps< .05). The results significantly broaden evidence-based alternatives for PA advising for inactive populations, with Virtual program improvements no worse than those achieved by Humans, while using less participant time (total advising hours=3.2 for Virtual, 6.9 for Human, P< .001).

PEER COACH DELIVERED STORYTELLING PROGRAM FOR DIABETES MEDICATION ADHERENCE: INTERVENTION DEVELOPMENT AND PROCESS OUTCOMES.

Susan Andreae, PhD MPH¹, Lynn J. Andreae, MPH², Monika M. Safford, MD³

¹University of Wisconsin-Madison, Madison, WI; ²University of Alabama at Birmingham, Birmingham, AL; ³Weill Cornell Medicine, New York, NY

Background: Medication adherence can improve health outcomes in patients with diabetes. However, diabetes medication adherence rates remain suboptimal, despite substantial efforts in recent years targeting this issue, and developing and implementing effective interventions continue to be challenging. We present the development and implementation of Living Well with Diabetes, a cluster randomized controlled trial of an intervention using peer support and storytelling to improve diabetes medication adherence in Alabama.

Methods: We used an iterative process that combined program adaptation, pretesting, and peer coach training and collaborated with community members and peer coaches for formative evaluation and qualitative feedback. Peer coaches were from the community of interest who had diabetes or took care of a family member with diabetes. Study participants were adults, living in the community, taking oral medications for diabetes, and were medication non-adherent or wanted help taking their medications.

Results: The finished program was six-month intervention delivered over the telephone. Participant materials included an activity book and educational videos. These videos integrated personal stories of community members accepting their illness and overcoming barriers to medication-taking and other self-care activities. To deliver the telephonic coaching, we trained and certified 19 peer coaches. The 473 participants enrolled in the study were mostly African-American (91%), women (79%), lower income (70% with annual income < \$20,000), and unemployed (73%). Program completion was 85%. Fidelity was high, with 82% of intervention participants completing all program sessions. Participants reported high program satisfaction (95%) and that they used and found the program materials (91%) and videos (96%) helpful. Participants felt that their peer was easy to talk with (93%), support received from their peer was great or good (95%), and they felt comfortable with their peer (92%). Moreover, participants reported that they felt that their peer knew the program well (93%) and that they would recommend a peer to a friend or a relative with a similar health condition (93%).

Discussion: Living Well was developed and implemented in high need communities in Alabama with high retention and fidelity. The participants were satisfied with the program and with their interactions with their peer coach. Our approach may be helpful for others seeking to develop and implement a medication adherence program in their communities.

MOMENTARY CHANGES IN HEART RATE VARIABILITY CAN DETECT RISK FOR EMOTIONAL EATING EPISODES

Adrienne S. Juarascio, Ph.D.¹, Rebecca J. Crochiere, B.A.², Tinashe M. Tapera, Master of Psychology³, Madeline Palermo, MS⁴, Fengqing Zhang, PhD¹

¹Drexel University, Philadelphia, PA; ²WELL Center, Drexel University, Philadelphia, PA; ³Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; ⁴University of South Florida, Tampa, FL

Objective: Emotion dysregulation is a known risk factor for a variety of maladaptive eating behaviors, including emotional eating. New passive sensing technologies offer the prospect of detecting emotion dysregulation in real-time through measurement of heart rate variability (HRV), a transdiagnostic bio-signal of emotion regulation, which may in turn signal risk of engaging in a maladaptive eating behavior. In the current study, our primary aim was to test whether momentary changes in HRV can be used to detect risk of experiencing an emotional eating episode in an ecologically valid setting using a wrist worn sensor.

Method: Participants were 21 adults with clinically significant emotional eating behaviors. Participants wore the Empatica E4 wrist-sensor and tracked all emotional eating episodes using ecological momentary assessment for four weeks. Time and frequency domain features of HRV were extracted in the 30-minute period preceding emotional eating episodes and control cases (defined as the 30 minutes prior to an EMA survey that did not contain an emotional eating episode). Support vector machine (SVM) learning models were implemented using time domain and frequency domain features.

Results: SVM models using frequency domain features achieved the highest classification accuracy (77.99%), sensitivity (78.75%), and specificity (75.00%). SVM models using time domain features still performed above chance, though were less accurate at classifying episodes (accuracy 63.48%, sensitivity 62.68%, and specificity 70.00%).

Discussion: Wearable sensors that assess HRV show promise as a tool for capturing risk of engaging in emotional eating episodes.

FLEX: AN APP THAT ENHANCES AUTOMATIC EVALUATIONS OF EXERCISE

Amanda L. Rebar, PhD¹, Magne Rasera, MS², Ryan E. Rhodes, Ph.D.³, David E. Conroy, PhD⁴, Ben Jackson, PhD⁵, James Dimmock, PhD⁵, Hein de Vries, PhD⁶, Camille E. Short, PhD⁷, Harshani Jayasinghe, MS⁸, Corneel Vandelanotte, PhD⁹

¹Central Queensland University, Cooe Bay, Queensland, Australia; ²Central Queensland University, Genk, Limburg, Belgium; ³University of Victoria, Victoria, BC, Canada; ⁴The Pennsylvania State University, University Park, PA; ⁵University of Western Australia, Perth, Western Australia, Australia; ⁶Maastricht University, Maastricht, Utrecht, Netherlands; ⁷University of Melbourne, Parkville, Victoria, Australia; ⁸The University of Adelaide, Adelaide, South Australia, Australia; ⁹Central Queensland University, Rockhampton, Queensland, Australia

Amidst the growing interest in dual process frameworks within exercise psychology research, evidence has established an association between exercise behavior and automatic evaluations of exercise (i.e., spontaneous evaluations based on mental associations between ‘exercise’ and ‘good’ or ‘bad’ that manifest into approach tendencies). Although associative learning-based training such as evaluative conditioning has been shown to be effective in lab-based settings, the training regimens are not inherently engaging and therefore it is unclear how to deliver this behavior change technique in a scalable manner. Gamification elements such as tracking progress, offering challenges with levels that vary incrementally in difficulty, and giving rewards can enhance engagement in health behavior interventions. This study was designed to test the effectiveness of a mobile health intervention to manipulate automatic evaluations of exercise in a real-world setting utilizing engaging features of gamification. Flex was designed based on evaluative conditioning with gamification elements. Participants ($N = 228$, 82% female, M age = 33) were randomly allocated to have access to either *Flex Exercise* – a game-based app which contained 70% exercise-related content or *Flex Control* – the same game-based app with no exercise content. The study was described to participants, not as an exercise intervention, but as a study on ‘brain games’. Participants completed an Implicit Association Test (IAT) and self-report questionnaire of exercise intention, habit, and affective judgments immediately after exposure to Flex and 24 hours later. Participants were then debriefed on the study’s true Purpose. A non-statistically significant between-group difference was observed immediately after exposure to Flex for automatic evaluations ($\beta = .06$); however one day following exposure, those in the *Flex Exercise* condition had significantly more favorable automatic evaluations of exercise than those in the *Flex Control* condition ($\beta = .15$, $d = 0.30$). The effect remained after controlling for intention, habit, and affective judgments. This study demonstrates the potential for mHealth interventions to influence automatic evaluations of exercise through engaging application of associative learning-based training. Future research is needed to see if these intervention effects translate into behavior change.

Paper Session 51

4:30 PM-4:45 PM

EFFECTS OF AN INTERNET-BASED COGNITIVE BEHAVIORAL THERAPY FOR INSOMNIA PROGRAM ON PRODUCTIVITY: A SECONDARY ANALYSIS

Kelly M. Shaffer, PhD¹, Fabian Camacho, M.S., M.A.¹, Eric Finkelstein, PhD², Karen S. Ingersoll, PhD³, Frances Thorndike, PhD⁴, Lee M. Ritterband, PhD¹¹University of Virginia School of Medicine, Charlottesville, VA; ²Duke-NUS Medical School, Singapore, N/A, Singapore; ³University of Virginia, CROZET, VA; ⁴Pear Therapeutics, Inc, Charlottesville, VA

Objectives: Insomnia is associated with lost work productivity. Prior studies suggest that cognitive-behavioral therapy (CBT) for insomnia, a first-line treatment for insomnia, may improve work productivity through at least six months post-treatment. In this secondary analysis of a large-scale randomized controlled trial, effects of CBT for insomnia delivered by Internet on both work-related and daily activity productivity were examined out to one year following participant baseline.

Methods: Participants (N=303) were randomized to receive either an Internet-based CBT for insomnia program (SHUTi: Sleep Healthy Using the Internet) or Internet-delivered patient education (PE). Participants completed the Work Productivity Activity Impairment at baseline (prior to randomization), end of the intervention period (post-assessment, 9 weeks post-baseline), and 6- and 12-month follow-ups. At each time point, measures of absenteeism, presenteeism, and total impairment were calculated for formally employed participants; daily activity impairment was calculated for all participants.

Results: Logistic regression controlling for baseline impairment demonstrated that participants randomized to SHUTi were about 50% less likely than PE to report any absenteeism, total impairment, or activity impairment at post-assessment ($p < .038$); however, these differences were not sustained at 6- or 12-month follow-ups ($p > .070$). Constrained longitudinal data analysis demonstrated that SHUTi participants reported lower overall levels of presenteeism, total impairment, and activity impairment at post-assessment ($p < .013$) relative to PE and differences were sustained at 6-month follow-up for presenteeism and total impairment ($p < .045$); effects were small to moderate ($0.23 < d < .034$). No differences were present by 12-month follow-up ($p > .178$).

Conclusions: Participants in both PE and SHUTi conditions tended to report declining work-related and daily activity impairment over time. Those in the SHUTi condition demonstrated more precipitous declines in impairment over the course of treatment, although differences between conditions were generally not sustained by 6- or 12-months after treatment. Findings suggest Internet-based CBT-I may help accelerate improvement in work-related and daily activity impairment, although further research is warranted to understand the extent to which low-intensity interventions such as insomnia psychoeducation may also produce long-term improvements.

OLDER ADULTS' REMEMBRANCE OF THE PAST AND IDEAS ABOUT THE FUTURE INFLUENCE PERCEPTIONS OF CURRENT LIFE: A QUALITATIVE STUDY

Giancarlo Pasquini, MA¹, Renee Gilbert, n/a², Isabella Bouklas, n/a², C. S. Bergeman, Ph.D.³, Stacey B. Scott, n/a²¹Stony Brook University, Port Jefferson Station, NY; ²Stony Brook University, Stony Brook, NY; ³University of Notre Dame, Notre Dame, IN

Aging theories emphasize older adults' perception of life remaining, the availability of social resources, and one's identity as important factors associated with physical health and emotional well-being (Carstensen et al., 1999; Charles, 2010; Krause, 2004). This qualitative analysis of interviews identified themes based on older adults' own descriptions of their experiences; results were interpreted in the context of aging theories.

Twenty-four participants ($M_{age} = 69.53$ years; age range = 63-78 years; 54% female; 58% White, 29% Black) from the Notre Dame Study of Health & Well-Being (Whitehead & Bergeman, 2014) completed interviews describing major turning points across their lives. Audio files were transcribed and analyzed for emergent themes using the constant comparative method (Maykut & Morehouse, 1994).

Twelve core themes emerged from the interviews, which clustered within four domains: *Health*, *Family*, *Death*, and *Outlook*. Themes within the *Health* domain suggested that participants often compared their health to their peers' health or to their expectations about health typical of someone their age. Participants described living with chronic disease and overcoming challenges with illness and some participants expressed a fear of physical decline or an anticipation of death. The *Family* domain consisted of participants' understanding of their identities as parents, children, and partners. Some participants described experiences that illustrated multiple identities such as past parenting experiences demonstrating their roles as parent and partner. Most participants described their relationships with family members as meaningful; although descriptions of past and current family conflict also emerged. The *Death* domain relates to participants' expectations of remaining life as some participants expressed an anticipation of death whereas others described anticipating more life. Additionally, the recollection of others' deaths shaped how participants thought about their current lives. The *Outlook* domain included participants' views towards their past and present lives, often expressing an overall satisfaction with their lives or describing a general life philosophy that guides their attitudes and understanding of their current lives.

Taken together, these results are consistent with many tenets across aging theories and the richness of qualitative data highlight important diversity in how older adults' view their current lives.

SEDENTARY BEHAVIOR OF LOW-MODERATE FUNCTIONING OLDER ADULTS AS MEASURED BY ACTIVPAL: COMPLIANCE AND ACCEPTABILITY.

Katie J. Thralls, PhD, MS, CSCS¹, Susan S. Levy, PhD²¹Seattle Pacific University, Seattle, WA; ²San Diego State University, San Diego, CA

Introduction: High amounts of sedentary behavior (SB) are related to adverse health in older adults. The activPAL device is the gold standard measurement for SB but little research has reported the acceptability of wear in older adults of lower physical function, the most sedentary age group¹⁻³

Purpose: This study reports the SB and compliance and satisfaction of activPAL wear in older adults of moderate-to-low physical function.

Methods: Participants (N=71; Mean_{age} = 87±6.6) were older adults of low-to-moderate physical function (i.e., ≤8 on the Short Physical Performance Battery⁴), instructed to wear the activPAL device for seven days and complete a sleep log. The device was waterproofed and attached with adhesive (i.e., TegadermTM) to the mid-thigh. After wearing the device, SB data were aggregated into daily averages of SB variables and participants completed a satisfaction survey.

Results: After removing sleep time, participants spent an average of 11.1±1.7, 3.3±1.6, and 1.0±0.4 hrs/day of time sitting, standing, stepping, respectively. They spent 74±11 %/day of their waking time sitting. All participants provided ≥4 valid (>10hrs/d) days and 94% (n=67) and 89% (n=63) provided 6 and 7 valid days, respectively. Most (75%; n=53) provided completed (>75% complete) sleep logs. Four percent (n=3) partially completed (25-75% complete) and 21% (n=15) did not complete (< 25% complete) a recorded sleep log. Based on the activPAL satisfaction survey, 93% (n = 64) indicated that the device was not bothersome at all. Most participants (88%; n=61) did not change the adhesive or need outside help while wearing (91%; n = 63) with anything related to the device. Nearly all 80% (n = 55) indicated they were willing to wear the device again.

Conclusion: The gold standard measurement for sedentary behavior, the activPAL, is acceptable in older adults of low-moderate physical function and maybe effectively used in in SB interventions in this population.

EXPLORING INTEGRATING YOGA AND A MATTER OF BALANCE EDUCATION FOR A FALL PREVENTION PROGRAM

Em V. Adams, M.S., CTRS, C-IAYT, RYT¹, Marieke Van Puymbroeck, Ph.D., CTRS, FDRT, RYT-500², Heather Torphy, M.S., CTRS, YT100³, Karen A. Kemper, MSPH, PhD², Cheryl J. Dye, PhD⁴, Arlene A. Schmid, PhD, OTR, FAOTA, RYT-200⁵, Brian C. Helsel, MS⁶¹Lehman College, New York, NY; ²Clemson University, Clemson, SC; ³Clemson University, Anderson, SC; ⁴Clemson university, Clemson, SC; ⁵Colorado State University, Fort Collins, CO; ⁶Clemson University, Greenville, SC

Exploring Integrating Yoga and Education for a Fall Prevention Program

Objective: The purpose of this study was to evaluate if combining a cognitive-behavioral fall prevention program- a Matter of Balance (AMOB) with an evidence-based therapeutic yoga program reduced fall risk factors for community-dwelling older adults to a greater degree than either program alone.

Methods: Community-dwelling older adults with concerns about falling were recruited through a local senior center. Potential participants attended an information session, signed an informed consent form, were screened to ensure they met inclusion criteria (score 3 or higher on the Mini-COG, be 60 years of age or older, have no contraindications for physical activity), completed a battery of psychosocial questionnaires, and completed physical performance measures. The 12-week intervention included eight sessions of AMOB led by a certified AMOB Master Trainer, and 16-sessions of therapeutic yoga (led by a yoga therapist (C-IAYT) or Registered Yoga Teacher (RYT-500)). The following instruments assessed outcomes at baseline (T1), between AMOB and yoga (T2), and again after the yoga intervention (T3): Chair Stand Test (CST), Timed Up and Go (TUG), Fullerton Advanced Balance Scale (FAB), University of Illinois Fear of Falling measure (FoF), Activity Specific Balance Confidence Scale (ABC), and Leisure Constraints Scale (LCS).

Results: A total of 13 participants with an average age of 76.00±6.69 completed the study. Friedman's test, a non-parametric repeated measures analysis, was conducted for each outcome and revealed a significant difference between scores on the TUG ($\chi^2=10.750(2)$, $p=.005$), FoF ($\chi^2=11.561(2)$, $p=.003$), and ABC ($\chi^2=16.884(2)$, $p=.000$). Post hoc analysis with Wilcoxon signed-rank tests was conducted with a Bonferroni correction applied, resulting in a significance level set at $p<0.017$. A significant difference was found on the ABC ($*Z=-3.180$, $p=.001$) between T1 and T2 indicating participants increased their confidence in their abilities throughout the MOB portion of the intervention. A significant difference was found on the TUG ($*Z=-2.521$, $p=.012$) between T2 and T3 indicating participants improved in agility and dynamic balance through the yoga component. There were significant differences found for FoF between T1 and T3 indicating that fear of falling decreased with the combination of the two components.

Conclusion: The education program improved in self-reported balance confidence while the yoga portion improved physical measures of dynamic and static balance. Finally, the participant's overall fear of falling improved only when combining the two interventions. Thus, findings suggest that combining cognitive-behavioral approaches and education with physical training may be more effective at reducing fall risk factors that either intervention alone.

6:15 PM-7:30 PM

PHYSICAL ACTIVITY OUTCOMES IN OLDER AFRICAN AMERICAN ADULTS. THE PAACE STUDY.

Robert L. Newton, PhD¹, Robbie Beyl, PhD¹, Callie Hebert, M.S.¹, Melissa N. Harris, CCRP¹, William P. Gahan, MD¹, Owen Carmichael, PhD¹¹Pennington Biomedical Research Center, Baton Rouge, LA

Introduction: Older African Americans face significant health disparities. Physical activity has been shown to reduce chronic disease risk factors, yet few physical activity studies have been conducted in this population. The purpose of the Program for African American Cognition and Exercise (PAACE) study was to determine if a community-based intervention on objective measures of activity in African American adults.

Methods: There were 56 older African Americans who were randomized into either a physical activity intervention (n = 28) or successful aging control (n = 28) group for 12 weeks. Participants in the intervention attended twice-weekly physical activity group sessions conducted at local YMCAs and were required to exercise 2-3 days per week at home for a total of 150 minutes of MVPA per week. Participants in the control group attended weekly educational sessions at an academic institution and did not receive a physical activity prescription. Assessments included self-reported physical activity, ActiGraph accelerometers, and Fitbit activity monitors (for participants in the intervention only).

Results: Participants were aged 69.3 (3.4) years, were majority female (69.6%), had a BMI of 32.3 (6.2), and ~50% had at least a college education. Attendance was 86% and 93%, for the control and intervention groups, respectively, and there was 100% retention. Participants in the intervention group self-reported more moderate to vigorous physical activity bouts per week (+3.5 (0.77) vs. -0.33 (0.79); $p < 0.001$) compared to those in the control group. Importantly, participants in the intervention group increased ActiGraph derived moderate to vigorous activity (7.3 (2.3) vs. 0.38 (2.3) min; $p = 0.037$) significantly more than the control group. Participants in the intervention group also increased ActiGraph derived steps per day significantly more than the control group (+787.8 (329.1) vs. -420.6 (334.6) steps, $p = 0.013$). Compliance with Fitbit wear was 82%.

Conclusions: PAACE is among the first studies to show that a 12-week community-based physical activity program can increase objectively measured physical activity among older African American adults. Longer follow-up is needed to determine if physical activity levels can be further increased and maintained, and if changes effect chronic disease risk factors.

MEDICATION ADHERENCE IN CHRONIC CONDITIONS: A SCOPING REVIEW OF BARRIERS, FACILITATORS AND INTERVENTIONS

Maria Karekla, PhD¹, Pinelopi Constantinou, n/a¹, Giorgos Georgiou, n/a², Andreas Panayides, n/a³, Alexia Papageorgiou, n/a⁴, Greta Wozniak, n/a¹, Angelos Kassianos, PhD⁵

¹University of Cyprus, Nicosia, Nicosia, Cyprus; ²European University of Cyprus, Nicosia, Nicosia, Cyprus; ³Department of Computer Science, University of Cyprus, Nicosia, Nicosia, Cyprus; ⁴University of Nicosia, Nicosia, Nicosia, Cyprus; ⁵UCL, London, England, UK

Objective: Medication non-adherence (MNA) constitutes a complex health problem contributing to increased economic burden and poor health outcomes. Almost one in two patients with chronic conditions reports low adherence to their prescribed medication. The purpose of this scoping review was to identify the barriers associated with MNA and the interventions and techniques aiming to improve adherence among adult patients with chronic conditions with high MNA (asthma, hypertension, epilepsy, diabetes and cancer).

Method: Published and unpublished peer-reviewed studies (both quantitative and qualitative) of chronic health conditions with medication adherence explicitly stated as the primary or secondary outcome were included. PubMed, PsycINFO and Scopus databases were screened with 95 studies included. A mixed methods framework was used to synthesize the data.

Results: Most commonly reported barriers to MNA across conditions were younger age, low education, low income, high medication cost, side effects, patient beliefs/perceptions, comorbidities and poor patient-provider communication. Additionally, digital interventions such as SMS/text message interventions were commonly reported and often led to improvements in adherence rates.

Conclusions: This is the first review examining barriers to MNA across chronic conditions and the psychological interventions used for improving adherence. It highlights the importance of administering multicomponent interventions digitally, and personalized to the patients' individual needs and characteristics, in response to the barriers patients face in adhering to their medication. Stakeholders are called to explore methods overcoming barriers identified and developing effective multicomponent interventions that can reduce the high rates of MNA.

CHARACTERIZATION OF CANCER-RELATED FATIGUE IN BREAST CANCER PATIENTS BY AGE GROUP THROUGH A MULTICENTER STUDY

Julia E. Inglis, Ph.D., R.D.¹, Luke J. Peppone, Ph.D., M.P.H.², Michelle C. Janelins, Ph.D., M.P.H.¹, Amber S. Kleckner, PhD³, Charles E. Heckler, PhD, MS¹, Jon F. Strasser, MD⁴, Howard M. Gross, MD, FACP,⁵ Thomas M. Anderson, D.O. / FACRO / FAOCR⁶, Gary R. Morrow, Ph.D., M.S.¹, Julie Ryan Wolf, Ph.D., M.P.H.⁷

¹University of Rochester Medical Center, Rochester, NY; ²University of Rochester Medical Center, Rochester, NY; ³University of Rochester, Rochester, NY; ⁴Medical Director Radiation Oncology/ Helen F Graham Cancer Center, Christiana Care Health System, Wilmington, DE; ⁵Dayton Physicians Network/ NCORP Board of Directors, Dayton, OH; ⁶Columbus - NCORP, Columbus, OH; ⁷University of Rochester/ NCORP/ SWOG, Rochester, NY

Background: Cancer-related fatigue (CRF) is a common symptom in patients as a result of cancer and cancer treatment. Often patients report greater symptoms during and after radiation treatment. Age may play a role, where younger patients self-report greater CRF symptoms than older patients. The aim of this study was to assess the change in CRF in breast cancer patients receiving radiation therapy by age group before and after radiation treatment.

Methods: In a phase II nationwide randomized controlled trial in the NCI Community Oncology Research Program (NCORP) network, female breast cancer patients receiving radiation therapy were followed over time. CRF symptoms assessed pre-treatment (T1), post-treatment (T2), at one week post-treatment (T3) and one month post-treatment (T4) using the Symptom Inventory (SI). Patients were divided into two age groups: younger age (< 60yrs, n=386) vs. older age (≥60 yrs, n=292). Multivariate regression analyses evaluated differences in CRF each time point.

Results: There were 678 patients with breast cancer in the analysis. Total CRF levels increased from T1 to T2 by 41% ($\beta \pm SE = 1.682 \pm 0.087$, 2.376 ± 0.103 respectively). CRF declined from T2 to T3 by 36.5% ($\beta \pm SE = 2.376 \pm 0.103$, 2.011 ± 0.098 respectively). At T4, CRF decreased by 79% from T3, and 46% below baseline levels ($\beta \pm SE = 1.22 \pm 0.084$, 1.682 ± 0.087) in the total population. The younger group reported greater CRF than the older group at both T1 ($\beta \pm SE = 2.380 \pm 0.120$ vs. 1.976 ± 0.120 ; $p = 0.047$, 95% C.I. 0.005, 0.804) and at T2 ($\beta \pm SE = 2.645 \pm 0.140$ vs. 2.120 ± 0.140 ; $p = 0.025$, 95% C.I. 0.068, 0.982).

Conclusion: Patients with breast cancer receiving radiation therapy experienced the most CRF symptoms before and immediately after radiation therapy. Symptoms decreased to below baseline levels one month after radiation treatment. Younger patients reported greater symptoms than older patients. Age and proximity to treatment are factors in patient-reported symptoms.

6:15 PM-7:30 PM

MEETING CHALLENGES OF CANCER-RELATED DISTRESS VIA WEB-BASED SELF-MANAGEMENT: ONLINE PSYCHOEDUCATIONAL PROGRAM USE ANALYSIS

Robin M. Lally, PhD, RN, AOCN, FAAN¹, Kevin A. Kupzyk, PhD¹, Steven M. Gallo, BS, MS²

¹University of Nebraska Medical Center, Omaha, NE; ²University at Buffalo SUNY, Buffalo, NY

Available resources and patient acceptance of clinical management for cancer-related distress pose ongoing challenges. Unguided, web-based psychoeducational interventions are an attractive option offering low resource utilization and easy patient access. Engaging patients meaningfully in such programs requires greater understanding of patients' use patterns. This analysis evaluated how women newly diagnosed with breast cancer used the unguided web-based, psychoeducational distress self-management program CaringGuidance™ while enrolled in a randomized pilot clinical trial.

Method: Women with stage 0 - II breast cancer diagnosed in the prior three months were randomized to 12-weeks of unguided CaringGuidance use versus usual care alone. Weekly email reminders, informational emails after cognitive-behavioral exercise views, and emails rewarding hours of use prompted the intervention group. The CaringGuidance analytics system collected user frequency, duration, and activity automatically, directing it to the CaringGuidance database. Data were collected on log-ins, sessions, and page view frequency, duration of sessions, total duration, and program components viewed (i.e. activity). Psychosocial variables were assessed at baseline and monthly.

Results: Complete program use data are available for 54 subjects. Of these subjects, 70% logged-in in all study months ($n = 38$), 28% ($n = 15$) were intermittent-users, and ($n = 1$) was a non-user. Initial analysis reveals that users logged-in a Mean 15.6 (SD = 9.9) times for a Mean 16.9 (SD = 10.4) sessions. Users accessed CaringGuidance 9 – 1265 total minutes ($M = 4.97$ hours SD = 3.4). Nine users (17%) accessed the program for the suggested total duration (480 – 1080 minutes). As expected, users' mean use-duration declined significantly over the 12 weeks ($F(2,104) = 40.21$, $p < .001$). Use-duration was not associated with psychosocial outcomes. However, users' 12-week program activity showed that fewer program component views by users was moderately associated with more month 3 depressive symptoms ($r = -.243$, $p = .096$) and intrusive/avoidant thinking ($r = -.237$, $p = .118$), but this did not reach statistical significance in this small sample.

Conclusion: CaringGuidance was used at least intermittently by 98% of assigned women when introduced within 12 weeks of breast cancer diagnosis. Program use predictively declined over 12 weeks of unguided access but taken with user satisfaction and initial efficacy reported previously, it is promising that reduced distress may be moderately associated with greater program activity.

POST TRAUMATIC STRESS DISORDER (PTSD) AND POST TRAUMATIC GROWTH (PTG) IN HISPANIC BREAST CANCER PATIENTS.

Karina I. Acevedo Fernández, n/a¹, Eida M. Castro Figueroa, PsyD, MS²¹Ponce Health Sciences University, Guaynabo, N/A, Puerto Rico; ²Ponce Health Sciences University, Ponce, N/A, Puerto Rico

Background: Cancer patients have a higher risk of experiencing PTSD than those patients without a cancer diagnosis. Exposure to psychosocial traumatic events is a well-known risk factor to systemic inflammation among the general population and post-traumatic growth (PTG) is known to be a protective factor. However, little is known about the relationship among PTSD, (PTG) and inflammation in Hispanic BC patients.

Method: This is a secondary preliminary data analysis of a pilot study aimed at exploring the rates of depression, early life stress and its relationship with inflammatory markers of BC tumor microenvironment. Recruitment is still ongoing (total n=32) and will be completed by January 2019. Participants are recruited before undergoing BC tumor surgery. Patients complete a package of surveys through interviews that includes measures of PTSD and PTG. Pearson Correlation Tests were used to explore correlation between the variables of interest. Tumor infiltration of pro-inflammatory macrophages will be assessed after completing recruitment.

Results: Preliminary data (n=20) show women mean age being 63years (SD:10.3). Sixteen participants (80%) reported experiencing trauma before the cancer diagnosis while four (20%) reported the cancer diagnosis as their experienced trauma. Descriptive analyses reveal that 30% of participants experienced re-experimentation of the trauma, 45% showed avoidance and 25% demonstrated cognitive alterations, negative thought and an increase in physiological reactivity. Also, 75% of participants showed significant symptomatology in at least one PTSD symptom while 100% reported significant scores of PTG after their traumatic event. These findings will be correlated with the biological data to explore associations among PTSD, PTG and BC tumor inflammation markers.

Conclusion: Little is known about the relationship between PTSD, PTGI and tumor inflammation, but from our analysis we can infer that there is a high rate of PTSD symptomatology in the study sample.

SUBJECTIVE SLEEP QUALITY AMONG PATIENTS WITH CANCER AND COMORBID DEPRESSION

Sarah N. Price, MA¹, Juanita I. Trejo, MPH¹, Laila Halaby, MA¹, Daney Guzman, n/a¹, Heidi Hamann, PhD¹, Karen L. Weihs, MD¹¹University of Arizona, Tucson, AZ

Introduction: Poor sleep has deleterious impacts on quality of life and treatment tolerance for patients with cancer, and it may place patients at increased risk for depression or exacerbation of mood symptoms. Diagnoses of cancer and depression are independent predictors of poor sleep quality, but less is known about subjective sleep quality among patients with both of these potential risk factors. This study examined the frequency and correlates of poor subjective sleep quality among patients with cancer enrolled in the Collaborative Oncology Project to Enhance Depression Care (COPE-D), a collaborative care intervention to treat depression among patients with cancer.

Methods: Subjects were 56 adult cancer survivors enrolled in COPE-D. Patients self-reported demographic and clinical characteristics (e.g. race/ethnicity, cancer type and stage, treatment status). Prior to intervention, sleep quality was evaluated using the Pittsburgh Sleep Quality Index (PSQI), general health status was measured using the PROMIS Global-10, social isolation was measured using the PROMIS Social Isolation- 4a, and depressive symptoms were measured using the 9-item Patient Health Questionnaire (PHQ-9).

Results: 94.6% of patients reported poor sleep quality (PSQI global scores ≥ 5) and 82% reported significantly poor sleep quality (global scores ≥ 8). Sex, primary language, race/ethnicity, employment status, cancer stage, cancer type, current chemotherapy, current radiation, and current anti-hormonal therapy were not significantly associated with poor sleep quality (p 's $> .05$). Markers of lower SES were associated with poor sleep, with patients reporting educational attainment of high school or less and those reporting annual incomes less than \$50,000 also reporting worse sleep quality (p 's $< .05$). Worse global mental ($r = -.37$, $p < .01$) and physical health ($r = -.48$, $p < .01$) were associated with poor sleep quality. Depressive symptoms and social isolation were not significantly associated with poor sleep quality (p 's $> .05$).

Conclusions: Cancer patients seeking treatment for depression report very high rates of poor sleep quality, with lowest SES patients reporting the worst sleep quality. Given the prevalence of significant sleep disturbance in this population, integrating principles of cognitive behavioral therapy for insomnia (CBT-I) into collaborative depression care may improve patient outcomes.

INTUITIVE INTERNET INTERVENTIONS: A QUALITATIVE STUDY OF WEB-BASED BEHAVIORAL SUPPORT FOR MEN WITH PROSTATE CANCER

Elizabeth Wang, MPH¹, June Chan, ScD², Rebecca Graff, ScD², Jeanette M. Broering, PhD, MPH, RN³, Justin Ramsdill, MS⁴, Kimi Daniel, MS⁵, Carol-Ann D. Mullin, MSPH⁶, Elizabeth R. Kessler, MD⁷, Kerri M. Winters-Stone, PhD⁸, Erin Van Blarigan, ScD², Stacey Kenfield, ScD²

¹UCSF, Stanford, CA; ²UCSF, San Francisco, CA; ³University of California San Francisco, San Francisco, CA; ⁴OHSU, Portland, OR; ⁵Oregon Health and Science University, Lake Oswego, OR; ⁶University of Colorado Cancer Center, Aurora, CO; ⁷University of Colorado School of Medicine, Aurora, CO; ⁸Oregon Health & Science University, Portland, OR

Background: Exercise and healthy diet can improve quality of life and prognosis in prostate cancer survivors, but there have been limited studies on the feasibility of web-based lifestyle interventions. In this report, we used qualitative methods to explore barriers to engagement with web-based behavioral support among men with prostate cancer who participated in a 12-week technology-based lifestyle intervention designed to support them in adopting healthy diet and exercise behaviors.

Methods: We conducted a 4-arm pilot study of men with prostate cancer (N=200) who received progressive levels of behavioral support (Level 1: website; Level 2: website with individualized diet and exercise recommendations; Level 3: website with individualized diet and exercise recommendations, Fitbit and text messages; and Level 4: website with individualized diet and exercise recommendations, Fitbit and text messages, phone call with an exercise trainer and phone call with a registered dietitian). We aimed to determine feasibility and estimate effects on lifestyle behavior; following the 12-week intervention, we held focus groups with volunteers from each of the four study arms. Here we conducted grounded theory analyses, including open, axial, and selective coding to generate codes and themes. Categories were refined across levels using embodied categorization and constant comparative methods.

Results: In total, 20 men with prostate cancer participated in the focus groups, with n = 5, 4, 5, and 6 in groups 1-4 respectively. While participants had varied familiarity with technology and expectations for the intervention, they converged on a number of concerns and preferences. We identified five common factors in participation, including: 1) individual preparedness (tech literacy, health literacy, readiness to change, and trust); 2) power dynamics (disconnect with past health experiences, guilt about non-adherence, comparison to other programming—technology, websites, devices); 3) environmental factors (competing priorities, home environment); 4) program design (framing expectations, flexibility/customizability); and 5) program support (educational, emotional).

Conclusions: These analyses suggest that a well-framed web intervention for men with prostate cancer needs to address disparities in technology and health literacy, mitigate power dynamics, and navigate friction from competing environmental factors. Through flexible and transparent web design, integration of key stakeholders (i.e. providers, family members), and effective coaching, web-based interventions may become a valuable tool to support prostate cancer survivorship.

PATIENT-REPORTED FINANCIAL TOXICITY AMONG INSURED CANCER SURVIVORS

Elizabeth S. Ver Hoeve, MA¹, Sarah N. Price, MA¹, Leila Ali-Akbarian, MD², Nurhyikmah Lothfi, BA¹, Heidi Hamann, PhD¹

¹University of Arizona, Tucson, AZ; ²University of Arizona Cancer Center, Tucson, AZ

Purpose: Fighting cancer is a costly battle, and understanding of the relationship between patient-reported financial toxicity (FT) and health outcomes can help inform interventions for post-treatment cancer survivors.

Methods: Stage I-III solid tumor, insured cancer survivors (N=103) completed a phone survey addressing FT (as measured by the standardized COverprehensive Score for financial Toxicity (COST) measure) and clinically relevant health outcomes (health-related quality of life [HRQOL] and adherence to recommended survivorship health behaviors). Univariate and multivariate analyses were used to assess demographic and disease-specific correlates of FT, along with the predictive value of FT on HRQOL and health behavior outcomes.

Results: Approximately 18% of respondents noted FT levels associated with significant financial burden. Greater FT was associated with Hispanic ethnicity, younger age, unpartnered status, non-retirement, lack of private insurance, lower level of educational attainment, and lung cancer (v. other solid tumor diagnoses). Greater FT was a meaningful predictor of increased anxiety, increased fatigue, and impaired physical functioning, even after controlling for relevant demographic and disease characteristics.

Conclusions: Although overall levels of FT were lower among cancer survivors in our sample compared to active treatment patients assessed in previous studies, financial burden continued to be a concern for a significant minority of cancer survivors and was associated with components of reduced HRQOL. Incorporation of FT assessment into survivorship care planning could enhance clinical assessment of survivors' FT vulnerability, help address the dynamic and persistent challenges of survivorship, and identify those most in need of intervention across the cancer care continuum.

PARENT AND CHILDHOOD CANCER SURVIVOR EXPERIENCES WITH AND BARRIERS TO HPV VACCINATION

Austin R. Waters, HBS¹, Karely Mann, BS², Perla L. Vaca Lopez, n/a³, Anne C. Kirchhoff, PhD, MPH⁴, Deanna Kepka, PhD, MPH⁵, Yelena P. Wu, PhD⁶

¹Huntsman Cancer Institute/University of Utah, Salt Lake City, UT; ²Huntsman Cancer Institute, SLC, UT; ³Huntsman Cancer Institute, Salt Lake City, UT; ⁴University of Utah, Salt Lake City, UT; ⁵University of Utah and Huntsman Cancer Institute, Salt Lake City, UT; ⁶Huntsman Cancer Institute, University of Utah, Salt Lake City, UT

Background: Childhood cancer survivors have lower HPV vaccination initiation rates than the general population (24% vs. 41%). HPV-associated cancers are 40% higher among female survivors of childhood cancer and 150% higher among male survivors compared to the general population. Improving HPV vaccination uptake among childhood cancer survivors is essential to improving their health outcomes. We conducted semi-structured interviews with adult survivors of childhood cancer and parents of younger survivors to evaluate their experiences with the HPV vaccine, barriers to HPV vaccination, and recommendations on how to promote survivor completion of the vaccine series.

Methods: Eligible survivors were ages 18-26 years, treated at Primary Children's Hospital (PCH) or Huntsman Cancer Institute between 2013-2018, had completed treatment, and were age eligible for the HPV vaccine. Eligible parents were at least 18 years of age, and the parent of a survivor under age 18 years who received treatment at PCH between 2013-2018, were done with treatment, and were age eligible for the HPV vaccine. Interviews were recorded, transcribed, coded and qualitatively analyzed using thematic content analysis.

Results: Survivors (N=10) were primarily female (60%), non-Hispanic white (90%), and on average 21.2 years of age (range 18-23). Half were HPV vaccinated (50%). Parents (N=10) were female (90%), ages 30-59 years (60%), and non-Hispanic white (80%). Of parents, 30% reported their child with cancer had received the HPV vaccine. Among those vaccinated (n=8), 100% reported that a healthcare provider recommended the vaccine, whereas among the n=12 unvaccinated, only 1 (8.3%) reported receiving a provider recommendation. Four distinct themes emerged about experiences with and barriers to HPV vaccination. First, survivors and parents reported that they lacked adequate information on the vaccine, which limited their ability to decide whether to get it. Second, among those who had been vaccinated, this was due to high trust in their providers who recommended the vaccine. Third, unvaccinated survivors or their parents felt that receiving a recommendation for the HPV vaccine by their oncologist was essential, as oncologists understand complex medical histories due to cancer better than primary care providers. Fourth, participants generally felt that reminders about the vaccine via mechanisms like text and emails would be helpful and result in getting vaccinated.

Conclusions: HPV vaccination is an important opportunity to prevent second cancers in young cancer survivors. Our results demonstrate that oncologists play an essential role in recommending the vaccine and providing vaccine information to assist childhood cancer survivors and their families with decision-making about the vaccine. At the same time, reminder systems are necessary to help survivors to complete the multi-dose HPV vaccine series.

COGNITIVE-BEHAVORIAL EFFECTS ON ACROPHASE AND MORNING DISTRESS IN GYNECOLOGIC CANCER

Janae L. Kirsch, M.S.¹, Christina S. McCrae, PhD², Michael E. Robinson, PhD¹, Elizabeth L. Kacel, PhD³, Deidre B. Pereira, PhD¹

¹University of Florida, Gainesville, FL; ²University of Missouri, Columbia, MO; ³Mayo Clinic, Gainesville, FL

Background: Rest-activity circadian rhythms assist in maintaining the body's 24-hour internal clock contributing to consistent sleep and wake times across days. Acrophase is one construct of circadian rhythms which assesses the actual clock time of peak activity during the day. Within cancer populations, earlier acrophase values have been associated with less anxiety, fatigue, older age, and better quality of life. This study examined the effects of a 6-week individual Cognitive-Behavioral Therapy intervention for insomnia and pain (CBTi.p.) on acrophase in women with gynecologic cancer.

Methods: Participants were 35 women (*M* age=59.43, *SD*=11.18) with clinically significant insomnia and gynecologic cancer enrolled in a randomized clinical trial examining CBTi.p. (*N*=18) versus Psychoeducation (*N*=17) effects on sleep, pain, mood, and stress hormones/cytokines. Daily acrophase was calculated from 14 days of wrist-worn actigraphy and sleep diaries collected at pre-intervention (T1), post-intervention (T2), and 6-8 week follow-up (T3). Acrophase was calculated by recording the most active hour occurring throughout the day as indicated by actigraphy. Morning distress, fatigue, and pain unpleasantness were obtained through daily ratings on a visual analog scale.

Results: Mixed linear models were used to examine the effect of CBTi.p. on daily acrophase. More advanced cancer stage (*b*=-.350, *p*=.047), older age (*b*=-.077, *p*=.001), and less morning distress (*b*=.037, *p*=.028) were associated with lower acrophase values. Women randomized to CBTi.p. had significantly lower acrophase values (*b*=-.011, *p*=.030) across days from pre-intervention through T2 and T3 compared to women randomized to Psychoeducation. Morning ratings of fatigue and pain unpleasantness were not significant predictors of acrophase in this sample. The overall model explained 3.3% of the within-person variance and 25.5% of the between-person variance in acrophase.

Conclusions: These results suggest that a 6-week individual CBTi.p. intervention reduced acrophase, a measure of circadian rhythm, in women with gynecologic malignancies and clinically confirmed insomnia. Future research should explore these relationships within a larger sample of gynecologic patients as well as in diverse cancer populations.

AN INFORMED/SHARED DECISION-MAKING APPROACH FOR PROSTATE CANCER SCREENING IN MEMBERS OF THE WORLD TRADE CENTER HEALTH PROGRAM

Allison Marziliano, PhD¹, Thomas Mistretta, MPH¹, Andrea Sookchan, MPH¹, Keisy E. Sanchez, BS¹, Mayer Bellehen, PhD², Jason Kornrich, Ph.D.³, Jason Wang, PhD⁴, Simon J. Hall, MD⁵, Jacqueline Moline, MD, MSc⁶, Michael A. Diefenbach, Ph.D.¹

¹Northwell Health, Manhasset, NY; ²Northwell Health, Bay Shore, NY;

³Northwell Health, Rego Park, NY; ⁴Northwell Health, Manhasset, NY;

⁵Northwell Health, Lake Success, NY; ⁶Northwell Health, Great Neck, NY

Background: First-responders to the World Trade Center (WTC) attacks have an increased risk for developing prostate cancer (PC). PC screening, however, is not part of their annual monitoring visit through the WTC Health Program (WTCHP). The goal of this project is to present data on: (1) knowledge of PC among WTCHP members, (2) the development of a tailored brochure for PC screening for WTCHP members, and (3) feasibility and acceptability of an informed/shared decision making approach from the clinician perspective.

Method: Twenty members of the WTCHP were recruited for 6 focus groups to provide their level of knowledge about PC, and feedback on the American Cancer Society's PC screening brochure. Separately, clinical providers (physicians, PAs, nurses; $n=7$) were asked to provide suggestions for content, comment on the feasibility and acceptability of the implementation of the shared decision protocol, and communicate training needs.

Results: From the focus groups' transcripts, several themes emerged: (1) high interest in PC screening, (2) minimal knowledge of higher susceptibility of PC for WTC first responders, (3) confusion about the cons of PC testing, and (4) uncertainty about the next steps following a positive screening result. Feedback on the existing ACS screening brochure consisted of: (1) the need for more tailored statistics and facts about the risks of PC, (2) more information on the cons of testing, (3) testimonials of men who had screening with positive/negative results, (4) a frequently asked questions section, and (5) targeted illustrations relevant to first responders. Clinical providers stated a need for communication examples to engage in shared decision making with their patients, but they were also concerned about the additional time the protocol would take. Additional training of providers was suggested to minimize time of implementation.

Conclusions: Overall, the tailored brochure and shared decision protocol was feasible and acceptable after incorporating all stakeholders recommendations into the program. Next steps include disseminating the tailored PC screening brochure to WTC first responders, and assessing PC screening uptake/rejection and the psychosocial environment in which these decisions are made.

IMMIGRANT STATUS, RACE AND SMOKING BEHAVIORS IN WOMEN DIAGNOSED WITH BREAST CANCER

Stephen Uong, MPH¹, Bette Caan, DrPH¹, Lawrence Kushi, ScD¹, Scarlett Gomez, PhD, MPH², Jacqueline Torres, PhD, MPH², Brittany Morey, PhD, MPH³, Candyce Kroenke, ScD, MPH¹

¹Kaiser Permanente Northern California, Division of Research, Oakland, CA;

²University of California, San Francisco, San Francisco, CA; ³University of California, Irvine, Irvine, CA

Background: Cigarette smoking has been shown to be associated with elevated risk of breast cancer (BC) mortality among women diagnosed with BC. Differences in smoking behaviors have been documented by immigration status and race. However, no prior work has examined how smoking behaviors differ by immigrant status in women with BC.

Objective: We evaluated the associations between immigrant status (foreign- or US-born), race, and smoking behaviors in a pooled cohort of Latina, Asian/Pacific Islander (API), and non-Latina White (NLW) women diagnosed with BC.

Methods: We included 6,045 Latina ($N=691$, 39.1% immigrant), API ($N=704$, 72.7% immigrant), and NLW ($N=4,650$, 8.2% immigrant) women diagnosed with BC who participated in the Kaiser Permanente Northern California prospective Life After Cancer Epidemiology (LACE) and Pathways Study cohorts. We used logistic regression to evaluate associations of immigrant status and race/ethnicity with current smoking. Among ever smokers ($N=2,663$), we used linear regression to evaluate associations with pack-years (PY) of smoking. We controlled for age at diagnosis, days between diagnosis and study enrollment, education, body mass index (BMI), and moderate/vigorous MET-hours of physical activity.

Results: Immigrant women were less likely to be current smokers (odds ratio (OR)=0.49, 95% confidence interval (CI):0.31-0.78) than were non-immigrants. Latina (OR=0.51, 95% CI:0.32-0.82) and API (OR=0.52, 95% CI:0.29-0.93) women were less likely to be current smokers than were NLW women. The associations between immigrant status and current smoking were similar across race/ethnic groups (p -interaction=0.76). Among ever-smokers, immigrant women smoked 4.73 (95% CI:2.25-7.21) fewer PY than did non-immigrants. Latina women smoked 7.35 (95% CI:4.62-10.07) and API smoked 4.31 (95% CI:0.56-8.07) fewer PY than did NLW women. The associations between immigrant status and smoking PY were similar across race/ethnic groups (p -interaction=0.87).

Conclusions: Among Latina, API, and NLW women diagnosed with BC, those who were immigrants were less likely to be current smokers and smoked fewer PY than US-born women.

INDOOR AND OUTDOOR TANNING AMONG UNITED STATES ADULTS: RESULTS FROM THE 2018 HEALTH INFORMATION NATIONAL TRENDS SURVEY

Jennifer M. Bowers, M.A.¹, Jennifer L. Hay, PhD²¹Memorial Sloan Kettering Cancer Center, Port Jefferson, NY; ²Memorial Sloan Kettering Cancer Center, New York, NY

Introduction: Tanning behaviors increase risk for skin cancers, the most common malignancies in the US. While indoor tanning is waning in the US, comparatively less is known about current rates of outdoor tanning, as well as demographic patterns.

Purpose: To examine rates of indoor and outdoor tanning in US adults, the relationship between these two types of tanning, and gender and age differences.

Method: Data were obtained from the National Cancer Institute 2018 HINTS survey of US adults. Indoor tanning was measured using the open response question, “In the past 12 months, how many times have you used a tanning bed or booth?” Outdoor tanning was measured using the question, “On warm sunny days, how often do you spend time in the sun in order to get a tan?” Response options included often, sometimes, rarely, never, and don’t go out on sunny days. SAS 9.4 programming was used to account for sample weighting to achieve representation of the US non-institutionalized adult population.

Results: The sample consisted of 3255 adults who responded to both tanning questions. Only 3.9% reported indoor tanning in the past year. In contrast, rates of outdoor tanning were substantial; 8.8% reported tanning outdoors “often,” and 17.6% “sometimes.” Indoor and outdoor tanning are related ($r = .15$, $p = .02$), with 26.9% of recent indoor tanners reporting outdoor tanning “often” and 38.2% “sometimes.” There were no significant differences in tanning frequency by age or gender.

Discussion: About one quarter of US adults tan outdoors at least sometimes. Few individuals tan indoors, but indoor tanners often engage in outdoor tanning as well. Tanning is evident across gender and all ages, indicating a need for public health intervention approaches, and emphasis on avoidance of outdoor as well as indoor tanning. Indoor tanning cessation efforts should address the harms of outdoor tanning. This descriptive research provides a snapshot of adults’ tanning behaviors, and the pervasiveness of outdoor compared to indoor tanning in 2018.

ADVANCED CANCER PATIENT AND CAREGIVER INTERACTIONS: A QUALITATIVE ANALYSIS OF PROTECTIVE BUFFERING

Dana Ketcher, PhD, MPH, CPH¹, Amy K. Otto, PhD², Maija Reblin, PhD², Casidee Thompson, CCMa³, Kristin G. Cloyes, PhD, MN, RN³, Lee Ellington, PhD³¹Moffitt Cancer Center, Land O Lakes, FL; ²Moffitt Cancer Center, Tampa, FL; ³University of Utah, Salt Lake City, UT

The social-cognitive processing model suggests communication can be beneficial in processing stressful events, such as cancer diagnosis and treatment. However, research indicates that protective buffering (PB), or avoiding communication in order to protect another’s emotions, is common among couples. The goal of this study was to qualitatively describe PB of cancer-related concerns in patient-caregiver dyads.

Eleven advanced cancer patients and their family caregivers ($n=22$) participated in individual interviews about their cancer-related communication with each other. Interview transcripts were analyzed using a theoretically-guided coding strategy to identify examples of how caregivers and patients described sharing and PB related to cancer.

Patients were on average 39 years old. Most (80%) were diagnosed with stage IV cancer and had received palliative care consultation. Caregivers were on average 43 years old; 82% were the patient’s spouse. All participants were white. Although all participants reported at the beginning of the interview they felt comfortable discussing anything with the other dyad member and did not hold anything back, aspects of PB were identified in 9 interviews (5 caregivers, 4 patients; 2 from the same dyad). Three caregivers reported avoiding communication about the potential for patient decline and end-of-life, and one reported avoiding discussing how the cancer diagnosis had impacted them personally. Patients mostly reported having open cancer discussions, but two reported avoiding communication in order to alleviate caregiver responsibilities. Patients also reported *caregivers* avoided discussions about cancer in general and two reported caregivers avoiding end-of-life specifically. Patients and caregivers who reported avoidance recognized that that the lack of communication was unhealthy for the relationship, though sometimes temporary avoidance was useful. For instance, one caregiver describes waiting until the patient felt bad during chemo to have difficult conversations so as to not “ruin the good days”.

These data demonstrate that PB is prevalent and that dyads engage in PB to avoid discussing patient decline, end-of-life, or burdening the other. This avoidance potentially has both adaptive and maladaptive uses between patients with advanced cancer and caregivers. Providing safe places and times to hold conversations about sensitive topics should be considered for inclusion within cancer treatment and provider care.

PRELIMINARY FINDINGS ON HRV AND STRESS RELATED TO BODY FAT % IN A TAI CHI EASY/QIGONG INTERVENTION FOR BREAST CANCER SURVIVORS

Linda Larkey, PhD¹, Narayanan Krishnamurthi, PhD¹, Dara James, MS¹, Jennifer Huberty, PhD²¹Arizona State University, Phoenix, AZ; ²ASU, Phoenix, AZ

Background: The numbers of breast cancer survivors has risen to 3.6 million this year. With a concomitant high prevalence of weight gain post-treatment, interventions that address body composition are important to examine in this population. Meditative Movement practices such as Tai Chi, Qigong and Yoga (incorporating body movement or postures, a focus on the breath, and a meditative state) have been shown to reduce weight and/or body fat under certain circumstances and this change may be related to reductions in stress.

Method: In the context of a larger, on-going randomized controlled trial testing effects of an eight-week, weekly Tai Chi Easy/Qigong (TCQ) intervention compared to an education control group on breast cancer survivors, age 45-75 years, we examined stress and a neurophysiological marker of stress, heart rate variability (HRV), in relationship to reduction in body fat percentage (BF%). EmWave Pro equipment with earlobe sensors captured HRV parameters. Tanita scales (using bioelectrical impedance) were used to assess BF%. The first 32 completers in TCQ (n=18) and education (EDU, n=14) were compared (t-tests) for changes in body fat percentage (BF%). Linear regressions were used to examine HRV parameters and stress (using the Perceived Stress Scale) relationships with BF%.

Results: All 32 participants were female breast cancer survivors, mean age 60.03 years. (sd 7.39), nine (23.3%) Latina, with the remaining Non-Hispanic White. No significant difference was found between study arms for BF%, but changes were in the expected direction (reduced for TCQ and increased in EDU). Decreased stress and improved HRV parameters (normalized coherence and total power, both frequency domain parameters) were significantly associated with reduction in BF% ($R=.526$; Adj $R^2=.199$, df 3, $F=3.563$; $p=.027$).

Conclusion: Changes in BF% in response to a Meditative Movement program over eight weeks for breast cancer survivors may be partially due to the overall reduction in stress. A key potential mechanism for understanding more about how TCQ (and Meditative Movement practices in general) may achieve results in body composition is HRV, particularly the parameters associated with changing the set-point in stress reactivity, such as coherence and total power in the frequency domain.

THE RELATIONSHIP BETWEEN MODERATE TO VIGOROUS PHYSICAL ACTIVITY AND MORTALITY IN ENDOMETRIAL CANCER SURVIVORS

Jessica Gorzelitz, MS¹, Amy Trentham-Dietz, PhD¹, John M. Hampton, MS², Ryan Spencer, MD, MS³, Polly Newcomb, MPH, PhD⁴, Lisa Cadmus-Bertram, Ph.D.⁵¹University of Wisconsin-Madison, Madison, WI; ²University of Wisconsin, Madison, WI; ³University of Wisconsin School of Medicine and Public Health, Madison, WI; ⁴Ired Hutchison Cancer Research Center, Seattle, WA; ⁵University of Wisconsin - Madison, Madison, WI

Background: Physical activity has been shown to reduce risk of death in those with breast and colorectal cancer, but there is insufficient evidence for this relationship in endometrial cancer survivors. Physical activity fluctuates throughout the life course, which makes measurement challenging and may influence the risk of mortality outcomes. The purpose of this study was to describe the relationship between reported physical activity and death in a population-based study of endometrial cancer.

Methods: Data were drawn from the Wisconsin Women's Health Study. Women participated in a telephone risk factor-based interview after identification by the state-wide cancer registry within 1 year of a diagnosis of endometrial cancer in 1992-95. Participants (87% of eligible) reported the frequency of moderate and vigorous physical activity performed at ages 12 and 20, and activities completed 5 years before cancer diagnosis. Death, including attributable cause, was ascertained via linkages with the National Death Index through 2016. Analyses used Cox proportional hazards regression in models of all-cause mortality, adjusted for age at diagnosis, body mass index, current cigarette smoking and stage of disease.

Results: Participants (n = 760) were, on average, 63.0 (\pm 7.0) years old at diagnosis, with mean BMI of 29.3 (\pm 7.0) kg/m². Most (60.4%) participants were deceased by 2016 with mean follow up time of 7.0 (\pm 4.2) years. Frequency of physical activity was highest at age 12, with mean reports of moderate activity of 4.3 (\pm 3.0) times per week and vigorous activity 1.7 (\pm 2.7) times per week. The adjusted hazard ratio of death associated with moderate and vigorous intensity physical activity 5 years before diagnosis was 0.99 (95%CI: 0.96-1.04) and 1.03 (95%CI: 1.03-1.12), respectively. Hazard ratio estimates for physical activity at ages 12 and 20 were similarly null.

Conclusions: After adjusting for known confounders, self-reported moderate and vigorous physical activity was not associated with all-cause mortality. Since physical activity was reported as intensity frequency per week, additional analyses will include a repeated measures approach with more sophisticated models to better describe the association of physical activity at different ages with endometrial cancer survival.

EFFECT OF A MULTILEVEL EHR-INTEGRATED PHYSICAL ACTIVITY INTERVENTION ON QUALITY OF LIFE AND SLEEP IN CANCER SURVIVORS

Somya Rastogi, MPH¹, Amye J. Tevaarwerk, MD², Mary Sesto, PT, PhD³, Ronald Gangnon, PhD³, Lisa Cadmus-Bertram, Ph.D.⁴¹University of Wisconsin- Madison, Madison, WI; ²University of Wisconsin, Madison, Madison, WI; ³University of Wisconsin, Madison, WI; ⁴University of Wisconsin - Madison, Madison, WI

Objectives: Cancer survivors commonly experience psychosocial and physical distresses that negatively affect quality of life. This pilot trial tested the effect of adding a multi-level, technology-based physical activity intervention module to a standard survivorship care plan for breast and colorectal cancer survivors. The objective of this study was to determine whether the physical activity module improved psychosocial and health related quality of life outcomes relevant to survivorship.

Methods: This pilot study enrolled fifty breast and colorectal cancer survivors, each enrolled alongside a support partner. Half of the dyads were assigned to receive a survivorship care plan augmented with a 12-week multicomponent physical activity module that included a Fitbit tracker (with data integrated into the electronic health record) and customized email feedback. The comparison group received the standard survivorship care plan alone. Outcomes were the SF-36, social support as measured by the ISEL, PROMIS sleep measures and physical activity beliefs. Data were analyzed using linear mixed modeling.

Results: Cancer survivors were aged 54.4 ± 11.2 years and were 2.0 ± 1.5 years since diagnosis. Relative to those in the comparison group, the intervention group experienced improved physical health ($p=0.12$, effect size: $d=0.39$), mental health ($p=0.06$, $d=0.59$), sleep impairment ($p=0.04$, $d=0.62$), and exercise self-efficacy ($p=0.03$, $d=0.60$).

Conclusion: The intervention delivered meaningful improvements in mental health and sleep impairment of the cancer survivors. If replicated in a larger sample, this study demonstrates that scalable, technology-supported interventions may be an efficacious and practical strategy for improving psychosocial health and health related quality of life of cancer survivors.

6:15 PM-7:30 PM

A PILOT IPOD AND MINDFULNESS-BASED INTERVENTION: DEPRESSIVE SYMPTOMS, BIOMARKERS, AND SURVIVAL AMONG LUNG CANCER PATIENTS

Chelsea Siwik, M.S.¹, Elizabeth Cash, PhD², Paul Salmon, Ph.D.³, Kala Phillips, PhD¹, Sandra Sephton, Ph.D.³¹University of Washington, Seattle, WA; ²University of Louisville School of Medicine, Louisville, KY; ³University of Louisville, Louisville, KY

Lung cancer patients experience elevated rates of depressive symptoms, which has been linked to dysregulated neuroendocrine and telomere biology, and earlier mortality. Given that many cancer patients face considerable burden, identifying interventions that are efficacious and feasible remains a priority. Thus, the primary aim of the current investigation was to pilot an iPod and mindfulness-based intervention (MBI), as MBIs have been shown to reduce depression and improve related outcomes among patients with cancer.

Non-small cell lung cancer patients ($N = 67$) diagnosed within 5 years reported on depressive symptoms, provided a blood sample for leukocyte telomere length (LTL) assessment, and collected saliva samples morning and evening across multiple days for cortisol assessment at baseline and follow-up. Patients were invited to complete an optional 3-month iPod and MBI between baseline and follow-up that involved listening to audio tracks adapted from the mindfulness-based stress reduction program; 25 patients completed the intervention. Patient's survival status was tracked. After controlling for baseline differences, ANCOVAs were used to test for differences in the slope of change in depressive symptoms, LTL, and diurnal cortisol profiles between groups. Kaplan-Meier analyses were conducted to examine the association between intervention use and survival. *Post-hoc* Cox Proportional Hazard regressions were used to test the association between change in LTL and survival to elucidate findings.

Results revealed the intervention was associated with an increase in depressive symptoms ($F(1,54) = 5.360$, $p = .024$, partial $\eta^2 = 0.090$; intervention: $M = .035$, $SE = .084$; non-intervention: $M = -.005$, $SE = .047$) and LTL ($F(1,34) = 5.454$, $p = .026$, partial $\eta^2 = 0.138$; intervention: $M = .0000423$, $SE = .000725$; non-intervention: $M = -.000327$, $SE = .000437$), after adjusting for chemotherapy at baseline, and shorter survival calculated from study entry ($p = .019$) and date of diagnosis ($p = .014$). *Post-hoc* analysis revealed longer LTL was associated with shorter survival calculated from date of study entry ($P(\text{Wald}) < .01$) and date of diagnosis ($P(\text{Wald}) = .026$), after controlling for the intervention.

Although results should be interpreted cautiously due to study limitations (i.e., small sample size, non-randomized design), the pilot intervention yielded unexpected associations that warrant further consideration. Results also suggest that longer, opposed to shorter, LTL may be prognostic for earlier mortality in this population.

EXPERIENCES OF AFRICAN-AMERICAN PROSTATE CANCER SURVIVORS: A META SYNTHESIS AND LITERATURE REVIEW

Florence Okoro, PhD¹, Beth Auten, MLIS, MA, AHIP²¹School of UNC Charlotte, Charlotte, NC; ²University of North Carolina at Charlotte, Charlotte, NC

Introduction: African-American men have about a 15 percent chance of developing prostate cancer, compared to about 10 percent chance for white men and more likely to die from the disease than white men - 4 percent versus 2 percent respectively. African American men who are already in a high-risk group for prostate cancer than their white counterparts are also at higher risk for post-treatment symptom distress and poor quality of life with lower survival rates.

The aim of this review is to synthesize the current literature on post-treatment survivorship experiences of African American men with prostate cancer. A full analysis of the current research will add a comprehensive guide to the current knowledge base and make recommendations for future studies.

Method: A health sciences librarian developed and ran extensive literature search in five data bases in September 2018: PubMed, CINAHL Plus with Full Text, PsycINFO (EBSCO), Web of Science, and Social Sciences Abstract (ProQuest). Searches in PubMed, CINAHL, and PsycINFO used keywords and controlled vocabulary terms (MeSH in PubMed, CINAHL Headings in CINAHL, Thesaurus of Psychological Index Terms in PsycINFO) for the following concepts: African-Americans, prostate cancer survivors, localized disease, and marital/relationship status. Searches in Web of Science and Social Sciences Abstract used keywords only. We identified 13 relevant studies published from 2008 to 2018 and did the quality appraisal using the validated Critical Appraisal Skills Program. We used Noblit and Hare's meta-ethnographic approach to analyze and synthesize the qualitative studies. We also analyzed quantitative studies related to the findings of the qualitative studies to add to the robustness of the meta-synthesis.

Results: Four major themes with eight sub-themes emerged from the analysis. The 4 major themes were - Coping strategies (spirituality, healthy behaviors, spouse/family support, and non-disclosure), Psycho-physical impacts (physical well-being, masculinity and self-esteem), Health system influence (treatment decision-making, healthcare provider influence), and socioeconomic impact.

Discussion/Conclusion: Our findings reveal that the experiences of African-American prostate cancer survivors are multiplex, related to their culture and socioeconomic context. This review highlights the need for studies with unpartnered African-American prostate cancer survivors to specifically explore and identify their unmet needs.

ANODYSPAREUNIA IN GAY AND BISEXUAL PROSTATE CANCER SURVIVORS

Christopher W. Wheldon, PhD, MSPH, MEd¹, Elizabeth J. Polter, MPH², B.R. Simon Rosser, PhD, MPH²¹Department of Social and Behavioral Sciences / College of Public Health / Temple University, Philadelphia, PA; ²Division of Epidemiology and Community Health / University of Minnesota, Minneapolis, MN

Introduction: The incidence of sexual dysfunction resulting from prostate cancer treatments is well established; however, sexual functioning is almost always operationalized as erectile function or as erections sufficient for vaginal intercourse. For many gay and bisexual men (GBM), receptive anal intercourse (RAI) is a common sexual behavior, but the effects of treatment have not been studied. Anodyspareunia is recurrent or persistent clinically significant pain experienced during receptive anal intercourse. It is estimated that 10-14% of GBM experience anodyspareunia and the majority of these cases describe the problem as lifelong. As the first study of anodyspareunia in this population, our objectives were: (1) to describe the prevalence of anodyspareunia in a sample of GBM prostate cancer survivors and, (2) to evaluate the degree to which anodyspareunia is associated with health-related quality of life.

Methods: Data were from the Restore-1 study, a cross-sectional online survey of 193 GBM in the U.S. or Canada who were treated for prostate cancer. For treatment, 53% had received surgery, 19% radiation, and 29% a combination of treatments. Average age and time since diagnosis were 63.4 (SD=8.2) and 5.63 (SD=4.6), respectively. Simple linear regression was used to evaluate associations between anodyspareunia, treatment type, past behavior, and the SF-12 Physical/Mental scales.

Results: There were 55 (28.5%) men who attempted RAI in the previous month. Approximately 29.1% reported severe anal pain (i.e., anodyspareunia) sufficient to stop intercourse. There was a significant association between anodyspareunia, pre- and post-treatment ($b=16.7$, $p=.01$). Of the 110 men who reported pleasurable RAI in the year prior to their prostate cancer diagnosis, 47 (42.7%) reported attempting RAI in the past month. Of these, 10 (21.3%) also reported anodyspareunia, which was negatively associated with the SF-12 Mental Component Score ($b=-8.8$, $p=.02$). Anodyspareunia did not differ by treatment received.

Conclusions: RAI was a common sexual behavior among a subset of GBM prostate cancer survivors. Anodyspareunia was higher among this group than in other populations, although not associated with treatment type. Culturally responsive cancer care for GBM should consider changes to RAI and its potential association with quality of life.

PERSPECTIVES OF GHANAIAAN HEALTH CARE PROVIDERS ON HPV VACCINATION: A QUALITATIVE STUDY BASED ON MULTI-THEORY MODEL

Cassandra Millan, B.S.¹, Matthew Asare, PhD, MPH, MBA², Beth A. Lanning, PhD, MCHES², Peter Agyei-Baffour, Ph.D.³¹Baylor University, McGregor, TX; ²Baylor University, Waco, TX; ³KNUST, Kumasi, Ashanti, Ghana

Introduction: Human Papillomavirus (HPV) vaccination is effective in preventing cervical cancer. However, HPV vaccination awareness and vaccination rates in Ghana are low and these factors have contributed to high rates of cervical cancer in the country. Typically, healthcare providers (i.e. physicians and nurses) are responsible for counseling and/or educating adolescents and parents about the HPV vaccination but little is known about the Ghanaian health care providers' attitudes and beliefs concerning HPV vaccination.

Purpose: The purpose of this study was to examine Ghanaian healthcare providers' perceptions and attitudes towards HPV vaccination and their vaccination recommendation behaviors.

Methods: We conducted three, sixty-minute focus group discussions with health care providers in the second-largest government hospital in Ghana. Sixteen semi-structured open-ended questions were used to guide the focus group discussions with additional follow-up questions added for clarifications. We explored general knowledge about HPV, vaccination recommendation behavior, physical environment, and socio-cultural factors associated with the HPV vaccination among the providers.

Results: The sample (n=29) included physicians (n=9), nurses (n=8), immunization field officers (n=5), and other healthcare professionals (n=7). The participants consisted of male (n=15) and females (n=14) between the ages of 29 and 42 years. Our analyses showed that healthcare providers rarely offer HPV vaccination recommendations because (a) physicians attend to acute illness and have limited time to discuss preventive care, including vaccination, with patients; (b) vaccines are delivered as community medicine where mobile clinics are delivered to the communities to vaccinate children in those communities; and (c) the concepts of routine medical checkup and preventive medicine, such as HPV vaccination, are not well integrated into the Ghana health care system. Additionally, we found (a) low urgency for HPV vaccination education programs due to competing priorities such as malaria and HIV/AIDS; (b) lack of awareness about the mechanism, safety, and efficacy of HPV vaccination; (c) lack of HPV vaccine accessibility (i.e. availability and affordability); and (d) stigma, misconceptions and religious objections associated with the vaccine (primarily, that it promotes promiscuity).

Conclusion: The findings of our study underscore the need for a comprehensive HPV vaccination program in Ghana. The program should be designed to (a) equip health care providers and the community with knowledge about the efficacy of HPV vaccination to prevent cancer, (b) address transportation issues for both vaccination delivery and access, and (c) address HPV vaccination-related stigma to increase vaccination uptake.

PHYSICAL ACTIVITY TRAJECTORIES FROM PRE- TO POST-CHEMOTHERAPY IN CANCER PATIENTS COMPARED TO CONTROLS IN A NATIONWIDE STUDY

Elizabeth Salerno, PhD, MPH¹, Eva Culakova, PhD, MS², Amber S. Kleckner, PhD³, Charles E. Heckler, PhD, MS², Po-Ju Lin, PhD, MPH, RD², Karen M. Mustian, PhD, MPH², Charles E. Matthews, PhD⁴, Michelle C. Janelins, Ph.D., M.P.H.²¹National Cancer Institute, Rockville, MD; ²University of Rochester Medical Center, Rochester, NY; ³University of Rochester, Rochester, NY; ⁴Nci, Rockville, MD

Objective: Physical activity (PA) has been consistently associated with improved physical function, quality of life, and survival during cancer survivorship; however, patterns of PA before, during, and after chemotherapy, as well as how these changes may differ from the general population, have not been fully characterized. We therefore examined PA levels and changes among patients with breast cancer (BC) undergoing chemotherapy compared to age-matched, non-cancer controls.

Methods: PA was measured using the leisure time physical activity questionnaire from the Aerobics Center Longitudinal Study at pre-chemotherapy (T1), post-chemotherapy (T2), and 6-months post-chemotherapy (T3). PA was categorized to all activities, exercise, and household activities in total minutes and Metabolic Equivalent Task (MET) hours/week. Participants were classified as meeting PA guidelines if they reported at least 150 minutes per week of moderate to vigorous intensity exercise. Within-group differences were tested by T-tests and chi-square tests. Longitudinal mixed effects models (LMMs) characterized differential rates of change in PA over time between patients and non-cancer controls, adjusting for age, race, menopausal status, cognitive reserve, body mass index, anxiety, and depression.

Results: Participants (N=942) included 580 BC patients (53.4±10.6 years) and 362 controls (52.6±10.3 years). At T1, 42% of controls were meeting PA guidelines. This proportion remained consistent across time with 44% meeting guidelines at T2 and 39% at T3. One-third of BC patients met PA guidelines at T1, dropping to 21% at T2 before rising to 37% at T3. At T1, BC patients reported an average of 11.1±15.7 exercise MET hours/week, significantly lower than controls (p=.02). These levels declined significantly in BC patients from T1 to T2 (7.6±11.9; p<.001), remaining lower than controls (p<.001). BC patients also reported significantly lower levels of all activities total minutes and MET hours/week at T2 (all p<.01). LMMs indicated several significant group by time interactions, confirming a steeper rate of decline in BC patients than controls from T1 to T2 for all PA outcomes (all p<.001). From T2 to T3, BC patients reported significantly increased PA across all outcomes compared to controls (all p<.03), with no significant difference in exercise levels between groups at T3 (all p>.64). Regardless of cancer status, significant predictors of exercise across time were age, body mass index, and depression.

Conclusion: These findings suggest that chemotherapy negatively impacts PA, reinforcing the importance of promoting PA during treatment. While BC patients returned to pre-chemotherapy PA levels six months post-chemotherapy, 63% to 79% of patients still failed to meet PA guidelines, highlighting a critical need for PA interventions during survivorship in addition to during treatment.

AFFECTIVE CONCERNS AND DESIRE FOR SUPPORT AT CANCER-RELATED HEALTHCARE VISITS

Brandon Q. Tran, MA¹, Kate Sweeny, PhD¹¹University of California, Riverside, Riverside, CA

Background: Cancer is often more than a medical diagnosis. For many, confronting cancer entails a shift in their identity and quality of life, as well as a lifelong sense of uncertainty as patients grapple with fears of recurrence, psychological distress, and physical limitations. Given these facets of the cancer experience, fields such as psycho-oncology have emerged with the goal of capturing the full scope of the cancer experience, highlighting the importance of integrative care that addresses both biomedical and psychosocial well-being.

Purpose: Our study sought to explore the affective experiences of cancer patients and the degree to which patients want their healthcare providers to provide psychosocial care during clinical interactions through *SupportScreen*, a state-of-the-art touch-screen interface that prompts patients to identify social, medical, and emotional issues and their desire to address these issues with their healthcare provider.

Method: In collaboration with the City of Hope in Duarte, CA, *SupportScreen* data from over 18,000 patients was analyzed to identify the extent to which patients reported psychosocial difficulties associated with cancer, whether these experiences differ across demographic backgrounds, and whether patients differ in their preferences for assistance from providers.

Results: Significant differences emerged in patients' affective concerns across demographic factors, with males, non-Hispanics, English speakers, and older, married, higher-income, and more-educated patients reporting fewer affective concerns and less frequently desiring assistance from providers. Conversely, more affective concerns were reported by females, Hispanics, non-English speakers, and younger, unmarried, lower-income, and less-educated patients, who also more frequently requested verbal and written assistance from providers to better cope with these issues.

Conclusion: Taken together, our results highlight disparities in patients' affective experiences when confronting cancer and provide novel insights that may help to tailor cancer care to increase patient-centeredness, minimize distress, and improve patient outcomes.

THE ROLE OF GENDER IN NEW ORAL ONCOLYTIC AGENT PRESCRIPTION EDUCATION

Eric Vachon, PhD, RN¹, Victoria Champion, PhD, RN, FAAN¹¹Indiana University, Indianapolis, IN

Background: While oral oncolytic agents (OOA) are both convenient and provide independence over traditional intravenous chemotherapy, patients are burdened with an increased responsibility for medication and symptom management, as well as the high costs of OOA drugs. Patient responsibility for oral chemotherapy requires extensive education from providers at the initiation of treatment, and research has demonstrated that females may actually receive less education about symptom management from providers than their male counterparts. The purpose of this work is to identify the type and source of OOA education (different providers, online, package insert), and to determine if gender influenced the source of care provider education (nurse, oncologist, pharmacist).

Methods: At initiation of a newly-prescribed OOA, 272 patients (136 males, 136 females) completed computer-assisted telephone interviews asking self-report questions pertaining to taking OOAs, managing side effects, paying for OOAs, as well as source of information such as providers, online information, or medication inserts. Gender influence and provider source was tested using chi-square; if any provider source was found to be significant binary logistic model would be used controlling for demographic variables (age, race, education, marital status, and income).

Results: Patients were on average 61-years-old (Range 23-90), with breast and GI being the most common cancers among them. Many patients received education from multiple sources. Only 66% of patients received some financial education, while nearly all patients received education on medication and symptom management from some source. Oncologists were the most common source at 88%, 72% of patients received education from a nurse, 63% from pharmacist, 82% received information from package insert, and only 25% used online sources. Chi square determined that oncology nurses were less likely to provide education to females compared to males, while no difference was found by gender for oncologists or pharmacists. The nurse binary logistic regression still showed females were less likely to receive education than males when controlling for demographics (OR .52, *p*.02).

Conclusions: While there was no difference between genders for oncologists, women were less likely to receive education from nurses. Bias training is needed for all providers to ensure quality care and education, especially for patients being burdened by the responsibilities of managing cancer and OOA therapy. Although nearly all patients received medication and symptom management education, only 66% of patients receiving financial education, which is concerning given the rising costs of OOA therapies. Additional resources should be utilized by providers to discuss patients' financial concerns at the initial prescription, so that they may be able to obtain their OOA throughout treatment.

PERCEIVED CULTURAL COMPETENCY OF HEALTHCARE PROVIDERS PREDICTS RECEPTIVITY TO COLORECTAL CANCER SCREENING AMONG AFRICAN-AMERICANS

Anurag Dawadi, MPH¹, Todd Lucas, PhD¹, Caroline Drolet, PhD¹, Hayley Thompson, PhD², Mark Manning, PhD², Louis A. Penner, PhD², James Blessman, MD³, Rhonda Dailey, MD⁴

¹Michigan State University, Flint, MI; ²Wayne State University/Karmanos Cancer Institute, Detroit, MI; ³Wayne State University, Detroit, MI; ⁴Wayne State University, Department of Family Medicine and Public Health Sciences, Detroit, MI

Background: Colorectal Cancer (CRC) is the second leading cause of cancer-related death in the United States. CRC is particularly burdensome to African-Americans, with lower rates of CRC screening playing a critical role. Patient perceptions of cultural competency in the delivery of healthcare may contribute to CRC screening uptake among African Americans. However, empirical data on cultural competency and CRC screening are lacking. The current research addresses this gap by examining whether African Americans' perceived cultural competency of their healthcare is associated with receptivity to CRC screening.

Objective: To examine whether African Americans' perceived cultural competency of their healthcare predicts receptivity to CRC screening and uptake of at-home CRC screening.

Methods: CRC screening deficient African Americans ($n=429$) completed a validated, patient-focused and generally-framed measure of perceived cultural competency in the delivery of their healthcare ($\alpha = .91$). Participants then watched a brief online tutorial about CRC risks, prevention, and screening. Receptivity to CRC screening was measured using Theory of Planned Behavior (TPB) constructs (attitude, norms, perceived control, and intentions). Participants were also given an opportunity to receive a no-cost at-home Fecal Immunochemical Test (FIT) screening kit through mail, and we measured willingness to receive (WTR) this FIT Kit as a behavioral outcome (yes-no). We assessed direct links from perceived cultural competency to TPB constructs, as well as indirect links to WTR.

Results: Perceived cultural competency predicted more favorable CRC screening attitudes, norms, and perceived control ($p's < .001$), as well as stronger CRC screening intentions ($p=.01$). Indirect effects of perceived cultural competency on greater WTR were fully mediated by links to CRC screening attitudes and intentions ($p's < .001$), whereas indirect effects on less WTR were mediated by perceived control ($p < .01$). Links from cultural competency to WTR were not mediated by norms ($p=.075$).

Conclusion: Perceived cultural competency of healthcare may play a crucial, yet still overlooked role in CRC screening uptake among screening deficient African Americans.

Methods: to augment feelings of culturally competent healthcare among racial minorities may be useful in addressing CRC screening disparities, although links to perceived control could paradoxically reduce WTR at-home CRC screening.

A FEASIBILITY STUDY OF 12-WEEKS OF SMARTPHONE-BASED HEALTH EDUCATION PODCASTS IN MYELOPROLIFERATIVE NEOPLASM PATIENTS

Breanne M. Laird, BS¹, Shannon M. Clark-Sienkiewicz, Ph.D.², Jennifer Huberty, PhD³, Ryan Eckert, MS⁴, Linda K. Larkey, PhD⁵, Ruben Mesa, MD⁶

¹Arizona State University, Scottsdale, AZ; ²Arizona State University, Tempe, AZ; ³ASU, Phoenix, AZ; ⁴UT Health San Antonio at MD Anderson, Tempe, AZ; ⁵Arizona State University, Phoenix, AZ; ⁶UT Health San Antonio, San Antonio, TX

Background: Patients with MPN (Myeloproliferative Neoplasms), rare blood cancers, have a relatively long-life expectancy, but experience chronic symptoms due to a lack of curative therapies. Our work suggests smartphone-based meditation is feasible and has preliminary effects on MPN patient symptom burden. However, an appropriate smartphone application-based control condition is needed to test efficacy of meditation in future studies. The purpose of this study was to determine the feasibility of a 12-week app-based health education podcast control group in MPN patients. We report pre- and mid-intervention findings here (6-weeks).

Methods: MPN patients were recruited using social media. Participants were asked to listen to ≥ 60 minutes of health education podcasts per week. Podcasts contained general cancer-related health education material. Participants tracked their time listening to the podcast in a weekly log. Assessments were conducted for sleep, pain-intensity, anxiety, depression, sexual function, global health and the MPN Symptom Assessment Form Total Symptom Score (MPN-SAF TSS) at pre-, mid (6-weeks) and post- (12-weeks) intervention.

Results: Ninety-six participants were enrolled in the study. To date, 31 participants have completed mid-intervention (6 weeks) and of those, one dropped out due to difficulties with the technology of the app. On average participants listened to 63 minutes of podcasts per week and were satisfied with the content. Only a small increase in physical health (baseline $M = 32.59$, 6-week $M = 34.76$, $p=.007$, $d = 0.27$) and a small decrease in MPN symptom burden was detected after 6-weeks (baseline $M = 26.79$, 6-week $M = 22.48$, $p=.008$, $d = 0.22$). Significant changes in pain, anxiety, depression, sleep disturbance, or mental health were not found.

Discussion: The current study presents preliminary feasibility of a mobile app podcast control condition. Participants were satisfied with the content, and they engaged in listening to a degree that is comparable to the expected meditation app participation per week, suggesting this will be an appropriate, time-matched control condition.

PALLIATIVE CARE KNOWLEDGE AND WORRY ABOUT CANCER RECURRENCE IN CANCER SURVIVORS

Jackelyn B. Payne, MPH¹, Jennifer M. Bowers, M.A.², Anne Moyer, PhD¹¹Stony Brook University, Stony Brook, NY; ²Memorial Sloan Kettering Cancer Center, Port Jefferson, NY

Background: Fear of cancer recurrence is a significant burden for many cancer survivors, warranting examination of possible contributing factors. Palliative care education is vital to informed decision making for cancer patients, but unintentional adverse effects that may extend into survivorship are understudied.

Purpose: To assess whether knowledge of palliative care was associated with worry about cancer recurrence in cancer survivors.

Methods: Data were obtained from the 2018 HINTS surveys of US adults by the National Cancer Institute. Participants were included if they responded “yes” to the question: “Have you ever been diagnosed as having cancer?” Knowledge about palliative care was measured using the question, “How would you describe your level of knowledge about palliative care?” Cancer information seeking was dichotomized using the question, “Have you ever looked for information about cancer from any source?” Health insurance status was dichotomized. General health was measured using the question, “In general, would you say your health is...” with response options, “Excellent,” “Very good,” “Good,” “Fair,” or “Poor.” The outcome, worry about cancer recurrence, was measured using the question, “How worried are you about getting cancer again?” with response options, “Not at all,” “Slightly,” “Somewhat,” “Moderately,” or “Extremely.” SAS 9.4 programming was used to account for sample weighting; results are representative of the US non-institutionalized adult population.

Results: 567 cancer survivors in the sample provided complete data for all variables. 65.61% had never heard of palliative care and 77.19% reported seeking cancer information. In a model that controlled for general health, health insurance, and cancer information seeking, which may otherwise explain cancer worry, knowledge about palliative care significantly predicted worry about cancer recurrence, with a significant change in $R^2 = .08$, $F(1,562) = 49.07$, $p < .001$.

Conclusion: Although a majority of cancer patients had never heard of palliative care, those who had experienced more worry about getting cancer again were more likely to be aware of it. Because how participants became aware of palliative care is unknown, it is unclear if conversations with health care practitioners are comforting or concerning.

PALLIATIVE CARE KNOWLEDGE AND INFORMATION SEEKING IN CANCER SURVIVORS AND CAREGIVERS

Jackelyn B. Payne, MPH¹, Jennifer M. Bowers, M.A.², Anne Moyer, PhD¹¹Stony Brook University, Stony Brook, NY; ²Memorial Sloan Kettering Cancer Center, Port Jefferson, NY

Background: Palliative care aims to improve the physical, emotional, and spiritual quality of life of patients and their families when cancer cannot be cured. Awareness of palliative care is understudied in cancer survivors and caregivers, as well as in the general population. Multiple barriers exist to the integration of palliative care other than lack of awareness, including oncologists' discomfort with and lack of training regarding how to address palliative care.

Purpose: To assess knowledge of palliative care in cancer survivors and cancer caregivers, as well as primary and trusted sources of information regarding palliative care.

Methods: Data were from the nationally-representative 2018 HINTS surveys of US adults by the National Cancer Institute. We assessed knowledge about palliative care, where respondents reported where they would go first to seek palliative care information, and who respondents trust the most as a source of information about palliative care. Missing data were excluded. SAS 9.4 programming was used for all analyses to account for sample weighting such that results are representative of the US non-institutionalized adult population.

Results: There were 3504 participants from the general population, 593 cancer survivors, and 593 cancer caregivers in the sample. Concerning knowledge of palliative care, 71.26% of the general population had no knowledge of it, compared to 65.61% of the cancer survivors and 51.35% of the cancer caregivers. Although both cancer survivors and caregivers reported health care providers as the first source they would go to for palliative care information (65.53% and 50.61%, respectively), caregivers were more likely to report turning to the internet (48.1%) than survivors (23.67%). However, survivors and caregivers both overwhelmingly reported health care providers as their most trusted source of information about palliative care (85.99% and 93.68%, respectively).

Conclusion: The majority of the US population is unfamiliar with palliative care, including those who have had cancer. Providers are still the first line of education about palliative care for cancer survivors and caregivers, as well as the most trusted as a source of palliative care information. Future research should explore pathways for informed communication about palliative care between care teams and patients.

CANCER FATALISM AND HEALTH INFORMATION SEEKING: EXPLORING DIFFERENCES ACROSS GENERATIONS AND RURAL GEOGRAPHIES

Samantha Paige, PhD, MPH, CHES¹, Jordan Alpert, PhD², Carma Bylund, PhD³¹University of Florida/STEM Translational Communication Center, Gainesville, FL; ²University of Florida/College of Journalism and Communication/UF Health Cancer Center, Gainesville, FL; ³University of Florida, Gainesville, FL

Background: Cancer fatalism, or pessimism and confusion about its prevention, is associated with high-risk health behaviors. Information seeking combats cancer fatalism; however, people at risk for cancer, including older and rural adults, experience health information seeking challenges such as inaccessibility, comprehension frustration, and quality uncertainty. Research asserts that we can encourage people to seek health information by promoting their confidence. However, limited research has tested the theoretical assumption that enhancing perceived confidence to overcome barriers in health information seeking will alleviate cancer fatalism.

Objective: To understand how perceived challenges and confidence in health information seeking attenuate or buffer fatalistic cancer beliefs across age and rurality.

Methods: In 2017, 895 adults from a large southeastern medical university's cancer catchment area participated in a random digit dial survey. Cancer fatalism and health information seeking challenges and confidence (4-pt Likert-type scales) were adopted from the Health Information National Trends Survey. ANOVAs and independent samples t-tests examined age and rural differences in cancer fatalism. A hierarchical linear regression was conducted to examine the interaction of perceived confidence and challenges in health information seeking on cancer fatalism, controlling for age and rurality.

Results: Participants were Millennials (18-35; 19%), Generation X (36-51; 23%), Baby Boomers (52-70; 40%), and members of the Silent Generation (71-115; 16.9%) who were from metro (78.9%) and non-metro (21.1%) counties (2013 RUCC definitions). Participants reported cancer fatalism ($M = 2.38$; $SD = .68$), with low perceived challenges ($M = 2.06$; $SD = .76$) and high confidence in health information seeking ($M = 3.73$; $SD = .99$). Cancer fatalism was high among the Silent Generation and non-metro adults, and it was associated with perceived challenges ($b = .20$; $SE = .03$; $p < .001$) and low confidence ($b = -.06$; $SE = .03$; $p < .05$) in health information seeking. High confidence in health information seeking attenuated cancer fatalism, but only when perceived challenges were already low ($b = .11$; $SE = .03$; $p < .001$).

Discussion: Alleviating intrinsic barriers to health information seeking is fundamental to address fatalistic cancer beliefs among older and rural adults. Enhancing confidence will be important for sustained information seeking once barriers are reduced.

RELATIONAL PROCESSES AND ADJUSTMENT AMONG YOUNG ADULTS WITH CANCER: THE ROLE OF TECHNOLOGY-RELATED COMMUNICATION

Katie Darabos, PhD¹, Michael A. Hoyt, Ph.D.², Jennifer S. Ford, PhD³¹The Children's Hospital of Philadelphia, Collingswood, NJ; ²University of California, Irvine, Irvine, CA; ³Hunter College, City University of New York (CUNY), New York, NY

Objective: Little attention has been paid to understanding how engaging in cancer-related interpersonal exchanges via varying modes of communication influences psychological well-being among young adults with cancer. This study explored the moderating role of mode of communication on the relationship of relational processes of disclosure and responsiveness with psychological well-being.

Methods: 61 young adults with cancer ($Age = 34.59$, $SD = 4.82$) completed a questionnaire about their most recent cancer-related conversation. Participants reported on mode of communication (i.e., face-to-face, text message, phone call) and relational processes of self- and support member- disclosure of thoughts, feelings, and information and how accepted, cared for, and understood they felt within the cancer-related conversation. Cancer adjustment included measures of functional well-being and depressive symptoms.

Results: There were no main effects of communication mode or relational processes on either indicator of adjustment to cancer. However, mode of communication did moderate the relationship between relational processes and adjustment to cancer. Greater relational processes of disclosure and responsiveness were associated with better functional well-being and lower depressive symptoms only among those who engaged in their most recent cancer-related conversation through technology-related communication and not for those engaged in face-to-face communication.

Conclusion: Relational processes that are likely to benefit psychological adjustment after cancer appear to be particularly advantageous in cancer-related interpersonal exchanges via technology-based communication among young adult survivors. Young adults commonly report feelings of social isolation and psychological distress after cancer. These findings suggest that technology-related communication holds promise as a way to strengthen support-related communication and protect against distress.

LATINO PATIENTS PERSPECTIVE: INTEGRATION OF FAMILY MEMBERS IN MEANING CENTERED PSYCHOTHERAPY

Normarie Torres-Blasco, PhD¹, Eida M. Castro, PsyD, MS², Maria Claros, B.S.³, Carolina Zamore, BA⁴, Rosario Costas-Muniz, PhD⁴

¹Ponce Health Science University, Ponce, N/A, Puerto Rico; ²Ponce Health Sciences University, Ponce, N/A, Puerto Rico; ³Memorial Sloan Kettering Cancer Center, North Bergen, NJ; ⁴Memorial Sloan Kettering Cancer Center, New York, NY

Objective: Family caregivers are a fundamental source of care for Latino cancer patients. Yet the family related psychosocial needs and perspectives of family caregiver's integration in psychological care of Latino patients with advanced cancer are not well understood. Changes in cancer care and delivery, along with the growing population of Latinos with advanced cancer and their caregivers, warrant increased attention to the roles and demands of caregiving and family needs. This presentation describes: 1) the perspective of Latino patients with advanced cancer on the role of the family in care, and 2) the correlation between family functioning and psychological symptoms (depression and anxiety).

Method: Quantitative (n=79) and qualitative data (semi-structured interviews, n=24) was collected from Latino patients with advanced cancer between 2015 and 2019 from a major cancer center (n=48), and two cancer clinics, one located in New York city (n=22) and the other in Ponce, Puerto Rico (n=12). Family functioning was measured with the Family Relationship Index and depression / anxiety with the Hospital Anxiety and Depression Scale. The semi-structured interviews were transcribed, and the data was analyzed using open coding thematic analysis. Correlation between family cohesion, and psychological factors was performed.

Results: Data shows that 81% of Latino advanced cancer patients reported low family functioning; and those with low family functioning had higher depression (r(75)=-.27, p=.02), anxiety (r(75)=-.27, p=.02), and hopelessness (r(75)=-.23, p=.05) levels. Higher family functioning was also strongly associated to lower anxiety (r(75)=-.39, p<.001). The themes and codes from the qualitative data revealed presumably on family relationships with emphasizes on the following themes: counseling; support; change after diagnosis; communication; conflict; sources of meaning; sources of love; sources of beauty; sources of humor; lesson of life; legacy for kids; family union; and coping mechanism.

Conclusion: Correlations between family cohesiveness and psychological symptoms (depression and anxiety) suggest that these components are crucial in the adjustment and well-being of Latinos with advanced cancer. Further, it revealed presumably the impact of family relationships in cancer coping, and likelihood of integrating family members into therapy.

OBESITY, DISTRESS AND DESIRE FOR SUPPORTIVE CARE AMONG PATIENTS DIAGNOSED WITH CANCER

Errol Philip, n/a¹, Cristiane Decat Bergerot, PhD², Marianne Razavi, PhD², Karen Clark, MS², Paulo Bergerot, MD², Matthew Loscalzo, LCSW²

¹UCSF School of Medicine, San Francisco, CA; ²City of Hope, Duarte, CA

Background: Obese weight status has been associated with an increased risk of several cancers, greater symptom burden and poorer prognosis. Cancer patients and survivors with obesity represent a vulnerable population who may need targeted supportive care services and health promotion efforts. The current study explored the association between obesity, psychosocial outcomes and supportive care requests among patients with breast, prostate, or colon cancer.

Methods: This retrospective study included 4,159 patients over the age of 55 who were diagnosed with postmenopausal breast (52.2%), prostate (38.7%) or colon cancer (9.1%). Prior to treatment, patients were screened for problem-related distress using a 33-item touch screen-based instrument and reported whether they desired supportive care services. Obese weight status was defined as a BMI ≥ 30 kg/m².

Results: Across diagnoses, most patients were married, non-Hispanic and had at least some college education, with a mean age of 66.7 years. Obese breast and prostate cancer patients reported higher rates of clinically relevant distress compared with non-obese patients (p< 0.05), whereas an opposite trend was noted for patients with colon cancer. Nearly 20% of patients requested supportive services, with similar rates found among obese and non-obese patients across all cancer types; however significant differences emerged in the problems that drove supportive care requests. Obese patients were more likely to request support regarding symptoms of depression (p< 0.05) and pain (p< 0.05) compared to non-obese patients.

Conclusion: The current study provides important insight into obesity-related differences among patients diagnosed with cancer. Obese weight status was associated with higher rates of distress and important differences in desire for supportive care, notably among two frequently reported symptoms in the context of cancer, pain and anxiety. These findings can help guide the development and implementation of supportive care services for this 'at-risk' population.

PALLIATIVE CARE AMONG ADULT CANCER SURVIVORS: KNOWLEDGE, ATTITUDES, AND CORRELATES

Julia Stal, BA¹, Mary Baron Nelson, PhD RN CPNP-PC², Carol Ochoa, MPH³, Erin M. Mobley, PhD, MPH¹, Joel Milam, PhD⁴, David Freyer, DO, MS⁵, Kimberly Miller, PhD⁴

¹University of Southern California, Los Angeles, CA; ²Keck School of Medicine of USC, La Canada Flintridge, CA; ³University of Southern California, Los Angeles, CA; ⁴USC, Los Angeles, CA; ⁵Children's Hospital Los Angeles, Los Angeles, CA

Background: Palliative care (PC) can improve quality of life and comfort for patients with serious illnesses such as cancer. The purpose of the present study is to examine cancer survivors' understanding and perception of PC.

Methods: Data were obtained from the Health Information National Trends Survey (HINTS 5, Cycle 2), a nationally representative survey of health-related information. Participants described their knowledge, attitudes, and understanding of the goals of PC. Descriptive statistics were examined; correlates of PC knowledge were identified in a weighted multivariable logistic regression model.

Results: The sample consisted of 593 individuals who reported a personal history of cancer of which, 344 were females (58%) and 246 were males (42%), aged 23 to 97 years ($M/SD = 65.88[18.21]$), with a mean time from diagnosis of 13.83 years ($SD: 18.21$). Sixty-four percent of participants indicated that they have never heard of PC. Of those who had, most strongly agreed that the goals of PC were to manage pain and other physical symptoms (74.5%), offer social and emotional support (64.5%), and help friends and family cope with a patient's illness (52.5%). Only 29.6% strongly agreed that a goal of PC was to give patients more time at the end of life. The majority of participants strongly disagreed with the following statements: "if you accept palliative care, you must stop other treatments," (46.7%); "palliative care is the same as hospice care," (29.1%); and "when I think of 'palliative care', I automatically think of death," (31.6%). In a multivariable model, being female (adjusted odds ratios [AOR] 2.01, 95% CI 1.13-3.57) and seeking cancer information from any source (AOR 1.31, 95% CI 1.04-1.66) were positively associated with knowledge of PC, while being younger than 40 years of age at time of survey (AOR 0.18, 95% CI 0.07-0.45) was negatively associated.

Discussion: These findings indicate low knowledge of PC among cancer survivors who may substantially benefit from this support. Further, while understanding of the purpose of PC is high among those with knowledge, many cancer survivors equate PC with hospice or death. Men, those who do not seek cancer health information, and younger patients were less aware of PC relative to comparison groups. Future research is needed to increase overall knowledge of PC among cancer survivors and to examine potential discrepancies between cancer patients' understanding of and attitudes towards PC services.

POSTTRAUMATIC STRESS-LIKE SYMPTOMS AMONG CANCER CAREGIVERS ACROSS THE ILLNESS TRAJECTORY AND NEUROENDOCRINE HEALTH OUTCOMES

Hannah-Rose Mitchell, MPH¹, Maria Llabre, PhD², Armando J. Mendez, PhD³, Youngmee Kim, PhD⁴

¹VA Palo Alto Healthcare System, Los Altos, CA; ²University of Miami, Department of Psychology, Coral Gables, FL; ³University of Miami, Miami, FL; ⁴University of Miami, Coral Gables, FL

Cancer can be perceived as traumatic to family caregivers, precipitating post-traumatic stress-like symptoms (PTSS). PTSS may be associated with neuroendocrine stress biomarkers, and thus serve as precursor to caregiver-related health decline. The current study examined a measurement model of caregiver PTSS and investigated longitudinally to what extent caregiver PTSS vary and are associated with neuroendocrine biomarkers in the two years post-diagnosis.

Family caregivers (N=155, age $M=49$, 72% female, 33% patient's spouse, 64% Hispanic, 20% income < \$40,000) of newly and recently diagnosed colorectal cancer patients participated in the study. Caregivers completed a psychosocial questionnaire and collected 4 saliva samples on 2 consecutive days at around 3 months post-diagnosis (T1), 11 months post-diagnosis (T2), and 20 months post-diagnosis (T3). Salivary cortisol was assayed and mean waking levels and diurnal slopes were computed. Caregiver age, body mass index, and sleep quality were covariates.

Confirmatory factor analysis (CFA) tested a model with 4 PTSS symptom clusters: three clusters measured by the Impact of Events Scale (hyperarousal, intrusive thoughts, avoidance) and one symptom cluster representing negative alterations in cognitions and mood with select questionnaire items. The 4 factor measurement model revealed adequate fit at T1 ($\chi^2(2)=1.52$ $p=0.45$, RMSEA=0.00, CFI=1.00, SRMR=0.01), T2 ($\chi^2(2)=3.43$ $p=0.18$, RMSEA=0.08, CFI=0.99, SRMR=0.02) and T3 ($\chi^2(2)=2.35$ $p=0.31$, RMSEA=0.04, CFI=0.99, SRMR=0.05). Standardized factor loadings ranged from 0.60 to 0.96 ($ps < .001$). Cross-lagged panel analysis revealed caregiver PTSS were stable across timepoints. Higher PTSS at T2 was concurrently significantly associated with lower waking cortisol levels ($\beta=-3.43$, $p=.02$), and marginally associated with flatter cortisol slope ($\beta=-0.52$, $p=.08$). PTSS at T1 marginally predicted lower waking cortisol levels at T2 ($\beta=-.69$, $p=.06$) and T3 ($\beta=-.21$, $p=.08$).

The 4-factor model of PTSS was psychometrically sound at each timepoint. Caregiver PTSS was stable across the cancer trajectory, which may be due in part to the enduring, persistent nature of cancer-related traumatic exposures. As caregiver PTSS in the first year manifested in dysregulated cortisol levels concurrently and at follow-up, this period may represent a critical time for psychosocial intervention to reduce potential psychophysiological impact of caregiving.

MODERATING EFFECTS OF PHYSICAL ACTIVITY ON THE ASSOCIATIONS OF QUALITY OF LIFE, DISTRESS, AND DYSPNEA IN ADVANCED LUNG CANCER

Reena Chabria, BA¹, Joseph A. Greer, PhD², Jennifer S. Temel, MD³, Kathryn Post, PhD, RN, ANP-BC²¹Massachusetts General Hospital, Boston, MA, MA; ²Massachusetts General Hospital, Boston, MA; ³MGH, Boston, MA

Background: Approximately 50% of patients with advanced lung cancer experience dyspnea symptoms which are associated with significant symptom burden, psychological distress, and poor quality of life (QOL). Existing research suggests that physical activity can improve QOL, distress and fatigue in some cancer populations. In this study, we explored the degree to which physical activity moderates the associations of these key patient-reported outcomes with dyspnea.

Methods: From 5/17/2017 to 10/30/2019, we enrolled 155 patients with incurable lung cancer and at least moderate breathlessness (i.e., Modified Medical Research Council Dyspnea Scale \geq 2) from two centers in Boston, MA in a trial of a behavioral intervention for dyspnea. Prior to randomization, patients completed baseline self-report measures of dyspnea (Cancer Dyspnoea Scale; CDS), QOL (Functional Assessment of Cancer Therapy-Lung; FACT-L), distress (Hospital Anxiety & Depression Scale; HADS), and physical activity status (Godin-Shephard Leisure Time Physical Activity Questionnaire; GSLTPAQ). We conducted moderation analyses of these baseline measures using linear regression with the PROCESS macro in SPSS.

Results: In the sample, worse baseline dyspnea was associated with lower QOL on the FACT-L ($r=-.44$, $p<.001$) and higher levels of distress per the HADS ($r=.42$, $p<.001$). Patient-reported physical activity on the GSLTPAQ significantly moderated the effects of the FACT-L ($B=-0.005$, $p=.046$) and HADS ($B=.013$, $p=.03$) scores on dyspnea symptoms (per the CDS). Specifically, the association of the FACT-L with the CDS became stronger at increasingly higher levels of patient-reported physical activity (Effect at 1 SD below Mean $=-0.15$ versus 1SD above the Mean $=-0.28$). This pattern was similar for the effect of the HADS on CDS scores at different levels of physical activity (Effect at 1 SD below Mean $=0.36$ versus 1SD above the Mean $=0.73$).

Conclusion: While dyspnea is significantly associated with worse QOL and higher distress, these relationships appear to be moderated by level of physical activity, such that the associations are stronger among those who report higher levels of activity. It is possible that engaging in physical activity exacerbates cancer-related dyspnea that may influence QOL and mood. Further research should investigate the relationship between physical activity and dyspnea, and continue to explore methods aimed at improving the patient-reported outcomes of dyspneic patients.

PRELIMINARY ANALYSIS OF PATIENT-CENTERED GOALS IN A CANCER SURVIVORSHIP TELEPHONE-BASED HEALTH COACHING INTERVENTION

Denalee M. O'Malley, PhD¹, Stacy N. Davis, PhD², Mariah Pierce, MPH Candidate², Alice Bator, MPH¹, Brittany Sullivan, MSPH³, Bianca Sanabria, MA¹, Lynn Clemow, PhD¹, Suzanne Miller, PhD⁴, Shawna V. Hudson, PhD⁵¹Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; ²Rutgers School of Public Health, Piscataway, NJ; ³RWJ-Family Medicine and Community Health, New Brunswick, NJ; ⁴Fox Chase Cancer Center/Temple University, Philadelphia, PA; ⁵Rutgers, New Brunswick, NJ

Background: Cancer survivorship self-management involves patient behavioral change to mitigate risks of cancer and its treatments. Health coaching may provide a novel way of increasing self-efficacy of survivors to engage post-treatment self-management to enhance psychosocial adjustment and engagement in regular follow-up visits. This study examines survivors' health coaching (HC) goals and the discussions related to their HC goal progress.

Methods: Survivors of localized (Stage I-III) breast, prostate and colorectal cancers ($n=29$) were recruited from primary care clinics in New Jersey and the New Jersey Cancer Registry to participate in a National Cancer Institute-funded intervention testing mHealth and HC interventions to increase self-management (R01 CA176838). A content analysis of the audio-recorded HC sessions was conducted to explore survivor generated self-management goals and breadth of discussions.

Results: Survivors of breast ($n=15$), colorectal cancer ($n=6$), and prostate cancer ($n=3$) completed the HC intervention. Survivors nominated lifestyle (58%), general health and surveillance (21%), late and long-term effect symptom management (14%) and coping (7%) goals. The most common lifestyle goal among survivors was weight loss/maintenance and increasing physical activity. Goal discussions surrounding late and long-term effects ranged from how to manage fatigue to addressing difficulty with mental tasks. Survivors that generated coping goals focused on managing stress and/or cancer recurrence fears and resuming dating while coping with sexual changes.

Conclusions: Cancer survivors' self-management goals are closely aligned to the care recommendations developed to promote optimal health for longer-term survivorship. Telephone-based HC has translational potential for supporting longer-term cancer survivors' behavioral change and self-management across different care settings.

INTERRELATIONSHIPS BETWEEN HEALTH-RELATED QUALITY OF LIFE AND EXECUTIVE FUNCTIONING AMONG ADULTS WITH BRAIN TUMORS OVER TIME

Tonya Pan-Weisz, Ph.D.¹, Michelle Tibbs, M.A.S.², Minh-Phuong Huynh-Le, M.D.², Vanessa Malcarne, Ph.D.³, Jona Hattangadi-Gluth, M.D.², Carrie McDonald, Ph.D., ABPP-CN²

¹Veterans Affairs San Diego Healthcare System, San Diego, CA; ²University of California, San Diego, La Jolla, CA; ³San Diego State University, San Diego, CA

Brain tumors and the associated treatment sequela are known to negatively impact patients' health-related quality of life (HRQoL) and executive functioning (EF). However, little is known about the associations between HRQoL and EF among adults with brain tumors before and after radiation therapy (RT). As part of a larger study, patients completed a self-report measure of HRQoL and a neurocognitive assessment, including four measures of EF, at four timepoints: pre-RT, three-months post RT, six-months post RT, and 12-months post RT. The four EF measures were combined to recreate an EF composite score, and cross-lagged panel model path analysis was used to examine the interrelationships between HRQoL and EF over time. At baseline, the sample ($N = 53$) included 31 men (58.5%) and 22 women (41.5%) who were primarily non-Hispanic White (81.1%), married (73.6%), and ranged from 20 to 75 years old ($M = 47.04$ years, $SD = 13.9$ years) with an average of 15 years of formal education ($SD = 2.6$ years). Most patients had either a high- or low-grade glioma (43.4% and 17.0%, respectively) and a subtotal resection (54.7%). A cross-lagged panel model with second-order auto-regressive paths, synchronous correlations, and cross-lagged predictor pathways fit the data well descriptively ($CFI = .95$, $RMSEA = .18$, $SRMR = .06$). HRQoL was more stable over time—the means were relatively unchanged across the four time points—compared to EF. HRQoL and EF were moderately, positively correlated ($r_s = .33$ to $.44$, $p_s < .05$) at all of the time points except for three-months post RT ($r = -.08$, $p = .60$). Only one cross-lagged pathway between HRQoL and EF was significant. Specifically, EF at six-months post RT was predictive of HRQoL at 12-months post RT ($\beta = .24$, $p = .049$). This finding suggests that patients' EF six months after RT may impact their HRQoL one-year post-RT completion. Although the mechanisms underlying this relationship remain unclear, it is possible that interventions to improve or preserve EF prior to six-months post RT may facilitate later improvements in HRQoL.

FEASIBILITY TRIAL OF TARGETED PAIN COPING SKILLS TRAINING FOR PERSISTENT PAIN AFTER BREAST CANCER SURGERY

Sarah S. Arthur, MA¹, Dana H. Bovbjerg, PhD², Francis J. Keefe, PhD³, Gretchen Kimmick, MD, MS⁴, Linda M. Sutton, MD³, Lynda Owen, PhD, CCRP⁵, Eun-Sil S. Hwang, MD, MPH¹, Kelvin B. Raybon, MD, FACP⁶, Jessica N. Coleman, BA³, Rebecca A. Shelby, PhD³

¹Duke University Medical Center, Durham, NC; ²University of Pittsburgh, Pittsburgh, PA; ³Duke University, Durham, NC; ⁴Duke University Medical Center / Duke Cancer Institute, Durham, NC; ⁵Duke Cancer Network, Durham, NC; ⁶Augusta Health, Fishersville, VA

Although surgery is an important part of curative treatment for breast cancer, persistent breast pain (PBP) following surgical removal of the tumor (lumpectomy or mastectomy) is not unusual, with prevalences ranging from 25-60%. The goal of the current study was to conduct a pilot randomized controlled trial to evaluate the feasibility and benefits of a targeted pain coping skills training (PCST) intervention developed for women with PBP following breast cancer surgery.

The primary aims of the study were to: 1) examine the feasibility, acceptability, and engagement in the targeted PCST protocol, and 2) examine the impact of the targeted PCST protocol on PBP in comparison to the usual care condition.

Breast cancer survivors with PBP ($n=26$) were recruited from a tertiary care medical center and a community clinic located in a medically underserved area. They met the following criteria: Stage 0 to III breast cancer; first breast surgery within the previous 9 months; average breast pain ≥ 3 out of 10 prior to enrollment. Participants were given printed health education materials and randomly assigned to receive either: 1) Targeted-PCST, or 2) usual care. Participants in the Targeted-PCST intervention completed 8 weekly sessions via telephone and were given an accompanying intervention workbook.

The study participation rate was 43% and the study retention rate was 81%. Engagement in Targeted-PCST sessions was high, with 92% of women completing all intervention sessions. Women reported that they were satisfied with the intervention ($M=5.0$; 1 to 5 scale). The Targeted-PCST group had significant decreases in pain severity and interference (PEG score) ($p=.04$, $d=-.82$) and in depressive symptoms ($p=.001$, $d=-.52$) compared to the usual care group. While the effect sizes for decreases in anxious symptoms and cancer-specific distress were moderate ($d=-.42$ and $d=-.45$, respectively), differences between groups were not statistically significant ($p_s \geq .17$). The Targeted-PCST group experienced significant decreases in pain catastrophizing ($p=.01$, $d=-.70$) and showed a trend for increases in self-efficacy ($p=.08$, $d=1.21$) compared to the usual care group.

This pilot study provides evidence of the feasibility and benefits of Targeted-PCST for breast cancer survivors. These findings provide strong support for future research to examine generalizability to other clinical settings and to explore the roles of catastrophizing and self-efficacy as mediators of beneficial effects.

6:15 PM-7:30 PM

FINANCIAL TOXICITY RELATES TO GREATER DISTRESS AND WORSE QUALITY OF LIFE AMONG BREAST AND GYNECOLOGIC CANCER SURVIVORS

Catherine Benedict, PhD¹, Sophie Fisher, BS², Lidia Schapira, MD², Sabrina Chao, n/a², Sarah Sackeyfio, n/a³, Tara Sullivan, n/a¹, Oxana Palesh, PhD, MPH²

¹Stanford University School of Medicine, Palo Alto, CA; ²Stanford University, Stanford, CA; ³Stanfordpassword1, Palo Alto, CA

Background: Cancer patients are increasingly faced with high costs and financial problems resulting from treatment and cost-sharing policies (e.g., higher deductibles, out-of-pocket expenses). “Financial toxicity” (FT) refers to distress and burden of treatment costs. Predictors and correlates of FT are not well understood.

Objectives: Preliminary analyses of a larger survey study evaluated: 1) patient factors related to FT and 2) associations between FT, distress, and quality of life (QOL).

Methods: Breast and gynecologic cancer patients completed a survey about cancer needs and concerns including FT (Comprehensive Score for financial Toxicity [COST]), distress (Patient Health Questionnaire [PHQ-4]), and QOL (Functional Assessment of Cancer Therapy [FACT-G]). Analyses included chi-square, t-tests, and ANOVAs. Separate regression models tested associations between FT and distress and QOL, controlling for covariates.

Results: Participants (N=220; 77% breast cancer) averaged 55.0 years old (SD=12.1), 3.5 years (SD=4.3) post-diagnosis, were racially/ethnically diverse (65% White, 26% Asian, 10% “Other,” i.e., Black, Native American, and Hawaiian/Pacific Islander; 13% Hispanic), and mostly partnered (72%) with private insurance (66%). A large proportion of women reported some FT (M=18.1, SD=11.2; range 0-44); 45% worried about financial problems as a result of cancer and 20% reported financial hardship due to cancer (“quite a bit/very much”). Greater FT was reported by women who identified as a non-Asian minority (“Other” vs. Whites and Asians, $p=.001$), Hispanic (vs. non-Hispanic, $p=.004$), and single (vs. partnered, $p=.03$), and those with lower education ($p<.001$) and income ($p<.001$). No differences in age, cancer type, treatment status, or insurance type were observed (p 's $>.10$). In separate models, greater FT related to greater distress ($B=.49$, $p<.001$) and worse QOL ($B=-.60$, $p<.001$), controlling for age, racial/ethnic identity, partnership status, education, income, time since diagnosis, and treatment status. In each model, FT accounted for 17.4% and 29.5% of the variance in distress and QOL, respectively, after accounting for covariates.

Conclusions: Cancer-related financial burden may impact patient subgroups disproportionately, particularly minorities and single women, with pervasive negative effects. Future research should explore ways to better prepare and support patients such as providing better education about treatment costs and financial counseling.

6:15 PM-7:30 PM

INTERSECTIONALITY AND THE QUALITY OF PATIENT-PROVIDER COMMUNICATION IN CANCER CARE

Alma M. Torres-Estrada, MPH¹, VERONICA L. IRVIN, Ph.D., MPH², Sunil K. Khanna, PhD³, Marie Harvey, DrPH, MPH², Cynthia M. Mojica, PhD², Daniel Fernando López-Cevallos, PhD, MPH²

¹Oregon State University, Albany, OR; ²Oregon State University, Corvallis, OR; ³Oregon State University, Corvallis, OR 97331, OR

Communication between patient and providers is aimed to create a good interpersonal relationship, to facilitate the exchange of information, and to include patients in decision making. When individuals engage in discussions with their doctors, they will bring with them their social identity, which might include attitudes and values, age, education, race, ethnicity, gender. Each social identity can represent a lower or higher influence of power. Intersectionality is the idea that multiple dimensions of social identity may increase the probabilities to produce inequalities as a result of underlying power structures (e.g., Foreign-born Latinas may experience higher inequality than U.S. born NHW females). The purpose of this study is to determine the association between the quality of patient-provider communication and the interaction of social identities (ethnicity, gender, and nativity) among adults with cancer. Data from the Health Information National Trends Survey (HINTS) will be analyzed for six iterations collected from 2011 to 2018. HINTS data's primary purpose is to collect information about cancer-related health communication access, usage, and practices. The HINTS target population is adults aged 18 or older in the civilian non-institutionalized population of the United States. For this analysis, we restrict our sample to those diagnosed with cancer $n=3125$. Perceived Patient-Provider Communication Quality (PPPCQ) is a seven-item scale to measure the patient's perception of the quality of communication with their health care providers with higher scores representing higher perceived quality of the communication. The HINTS protocol defines “provider” as any doctor, nurse, or other health care professional seen within the past 12 months. Three social identities will assess intersectionality: 1) race/ethnicity (Hispanics, Non-Hispanic White, and Non-Hispanic Black), 2) gender, and 3) nativity (the U.S. and foreign-born). Multivariate models will regress PPCQ and social identity variables. Intersectionality will be analyzed as interactions of the social identity variables.

Results: Descriptive analysis of the social identity of the sample include: 1) 33% racial and ethnic minority (7.5% Hispanics, 8.9% Non-Hispanic Black, and 67% Non-Hispanic White), 2) 58% female, and 3) 8% foreign-born. 42.6% of the sample report at least one social identity with a lower structure of power (racial-ethnic minority, female or foreign-born), 13.6% of the sample report 2, and 3% report three social identities with lower structure of power. The PPCQ had a mean of 84.7 (SD = 16.9).

PATIENT EXPECTATIONS AS MODERATORS OF BREAST CANCER SURVIVORS' RESPONSE TO GROUP PSYCHOSOCIAL INTERVENTIONS

Malwina Tuman, Doctoral Candidate¹, Taylor Coats, MA¹, Kailey Roberts, PhD¹, Elizabeth A. Schofield, MPH², Elizabeth Slivjak, BA³, Greta Jankauskaite, BA⁴, Wendy G. Lichtenthal, PhD¹

¹Memorial Sloan Kettering Cancer Center, New York, NY; ²Memorial Sloan-Kettering Cancer Center, New York, NY; ³University of Colorado Boulder, Boulder, CO; ⁴University of Maryland, College Park, MD

Patient expectations are viewed as a powerful determinant of treatment response across psychosocial interventions, such that positive expectations about how effective treatment will be are generally related to greater therapeutic gains. Despite this evidence, expectations are often not considered when evaluating the efficacy of psychosocial intervention trials. The purpose of this study was to examine the impact of patient expectations on outcomes of an American Cancer Society-funded pilot randomized controlled trial comparing Meaning-Centered Group Psychotherapy for Breast Cancer Survivors (MCGP-BCS) to a standardized support group (SG), both delivered virtually.

BCS ($n=59$) with elevated distress were randomly assigned to eight 90-minute sessions of either MCGP-BCS or SG. BCS' treatment expectations were measured at baseline using the Credibility and Expectancy Questionnaire (CEQ). To examine the influence of expectations on meaning-related outcomes (i.e., Functional Assessment of Chronic Illness Therapy-Spiritual Well-Being Scale [FACIT-Sp] and Posttraumatic Growth Inventory [PTGI]) assessed at baseline, post-intervention, and three months post-intervention, generalized estimating equation analyses were conducted to examine treatment effects controlling for expectations.

Significant Time \times Condition interaction effects were observed for spiritual well-being when controlling for expectations. Specifically, compared with their baseline scores (Total FACIT-Sp $M=24.43$, $SE=1.49$ for MCGP-BCS; $M=26.40$; $SE=1.91$ for SG), participants in MCGP experienced a greater increase in spiritual well-being post-intervention ($M=31.81$, $SE=1.56$ versus $M=29.56$, $SE=2.09$; $p=.048$), which was sustained at follow-up ($M=31.70$, $SE=1.76$ for MCGP-BCS versus $M=26.89$, $SE=1.86$ for SG; $p=.005$). Further, there was a significant Time \times Condition \times Expectations interaction effect ($p=.045$) on PTGI scores such that individuals in MCGP-BCS with high expectations experienced greater improvement in posttraumatic growth between baseline and follow-up compared to individuals with lower baseline expectations. In the SG, lower expectations at baseline were associated with increases in posttraumatic growth at follow-up whereas higher baseline expectations were not.

These findings indicate patient expectations can have impact on therapeutic outcomes, suggesting expectations should be routinely measured in intervention trials and might be modulated in ways that maximize treatment outcomes.

DO SOCIAL SUPPORT AND INFLAMMATION PREDICT PROGNOSIS IN PATIENTS WITH ACUTE CORONARY SYNDROMES?

Tiffany Ju, BA¹, Jonathan Shaffer, PhD¹, Kevin Masters, PhD¹, Karina Davidson, PhD, MASc²

¹University of Colorado Denver, Denver, CO; ²Feinstein Institute for Medical Research, Northwell Health, New York, NY

Background: Low perceived social support is associated with poor cardiac outcomes and higher all-cause mortality (ACM) in patients with acute coronary syndromes (ACS). This relationship may be mediated by immune function. Moreover, sex may moderate the social support-cardiac outcomes association.

Aims: To determine if: 1) social support predicts time to ACM and major adverse cardiac events (MACE), 2) peripheral inflammation, measured by C-reactive protein (CRP), mediates the relationship between social support and MACE/ACM, 3) sex moderates the aforementioned relationships.

Methods: 250 ACS patients (73% male) were drawn from 1,087 participants in the Prescription Use, Lifestyle, and Stress Evaluation (PULSE), a prospective, observational study of patients hospitalized after an ACS, based on complete data on all variables. Selected patients ($M=61.3$ yrs, $SD=10.3$) were younger compared to the overall sample [$M=64.7$, $SD=11.8$; $t(1085)=-4.1$, $p<0.05$], more likely to be African-American (20.6% vs. 18.6%), and less likely to be white [60.9% vs. 64.9%; $X^2(6, N=1078)=12.6$, $p<0.05$]. Patients completed the ENRICH Social Support Instrument (ESSI) at baseline (max score=30). Serum CRP was collected at baseline and one-month follow-up. The first recurrence of a MACE [i.e., hospitalization for nonfatal MI, unstable angina (UA)], or urgent coronary revascularization] and ACM were ascertained through 12 months and adjudicated by two cardiologists. Multiple regression and Cox proportional hazards survival analysis were conducted.

Results: 23.3% of the sample experienced a MACE/ACM. Social support ($M=25.9$; $SD=4.9$) was not significantly associated with MACE/ACM in adjusted analysis ($HR=1.0$; $CI, 0.8-1.3$; $p=0.84$) with covariates including age, education, BMI, medical comorbidities, and depression. Social support did not significantly predict CRP levels at one-month ($R^2=0.2$, $\beta=0.02$, $p=0.56$). Though women (6.0 mg/l) had significantly higher levels of CRP at one-month than men (3.0 mg/l), sex was not a significant moderator of social support and CRP ($R^2=0.2$, $\beta=-0.01$, $p=0.36$).

Conclusions: Contrary to our hypothesis, social support did not predict MACE/ACM in ACS patients. The findings of this study add to the literature underscoring the complexities of social support in health outcomes. Similar to the ENRICH trial, the overall high levels of social support reported in this sample may have made it difficult to detect the effect of social support on cardiac and mortality outcomes.

IMPACT OF SMARTPHONE BREATHING MEDITATION UPON SYSTOLIC BLOOD PRESSURE AMONG PRE-HYPERTENSIVE ADULTS.

Jessica Chandler, PhD¹, Luke Sox, B.S.¹, Alison Neely, HS¹, Lauren I. Feder, B.S.¹, Kinsey N. Kellam, Bachelor of Arts, Biology¹, Samantha T. Pairet, B.S.², John Sieverdes, PhD³, Frank Treiber, PhD¹

¹Medical University of South Carolina, Charleston, SC; ²Medical University of South Carolina, Mount Pleasant, SC; ³College of Charleston, Charleston, SC

Background: Pre-hypertension (HTN), a primary risk factor for HTN, affects ~33% of adults. Chronic stress is a risk factor for HTN and CVD. A previous 6-month dose-response trial using the breathing meditation smartphone app, Tension Tamer (TT), suggested combination of dosage levels over time might have the greatest influence upon sustained adherence and systolic blood pressure (SBP) reduction among SBP pre-hypertensive adults. The TT app, compatible on both iOS and Android platforms, uses audio/video clip instructions and proprietary embedded, validated reflective photoplethysmography software that captures continuous real-time heart rate from a user's fingertip placed over camera lens during meditation sessions. Users receive immediate feedback graphs after each session showing their changes in heart rate. They also receive motivational/social reinforcement SMS text messages based upon previous day's levels of adherence. We conducted a two-arm 12-month small-scale efficacy RCT among pre-HTN adults with primary outcome of resting SBP changes.

Methods: Eighty adults (mean age: 42.8 yrs; 39 males; 43 White; 37 Black) with verified JNC8 defined pre-HTN on 3 consecutive sessions (mean SBP: 128.3 mmHg; 95% recruitment rate) were randomly assigned to TT or healthy lifestyle attention control groups. Each group received the same twice-daily dosage schedule (month 1: 15 min, months 2-3: 10 min; months 4-12: 5min).

Results: Mixed modeling results revealed a significant group x time effect for SBP ($p < .01$). Post hoc analyses indicated the TT group showed greater SBP reductions at months 3: -9.2 vs -2.8, 6: -9.2 vs -1.6 and 12: -10.7 vs -2.8 mmHg (all $ps < .01$). Average adherence across the 12 months was higher in the TT group: month 1: 75.0% vs 62.4%, month 3: 75.3% vs 56.9%; month 6: 72.9% vs 48.6%; and month 12: 62.9% vs 43.2% (all $ps < .01$).

Conclusion: The TT app is acceptable, sustainable and shows promise in reducing SBP in adults with pre-HTN. Preparations are underway for a large-scale efficacy RCT.

A COMMUNITY-BASED DIETARY INTERVENTION TO REDUCE CARDIOVASCULAR DISEASE RISK FACTORS IN A LOW INCOME, MINORITY POPULATION

Aisha H. Montgomery, MD, MPH¹, Abdullah A. Mamun, PhD¹, Heather Kitzman, PhD¹, Donald E. Wesson, MD, MBA¹

¹Baylor Scott & White Health, Dallas, TX

Introduction: The disparity of cardiovascular disease (CVD) in underserved, low-income and ethnic minority communities has been well documented. Low-income populations experience higher rates of CVD-related complications, emergency room visits, in-patient hospitalizations, and mortality when compared to other groups. Confounding socio-economic factors include less access to primary care and higher uninsured rates.

Methods: The "Fruit and Veggies for Kidney Health" study was designed to improve chronic kidney disease (CKD) outcomes and reduce CVD risk in a primarily low-income, African American (AA) population by providing access to base-producing fresh fruits and vegetables (F & V) in a South Dallas food desert. We conducted participant recruitment and screening at various local churches and community health fairs. All participant visits occurred at the Baylor Scott & White Health and Wellness Center, a research and population health entity of Baylor Scott & White Health. Participants were enrolled and randomized to one of two study arms: free F & V for 6 weeks (F & V only) or free F & V with educational cooking and nutrition class for 6 weeks (F & V + Cook). Participants ($n=97$) were 100% AA, aged 55.2 ± 11.7 years, and 46.8% low-income ($< \$25,000$).

Results: At baseline, participants had BMI 34.9 ± 8.4 kg/m², 62.9% had high blood pressure (SBP ≥ 130 or DBP ≥ 80) and 28.9% had diabetes (HbA1c $\geq 6.5\%$). 87% of participants completed at least 5 scheduled visits within 6 weeks. Average post intervention (6-weeks from baseline) vs. baseline intake was higher for both fruits (whole or cut fruit, except juice) (3.0 ± 2.8 vs. 1.6 ± 2.1 cups/day, $p < 0.0001$) and vegetables (5.2 ± 3.5 vs. 3.7 ± 2.9 , $p < 0.01$). Pre/post analyses showed reductions in systolic blood pressure of 4.1 ± 15.1 ($p = 0.02$) and HbA1c by $0.26 \pm 0.70\%$ ($p < 0.01$) among participants. These preliminary data showed no statistically significant changes in body mass index or diastolic blood pressure, however the study is ongoing.

Discussion: The "Fruit and Veggies for Kidney Health" study employs an innovative approach to screening by leveraging trusted community-based institutions and employs an innovative intervention of F&V that is directly accessible to community residents to reduce CVD risk factors and thereby reduce health disparities and possibly improve CKD and CVD outcomes within low-income, ethnic minority groups at a population level. Furthermore, the study may lead to development of cost-effective models to reduce the healthcare burden of CKD and CVD in the community.

REAPPRAISAL PREDICTS GREATER RESPIRATORY SINUS ARRHYTHMIA AMONG BEREAVED ADULTS

Roman Palitsky, MA, MDiv¹, John M. Ruiz, University of Arizona², Sydney Friedman, B.S. Psychology², Da'Mere T. Wilson, B.A.², Laura Kassmann, MFA³, Daniel Sullivan, PhD², Mary-Frances O'Connor, PhD²

¹Brown University, University of Arizona, Providence, RI; ²University of Arizona, Tucson, AZ; ³University of Arizona, Tucson, AZ

Bereaved adults experience heightened cardiovascular risk during a time when they must cope with the profound stressor of their loss. Greater cardiac vagal control, indexed by higher respiratory sinus arrhythmia (RSA), is associated with better cardiovascular health on one hand, and with adaptive coping and emotion regulation on the other. Greater use of reappraisal, an emotion regulation strategy that involves changing how one thinks about a situation in order to regulate emotion—has been linked higher RSA in diverse populations. We anticipated we would find a positive relationship between RSA and reappraisal among bereaved adults. We examined preliminary data from the Emotion Regulation Diary Study. For this study, adults within the first year of bereavement of a family member or close loved one were recruited in a mid-sized Southwestern city. Participants completed a set of initial questionnaires prior to completing a 14-day daily diary, and then returned for collection of cardiovascular data including ECG during an emotion elicitation protocol. Data from the first 41 bereaved adults to complete the study ($M = 67$, $SD = 14.51$) was analyzed. Reappraisal was derived from the Emotion Regulation Questionnaire (ERQ), a 10-item Likert scale (1 = strongly disagree, 7 = strongly agree) that queries reappraisal and suppression strategies, among the initial survey measures. Resting RSA was collected via ECG approximately 14 days later, during a 10 minute resting baseline. Frequency domain analyses were used in Mindware 3.2 software to derive log-transformed HF/RSA. Regression analyses found that higher reappraisal scores predicted greater RSA, adjusting for age, emotional suppression, and bereavement symptom severity ($B = .55$, $SE = .25$, $p = .037$). Although these results do not establish a causal link, they provide evidence that emotion regulation strategies may play a role in the cardiovascular health of bereaved people. Accordingly, emotion regulation is an appropriate target for bereavement research, and may inform health interventions that can reduce risk of morbidity and mortality among bereaved people.

PATIENT PERCEPTIONS OF CHF AND BARRIERS TO PHYSICAL ACTIVITY: FEASIBILITY TESTING OF A CUSTOMIZABLE PA INTERVENTION

Carly Grant, BS, M2¹, Christa Wamsley, BS², Nunzio Gaglianello, MD¹, Ann Swartz, PhD³, Sandile Nukuna, MS¹, David Nelson, PhD¹, Sergey Tarima, PhD¹, Edith Burns, MD⁴

¹Medical College of Wisconsin, Milwaukee, WI; ²UW-M, Milwaukee, WI;

³University of Wisconsin-Milwaukee, Milwaukee, WI; ⁴Zucker School of Medicine at Hofstra-Northwell, Manhasset, NY

Introduction: Congestive Heart Failure (CHF) is a common and debilitating condition. It afflicts nearly 6.5 million adults in the US and about half die within 5 years of diagnosis. Physical activity (PA) of both light and moderate-vigorous intensity reduces risk of hospitalization and mortality. Despite this, fewer than 10% of patients achieve currently recommended goals. Barriers to PA may include anticipated symptoms, fear these indicate worsening of heart function, and perception that developing a vigorous routine is an insurmountable task. The goal of the present project is to develop an intervention assisting patients to more accurately interpret PA-related symptoms, set achievable and progressive goals for increasing PA, and provide objective feedback on progress to optimize long-term maintenance.

Methods: The prototype pilot intervention is based upon a revised "Move More Sit Less" toolkit, integrated symptom assessment log, Fitbit device for tracking activity and sleep, and related Smartphone application. Participants are contacted weekly to set step goals, document intensity/severity of symptoms, and report issues/concerns. All data is collected and stored in REDCap.

Results: Three participants aged 41, 51, and 69 (2 men and 1 woman) with average CHF ACC/AHA Stage C were recruited from the Heart and Vascular Clinic at a tertiary academic medical center to test the intervention process and provide detailed feedback. Participants had an average of 3 comorbidities, and took a range of 11 - 28 medications daily. Each participant identified a primary symptom of concern (i.e. fatigue, shortness of breath, chest pain). Baseline step values averaged 5 to 10 thousand per day and increased throughout the 4-week feasibility trial. All participants consistently wore the Fitbit and successfully tracked daily symptom experience. The greatest difficulty was initially downloading and syncing the Fitbit and Smartphone applications. All three pilot participants have been rolled over into a three-month intervention.

Conclusion: This project demonstrated feasibility of using a publicly available PA toolkit integrated with symptom assessment and objective tracking and feedback on PA for engaging CHF patients in active behavior change. Patients expressed increased awareness of sedentary behavior and symptom management while giving insight for future improvements. A 3-month intervention with 30 participants is currently underway.

MULTIDISCIPLINARY IMPLEMENTATION OF A POPULATION HEALTH MANAGEMENT INTERVENTION FOR CARDIOVASCULAR DISEASE RISK FACTORS

Karen Goldstein, MD MSPH¹, Allison A. Lewinski, PhD MPH RN², Hayden B. Bosworth, PhD³, Jennifer M. Gierisch, PhD, MPH⁴, Courtney White-Clark, MS⁵, Felicia McCant, MSSW⁶, Leah Zullig, PhD¹

¹Durham VA HSRD, Durham, NC; ²Durham Center of Innovation to Accelerate Discovery and Practice Transformation, Durham Veterans Affairs Health Care System, Durham, NC; ³Duke University, Durham, NC; ⁴Duke School of Medicine Department of Population Health Sciences and Durham VA ADAPT, Durham, NC; ⁵Durham VA HSRD, Durham, OK; ⁶Durham VA HSR&D, Durham, NC

Background: Implementing population-level interventions within a healthcare system requires longitudinal stakeholder involvement and multidisciplinary expertise. We sought to improve cardiovascular disease (CVD) risk among rural Veterans via an intervention addressing multi-level barriers including provider (competing demands), patient (risk awareness), and system (under-empowered teams). We describe a multidisciplinary team approach to intervention adaptation and implementation informed by structured consultation with key stakeholders.

Methods: Our team included a: behavioralist, clinical interventionist, primary care physician, implementation scientist, nurse scientist, project coordinators, and a clinical nurse. We developed an intervention to: 1) identify patients with uncontrolled blood pressure and/or with hyperlipidemia but not on statin therapy; 2) activate patients via personalized letters; 3) identify behavioral goals guided by patient preferences; and, 4) communicate patient goals and suggested CVD risk reduction plan to primary care. Stakeholder engagement activities included: input from existing CVD programs, feedback from Veterans Research Engagement Panel, and clinic-level debriefings. Our biweekly intervention debriefs were guided by the Stirman Adaptation Framework.

Findings: To date, 100 patients received activation letters. Of that number our population health manager was able to speak with 69; 38/46 Veterans kept scheduled appointments with their providers after receiving the intervention, and 33/54 Veterans that did not have a scheduled appointment with a provider made one. Notably, after the intervention, 54/100 Veterans initiated contact with a healthcare provider (ie, primary care physician or specialist) to have their blood pressure checked, medications modified, or obtain a referral for another provider or service (e.g., weight loss, smoking cessation). In addition, we identified critical adaptations to facilitate uptake within VA clinical practice including message tailoring, timing of activation letters, and alignment with ongoing primary care practices.

Conclusions: A collaborative team of multidisciplinary researchers can inform intervention adaptation, build stakeholder buy-in, and facilitate the development of a sustainable intervention within a clinical practice setting. The VA is an ideal venue for team-based implementation science and real-time adaptation of population-level interventions. Our project lays an important foundation for developing rigorous and relevant interventions that will assure that rural Veterans have access to effective, context-appropriate CVD risk management options.

A SYSTEMATIC REVIEW OF PSYCHOSOCIAL CORRELATES OF PAIN IN PEDIATRIC INFLAMMATORY BOWEL DISEASE

Lexa K. Murphy, PhD¹, Rocio de la Vega, PhD², Rona L. Levy, PhD³, Tonya M. Palermo, PhD⁴

¹Seattle Children's Research Institute, Seattle, WA; ²Seattle Children's Research Institute, Seattle, WA; ³School of Social Work, University of Washington, Seattle, WA; ⁴University of Washington School of Medicine; Seattle Children's Research Institute, Seattle, WA

Background: Pain is a common symptom in pediatric inflammatory bowel disease (IBD) and is associated with poor psychological and disease outcomes and increased healthcare use. Pain in pediatric IBD has traditionally been attributed to disease activity, yet there is emerging evidence in adults that psychosocial correlates are stronger predictors of pain. This study aims to review the evidence for psychosocial correlates of pain in pediatric IBD within a developmental framework (child, parent, and family-level correlates of pain) to identify gaps in knowledge and inform future research.

Methods: A systematic review was conducted using a comprehensive search (MEDLINE, Embase, PsycINFO). Inclusion criteria was 1) pediatric samples (< 19 years) with an IBD diagnosis; 2) associations between pain (intensity/severity or impact) and a psychosocial factor (individual, parent, family-level). N=2643 records were identified; N=11 met inclusion (20% abstracts double coded, 98% agreement). A narrative review was conducted. Quality was assessed via the NIH Quality Assessment Tool.

Results: Regarding child-level psychosocial correlates of pain, N=6 studies found significant associations between internalizing symptoms (anxiety and depression) and pain (small-large correlation magnitudes). N=2 studies found significant associations between catastrophizing and pain (small-large correlations). N=1 study each found a significant association between worry pain, and pain beliefs and pain. N=1 study found no significant association between active coping and pain. Regarding parent-level psychosocial correlates of child pain, one of two studies found a significant association between parent catastrophizing and pain. N=1 study examined parent stress and coping and found no significant associations with child pain. N=1 study examined parent protective responses and catastrophizing and found no significant associations with child pain. All associations were in the positive direction. No studies examined family-level factors (e.g., family stress, communication). Included studies were all cross-sectional; overall study quality was moderate.

Conclusions: Psychosocial factors are associated with pain in pediatric IBD, with the strongest evidence for an association between pain and child anxiety/depression symptoms and catastrophizing. Future studies are needed to more comprehensively measure pain and to examine parent-level and family-level factors.

PERCEIVED PARENTAL INFLUENCE ON HEALTH BEHAVIORS IN LATINO ADOLESCENTS

Erica Soltero, PhD¹, Neeku Navabi, n/a², Gabriel Shaibi, PhD³¹Baylor College of Medicine, Houston, TX; ²Arizona State University, Phoenix, AZ; ³Center for Health Promotion and Disease Prevention, Phoenix, AZ

Background: Family-level factors such as parenting practices and parental support represent key social determinants of health for youth; however, more research examining family dynamics is needed to better understand familial influences on obesity-related health behaviors in adolescents. The purpose of this study was to examine qualitative narratives from Latino youth with obesity, to examine patterns of parental social support for healthy behaviors.

Methods: Latino adolescents (girls=8; boys=8; age=14.4±1.5) with obesity (BMI%=98.8±0.9) completed an in-depth interview of 10 semi-structured questions. Two coders used a constant comparison approach to capture emergent themes on parental influences on health behaviors including physical activity and diet.

Results: Youth reported living in parental households consisting of two parents (*N*=10), blended families (*N*=1), separated parents (*N*=2), or female headed household (*N*=3). The majority of youth (88%) described mom as a positive influence on health behaviors, reporting that mom typically provides healthy foods and motivation for physical activity. Moms were identified as the primary source of instrumental (31%) and emotional support (31%), with fewer reports (13%) of informational support for health behaviors. Just over half of participants (56%) described dad as a positive influence on health behaviors. Dads were frequently described as working long hours, too busy to play, or too tired. Dads primarily provided instrumental support (19%), with no reports of dads providing emotional support and few reports of dads providing informational support (13%). Five participants (all girls) described their dad as a negative influence on health behaviors. Some youth reported that instrumental (19%) and informational (6%) support was equally received from both parents; however, emotional support from both parents was not reported.

Conclusion: Consistent with cultural norms and values, moms were viewed as primary sources of support and resources to support health behaviors, whereas dads were less likely to be described as supportive and in a sub-sample of girls may even undermine health behaviors. Strategies that leverage parental roles and equip Latino parents with skills to support health behaviors are needed to address disparities in high-risk Latino youth

OBESITY AND EATING DISORDER DISPARITIES AMONG SEXUAL AND GENDER MINORITY YOUTH: FINDINGS FROM THE ABCD STUDY

Natasha A. Schvey, PhD¹, Arielle Pearlman, B.A.¹, Mikela A. Murphy, BA², Joshua C. Gray, PhD¹¹Uniformed Services University, Bethesda, MD; ²The Uniformed Services University of the Health Sciences, Baltimore, MD

Background: Sexual and gender minority (SGM) youth may be at increased risk for eating and weight disorders compared to non-SGM youth. Though many youth identify as gay or gender non-conforming in childhood, the majority of studies assess older adolescents and rely on self-reported height and weight. Determining whether health disparities emerge prior to adolescence may have important implications for prevention. The current study, therefore, utilized data from the Adolescent Brain and Cognitive Development (ABCD) study to compare the prevalence of obesity and eating disorders among SGM and non-SGM youth.

Methods: Children underwent an in-person assessment including measured height and weight and self-report questions about sexual orientation and gender identity. The KSADS was administered to assess both sub- and full-threshold eating disorders. Logistic regressions, adjusting for sex assigned at birth, age, race, and family income were conducted to test for differences in obesity status and eating disorder presence among SGM youth versus non-SGM youth.

Results: The study comprised 4,448 participants (*Age*: 10.0y; *MBMI*%ile: 59.84; 47.3% female; 57.8% nonHispanic white), of whom 58 (1.3%) were probable sexual (*n* = 42) and/or gender (*n* = 23) minorities. The prevalence of obesity among SGM and non-SGM youth was 25.9% and 15.1%, respectively. Adjusting for covariates, SGM youth were significantly more likely to have obesity compared to their non-SGM peers (OR: 2.69, *p* = .002). More specifically, SGM females were 2.65 times more likely to have obesity compared to non-SGM females and SGM males were 2.87 times more likely to have obesity than non-SGM males (*ps* < .038). SGM youth were not significantly more likely to have an eating disorder as compared to non-SGM youth (12.1% and 10.3%, respectively). However, SGM males were significantly more likely to have an eating disorder compared to non-SGM males (OR: 5.23, *p* = .004).

Conclusion: Results indicate that SGM youth are significantly more likely to have obesity compared to their non-SGM peers, and that SGM males are significantly more likely to have an eating disorder as compared to non-SGM males. This study indicates that weight and eating disorder disparities in SGM youth may begin in childhood. Research is needed to elucidate the mechanisms that contribute to health disparities in this population.

SOCIAL MEDIA USE AND THE PSYCHOLOGICAL WELL-BEING OF SCHOOL AGED CHILDREN

Julia M. Snell, n/a¹, Emilee Bradley, n/a², Ashley Oakley, n/a¹, Emma L. Monnin, n/a¹, Madison Schloemer, n/a², Emma Studer, n/a³, Allison Kiefner-Burmeister, PhD²

¹University of Findlay, Findlay, OH; ²The University of Findlay, Findlay, OH; ³The University of Findlay, Bloomville, OH

Heavy use of social media has been shown to negatively impact children's body image, self-esteem, and overall psychological well-being (Richards, Caldwell & Go, 2015; Ahadzadeh, Ong, & Sharif, 2016). The current study investigated the relationship between social media use, body image, and anxiety with school age children. Further, social media use was investigated via parent-report and directly from children's cell phones. This study is the first to compare actual and perceived child social media use.

A total of 102 participants between 8 and 17 years old ($M = 14.09$ $SD = 1.86$) participated in this study. The sample was 82% White, and 53% female. Participants responded to paper and pencil questionnaires evaluating their media influence, body image, and anxiety in addition to having their cell phone system settings examined for actual time spent on social media in hours.

Pearson's Correlations and t-tests were conducted to examine perceived and actual media use. While parent-reported time for self and child time on social media related ($r = .573$, $p = .000$), parents drastically over-reported their child's time spent on social media with parent reported child use in hours per week ($M = 21.04$, $SD = 17.35$) and child actual use by the phone recording ($M = 14.46$, $SD = 10.65$) differing significantly ($t(63) = 2.27$, $p = .012$). These results suggest that parents are not aware of how much time their child actually spends on social media.

There were also relationships found for child social media use recorded by phone and psychological variables. Social media use was positively related to media internalization ($r = .288$, $p = .018$) and media pressure ($r = .254$, $p = .038$), but was not related to anxiety ($r = -.157$, $p = .197$).

Further, an independent samples t-test was conducted to compare the difference in participant gender in response to their awareness of how much the media influences their body image. A difference was seen between how the two genders feel aware of media's influence ($t(96) = 2.41$, $p = .018$), such that males were higher ($M = 2.11$, $SD = 0.61$) than females ($M = 1.81$, $SD = .60$). These results suggest that a child's gender and subsequent gender norms may influence the way they process media and how much awareness they have of the way that media impacts their body image perceptions.

PARENT NATIVITY AND CHILD ASTHMA CONTROL IN MEXICAN-AMERICAN FAMILIES: A PSYCHOSOCIAL PERSPECTIVE

Kimberly Orozco, BA¹, Oksana Pugach, PhD², Genesis Rosales, MSW², Nattanit Songthangtham, MPH², Molly Martin, MD³, Sally Weinstein, PhD³

¹University of Illinois College of Medicine at Chicago, Chicago, IL; ²Institute for Health Research and Policy of the University of Illinois at Chicago, Chicago, IL; ³University of Illinois at Chicago, Chicago, IL

Background: Prior research has demonstrated the protective effects of parent foreign nativity on childhood asthma outcomes in Mexican Americans. Some theories have been proposed to explain this association effect, but few studies have explored the psychosocial influences on this relationship. This study explored the roles of parent depression and social support on the parent nativity-child asthma control relationship.

Methods: Data were obtained from the Asthma Action at Erie trial (NCT02481986), a randomized comparative effectiveness trial designed to test community asthma interventions in parent-child dyads. The sample was restricted to Mexican American caregivers ($N=165$) to examine the nativity effect. Mediation and moderation analyses of parent depression and social support on the relationship between parent nativity and child asthma control were performed. Child asthma control was measured with the Childhood Asthma Control Test or Asthma Control Test (cACT/ACT); parental depression with the Patient Health Questionnaire (PHQ-9); and social support with the 24-item Patient-Reported Outcomes Measurement Information System (PROMIS) social support scales (subscales of emotional, informational, and instrumental support). Analyses also examined the association between parent nativity and child asthma control across duration of years in the U.S. for Mexico-born parents.

Results: As predicted, the protective effects of foreign parent nativity on child asthma control were observed; children of Mexico-born parents had better asthma control ($Est=1.82$, $SE=0.86$, $p = .034$) compared to children of US-born parents. Among Mexico-born parents ($N=95$), a quadratic association indicated that child asthma control gradually declines with increasing number of years spent in the U.S. until the lowest point at 15 years, after which asthma control slowly improved and returned to baseline. US-born parents reported more symptoms of depression than Mexico-born parents ($Est=-1.59$; $SE = 0.41$, $p < .001$). Parent depression was found to mediate the pathway between parental nativity and childhood asthma control ($p < .001$). Instrumental support was found to moderate this relationship (Instrumental Support x Nativity $Est=-0.10$, $SE=0.05$, $p=.04$). Emotional and informational support were not significant moderators of the nativity-asthma relationship.

Conclusions: Parental depression may help explain the relationship between parental nativity and childhood asthma control in Mexican Americans. Social support, particularly instrumental support, strengthens the protective nativity effect on child asthma control. When developing pediatric asthma interventions, considerations to address parental depression and social support are critical in Mexican American families.

INTERNALIZING AND EXTERNALIZING SYMPTOMS AS MEDIATORS OF ASSOC BETWEEN COG FLEXIBILITY AND FAMILY CONFLICT IN TEENS WITH T1D

Billie J. Goddard, B.A.¹, Amy Hughes Lansing, Ph.D.¹, Catherine Stanger, Ph.D.²¹University of Nevada, Reno, Reno, NV; ²Dartmouth College, Lebanon, NH

Introduction: Teens with type 1 diabetes experience increased family conflict, especially around topics related to diabetes care, and this increased family conflict contributes to lower quality of life and less optimal disease management. Moreover, diabetes family conflict is even more pronounced in teens with co-morbid type 1 diabetes and psychopathology. Difficulties in cognitive flexibility have been associated with higher family conflict and psychopathology in teens without type 1 diabetes. However, cognitive flexibility has not been examined in the context of higher family conflict and psychopathology in teens with type 1 diabetes. It was hypothesized that decreased teen cognitive flexibility would be associated with increased diabetes family conflict in part through increased teen internalizing and externalizing symptoms.

Methods: Ninety-three teens with type 1 diabetes and their parents participated in similar baseline surveys for a diabetes intervention and/or neuroimaging study. Measures included parent report on cognitive flexibility via the Behavior Rating Inventory of Executive Function, Shift subscale, on internalizing and externalizing psychopathology via the Child Behavior Checklist, and on the Revised Diabetes Family Conflict Scale. Linear regression analyses were conducted to test for mediation separately for internalizing and externalizing symptoms while controlling for pump status and length of diagnosis.

Results: First, increased problems with cognitive flexibility were associated with increased diabetes family conflict ($b = .202$, $t(93) = 3.717$, $p < .001$). Increased problems with cognitive flexibility were also associated with internalizing symptoms ($b = .445$, $t(93) = 5.431$, $p < .001$) and externalizing symptoms ($b = .428$, $t(93) = 5.434$, $p < .001$). When cognitive flexibility and internalizing or externalizing symptoms were examined together, results were consistent with mediation: increases in both mediators (internalizing and externalizing symptoms), controlling for cognitive flexibility, were significantly associated with increased diabetes family conflict ($b = .249$, $t(93) = 3.764$, $p < .001$ and $b = .289$, $t(93) = 4.287$, $p < .001$, respectively) and cognitive flexibility was no longer a significant predictor of diabetes family conflict (p 's $> .05$).

Conclusion: Consistent with full mediation, the findings suggest that increased internalizing and externalizing symptoms explained the association between decreased cognitive flexibility and increased diabetes family conflict. Cognitive flexibility may be an important target for intervention in high-conflict families with teens experiencing co-morbid type 1 diabetes and psychopathology.

MULTI-LEVEL SOCIAL CONTEXTUAL INFLUENCES ON ASTHMA CARE AMONG FAMILY CAREGIVERS

Julie S. Spray, Ph.D.¹, Jean Hunleth, PhD, MPH², Julia Maki, PhD³, David Fedele, PhD⁴, Sienna Ruiz, BA⁵, Cassidy Sykes, BA, MPH⁶, James A. Shepperd, PhD⁴, Sreekala Prabhakaran, MD⁴, Erika A. Waters, PhD, MPH⁷

¹Washington University in St. Louis, Saint Louis, MO; ²Washington University School of Medicine, Saint Louis, MO; ³Washington University, St. Louis, MO; ⁴University of Florida, Gainesville, FL; ⁵Institute of Public Health, St. Louis, MO; ⁶Institute for Public Health, Washington University School of Medicine, St. Louis, MO; ⁷Washington University in St. Louis, St. Louis, MO

Background: Pediatric asthma management often occurs outside of clinical encounters. Limited understanding of how multiple levels of the social context can influence family asthma management practices may constrain providers' ability to best serve families of children with asthma. We explored this issue among caregivers of children with asthma.

Methods: 41 caregivers of children (< 18 years old) with asthma were interviewed using an adapted McGill Illness Narrative Interview. Most caregivers were black (80%) and/or had low SES (78%). The age range of the children was wide; 7 caregivers had children age 0-4, 22 caregivers' children were age 5-11, and 12 caregivers' children were age 12-17. Caregivers were from St. Louis, Missouri ($n=25$) or Gainesville, Florida ($n=16$). We performed deductive and inductive coding and made constant comparison of codes and cases (e.g., across sites; between SES categories).

Results: 5 primary themes shaped caregivers experiences: (1) the child's health history and agency (i.e., their ability to take independent action and/or influence the surrounding environment and people); (2) household dynamics and division of labor; (3) the local context, including environmental and housing factors as well as schooling; (4) political and economic processes, including the structure of the healthcare and social welfare systems; and (5) the different ways of conceptualizing the meanings of childhood. We also found evidence linking provider misunderstandings of these social contextual elements to provider-caregiver relations and trust.

Conclusion: Caregivers identified multiple levels of the social context that affected their experience of caregiving. We place caregiver experience at the center of these levels (child; household; local context; larger-scale processes), which were interrelated and interdependent. We demonstrate that these contextual factors can shape and challenge asthma management by complicating understandings of caregiving and caregiver responsibility. We suggest ways to improve clinical interactions with caregivers. We also identify the need for policy change to address structural factors that constrain caregivers' ability to mitigate asthma symptoms.

MINDFULNESS, PROBLEMATIC INTERNET USE AND EMOTIONAL HEALTH AMONG COLLEGE STUDENTS

Jamie Bodenlos, Ph.D.¹, Jack Peltz, PhD², Julie Kingery, PhD³, Kathryn Oswald, n/a⁴¹Hobart and William Smith Colleges, Baldwinsville, NY; ²Daemen College, Rochester, NY; ³Hobart & William Smith Colleges, Geneva, NY; ⁴Hobart and William Smith Colleges, Geneva, NY

Dispositional mindfulness has been associated with several high risk behaviors such as problematic alcohol use, drug use, and distracted driving (Bodenlos et al., 2013; Brett et al., 2017; Christopher et al., 2013). It has also been negatively associated with addiction cravings among adults (Baker et al 2019). One high risk behavior that has been gaining attention in its link to mindfulness is problematic internet use. This behavior has been associated with several poor emotional and physical health outcomes among college age students such as depression, anxiety, poor sleep, BMI, and general health (Kawabe et al., 2016; Canan et al., 2014; Lam, 2014). Higher levels of mindfulness have been associated with lower likelihood of preference for online social interactions and better regulation of internet use (Gámez-Guadix & Calvete 2016). Dispositional mindfulness has also been associated with better physical and emotional health (Bodenlos et al., 2015; Grossman et al., 2004; Roberts and Danoff-Burg, 2010). The current study sought to examine the relationship between mindfulness and emotional health. The primary aim was to determine if problematic internet use was a mediator in the relationship between mindfulness and emotional health. Participants were 353 undergraduate students from a college in the Northeast. Participants completed the Five Facet Mindfulness Questionnaire (FFMQ), the Internet Addiction Scale (IAT), and the emotional functioning subscale of the SF-36 (Medical Outcomes Study Short Form Survey). Controlling for both age and gender, results suggested that students' levels of problematic internet use mediated the association between their levels of mindfulness and emotional health. Specifically, higher levels of mindfulness were associated with lower levels of problematic internet use, which, in turn, were associated with higher levels of emotional health. This data provides initial evidence as to how mindfulness could improve health specifically through its effects on screen time and internet use.

EXPLORING SUBGROUP RESPONSE IN A STUDY OF YOGA FOR VETERANS WITH CLBP

Adhana McCarthy, MPAS, PA-C¹, Erik Groessl, PhD²¹SDSU/UCSD Joint Doctoral Program in Public Health, San Diego, CA; ²UC San Diego, La Jolla, CA

Chronic low back pain (cLBP) is a debilitating health problem. It is the third most common reason for physician visits and one of the most common reasons for prescribing opioids. Updated cLBP clinical practice guidelines highlight an inclusion of more effective non-pharmacological treatments. Yoga is a non-pharmacological treatment with substantial evidence supporting its use. Studies of yoga have indicated differential effects of yoga's effects on medical conditions based on gender and age. A recent clinical trial with 150 military veterans found that veterans assigned to yoga reported significantly greater improvements in disability, pain severity and interference, fatigue, and quality of life. Our objective was to examine whether sociodemographic subgroups responded differently to yoga in the prior study.

We conducted secondary analyses of data from the previous RCT, employing correlations and linear regression to identify relevant variables and examine whether they were associated with a clinically significant reduction in back-pain related disability at 6 months. Disability was measured with the Roland-Morris Disability Questionnaire. Experts have established that a 30% reduction in RMDQ scores is an optimal marker for a clinically significant reduction in disability. First, we selected demographic variables that had been correlated with group assignment or the reduction in disability scores in previous analyses. Gender, age, and homelessness in the last 5 years met this criterion. We then ran a series of linear regressions adding these variables to the group assignment variable showing yoga participants had greater reductions in disability.

Yoga group assignment remained significant throughout. Gender was marginally significant when added ($p = 0.062$). History of homelessness was not significant when added to the model. Age was significant when added ($p = 0.024$) and gender became a less relevant predictor ($p = 0.167$). RMDQ score was 0.008 lower for each additional year of age. Women were significantly younger than men in the overall sample (48.0 vs 55.5, $p = 0.002$) and trended toward a higher rate of clinical improvement in the whole sample (56% vs 36%, $p = 0.091$) and in the yoga group (77% vs 51%, $p = 0.090$).

In conclusion, younger age, and to some extent female gender, were associated with a higher rate of clinically significant reductions in disability after a yoga intervention for veterans with cLBP.

ATTITUDES TOWARD SPIRITUALLY INTEGRATED INTERVENTIONS IN PSYCHIATRIC INPATIENTS

Alexis D. Abernethy, Ph.D.¹, Joseph Currier, Ph.D.², Sarah Schnitker, Ph.D.³, Charlotte V. Witvliet, Ph.D.⁴, Lindsey M. Root Luna, Ph.D.⁴, Joshua D. Foster, Ph.D.⁵, Karl J. Van Harn, DMin⁶, Janet S. Carter, MDiv⁷

¹Fuller Theological Seminary, Pasadena, CA; ²University of South Alabama, Mobile, AL; ³Baylor University, Waco, TX; ⁴Hope College, Holland, MI; ⁵University of South Alabama, Mobile, AL; ⁶Pine Rest Christian Mental Health Services, Grand Rapids, MI; ⁷Pine Rest Christian Mental Health Services, Grand Rapids, MI

Recent efforts have sought to obtain a more complex and nuanced understanding of spirituality and health correlates that have implications for clinical practice. This study described attitudes toward specific strategies for incorporating spirituality in psychotherapy and clarified whether patient's attitudes toward spiritually integrated care might be associated with overall spirituality and prominent forms of spiritual struggles. This sample was recruited from seven inpatient psychiatric units at a non-profit behavioral health center in the Midwest. The inpatients (N=230) averaged 31.83 years of age ($SD = 14.84$), were predominantly female (59%), and Caucasian (85%) followed by Black (4.8%), LatinX (3.9%), Other (3.9%) and Multiracial (3%). A correlational design was used to examine associations among these measures at intake: Spiritual Transcendence Index, Religious and Spiritual Struggles Scale (RSSS), and the Perceived Appropriateness of Spiritually Integrated Interventions Scale. Using hierarchical regression, spiritual transcendence explained a significant portion of variance in patients' overall attitudes toward incorporating spiritual interventions in psychotherapy or counseling, $\Delta R^2 = .29$, $F_{\text{change}}(1, 228) = 90.76$, $p < .001$. The addition of the RSSS subscales in the second model further added to the explained variance, $\Delta R^2 = .08$, $F_{\text{change}}(6, 222) = 4.54$, $p < .001$. In the final model, patients who derived a stronger sense of transcendence from their spirituality, $p < .001$, those who were experiencing moral struggles at the time of seeking care, $p = .047$, and Caucasian patients, $p = .016$, were more likely to report favorable attitudes toward spiritually integrated care. Spiritual transcendence and moral struggles may be important factors that inform patient's preferences for spiritually integrated care.

UTILIZING FAITH BASED VOLUNTEERS TO DELIVERY CARE COORDINATION TO REDUCE HOSPITAL UTILIZATION

Abdullah A. Mamun, Ph.D.¹, Kenneth Halloran, MPH¹, Donna Stauber, Ph.D.¹, Devin Killen, n/a¹, Christopher Valmores, n/a², Heather Kitzman, Ph.D.¹

¹Baylor Scott & White Health, Dallas, TX; ²Baylor Scott & White Health, Temple, TX

Background: Evidence suggests that preventive health programs in faith-based organizations can improve health outcomes. However, the effect of faith-based programs in reducing emergency department (ED) and inpatient services use is not clear. In this study, we compared hospital utilization of patients enrolled in a faith-based delivery care coordination program versus a matched eligible but unenrolled referent group of patients.

Methods: This observational study included 128 patients (68% women, mean[SD] age: 68.1 [13.5], 61% White, 30% African-American, and 12% uninsured) who visited Baylor Scott and White Health (BSWH) emergency and inpatient departments. Sixty-four patients self-selected to enroll in the faith-based delivery care coordination program from 2016 to 2019. A referent group (n=64) was selected from the hospital's electronic health record (EHR) system using a propensity score measured from demographic and past clinical attributes. Hospital utilization data was obtained from the EHR for one year for intervention and referent groups. In partnership with BSWH, the Faith in Action Initiative trains volunteers from local churches to become Faith Community Caregivers (FCCs). For a year, FCCs spend one hour/week with a patient to serve as an advocate/health translator, help pick up prescriptions, and encourage adherence to plan of care, medication regimen and follow up appointments. The primary outcomes were the number of ED visits and inpatient visits during the follow-up year. Cox-proportional hazard models were used to estimate an additional risk of ED and inpatient department visit.

Results: Compared to the referent group, the patients in the faith-based delivery care coordination program were 22% less likely to experience an additional ED visit during the one-year follow-up time (hazard ratio = 0.78, p-value = 0.04). Despite the overall benefit of the intervention on reducing the ED visits, African-American patients were 2.2 times more likely to experience an additional ED visit (hazard ratio = 2.2, p-value < 0.0001) in comparison to the Whites. There was no significant difference in the number of inpatient visits (hazard ratio = 1.11, p-value = 0.60) between the intervention and referent groups.

Conclusions: The faith-based delivery care coordination program, Faith in Action Initiative, was effective in reducing ED visits, but did not significantly reduce inpatient visits. Future research should evaluate participant characteristics, volunteer attributes, and intervention implementation to optimize the program on health care outcomes.

FIT WITH FAITH

Nathan West, B.S./M.S.¹, Brook E. Harmon, RD, PhD¹, Benjamin Webb, Ph.D.², Stacy Smith, Rev., Ph.D.³, Brandi M. Johnson, BSEd⁴

¹University of Memphis, Memphis, TN; ²Department of Applied Health, Southern Illinois University Edwardsville, Edwardsville, IL; ³Faith and Health Division, Methodist Le Bonheur Healthcare, Memphis, TN; ⁴University of Tennessee Health Science Center, Memphis, TN

Chronic disease prevalence is high among clergy, yet their lifestyles make it difficult to engage them in health programs. Spouses are a source of support, especially in promotion of healthy eating and physical activity. Health disparities impacting the US also impact clergy putting African-American clergy at risk for negative health outcomes. *Fit with Faith* tested the feasibility and impact of a 10-week, multiple-behavior change intervention for African-American clergy and spouses. The curriculum was informed by focus groups, which encouraged a combination of eHealth and traditional components: 3 face-to-face sessions, 3 phone calls, 5 competitions (e.g., who can track the most days), weekly emailed educational materials, daily interactions on the MyFitnessPal app. Assessments were taken pre- and post-intervention and included height, weight, waist and hip circumferences, and blood pressure measured by staff. Diet was assessed using NCI's online 24-hour recall system, physical activity via accelerometer, and demographics and psychometrics using online surveys. Data were normally distributed and paired samples t-tests used to examine differences in pre-post outcomes. Participants (n= 20, 10 couples) were on average 51.1±13.5 years old, obese (60%) and had elevated blood pressure (70%). Most participants attended all meetings (70%) and most calls (50-65%) but did not engage in any competitions (70%) or with the app (50-75%, no activity). There was a statistically significant decrease in BMI from pre (31.9±1.93) to post intervention (31.5±1.89, $t(19) = 2.65$, $p = 0.02$). No difference was seen in calories consumed, but a statistically significant increase was seen in fiber pre (12.4±6.68) to post intervention (17.0±9.27, $t(12) = -2.51$, $p = 0.03$). No differences were seen in steps taken or minutes of moderate-to-vigorous physical activity. A statistically significant increase was seen in self-regulation cognitive items from pre (17.8±3.63) to post intervention (20.2±3.01, $t(18) = -3.01$, $p = 0.01$). While not statistically significant, blood pressure decreased but increases were seen in occupational distress and perceived stress. *Fit with Faith* showed modest success given the small sample and short duration of this pilot study. Future research should examine how to reach this population since eHealth components were not successful. Additional research is needed on stress, which participants either became more aware of or slightly increased during the study.

EXPLAINING THE SPIRITUALITY-HEALTH RELATIONSHIP: THE ROLE OF DIFFERENT TYPES OF POSITIVE AFFECT

Derek Sims, n/a¹, Raymond Giesler, PhD¹

¹Butler University, Indianapolis, IN

Spirituality has been found to predict physical health in numerous studies, leading some investigators to suggest that spirituality may play a causal role in promoting health. To explain this relationship, investigators have proposed a variety of mediating variables (e.g., self-regulatory ability, health-protective behaviors, meaning in life). More recently, researchers have also begun to consider the salutary role of positive emotions in this context. However, which positive emotions might be serving as the 'active ingredients' in the spirituality-health relationship remains unclear. In the current investigation, we focus on three different types of positive affect associated with both spirituality and health that have rarely been examined simultaneously in this context: awe, joy and contentment. As part of a larger cross-sectional survey study, items from previously validated measures of physical health, spirituality, awe, joy and contentment were administered to a sample of young adults (n=254). Bivariate correlations indicated that although the measures of positive affect were correlated, with most r 's in the .40's and .50's, their level of association was not high enough to preclude examining each variable individually. Each of the positive affect variables also correlated significantly with both spirituality and health, with r 's ranging from .13 to .31. Using regression based, mediational analyses, awe (Sobel $z = 2.36$, $p = .018$), joy (Sobel $z = 1.91$, $p = .056$) and contentment (Sobel $z = 2.24$, $p = .025$) met conservative criteria for acting as partial mediators. Multiple mediation procedures utilizing bootstrapping were then used to examine all three mediators simultaneously; indirect effects and the 95% CI were computed for each of 5,000 bootstrapped samples. In terms of the relation between spirituality and physical health, neither joy (indirect effect = -.0059, 95% CI [-.0258, .0105]) nor awe (indirect effect = .0133, 95% CI [-.0044, .0364]) remained significant. However, contentment did (indirect effect = .0168, 95% CI [.0012, .0420]). Though correlational, the results suggest that of the three, contentment may serve as the primary 'active ingredient' in the spirituality-health relationship. These findings shed light on the complex role of affect in the spirituality-health relation and also suggest that interventions including a spiritual component may benefit by specifically emphasizing practices that foster feelings of contentment.

EXPLORING CANCER PATIENTS' DECISION-MAKING AFTER FERTILITY PRESERVATION COUNSELING: A MIXED METHODS ANALYSIS

Sanjana Ramesh, MPH¹, Courtney L. Scherr, PhD², Hannah Getachew-Smith, MPH², John J. Brooks, MS²¹Northwestern U School of Communication, Chicago, IL; ²Northwestern University, Chicago, IL

Background: Cancer survival rates are high, but leading cancer therapies pose high infertility risk. Future fertility is a significant concern identified by cancer patients of reproductive age. National guidelines recommend fertility preservation counseling (FPC) between diagnosis and treatment, but FPC provision is currently lacking; cancer survivors report high levels of decisional conflict about fertility preservation. The current study explored how a designated FPC patient navigator facilitated decision-making about fertility preservation.

Methods: Using a mixed-methods study design, cancer patients of reproductive age ($N = 49$) were retrospectively recruited from a large university hospital to participate in a cross-sectional survey and semi-structured interview. A validated decisional conflict scale and its subscales (informed, values clarity, uncertainty, support) were administered, and scores were interpreted on a 100-point scale (< 37.5 = low decisional conflict). Interviews lasted up to one hour and included questions about decisional conflict. Two coders used deductive content analysis guided by decisional conflict subscales. We present the means for each subscale, followed by insight from the interviews.

Results: Coders were reliable at Krippendorff's $\alpha = .96$. Most participants were female ($n = 38$; 77.5%), experienced low decisional conflict ($M_{\text{overall}} = 21.7$), and did not preserve fertility ($n = 31$; 63.2%); all subscale scores also indicate low decisional conflict. Yet, interview data suggest some participants felt uncertainty or regret about fertility decisions. Participants scored highest on the informed subscale ($M_{\text{informed}} = 31.4$). A multidisciplinary team approach, supplemented with written materials, supported informed decision-making. However, some participants were overwhelmed and felt that information about side effects, treatment efficacy, and follow-up in survivorship was missing. FPC effectively provoked values clarity ($M_{\text{values}} = 28.8$), which was influenced by life stage (e.g., age, relationship status, parity), morals, and perceived treatment urgency. Ultimately, most patients felt certain about their decision ($M_{\text{certainty}} = 21.7$) because they were afforded some control over their reproductive future. Participants felt well supported in decision-making ($M_{\text{support}} = 18.1$). FPC patient navigation allowed patients to receive instrumental support from providers and emotional support from family members.

Discussion: Patient navigators can optimize preference-sensitive decision-making about fertility preservation among cancer patients by coordinating a multidisciplinary approach to FPC. Results indicate some unmet information needs may increase decisional conflict. Future research should investigate which specific processes within the FPC patient navigation model are associated with reduced decisional conflict.

LIMITATIONS OF CURRENT ASSESSMENTS OF DON'T KNOW RESPONDING IN PERCEIVED RISK STUDIES: IMPLICATIONS FOR DECISION MAKING THEORY

Jennifer L. Hay, PhD¹, Jack Pohler, Undergraduate Student², Erika A. Waters, PhD, MPH³, Heather A. Orom, PhD⁴, Marc T. Kiviniemi, PhD CPH⁵¹Memorial Sloan Kettering Cancer Center, New York, NY; ²University of Kentucky, Lexington, KY; ³Washington University in St Louis, St Louis, MO; ⁴University at Buffalo, BUFFALO, NY; ⁵University of Kentucky, Lexington, KY

Theories typically assume individuals have risk perceptions and use them to make health decisions. However, 47% percent of a US population representative sample say they do not know (DK) their risk for colorectal cancer when given DK as a response option. Potentially contributing to this disconnect is that studies may not adequately assess DK responses. We examined assessment practices for studies that examine the relation of perceived risk for colorectal cancer to engagement in colorectal cancer screening.

Methods: A meta-analysis conducted by Atkinson et al (2015) identified 58 published articles assessing both perceived risk for colorectal cancer and screening behavior. We coded each article for: a) whether a DK response was assessed; b) if so, if it was included as a response option or only coded if spontaneously generated by a participant; and c) how DK responses were treated in analyses. The meta-analysis reported effect size was used to examine the effect of assessment practice on observed risk-behavior relations.

Results: Of the 58 studies, only 5 measured or coded DK responses. 2 of the 5 included a DK response option, whereas the other 3 only coded a DK response if a participant spontaneously generated it. The overall average effect size for the 5 studies that included a DK response was 0.05, relative to 0.13 for those that did not include a response option. Only 1 study reported the rate of DK responses -- for that study, the rate was comparable to other colorectal cancer DK studies (37% DK response rate). All studies that provided or coded a DK response treated those responses as missing data. For studies that did not provide an option, very few report missing data rates, but those that do have rates that suggest a substantial proportion of "potential" DK responses (up to 22% missing data). Similarly, very few studies report distributions of responses but those that do have distributions consistent with a meaningful number of participants having a lack of knowledge about their risk (e.g., an overrepresentation of responses in the lowest possible risk category).

DISCUSSION: Although work assessing DK responses suggest that they are highly prevalent in the population, the overwhelming majority of risk perception studies fail to assess or account for DK responses. Not only does this impact scientific understanding of the prevalence of not knowing one's risk but may also impact scientific understanding of perceived risk-behavior relations.

COMMUNICATING EFFECTIVELY: EXPLORING PATIENT EMPOWERMENT IN SURGICAL CONSULTATIONS

Sandra A. Rosales, n/a¹, Brandon Q. Tran, MA¹, Kate Sweeny, PhD¹¹University of California, Riverside, Riverside, CA

Background: Effective communication is critical for facilitating patient outcomes such as adherence and satisfaction. Most of the literature examining healthcare communication focuses on the clinician's role and techniques medical professionals can employ to improve their communication with patients. In contrast, relatively little evidence has highlighted the prevalence of patient-focused strategies for improving communication, such as patient empowerment.

Purpose: Our study sought to qualitatively explore the prevalence of patients' engagement during medical interactions via empowerment strategies to optimize communication with their physician.

Method: 146 audio recorded pre-surgical consultations between physicians and patients were analyzed along with questionnaire data collected before and after the consultation. Each transcript was closely examined to derive a comprehensive list of techniques used by patients within these interactions.

Results: Eight empowerment strategies were identified: *delaying the physician, summarizing the consultation, asking multiple questions, expressing personal goals, providing preparatory materials, disclosing an agenda, self-diagnosing, and verifying information*. Findings indicated that less than a third of patients utilized any strategy during their consultation. *Asking multiple questions* emerged most frequently, whereas *self-diagnosing* was rarely present. Productive strategies included *delaying the physician, summarizing the consultation, and expressing personal goals*, as they were linked to beneficial patient outcomes such as greater positive emotion, less negative emotion, and more favorable perceptions of the physician. *Verifying information, self-diagnosing, and disclosing an agenda* seemed less productive, as they were linked to greater negative emotions, less perceived control, and less favorable perceptions of the physician.

Conclusion: Our results reveal some seemingly empowering strategies patients utilize that may lead to counterproductive outcomes, as well as productive strategies that may empower patients and improve communication efficacy. Taken together, these findings offer novel insight that can be applied to the innovation of policy and practice interventions to emphasize effective strategies patients can employ to improve communication quality during medical interactions, establishing a more interactive dynamic between physicians and patients.

RELATIONS AMONG AFFECT, URGE, SELF-EFFICACY, AND LAPSE BEHAVIOR DURING A QUIT ATTEMPT IN ASIAN AMERICAN EMERGING ADULTS

Ian Kim, MFA¹, Chih-Hsiang "Jason" Yang, PhD², Jennifer B. Unger, Ph.D.³, Jimi Huh, PhD³¹University of Southern California, Pasadena, CA; ²University of South Carolina, Columbia, SC; ³University of Southern California, Los Angeles, CA

Background: – Smoking is the leading cause of preventable chronic disease and death in the United States. Many smoking cessation interventions have been proved effective for encouraging initial quit attempts, however, the processes underlying the continued abstinence are still largely unknown. No trend of increase in the population cessation rate has been observed over the last two decades.

Conclusions: – As a step toward addressing this research gap, using a dual process model perspective, this study was designed to capture the joint influence of factors on lapse during quit attempts, by investigating concurrent and lagged associations between three automatic constructs, *positive affect, negative affect, and smoking urge*, one reflective construct, *abstinence self-efficacy*, and a specific behavioral outcome, *lapse*.

Methods: – 57 daily smoking Asian American emerging adults (Age 18-25 years, $M = 21.72$, $SD = 2.14$) were monitored during their 4-week quit attempts. During the attempts, personalized smartphone-based ecological momentary interventions were delivered to each participant as a reminder in their natural context. At the end of each day, participants were asked to complete the questionnaires that contained a set of questions regarding daily affect, smoking urge, abstinence self-efficacy, and number of cigarettes smoked since the previous questionnaire. Bivariate time series models were estimated for concurrent and lagged associations between daily affect, urge, self-efficacy, and lapses status.

Results: – Affects and urge had shorter-lived, acute effects than self-efficacy on lapse risk. Low levels of background self-efficacy were the strongest, direct predictor of increased future lapse risk ($r = -0.54$, $p < .01$), leading by 2 days. Lapses status was a significant predictor of next day relapse behavior ($r = 0.96$, $p < .01$). Affects, urge, and lapse behavior were shown to have bidirectional impact on each other.

Conclusions: – While specific action may require reflective rather than automatic processes, in order to sustain the cessation behavior during quit attempts, the first construct that is important is regulation of automatic components, such as controlling urges. Interventions that monitor momentary states of automatic components and provide a practice for reflective action based on the momentary changes, along with consideration of the variability in latency and lags of different factors, will result in more reliable access to prolonged abstinence maintenance during quit attempts.

STUDENT EMPLOYMENT AND SOCIOECONOMIC STATUS ON MEDICAL CAREER-RELATED DECISION MAKING

Taylor L. Duffy, n/a¹, Yaser Ahmad, n/a², Keith Brazendale, PhD³¹University of Central Florida, Orlando, FL; ²University of Central Florida, Orlando, FL; ³University of Central Florida, Orlando, FL

Background: The transformation of undergraduate students into physicians is a rigorous progression. When analyzing the medical school admissions process, a great deal of emphasis is placed on the pre-medical years. In a bid to ensure a competitive application, pre-medical students must consistently participate in an array of career-specific extracurricular experiences (e.g., undergraduate research, clinical volunteering), all while simultaneously tending to college coursework and personal responsibilities.

The decisions that undergraduate students make while in college are heavily influenced by a student's socioeconomic status (SES). One component of the classical decision-making theory focuses on determining desirability of an action based on costs and ramifications of outcomes. If a student of a lower SES has to make a choice between pursuing unpaid clinical shadowing for career-related development versus pursuing career-unrelated employment for potentially-needed income, then the costs and ramifications of each decision undoubtedly come into play. A student's sociodemographic status (e.g. first-generation student) also influences these decisions due to a lack of educational guidance from a parent or guardian.

Purpose: This cross-sectional study aims to explore the relationship between SES and 1) employment in pre-medical years, and 2) involvement in field-related extracurricular activities.

Methods: Data will be collected from approximately 200 pre-medical students in the form of a brief survey administered via Qualtrics. Survey questions will capture participant demographics, including SES status, employment, and ask about involvement in extracurricular activities.

Results: Survey data is currently being collected, with a projected completion date of January 2020. This study will examine the association between SES and key outcomes of interest, such as employment and extracurricular activities during pre-medical years. Secondary analyses will explore the previous associations in first-generation students. We hypothesize that a student of a lower SES will report working a greater number of hours and, thus, report decreased involvement in career-related extracurricular activities.

Additional Implications of Study: First-generation college students lack family members who possess post-secondary education. This potentially results in these students having less guidance on making career-related decisions, such as pursuing career-related extracurricular and employment opportunities. This study seeks to determine the varying impact of SES on this decision-making process.

THE ROLE OF ANTICIPATED AFFECT IN HEALTH RISK INFORMATION AVOIDANCE

Angela E. Johnson, MA¹, Jennifer L. Howell, PhD²¹University of California Merced, Merced, CA; ²University of California, Merced, Merced, CA

Two studies (N = 684) examined the role of anticipated affect in the decision to learn or avoid health risk information. To our knowledge, the causal role of anticipated affect in information avoidance has not been investigated. In Study 1 participants completed a risk calculator for type 2 diabetes and were assigned to one of four essay conditions as part of a 2 (affect valence: positive, negative) x 2 (time: current, future) between-subjects design. After writing an essay about current or anticipated positive or negative affect, they received the opportunity to learn their risk feedback. Unfortunately, the manipulation did not influence affect in the expected way. As such, we examined the correlation between self-reported affect and the decision to learn or avoid risk feedback. The results indicated that negative anticipated affect was the only form of affect associated with the desire to avoid information—those anticipating negative affect in response to learning their diabetes results were more likely to avoid risk feedback. We designed Study 2 to extend the findings of Study 1 by focusing on a different form of negative anticipated affect: anticipated regret for avoiding information. We reasoned that anticipated regret about avoiding information might work to reduce information avoidance; therefore functioning in the opposite direction of negative anticipated affect toward bad news. Participants completed the same type 2 diabetes risk calculator used in Study 1. Next, participants assigned to the experimental condition responded to a short essay question prompting them to describe a time they felt regret and answered questions about possible anticipated regret. Participants in the control condition completed the same task, but focused on a neutral topic: modes of transportation. As in Study 1, participants then opted to either view or avoid their diabetes risk. The results revealed that those who focused on anticipated regret avoided their risk feedback (42%) less frequently than those in the control group (58%). Taken together, the results of these two studies suggest that although negative anticipated affect in response to risk results might relate to increased information avoidance, focusing on anticipated regret for avoiding those results can decrease health information avoidance. These results suggest the utility of future studies examining the causal role of affect in health information avoidance.

STRESS AS A MODERATOR TO SELF-REGULATION FOR LATE ADOLESCENTS WITH TYPE 1 DIABETES

Avia L. Gray, MA¹, Cynthia A. Berg, Ph.D.², Deborah J. Wiebe, PhD, MPH³¹The Univeristy of California at Merced, Merced, CA; ²University of Uah, Salt Lake City, UT; ³University of California, Merced, Merced, CA

Self-regulation is a key aspect of engaging in positive health behaviors to manage type 1 diabetes (T1D) and prevent serious health complications. Self-regulation skills such as Executive Functioning (EF) may be particularly important during late adolescence, but may be moderated by multiple life stressors as they begin to transition into emerging adulthood. We examined perceived stress as a moderator of the relationship of EF with T1D self-management behaviors and HbA1c. Seniors in high school ($N = 241$, female = 61.4%, M (SD) age = 17.74 (.38) years) with T1D completed performance-based measures of EF, self-reported problems in EF (i.e., BRIEF), perceived stress, and T1D self-management behaviors; a home assay kit measured HbA1c. Regression analyses showed stress was independently associated with lower self-management ($b = -.035$, $p < .001$) and higher (poorer) HbA1c ($b = .288$, $p = .048$). BRIEF was also related to lower self-management ($b = -.002$, $p < .000$), but not to HbA1c ($b = .011$, $p < .072$), and stress did not moderate these relationships. Performance EF was unrelated to self-management when entered simultaneously with stress ($b = .006$, $p = .134$), but stress remained associated with self-management ($b = -.034$, $p = .003$) and moderated the relationship of performance EF with self-management ($R^2 = .081$, $b = .015$, $p = .013$). At higher levels of stress, those with lower performance EF had worse self-management than those with higher EF (predicted means = .40 vs .47); at lower levels of stress, however, performance EF was unrelated to self-management (predicted means = .70 vs .68). Performance EF was related to lower HbA1c when entered simultaneously with stress ($b = -.171$, $p < .002$). Stress was not uniquely associated with HbA1c ($b = .264$, $p < .074$), but did moderate performance EF links to HbA1c ($R^2 = .131$, $b = -.185$, $p < .016$). Again, at higher levels of stress, those with lower EF had higher HbA1c than those with higher EF (predicted means = 8.92 vs 7.64); at lower levels of stress, EF was unrelated to HbA1c (predicted means = 7.88 vs 7.78). Results revealed that those with poorer EF capabilities may be challenged by stress during late adolescence. Helping those with poorer EF skills to develop stress management and coping strategies may be helpful for T1D health at this high-risk time of development.

HEALTHCARE PROVIDER PERCEPTION OF DIABETIC PATIENT DISEASE MANAGEMENT AND USE OF REMOTE HEALTH TECHNOLOGY

Jordan A. Schueler, Bachelor of Arts in Psychology¹, Farzan Sasangohar, Ph.D.¹, Sherecce Fields, PhD¹, Solangia Engler, MS²¹Texas A&M University, College Station, TX; ²Texas A&M University, COLLEGE STATION, TX

Background: Diabetes is estimated to affect one out of every ten adults in the United States. The aim of this study was to gather information from healthcare providers, specifically about a) perceived patient barriers and facilitators to managing their disease, b) the providers' own struggle with getting patients to effectively and consistently manage their disease, c) opinions on using remote health technology to treat diabetes, and d) the likelihood that they will use these technologies to treat diabetic patients in the future.

Methods: Healthcare providers from a low-income area in south Texas ($n = 8$) were recruited for a focus group discussion. Eligible participants were current healthcare providers who work with diabetic patients.

Results: Most of the healthcare providers who participated were registered nurses or nurse practitioners (75%, or 6/8), ranging in age from 39-80 years, and 75% (6/8) were female. Many themes emerged from the discussion. For instance, the most frequently-reported perceived patient barriers for diabetes self-management were: limited access to resources (i.e., healthier food, transportation to medical appointments, treatments that require insurance), and disbelief in their own ability to manage their diabetes. The healthcare providers shared their experiences of caring for diabetic patients, including their patients' non-compliance with following dietary or educational advice and taking medication, or when their patients believed that their provider was the cause of ineffective management. Most healthcare providers were hopeful about the use of remote health technology among diabetic patients, especially if patients can have access to their own health information and see graphic trends of their progress. However, they also shared some possible barriers for using the technology, especially in older or homeless populations.

Conclusions: The main concerns for healthcare providers toward their patients were that they do not have the resources or lack the motivation and education to care for their diabetes. Although their perception of the use of remote health technology was optimistic, they still shared some potential population-specific barriers for practical usage. This focus group captured valuable information from healthcare providers practicing with diabetic patients in a low-income area. This information will be able to educate further research and development of remote health technology.

ILLNESS APPRAISAL AND POSITIVE INTERACTION IN COUPLES WITH TYPE 1 DIABETES

Eunjin L. Tracy, Ph.D.¹, Cynthia Berg, Ph.D.², Katherine J. Baucom, Ph.D.², Vicki S. Helgeson, Ph.D.³¹University of Utah, SALT LAKE CITY, UT; ²University of Utah, Salt Lake City, UT; ³Carnegie Mellon University, Export, PA

For many adults with type 1 diabetes (T1D), daily management behaviors such as checking blood glucose levels, administering insulin, and making healthy diet choices occur in the context of romantic relationships. Dyadic coping theories posit that couples' coping behaviors can be affected by how couples appraise the illness. Shared illness appraisal is the perception that the illness is "our problem" rather than the individual problem of the person with T1D. We examined how average daily illness appraisals of persons with T1D and their spouses were linked to coders' ratings of partners' positive interaction (a composite of valence, positivity, and communal coping) during a discussion about T1D, and whether positive interaction was most beneficial for diabetes outcomes and psychological health when it occurred in the context of shared illness appraisals. 199 persons with T1D (Mage = 46.82) and their spouses (Mage = 46.41) completed a 14-day diary where they reported on their own illness appraisal. They then completed a series of questionnaires including measures of relationship satisfaction and life satisfaction. Persons with T1D additionally reported their diabetes distress, and self-care behaviors. Finally, they completed a measure of affect before and after an 8-min discussion about a concern related to T1D. A team of seven coders watched the video-recorded discussions and coded each partners' positive interaction based on both verbal and nonverbal behavior. Regressions revealed that greater shared appraisal of persons with T1D was associated with greater own positive interaction, but spouses' shared appraisal was not associated with their own positive interaction. Spouse positive interaction was associated with lower average daily blood glucose (BG) mean and risk for high- and low-bg levels. Furthermore, greater positive interaction in persons with T1D was related to greater emotional well-being and lower depressive symptoms when they held greater shared illness appraisals. Results suggest that appraisal and coping of persons with T1D and their partners are important to consider, and that positive interaction may be more beneficial for psychological health depending on the appraisal of the person with T1D.

SATISFACTION WITH HEALTH CARE SERVICES FOR INDIVIDUALS WITH TYPE 1 DIABETES WHO HAVE EXPERIENCED DIABETIC KETOACIDOSIS

Amanda Cary, B.A.¹¹Regent University, Virginia Beach, VA

Although 1 out of every 4 dollars spent by hospitals when working with Type 1 Diabetes (DM1) is used on Diabetic Ketoacidosis (DKA) admissions, little is known about the overall satisfaction of these patients with their experience in the health-care system. DKA is a life-threatening complication of DM1 with a 1-5% mortality rate. Furthermore, some research estimates 64% of cases of DM1 are initially diagnosed as a result of the occurrence of DKA. The purpose of this study is to investigate existing research on the overall health care satisfaction of individuals with DM1 who have experienced DKA. A literature review was performed using PsycNet, PubMed, MEDLINE plus, and the Nursing and Allied Health Database. A search with keywords Type 1 Diabetes, Diabetic Ketoacidosis, satisfaction, and health care resulted in 14 relevant studies. Findings across these studies were consistent, with all studies that examined the below elements of satisfaction consistently finding positive results. Given the impact of quality of care on satisfaction, 8 studies examined uniformity of care and found patterns of DKA misdiagnosis, ranging from 14.2% to 21%, and non-adherence to best care standards (e.g., recommended use of the Intensive Care Unit ranged from 2.1% to 87.7%). Patient reports of desire for increased and/or improved education on diabetes self-management, as well as DKA and its consequences were found in 7 studies (3 quantitative and 4 qualitative). Reports of stigmatizing language and related behavior by health care providers were found in 3 studies (1 quantitative and 2 qualitative). Furthermore, in 6 studies (2 quantitative and 4 qualitative) patients reported a desire for providers to address DKA related psychosocial factors during their hospital stay. In conclusion, the research suggests a need for prioritizing the use of best practice standards when treating DKA, as well as providing thorough education to the patient and taking into consideration how DKA can impact the patient psychosocially. In light of these findings, the extensive research indicating the impact of patients' perception of care and the benefits of holistic care, related enhancements to DM1 self-management after initial DKA episodes may contribute to reduced recurrence DKA episodes. Furthermore, there is a need for future research to target evaluation of interventions that incorporate such holistic care. Further discussion of implications for research and practice will be discussed.

AUTONOMY SUPPORT AMONG PATIENTS WITH DIABETES: LINKS WITH DIABETES SELF-CARE, METABOLIC OUTCOMES, AND 5-YEAR CARDIAC RISK

Aaron A. Lee, Ph.D.¹, Michele Heisler, M.D.², Patric J. Leukel, B.A.³, Maria K. Mor, Ph.D.⁴, David S. Obrosky, MS⁵, Ann-Marie K. Rosland, M.D., M.S.⁶

¹University of Mississippi, Oxford, MS; ²University of Michigan, Ann Arbor, MI; ³University of Mississippi, University, MS; ⁴VA Center for Health Equity Research and Promotion (CHERP), Pittsburgh, PA; ⁵VA Pittsburgh Healthcare System/University of Pittsburgh, Pittsburgh, PA; ⁶VA Pittsburgh Healthcare System, Pittsburgh, PA

Introduction: People with diabetes who receive more autonomy support (support that emphasizes individuals' agency in their disease self-management) for diabetes management from family members and friends (supporters) have higher diabetes self-efficacy, lower diabetes distress, and better glycemic control. However, the relationship of autonomy support from family supporters with patient activation, important diabetes self-care activities, or cardiac risk factors is unknown.

Methods: This study used baseline data from 239 pairs of Veterans with type 2 diabetes at risk of diabetes complications and their supporters enrolled in a behavioral intervention trial. Patients' perceived level of autonomy support was assessed using the Important Others Climate Questionnaire-6. Outcomes included patients diabetes self-management adherence days/week (diet, exercise, medication adherence, foot care, checking blood glucose) measured using the Summary of Diabetes Self-Care Activities subscales, patient activation measured using the Patient Activation Measure, metabolic outcomes (glycated hemoglobin A1c [HbA1c], systolic blood pressure [SBP], non-HDL cholesterol [non-HDL-C] and 5-year diabetes-specific risk of a cardiac event using the UKPDS risk score. We used linear regression to examine associations between autonomy support and each outcome, controlling for insulin use and supporter-patient co-residence.

Results: Greater autonomy support was associated with better overall diet (B=0.48, 95%CI [0.20, 0.76], p=.001), more frequent exercise (B=0.29, 95%CI [0.03, 0.55], p=.027) and medication taking (B=0.23, 95%CI [0.06, 0.41], p=.008) but not with specific diet components of limiting high fat foods and eating fruits and vegetable (B=0.18, 95%CI [0.03, 0.39], p=.092), checking blood glucose (B=0.14, 95%CI [-0.08, 0.36], p=.526), or foot care (B=0.21, 95%CI [-0.05, 0.48], p=.117). Autonomy support was associated with greater patient activation (B=3.25, 95%CI [1.88, 4.61], p<.001) but not with HbA1c (B=-0.12, 95%CI [-0.31, 0.08], p=.167), SBP (B=0.13, 95%CI [-2.08, 2.33], p=.876), or non-HDL-C (B=1.15, 95%CI [-6.89, 4.60], p=.725). Higher autonomy support was significantly associated with lower 5-year cardiac risk (B = -1.21, 95%CI [-2.39, -0.03], p = .044).

Conclusion: Autonomy support for diabetes self-management is associated with important self-care activities and with greater patient activation. Autonomy support was not associated with any individual metabolic outcomes but was associated with lower 5-year cardiac risk. Our findings suggest that autonomy support from family and friends may play an important role in patients' diabetes management and should be explored in prospective analyses.

VIRTUAL REALITY TO CHANGE RISK PERCEPTIONS AND PROMOTE ENROLLMENT IN THE DIABETES PREVENTION PROGRAM AMONGST HIGH RISK ADULTS

Bryan Gibson, DPT, PhD¹, Steven Godin, MS, Ph.D., MPH, PHI Certificate², Vishnu Sundares, MD¹, Julia Schaeffer, MSW¹, Gregory Bayles, BA, MEAE³, Roger Altizer, PhD⁴

¹University of Utah, salt lake city, UT; ²University of Utah School of Medicine, Salt Lake City, UT; ³University of Utah, Salt Lake City, UT; ⁴university of Utah, salt lake city, UT

Background: Prior research has demonstrated that Virtual Reality (VR) applications are an effective adjunctive therapy in the treatment of substance abuse, phobic, and post-traumatic stress disorders. However, there is very little research testing VR to motivate change in health related behaviors.

We are pilot testing two brief (3-minute) VR videos that provide vicarious experience of potential complications of Type 2 Diabetes (diabetic retinopathy and heart disease). We hypothesized that after watching the VR videos, at-risk individuals' affective and experiential risk perceptions regarding Type 2 Diabetes will increase. Secondly, we hypothesized that changes in risk perception will not be associated with the participants' numeracy or health literacy. Our long term goal is to test the efficacy of these videos (deployed via mobile phone) for increasing enrollment in the Diabetes Prevention Program (DPP).

Methods: We are identifying individuals with prediabetes at a low income clinic serving primarily Hispanic adults and recruiting them to participate via phone. Participants first provide demographic information and then complete a Risk Perception questionnaire based on the "tripartite model of risk perception", followed by viewing of the two VR videos. Two weeks later, they are sent a link to a follow-up survey to provide qualitative feedback on the VR videos, the risk perception questionnaire, a subjective numeracy scale, a health literacy assessment, and questions about whether they have enrolled in the DPP, and which contextual factors influenced their decision to enroll or not (e.g. cost, travel, etc.).

We are using thematic analysis to analyze the qualitative feedback, a paired t-test to examine within-subject changes in deliberative, affective and experiential risk perceptions, a linear model to examine associations between change in risk perceptions and individuals' subjective numeracy and health literacy, and descriptive statistics of the contextual factors related to enrollment in the DPP.

Results: To date we have identified 169 individuals with prediabetes from the clinic's records and contacted them, 78 have participated in the baseline measurement and viewed the VR videos. Data collection is ongoing, and our target is to collect and report on complete data from 100 participants.

Conclusion: We are conducting a novel pilot test of mobile Virtual Reality and testing its efficacy in changing risk perceptions and motivating enrollment in the DPP.

A SECONDARY QUALITATIVE ANALYSIS OF PROVIDERS' USE OF LANGUAGE IN DIABETES CARE

Elizabeth A. Beverly, PhD¹, Allyson Hughes, PhD²¹Ohio University Heritage College of Osteopathic Medicine, Athens, OH; ²T1D Exchange, Boston, MA

Diabetes stigma refers to negative feelings, such as exclusion, rejection, or blame, associated with having diabetes. A recent study of adults found three-quarters of people with type 1 diabetes and half of people with type 2 diabetes experience stigma. When people internalize diabetes stigma, they are less likely to perform self-care behaviors and form meaningful social interactions with friends and loved ones. Given the harm of stigmatization, several diabetes organizations have published position statements recommending language that is free from stigma. The purpose of this secondary qualitative analysis was to assess the frequency of stigmatizing language in a sample of 43 healthcare providers. The original aim of the qualitative study was to assess barriers to and facilitators for diabetes care in Appalachian Ohio. A purposive sample of 43 providers (mean age=45.3±12.0, 67.4% female, 95.3% white, 34.9% physicians, 21.4% nurses, 11.9% NPs, 7.1% CDEs, 7.1% pharmacists, 7.1% psychologists, 9.6% other providers, 17.3±11.6 years of experience) participated in semi-structured interviews. Interviews were transcribed, coded, and analyzed via content and thematic analyses using NVivo 12 software. This secondary qualitative analysis revealed two themes: 1) Use of Labeling Language: Thirty of the 43 (69.8%) participating providers labeled people with diabetes as “diabetics” in their interviews, with some providers using this term more than 20 times in their interviews. Further, 16 of the 43 (37.2%) providers referred to people with diabetes as “non-compliant” when discussing self-care behaviors. 2) Use of Language with Negative Connotations: Providers (n=25, 58.1%) frequently talked about A1C levels with “good” or “bad” value judgments and emphasized the goal of achieving “control” in diabetes. Other negative terms included “testing” (n=14, 32.6%) for blood glucose levels and “regimen” (n=8, 18.6%), which can imply a sense of failure and/or restriction in people with diabetes. In sum, providers frequently used stigmatizing language when talking about people with diabetes. These findings offer a real world glimpse of how providers talk about people with diabetes considering the original aim of the study was not focused on use of language. Future continuing medical education should incorporate recommended language in diabetes and integrate experiential learning to facilitate understanding and improve retention.

6:15 PM-7:30 PM

ASSOCIATION BETWEEN DURATION OF TYPE 2 DIABETES AND LIFESTYLE BEHAVIORS AMONG ADULTS WITH TYPE 2 DIABETES, USING THE 2018 BRFS.

Ruth G. St Fleur, BA¹, Blanca Noriega Esquivas, MD, MSPH², Sara M. St. George, PhD³¹University of Miami Miller School of Medicine, Department of Public Health Sciences, Miami, FL; ²University of Miami - Miller School of Medicine, Doral, FL; ³University of Miami Miller School of Medicine, Miami, FL

Background: Long term management of Type 2 diabetes through physical activity (PA) and diet helps achieve glucose control and improves blood pressure, which in turn reduces the risk of complications and cardiovascular as well as all-cause mortality. A diabetes diagnosis can serve as a motivating event for the initiation of behavior changes. However, adherence to those changes can be challenging and short-lasting.

Objective: The purpose of this study is to assess levels of physical activity as well as fruit and vegetable consumption in individuals with type 2 diabetes as a function of the duration of the disease.

Methods: We conducted a cross-sectional study using data from the 2018 Behavioral Risk Factor Surveillance System (BRFSS). We included 50,267 adults with diabetes and categorized them based on their disease duration (< 5 years vs. ≥ 5 years). PA was assessed as meeting the recommended 150min/week and the number of fruits and vegetables consumed daily was reported. Logistic regression models were used to determine the association between health behaviors (PA, fruit and vegetable intake) and diabetes duration, after adjusting for demographics and comorbidities such as age, income, race, weight status, cardiovascular disease and stroke.

Results: Adults with a duration of diabetes of less than 5 years were younger (54.9 vs. 60.6), more likely to be married (54% vs. 52%), with higher income (>\$50,000 = 33% vs. 29%), and obese (56% vs. 52%) compared to adults with a duration of diabetes of at least 5 years (p<0.05). There were no significant differences by sex, race, and education. In the fully adjusted regression models, having diabetes for less than 5 years was significantly associated with meeting the recommended 150 minutes of moderate PA per week (OR = 1.269, CI = 1.136-1.418). No significant association was observed for fruit or vegetable intake.

Conclusion: Many interventions have focused on initiating behavioral changes in patients at risk for or newly diagnosed with type 2 diabetes. Our results indicate that individuals with greater duration of diabetes are less likely to meet physical activity guidelines, even when complications and comorbidities are accounted for. Future research should aim to better understand factors associated with health behaviors in those who have had diabetes for longer.

PROTOTYPE DESIGN AND MIXED METHOD EVALUATION OF ROBOT-ASSISTED PHARMACY DIABETES CARE IN TAIWAN

Ching-Ju Chiu, n/a¹, Lin-Chun Hua, n/a²¹Institute of Gerontology, College of Medicine National Cheng Kung University, Tainan, Tainan, Taiwan (Republic of China); ²National Cheng Kung University, Tainan, Tainan, Taiwan (Republic of China)

Background: Taiwan has implemented refillable prescriptions for patients with chronic illnesses for years. Patients tend to have their prescriptions refilled in nearby clinic pharmacies instead of going back to hospital. So far, there are more than 8000 pharmacies in Taiwan. Because of its high accessibility and be part of daily life, community pharmacy can further narrow the gap between large medical institutions and personal care. Chronic disease patients such diabetes patients can also be supported by medical resources in the community such as community pharmacy. Recent years, increasing study support personal health care through technology might help. However, less research has used on robots and lack the link between robots and the current medical fields. Hence, the aim of this study is to develop a health care robot prototype that can be integrated into current community pharmacists. Method This is a three phase study. Phase 1 is to design and develop the prototype diabetes care robot. At phase 2 and 3, we used mixed methods to collect quantitative and qualitative data in order to improve the current prototype. After the prototype is set up, we conducted the tests in the community pharmacies. The Participants included type 2 diabetes patients over 45 years old and community pharmacists. For diabetes patients, it is a one-group pretest-posttest design. It took 15-20 mins for diabetes patients to interact with the prototype robot. We created a self-administered questionnaires. Questions includes demographic characteristics, diabetes knowledge test, self-efficacy for diabetes and feasibility of the prototype. After interaction, we interviewed both pharmacists and patients to feedback, such as suggestions, expectations, real needs and future development of diabetes care robots. Results There were 30 diabetes patients and 10 community pharmacists participated in the study. In this research, a paired t-test was used to compare the differences before and after interacting with the robots. The analyzed data shows the significant difference between pre-test and post-test of diabetes knowledge test ($p < .001$) and feasibility of the robot ($p = .012$). Qualitative findings include five domains. (1) Health education may be the key role robot can help. (2) Robot-enhanced convenience of screening and data collection. (3) Distrust and negative feelings about the robot. (4) Robots can make patients feel more interactive. (5) Robot seemed to provide new services.

Conclusion: Both community pharmacist and diabetes patients, report the use of robots is acceptable, and it is considered feasible for robots to promote their health care in the future.

6:15 PM-7:30 PM

INTERVENTION ENHANCEMENT STRATEGIES AMONG ADULTS WITH TYPE 2 DIABETES IN A VERY LOW-CARBOHYDRATE WEB-BASED PROGRAM

Laura Saslow, PhD¹, Judith T. Moskowitz, PhD², Ashley E. Mason, PhD³, Jennifer Daubenmier, PhD⁴, Amanda L. Missel, MS⁵, James E. Aikens, PhD¹, Sarah Kim, MD³, Frederick M. Hecht, MD⁶¹UM, Ann Arbor, MI; ²Northwestern Medicine, Chicago, IL; ³UCSF School of Medicine, San Francisco, CA; ⁴San Francisco State University, San Francisco, CA; ⁵University of Michigan, Ann Arbor, MI; ⁶University of California, San Francisco, San Francisco, CA

Background: Adults with type 2 diabetes may experience health benefits, including glycemic control and weight loss, from following a very low-carbohydrate, ketogenic (VLC) diet. However, it is unclear which ancillary strategies may enhance these effects.

Objective: The purpose of this pilot study was to estimate the effect sizes of three intervention enhancement strategies (text messages, gifts, and breath vs. urine ketone self-monitoring) that may improve outcomes of a 12-month web-based ad libitum VLC diet and lifestyle intervention for adults with type 2 diabetes. The primary intervention also included other components to improve adherence and well-being, including positive affect and mindfulness, as well as coaching.

Methods: Overweight or obese adults ($n=44$, BMI 25-45 kg/m²) with type 2 diabetes (i.e., glycated hemoglobin (HbA1c) $\geq 6.5\%$), prescribed either no glucose-lowering medications or metformin alone, participated in a 12-month web-based VLC and lifestyle intervention. Using a 2x2x2 randomized factorial design, we compared three additional enhancement strategies: (a) near-daily text messages about the intervention's recommended behaviors (texts $n=22$ vs. no texts $n=22$), (b) mailed gifts of diet-relevant foods and cookbooks (6 rounds of mailed gifts $n=21$ vs. no gifts $n=23$), and (c) urine- or breath-based ketone self-monitoring (urine $n=21$ vs. breath $n=23$). We assessed HbA1c and weight at baseline, 4, 8, and 12 months. We evaluated whether each enhancement strategy exerted a differential impact upon HbA1c and weight at 12 months against an a priori threshold of Cohen's $d \geq 0.5$.

Results: We retained 73% of participants ($n=32$) at 12 months. The intervention, across all conditions, led to 12-month improvements in glucose control and body weight. In ITT analyses, mean HbA1c reduction was 1.0% and mean weight reduction was 5.3%, whereas among study completers these reductions were 1.2% and 6.3%, respectively, all with a $P < .001$. In ITT analyses, no enhancement strategy met the effect size threshold. Considering only study completers, two enhancement strategies showed a differential effect size of $d \geq 0.5$: text messages (vs. no text messages) for HbA1c reduction and urine ketone self-monitoring (vs. breath ketone self-monitoring) for weight reduction. Cohen's d s for gifts (vs. no gifts) were at least 0.2. Qualitative data suggested that participants generally liked the text messages and gifts, but found the breath meter difficult to use.

Conclusions: Text messages, gifts of food and cookbooks, and urine-based ketone self-monitoring may potentially enhance the glycemic or weight loss benefits of a web-based VLC diet and lifestyle intervention for individuals with type 2 diabetes. Future research could investigate other enhancement strategies to help create even more effective solutions for type 2 diabetes treatment efforts.

MEDICATION TAKING BEHAVIOR AMONG ADULTS WITH TYPE 2 DIABETES AND POLYPHARMACY

Andrea M. Russell, MS¹, Lauren Opsasnick, MS¹, Guisselle Wismer, MPH¹, Matthew O'Brien, MD, MPH¹, Stacy Bailey, PhD, MPH¹, Michael S. Wolf, PhD, MPH¹

¹Northwestern University Feinberg School of Medicine, Chicago, IL

Background: Taking prescribed (Rx) medications, especially in the context of 'polypharmacy' (5 or more Rx medications), can be one of the most complex health behaviors. Effective organization and daily scheduling of multi-drug regimens is one of the most critical tasks for proper adherence and persistence to treatment, in order to achieve optimal management of chronic conditions, such as type 2 diabetes. Experimental medication dosing tasks using hypothetical regimens have found patients with lower health literacy are at greater risk of misunderstanding medication instructions and over-complicating dosing.

Objective: To examine actual daily dosing patterns of primary care patients with type 2 diabetes and polypharmacy.

Methods: This analysis used baseline data from a clinical trial conducted among patients with type II diabetes (N=451) recruited from two Federally Qualified Health Centers in Chicago, IL. Patients were primarily Hispanic (73%) and nearly all had limited health literacy (89%). In the interview, patients were asked to review their medication regimens and demonstrate how they typically dose out each medication daily. The total number of times medication was taken over the course of a 24 hour period was derived. As the widely endorsed Universal Medication Schedule considers dosing medication 4 or fewer times per day as acceptable, dosing over-complication was defined as taking medications 5 or more discrete times per day. Kruskal-Wallis, chi-square and fisher's exact tests were used to examine associations between sociodemographics and dosing frequency.

Results: The average regimen size of the sample was 7.6 (SD=3.59, range 2-24) daily prescription medications and patients were taking medicine on average 3.2 times daily, with a range of 1 and 9 discrete times per day. As many as 17% (N=76) of patients over-complicated regimens. Older age, lower income and lower education were associated with higher frequency of daily dosing (all p values < .05). Patients who over-complicated dosing were more likely to report poorer health status (p=.02).

Conclusions: Nearly one in five patients with Type II Diabetes contending with complex regimens reported overly-complicated dosing their medications schedules. This may go unnoticed by clinicians but increase patients risk of poor adherence, safety concerns suboptimal clinical outcomes.

PSYCHOSOCIAL SCREENING FOR YOUTH WITH DIABETES

Eileen Davis, PhD¹, Janine Sanchez, MD², Annette M. La Greca, PhD³, Alan M. Delamater, PhD²

¹Department of Pediatrics, Miami, FL; ²University of Miami Miller School of Medicine, Miami, FL; ³University of Miami, Coral Gables, FL

Objectives: Research indicates that youth with diabetes have high rates of psychological disorders that can interfere with successful diabetes management. Clinical practice guidelines recommend routine, preventive psychosocial screening across a variety of domains. This study reports on the results of universal, comprehensive psychosocial screening in an integrated pediatric diabetes clinic.

Methods: Pediatric patients with diabetes 12 years and older were screened using brief standardized measures for depression, anxiety, diabetes stress, family conflict, and insulin regimen adherence. The screeners were completed on tablets in the waiting room before the appointment. If patients scored above a pre-determined cutoff on any measure, the psychology team conducted a consultation. Glycemic control was measured by routine hemoglobin A1c.

Results: 281 12-17 year-old youth (M age=14.9 years, 56% female, 86% with type 1 diabetes) completed the screener over a 12-month period. The following percentages of youth screened positive: depression, 23.5%; anxiety, 19.1%; diabetes stress, 21.1%; family conflict, 11.2%; and insulin non-adherence, 38.1%. Youth with poor glycemic control (A1c > 9%, 36.3%) were more likely to screen positive for depression (30.4%, p< .05), diabetes stress (36.6%, p< .001), and family conflict (21.8%, p< .001). Those with poor insulin adherence were more likely to screen positive for anxiety (26%, p< .05), diabetes stress (29.8%, p< .01), and family conflict (18.3%, p< .01).

Conclusions: Routine psychosocial screening can identify the high percentage of youth who screen positive for depression, anxiety, stress, and family conflict. These youth are more likely to have poor glycemic control and insulin regimen adherence problems.

PREVENTING TYPE 2 DIABETES AMONG SOUTH ASIAN AMERICANS THROUGH COMMUNITY-BASED LIFESTYLE INTERVENTIONS: A SYSTEMATIC REVIEW

Shahmir H. Ali, BA¹, Supriya Misra, ScD¹, Niyati Parekh, PhD¹, Bridget Murphy, MS, RDN, CDE, CDN¹, Ralph J. DiClemente, PhD¹

¹NYU College of Global Public Health, New York, NY

The rise of type 2 diabetes in the US is a pressing public health challenge, and South Asians contribute a disproportionate amount to this diabetes burden. Culturally tailored lifestyle interventions have been explored in Europe as an effective diabetes prevention method among South Asian migrants, however their effectiveness in US settings remains unclear. This systematic review aimed to characterize and evaluate the effectiveness of community-based lifestyle interventions among South Asians living in the US. A PRISMA-informed search of Pubmed, Embase, Cochrane, Web of Science, and clinical trial registry databases using key words pertaining to South Asians migrants and diabetes indicators (glucose and insulin outcomes) was conducted of interventional or baseline studies of community-based lifestyle interventions. Screening of 1571 studies and independent full text assessment of 43 studies led to 7 studies included in the final qualitative synthesis. Most interventions focused on cultural and linguistic adaptations of past chronic disease prevention curriculums through group-class formats. Populations varied significantly by gender, educational attainment, and occupation, while almost all studies exclusively studied first-generation immigrants. Effectiveness was largely measured through HbA1C and random plasma blood glucose, with three of the five studies involving statistical analysis observing improvements in these indicators post-intervention. Contextualizing these findings with past literature, this study recommends 1) greater exploration of community-based lifestyle interventions with higher quality diabetes indicators (such as fasting blood glucose) in US-based South Asian communities, 2) expanding beyond traditional formats of group-class based lifestyle interventions and exploring the use of technology and more active intervention components, and 3) greater research on diabetes prevention among South Asians of differing migration statuses in the US (notably second generation communities).

MEASURING DIABETES KNOWLEDGE IN HISPANICS WITH TYPE 2 DIABETES

Jie Hu, PhD, RN, FAAN¹, Karen A. Amirehsani, PhD,FNP-BC², Thomas P. McCoy, PhD, PStat², Debra D. Wallace, PhD, RN, FAAN², Sheryl L. Coley, DrPH²

¹The Ohio State University, Columbus, OH; ²The University of North Carolina at Greensboro, Greensboro, NC

Purpose: Hispanic Americans suffer disproportionately from diabetes and health complications. Assessing diabetes knowledge is a critical step to identify educational gaps for diabetes self-management interventions. The purpose of this study was to examine reliability and validity of the Spoken Knowledge in Low Literacy in Diabetes Scale (SKILLD) in measuring diabetes knowledge among Hispanics with type 2 diabetes.

Methods: A total of 111 Hispanic participants with type 2 diabetes (T2DM) comprised the study. Participants were recruited in the clinics and churches in the Southeastern U.S. The Spanish version of the SKILLD measures diabetes knowledge. The Summary of Diabetes Self-Care Activities (SDSCA) measure was used to test convergent validity. Reliability via internal consistency was estimated using Kuder-Richardson 20 (KR-20). Item analysis and exploratory factor analysis (EFA) was conducted on the ten dichotomous items comprising the Spanish SKILLD instrument. Item analysis consisted of estimating the percentages of participants getting each item correct, the corrected point-biserial correlations (item-to-total), and KR-20 with each item removed. Since items were dichotomous, EFA was performed after estimating tetrachoric correlations among the items in Mplus v7.3. Spearman rank correlations of SKILLD scores with Diabetes Self-Care Activities (SDSCA) scores were inspected for evidence of convergent validity as well as with HbA1c level and duration of diabetes.

Results: The average SKILLD score was 35.1% ($SD = 23.4\%$). The percent correct response for each of the 10 SKILLD items ranged from 4.5% to 56.8%. The estimated reliability via internal consistency was adequate ($KR-20 = 0.706$). EFA of the ten SKILLD items modestly indicated one factor could be retained. Spearman rank correlations of SKILLD scores with diabetes self-care activities were significant and positive for feet ($r_s = 0.26, p = 0.014$). SKILLD scores were significantly correlated with duration of diabetes (years) ($r_s = 0.27, p = 0.004$). Those using insulin ($n = 26$ (23%): $45.4\% \pm 23.4$ vs. not using ($n = 85$ (77%)): $32.0\% \pm 22.6, p = 0.015$) and that had a higher level of education (High school to some college ($n = 30$ (27%)): $45.3\% \pm 20.6$ vs. Less than 12 years ($n = 81$ (73%)): $31.4\% \pm 23.3, p = 0.005$) had significantly higher SKILLD scores.

Conclusions: The Spanish SKILLD showed acceptable reliability and adequate validity in the sample of Hispanics with type 2 diabetes. The SKILLD scores in this study have shown low knowledge to diabetes in this sample. Clearly, diabetes education tailored to low literacy needs to be delivered to Hispanics in the communities. The specific lack of knowledge of hypo/hyperglycemia exposes participants to severe short and long term consequences of diabetes complications. Priority intervention must include more effective education for hypoglycemic symptom recognition and treatment.

SCHOOL SALAD BARS AND LUNCH ENERGY INTAKE: A PLATE WASTE ANALYSIS AMONG TITLE I ELEMENTARY SCHOOLS WITH UNIVERSAL FREE MEALS

Hollie Raynor, PhD, RD¹, Laura M. Thornton, N/A², Suzanne E. Mazzeo, PhD³, Alexandra Sova, B.S.⁴, Melanie K. Bean, PhD³

¹University of Tennessee, Knoxville, TN; ²University of North Carolina at Chapel Hill, RICHMOND, VA; ³Virginia Commonwealth University, Richmond, VA; ⁴Drexel University College of Medicine, Philadelphia, PA

Background: School salad bars are promoted to prevent/reduce childhood obesity by increasing fruit and vegetable (F&V) intake. It is assumed that with greater F&V intake, reduced energy intake occurs. To better understand the effect of school salad bars on lunch energy intake, this study examined lunch energy intake, both total and by meal components, in schools with salad bars (SB) compared to schools serving pre-portioned F&Vs (Control).

Methods: Three pairs of Title I elementary schools (A, B, C) with and without salad bars in central Virginia were matched on % racial/ethnic minority students and the cafeteria environment and randomly selected. The primary difference between schools was how Vs were served (salad bar or pre-portioned). Students in grades 1-5 were eligible (92.5% NSLP participation; 98.6% minority; 100% free meals). To determine lunch intake, digital images were taken before and after consumption. Trained raters (intrate reliability > 0.80) documented selection (to the nearest $\frac{1}{4}$ c for self-serve) and intake in 20% increments, with beverages rated to the nearest $\frac{1}{2}$ oz. Reference portions were used for nutrition analyses. Energy intake was calculated for total meal, Fs, Vs, entrées, snacks, and beverages. As multilevel models found a significant group*pair interaction, multilevel models examined group differences (SB vs Control) by pair (A, B, C) in outcomes accounting for sex, grade, and nesting within schools and stratified by pair.

Results: Overall, 1155 trays were rated ($n=532$ SB; $n=623$ Control). Mean total lunch energy intake ranged from 249.6 ± 132.3 kcal to 434.6 ± 161.0 kcal for SB, and 260.0 ± 153.4 kcal to 391.9 ± 190.8 kcal for Control. Pairs A and C's lunch energy intake was significantly ($p < 0.05$) greater for SB vs Control, whereas differences were not found for Pair B. Pairs A and C also reported significantly ($p < 0.05$) greater entrée energy intake in SB vs Control, whereas Pair B reported significantly ($p=0.007$) less entrée energy intake in SB vs Control. Pairs B and C had significantly ($p < 0.0001$) greater V energy intake in SB vs Control.

Conclusion: Mean energy intake from all lunches was < 450 kcal, indicating school lunch was not providing excessive energy. Schools with salad bars did not have lower lunch energy intake. Differences across pairs in energy intake, both in total and by meal components, varied in all comparisons, indicating that intake may be influenced by foods served or school-level factors not assessed.

HELPING PARENTS PROVIDE VEGETABLE SNACKS: IDENTIFYING AN IMPACTFUL STORE DISCOUNT MAGNITUDE AND FACTORS THAT INFLUENCE APPEAL

Sara Folta, PhD¹, Stephanie Anzman-Frasca, PhD², Marisa Tsai, MS, MPH³, Jeanne P. Goldberg, PhD⁴, Sarah Johnson, MS, MPH⁵, Sean B. Cash, Ph.D.¹¹Tufts University, Boston, MA; ²Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY; ³Nutrition Policy Institute, San Francisco, CA; ⁴Tufts University, Newton Centre, MA; ⁵Massachusetts Institute of Technology (MIT), Cambridge, MA

Purpose: Snacks contribute nearly one quarter of children's daily energy intake. Snacktime therefore represents an opportunity for parents to provide foods with key nutrients. Instead, the most common snack foods are major contributors to children's consumption of added sugars, saturated fat, and sodium. Parents face major barriers to providing healthier snacks, including perceptions of high cost and lack of child acceptance. Previous research suggests that grocery store discounts may shift purchases towards healthier snack foods such as vegetables, however additional research is needed to identify what magnitude of discount is impactful for parent shoppers. Research is also needed to understand how to increase child acceptance of vegetable snacks. The purpose of this study was to obtain economic and qualitative data to optimize interventions for parents to promote vegetable snacks for children.

Methods: We partnered with community organizations serving families in Massachusetts and New York to conduct an online survey with parents (n=516) to estimate whether and how much of a discount would influence vegetable snack purchases by estimating willingness-to-pay using the contingent valuation method, using baby carrots as a sample product. We conducted four focus group discussions with children in Massachusetts (n=21) designed to help understand how to increase the appeal of vegetable snacks.

Results: Parent survey respondents had an average of 1.7 children (SD 1.1) with a mean age of 8.5 years (SD 2.6). Sixty-four percent of parent respondents were white and 42% were eligible for free-or-reduced-price school meals. Most (70%) accepted the current market price for baby carrots. Among parents who did not accept the market price, contingent valuation analysis revealed that a discount amount of approximately 30% would shift purchasing behavior. Focus group results revealed that the appeal of vegetable snacks to children was influenced by preparation, presentation, autonomy, and familiarity.

Conclusion: This study lays the groundwork for effective interventions to promote the provision of vegetable snacks by parents. Such interventions could include multiple strategies to address barriers to child vegetable consumption, such as partnerships with stores to provide discounts on vegetables and educational materials for parents with strategies to increase the appeal of vegetable snacks.

PARENTAL OVERPOUR: EXPLORING SERVING SIZE ESTIMATION FACTORS AMONG PARENTS

Ashlie Johnson, MS¹, Ashley Haberman, n/a², Dan Graham, Ph.D.²¹Colorado State University, Fort Collins CO, CO; ²Colorado State University, Fort Collins, CO

Serving size guidance on food and beverage labels is one attempt by policymakers to increase consumer understanding of the amount recommended to consume in a single sitting. Serving size estimation is related to several factors such as hunger levels, health numeracy, and the metric of measurement (Brogden & Almiron-Roig, 2011; Regan et al., 2018). Further research is needed to identify how additional factors, such as food type and public policy tools, are associated with one's perception of serving sizes. This study used products with Front of Package (FOP) labels (a 1-4 star healthfulness rating) to test how an informative public service announcement (PSA) introducing and explaining the star-based labels would impact serving size estimations and how serving size estimations differ by food type. 175 parent-child dyads were randomly assigned to either see a PSA for an FOP label (n = 59) or not (n = 113), before completing a mock grocery store task and several post-shopping tasks including a serving size estimation task. Serving size estimation data from 172 parents (93% female, M age = 38.4, 87% white, 14% Hispanic) for 4 foods – 2 cereals (a dense, crunchy wheat and barley cereal, and a rice cereal) and 2 snack foods (potato chips, and pretzels) were analyzed. It was predicted that those who viewed the PSA for the FOP labels would estimate smaller portions of less healthful foods (i.e., chips, pretzels), relative to foods earning more stars (i.e., the cereals). Linear regressions showed that seeing the PSA predicted neither total serving size estimations ($R^2 < .001$, $F(1, 686) = 0.174$, $p > .05$) nor serving size estimations for individual foods (All $R^2 < .01$, $F_s(1, 170)$ ranged from 0.245 – 1.66, $p_s > .05$). However, regression analyses indicated that food type was a significant predictor of serving size estimation, predicting around 91% of the variance ($R^2 = .910$, $F(3, 684) = 2294$, $p < .001$). Holding other estimations constant, it was shown that – consistent with predictions – parents overestimated serving sizes for the dense wheat and barley cereal ($M = 5.8\%$ overestimation) and for pretzels ($M = 12.8\%$ overestimation), but they underestimated the serving size of the rice cereal ($M = 26\%$ underestimation) and potato chips ($M = 9.1\%$ underestimation). Findings suggest that while watching a PSA about labeling may not have a significant impact on serving size estimations of foods with the advertised labels, the type of food is associated with the degree to which an individual may over/underestimate serving sizes. Overestimation of serving sizes and increased portion sizes may be implicated in over-consumption of certain food types. By identifying factors related to errors in serving size estimation, researchers can highlight areas of potential bias useful in providing feedback to those hoping to improve the accuracy of their estimations.

RELATIONSHIP BETWEEN ADDED SUGAR CONSUMPTION AND MENTAL HEALTH AMONG MIDWESTERN COLLEGE STUDENTS

Jerome Kotecki, n/a¹, Maurita A. Greene, n/a¹, Tya Arthur, n/a², Jagdish Khubchandani, n/a², Jay Kandiah, n/a¹¹Ball State University, Muncie, IN; ²Ball State University, Muncie, IN**Objective:** The aim of this study was to examine the relationship between added sugar consumption and mental health in college students.**Methods:** A 45-item electronic survey was sent to a cross-sectional sample of undergraduate students at a Midwestern University after being tested for face, content, and construct validity. Added sugar consumption was assessed using 3 items measuring sweets, soft drinks, and specialty drinks containing sugar by employing a 5-point Likert scale ranging from 'never' to 'always'. Mental health was assessed in three ways. First, with the Kesslers-6 (K6) scale to measure psychological distress over the past month. The K6 employs a 5-point Likert scale ranging from 'none of the time' to 'all the time' for its 6 items. Second, with the Perceived Stress Scale (PSS-10) to measure perceived and chronic stress. The PSS-10 employs a 5-point Likert scale ranging from 'never' to 'very often'. Third, with the CDC's Healthy Day Measure of how many days during the past 30 days was one's mental health not good.**Results:** A total of 1,170 students completed the survey (response rate=92.3%). The majority were Whites (82.3%), female (67.5%) and 18-20 years old (79.1%). The mean added sugar score was 9.64 ± 2.38 . The three mean mental health measures were: K-6 11.05 ± 5.07 , PSS-10 20.42 ± 6.40 , and number of days mental health not good 9.38 ± 8.22 . Statistically significant relationships ($p < 0.05$) existed between K6 (-.21), PSS-10 (-.21), and Healthy Mental Days Measure (-.16), and added sugar consumption. Since higher scores on the stress and healthy mental days scales are negative while higher scores on the added sugar are positive for health, the negative correlations indicate increased sugar intake is paired with increase stress and more unhealthy days. Furthermore, differences were found between gender ($t(728.96) = 3.14, p = .002$) but not race ($F(2,1167) = 0.69, p = .50$) for the added sugar consumption score.**Conclusions:** The downfalls of high added sugar consumption are not limited to weight gain, obesity, Type 2 diabetes, cardiovascular disease, and many cancers. Consuming too much sugar may also increase young adults' risk of mental health disorders. While college counselors and health professionals address stress and mental health issues in students, consideration should be given to addressing added sugar consumption behaviors that may be associated with mental health.

ASSOCIATION BETWEEN APPEARANCE-BASED DISCRIMINATION AND BINGE EATING DISORDER AMONG SEXUAL MINORITY MEN

William Grunewald, BS¹, Alexandra D. Convertino, BS², Steven A. Safren, Ph.D.³, Matthew J. Mimiaga, ScD, MPH⁴, Aaron J. Blashill, Ph.D.¹¹San Diego State University, San Diego, CA; ²SDSU/UC San Diego Joint Doctoral Program in Clinical Psychology, San Diego, CA; ³University of Miami, Coral Gables, FL; ⁴Brown University, Providence, RI

Numerous studies have tied weight-based discrimination to binge eating and binge eating disorder (BED) in various samples. One group that encounters frequent discrimination is sexual minority men (SMM). Minority stress theory posits that minority groups, like SMM, face excess stressors due to their stigmatized position in society. Given this elevated stress, SMM may be at increased risk of developing BED; however, this association is currently underexplored. Thus, the current study examined the association of various forms of discrimination, inclusive of appearance-based discrimination (which may be salient for SMM due to their endorsement of the mesomorphic ideal), and probable BED diagnosis in a sample of SMM. A sample of 189 SMM from the greater Boston area were recruited in order to pilot an at-home rapid HIV detection test. After recruitment, participants completed self-report questionnaires assessing frequency of different forms of perceived discrimination (appearance, race, sexual orientation, income, etc.) and probable BED diagnosis via the PHQ-ED. A hierarchical binary logistic regression model with three steps was used to examine the association of different forms of discrimination and probable BED diagnosis. These steps were 1.) physical appearance discrimination predicting probable BED diagnosis as the binary outcome variable, 2.) adding the remaining forms of discrimination as predictors, and 3.) including additional socio-demographic covariates. 4.2% of the sample screened positive for probable BED. Appearance-based discrimination was the most common form of discrimination reported (47.2%), followed closely by income (45.1%) and sexual orientation (44.0%). Appearance-based discrimination was significantly associated with probable BED diagnosis over and above all other forms of discrimination and sociodemographic variables, OR = 2.82, 95% CI = [1.52, 5.25], $p = .001$. Of note, appearance-based discrimination was the only form of discrimination that significantly predicted probable BED diagnosis. Findings suggest that appearance-based discrimination may be related to BED in SMM. Future research should examine these associations longitudinally in order to establish temporal ordering. Due to the reported frequencies of discrimination, clinicians may consider assessing appearance-based discrimination among SMM patients so as not to assume that sexual orientation discrimination is the most predictive form of discrimination for BED.

GARDENING FOR HEALTH: DEVELOPING A SCHOOL GARDEN AND HEALTHY EATING CURRICULUM FOR NAVAJO ELEMENTARY SCHOOLS

India J. Ornelas, PhD¹, Emily V. Brown, MPH², SONIA BISHOP, BS², Brandon W. Francis, Environmental Studies³, Kevin Lombard, PhD⁴, Shirley A.A. Beresford, PhD¹

¹University of Washington, Seattle, WA; ²Fred Hutchinson Cancer Research Center, Seattle, WA; ³NMSU, Farmington, NM; ⁴New Mexico State University, Farmington, NM

Background: Navajo youth are at increased risk for obesity, diabetes and cancer, in part due to low fruit and vegetable consumption. Barriers to healthy eating include limited access to fresh fruits and vegetables and lack of knowledge regarding nutrition guidelines.

Methods: In collaboration with community partners, we developed a program to increase fruit and vegetable consumption among Navajo (Diné) youth. The program includes elementary school-based gardens and a gardening and healthy eating curriculum for 3rd and 4th grade students. We built on existing school-based garden programs and modified lessons to include aspects of Navajo culture, such as traditional growing practices and foods. Formative work included focus groups with Navajo parents and children and a pilot demonstration program that assessed feasibility of delivering the garden and curriculum. We conducted interview assessment of parents and children's satisfaction with the program. We used the pilot results to further adapt the curriculum. The modified program is being tested in a randomized control trial in six elementary schools in two communities on the Navajo Nation.

Results: Themes from the parent focus groups included: strong value in having a school-based garden, desire to expose their child to new fruits and vegetables, interest in activities incorporating Navajo culture and opportunities to learn about gardening and cooking. Themes from the student focus group included: wanting to learn more about gardening and interest in eating foods they grow themselves. Our original curriculum consisted of 12 healthy eating lessons and 12 gardening lessons implemented throughout the academic school year for 1st – 5th grade students. Pilot testing identified lessons that were too complicated and helped reorder the lessons for improve flow and synergy between lessons. The revised healthy eating and gardening curriculum consists of 10 lessons each, targets 3rd and 4th grade students, and meets state and tribal teaching standards. Lessons include: reading a recipe, eating for energy, eating a variety of fruits and vegetables, native plants and Navajo ecology and garden maintenance.

Conclusions and Future Recommendations: Formative research and pilot testing can inform the development of culturally relevant health promotion interventions. Results from our study can guide future research on healthy eating and gardening in elementary schools on the Navajo Nation.

PLACE BASED TEXT MESSAGES AS AN APPROACH TO IMPROVE FRUITS AND VEGETABLE AMONG RURAL FOOD INSECURE ADULTS

Alison A. Gustafson, PhD, MPH, RD¹, Alison A. Gustafson, MS, RD¹

¹University of Kentucky, Lexington, KY

Research to date has shown that rural communities face greater barriers to healthy eating and being physically active, which contributes to higher rates of obesity and chronic disease compared with their urban counterparts. **Utilization of technology may be an effective approach to help improve health outcomes among these unique communities.** Currently, 71% of rural residents own a smart phone, and 92% of ages 30-49 and 79% of ages 50-64 own a smart phone as well. Thus, this intervention will utilize smart phones as a way to provide healthy nudges during the day. The randomized control trial intervention (n=520) will utilize a Cooperative Extension developed app (Fit Blue KY) that allows for in the moment text messages (place – based messages) to be sent to rural residents (n=8 counties) when they are at various food venues (grocery stores, supercenters, dollar stores) and at home to assist with making healthier food and beverage choices. Based on preliminary data residents are more likely to respond (reply to the text message) to helpful behavior based text message nudges that are affective in nature rather than educational. In addition, residents are receptive to text message nudges that are tailored to the location they are in rather than a general message about shopping behaviors. Implications of these preliminary results assist with development of text messages for the large scale intervention and help to guide dissemination across a variety of health settings.

MOTHERS' DASH DIET ADHERENCE AND WEEKLY FOOD PURCHASES AFTER BRIEF EPISODIC FUTURE THINKING INTERVENTION

Kelseanna Hollis-Hansen, MPH¹, Jennifer Seidman, n/a², Leonard Epstein, PhD³¹University at Buffalo Division of Behavioral Medicine, Buffalo, NY; ²University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY; ³University at Buffalo, Buffalo, NY

Background: Prospection has been shown to help mothers forego the temptation to buy and eat higher calorie nutrient poor foods in favor of buying and eating fewer calories and healthier macronutrient profiles in laboratory tasks and in brief field studies. The present study extends those findings to examine whether EFT improves dietary behavior or grocery purchasing from baseline to follow-up over a longer period of time.

Methods: The present study was a one-week EFT intervention on mothers' dietary behaviors and food purchases delivered through a mobile ecological momentary intervention (EMI) tool. We used a mixed methods design, whereby participants were randomized to one of four groups: EFT or standardized episodic thinking (SET) with dietary approaches to stop hypertension (DASH) diet education or food safety education. Participants listened to their cues using their preferred device and returned one week later to complete a follow-up dietary recall and submit food receipts. Mixed linear models were used with EFT and education as dummy coded independent variables and baseline and follow-up DASH diet adherence scores and nutrients purchased as repeated measures dependent variables in separate models.

Results: There was an EFT effect on DASH diet adherence scores, such that mothers in the EFT groups increased their DASH adherence scores over the one-week intervention ($p < .05$). There was an EFT effect on milligrams of sodium purchased ($p < .05$) and a trend towards a decrease in grams of fat purchased ($p = .06$), however, there was no significant effect of EFT on calories or other macronutrients purchased ($> .05$).

Discussion: EFT had a small positive effect on participant's dietary behaviors, and may have led to a decrease in sodium purchased, but did not change the calorie content or overall quality of grocery purchases. It is possible that intervening with mothers alone wasn't enough to make food purchase changes for the entire household over a longer period of time. Previous research has found that EFT has large acute effects on behavior and decision-making, but future studies should seek to identify if there is long term efficacy of EFT interventions.

PEDIATRIC FOOD CHOICES: THE RELATIVE IMPORTANCE OF TASTE, HEALTH, AND WHAT YOUR MOTHER DOES

Haley Killian, MA¹, Amanda S. Bruce, PhD², Ann M. Davis, PhD, MPH, ABPP², Oh-Ryeong Ha, PhD³¹University of Missouri - Kansas City, University of Kansas Medical Center, Center for Children's Healthy Lifestyles and Nutrition, Kansas City, MO; ²University of Kansas Medical Center & Center for Children's Healthy Lifestyles and Nutrition, Kansas City, KS; ³University of Missouri - Kansas City, Kansas City, MO

In the U.S., 19% of youth aged 2-19 are obese (CDC, 2017). Thus, prevention and intervention programs are essential. Better understanding of factors impacting food choice can inform programs. Parents play a key role in children's food choices and food-related attitudes (Wrotniak et al., 2005). A neuroimaging study reported that maternal food choices play a regulatory role in children's food choices (Lim et al., 2016). The synchrony of food choices in mother-child dyads has not been explicitly examined. The present study examined the relationship between the importance of taste and health on food attitudes and choices in mother-child dyads. In addition, given that advertising impacts children's food choices (Bruce et al., 2016; Fakhouri, et al., 2013), this study examined the relationship between maternally perceived advertising influence on children and children's food attitudes. Thirty-nine children aged 8-12 years ($M = 10.40$, $SD = 1.41$; BMI percentiles $M = 63.81$, $SD = 31.55$) and mothers ($M_{age} = 39.75$, $SD = 6.38$; BMI $M = 28.97$, $SD = 6.78$) were recruited from the Kansas City area. Mothers and children completed computerized food rating and choice tasks asking them to rate 30 healthy and 30 unhealthy foods on health, taste, liking, and choice (Ha et al., 2018). They also reported on demographics, attitudes on food choice, and eating behavior. Preliminary results indicated a significant negative relationship between maternal health importance on food choices and the importance of taste on child's food liking ($r = -.36$, $p = .03$), and a negative relationship between maternal health importance on food liking and her child's own liking based on taste ($r = -.33$, $p = .04$). As a mother placed less importance of health on food choices, the child placed more importance of taste on food liking. Results also indicated that a mother's perspective on the advertising's impact on her child was positively related to the importance of taste on child's food liking ($r = .43$, $p = .01$). When a mother reported commercial advertising having a high influence on her child, the child placed more importance on taste on liking of food. This study is ongoing, and more data will be collected. With high utilization of family-based treatment for obesity, it is helpful to understand how parents use health and taste in food choice and the relationship to those factors in their child. This knowledge could guide future childhood obesity prevention and intervention programs.

INTERACTIONS AMONG REWARD SENSITIVITY AND FAST FOOD ACCESS ON HEALTHY EATING IN ADOLESCENTS

Shirlene D. Wang, BA¹, Michele Nicolo, PhD², Li Yi, MS/MS¹, Genevieve F. Dunton, PhD, MPH¹, Tyler B. Mason, PhD¹¹University of Southern California, Los Angeles, CA; ²Keck School of Medicine Preventative Medicine, Pasadena, CA

Food cues in the environment may contribute to obesity as the consumption of foods high in sugar and fat may reinforce reward pathways in the brain. This response may vary due to person-level differences such as motivation. To understand how individual factors lead to the consumption of low-quality foods, this study aimed to examine the moderating role of availability of fast-food outlets in the environment on the relationship between approach motivation and healthy eating in children.

Children (N=152; 55% female; m_{age} : 12.5 \pm 0.93 y) completed a questionnaire assessing approach motivation using the drive and reward responsiveness subscales of the Behavioral Activation System (BAS) scale. Two 24-hour dietary recalls were conducted, and Healthy Eating Index (HEI) scores were calculated from the dietary data. Fast food environment (FFE) was operationalized as the total number of fast-food outlets within 1km around participants' home address in 2017, derived using GIS as a measure of average exposure to unhealthy food cues. SPSS PROCESS was used to examine statistical interactions between approach motivation and FFE in relation to HEI scale. Covariates included participants' sex, age, BMI, ethnicity, and family income level.

Bivariate correlations and multiple regression analysis did not find main effects of BAS on HEI total score. Interactions between FFE and BAS drive ($p=.102$) and BAS reward ($p=.056$) were marginally significant on HEI, thus, HEI subscales for adequacy (dietary components to increase i.e. fruits and vegetables) and moderation (components to decrease i.e. sodium and saturated fat) were further examined. Interactions were found between FFE and BAS drive ($p=.021$) and BAS reward ($p=.005$) on HEI adequacy. For individuals who had lower access to fast food outlets, there was a stronger positive association between higher BAS drive and reward scores and HEI adequacy scores. There was no interaction between BAS drive or reward with FFE in predicting HEI moderation scores ($p=.931$ and $.925$).

The association between approach motivation and healthy diet varied depending on children's FFE such that high FFEs weakened the association between reward sensitivity and adequacy (higher diet quality). By examining reward sensitivity to potential food cues in residential neighborhood food environments, it is possible to understand which children are more sensitive to environmental food cues and implement policies to buffer these influences.

IMPROVEMENTS IN REWARD BASED EATING THROUGH GENERAL MINDFULNESS INTERVENTION EXPLAINED BY IMPROVEMENTS IN TRAIT MINDFULNESS

Sarah M. Fisher, BA¹, Julie Vaccaro, BS², Elissa S. Epel, PhD², Rachel M. Radin, PhD³, Aric Prather, PhD²¹University of California, San Francisco, San Francisco, CA; ²University of California, San Francisco, San Francisco, CA; ³Osher Center for Integrative Medicine, San Francisco, CA

Reward-based eating drive, characterized by lack of control over eating, lack of satiation, and preoccupation with food, is an important yet overlooked behavioral phenotype among individuals with overweight and likely explains why many fail to see long-term results in standard behavioral weight loss programs. It is unclear whether general mindfulness programs can directly target reward-based eating drive, although it is plausible that increased overall mindfulness could promote greater self-regulatory control with regards to food. Therefore, we performed secondary analyses from an RCT evaluating the effects of a digital meditation program on work stress. We specifically examined outcomes related to reward-driven eating, as well as the moderating effect of weight status and potential mediating factors, such as mindfulness and perceived stress. We randomized 1056 employees at a large public university, reporting moderate-to-high levels of stress and no regular meditation practice, to either a self-guided, digital meditation intervention (IX) or a waitlist control condition (WL). We assessed reward-based eating drive with the Reward-based Eating Drive (RED-9) scale, subjective mindfulness with the Mindfulness Attention Awareness Scale (MAAS), and perceived stress with the Perceived Stress Scale (PSS), at baseline and 4- and 8-weeks post-randomization. We used linear mixed modeling to examine the effect of treatment randomization on changes in RED-9 and SPSS PROCESS Macro to examine the potential mediating roles of MAAS and PSS. We found a significant main effect of treatment randomization on 8-week changes in RED-9, such that those in IX (vs. WL) evidenced greater decreases in RED-9 ($t = 4.21$, $p < .001$, 95% CI: -2.06, -0.75). We found a moderating effect of weight status, such that participants with (vs. without) overweight exhibited the greatest decreases in RED-9 in response to treatment (-3.48 vs. -1.88, $p = .01$). Improvements in 4-week MAAS scores mediated this association (indirect effect: $B = 0.51$, 95% CI: 0.31, 0.76), explaining 20% of the total effect. Decreases in PSS did not account for the effect of intervention on changes in RED-9 (indirect effect: $B = 0.17$, 95% CI: -0.11, 0.47). In a generally healthy sample of non-weight loss treatment seeking adults, we found preliminary support for a light-touch, general mindfulness program in improving reward-related eating symptoms, particularly among those with overweight. Furthermore, our analyses point to mechanisms of improvements in mindfulness, rather than perceived stress, as important opportunities for intervention refinement. Future research should be done to examine the relative contribution of meditation dosage, as well as changes in actual eating behaviors and weight over the 8-week period.

ROADMAP TO PARENTHOOD: DEVELOPMENT OF AN ONLINE DECISION AID AND PLANNING TOOL FOR FAMILY-BUILDING AFTER CANCER

Catherine Benedict, PhD¹, Katherine L. Dauber-Decker, PhD in Biomedical Sciences², D'Arcy S. King, Ph.D.³, Jennifer S. Ford, PhD⁴, Michael A. Diefenbach, Ph.D.³

¹Stanford University School of Medicine, Palo Alto, CA; ²Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Manhasset, NY, Manhasset, NY; ³Northwell Health, Manhasset, NY; ⁴Hunter College, City University of New York (CUNY), New York, NY

Background: Young adult (YA) cancer survivors who receive gonadotoxic treatment often face complex decisions about family-building with limited reproductive care post-treatment. Based on extensive pilot work and a patient-centered design approach, we developed a prototype of a web-based decision aid and planning tool, "Roadmap to Parenthood." Design sprints were used to develop and optimize prototype iterations. This study presents usability testing results and the impact of patient-centered design processes on website development.

Methods: Participants (N=10) represented the target user group; YA female survivors who completed gonadotoxic treatment and desired future children. Each completed one "think aloud" usability testing session. After 6 sessions (Round 1), initial website revisions were made; followed by 4 more sessions with the updated website (Round 2). The standardized System Usability Scale (SUS), Website Quality measure (WEBQUAL), and e-Health Impact Questionnaire (eHIQ) assessed website usability, quality, and health impact. Qualitative analyses of "think aloud" testing included transcript coding and thematic analysis. Scores on quantitative measures were compared from Round 1 to Round 2 to assess website updates and inform iterative design modifications.

Results: Participants averaged 31 years old and were mostly White (90%). Three major themes for website improvement were identified: Usability, Visibility and Navigation, and Content and Usefulness. Examples include changes to the layout to improve functionality and ease-of-use, "call out" buttons to guide the user journey, and design changes to optimize health literacy (e.g., simplified data presentation). Following revisions, Round 2 testing confirmed usability improvement, resulting in user comments that focused on more nuanced aspects of design and content. For example, specific words and images were identified as anxiety-provoking. Changes were made addressing users' emotional experience (e.g., word and color choice). Scores on all quantitative measures improved from Round 1 to 2, demonstrating improved usability and website quality, and a positive impact on health management.

Conclusions: Patient-centered healthcare, including the development of supportive care resources, must involve input from the target patient group. Usability testing revealed key areas of design modification to address patient user needs. Website changes are currently underway based on final usability testing results. Further testing with a more diverse patient group may be warranted. Future research will pilot test the decision aid in a single-arm study.

DOES MINDFULNESS MITIGATE RISK FACTORS FOR SMARTPHONE ADDICTION?

Timothy Regan, M.A.¹, Bethany L. Harris, B.S.², Matthew Van Loon, n/a¹, Sherece Fields, PhD¹

¹Texas A&M University, College Station, TX; ²Texas A&M University, Bryan, TX

Background: There is growing public health concern regarding the potential addictive nature of smartphones. Mindfulness is defined as a disposition towards open, receptive awareness of and attention to what is taking place in the present moment. Mindfulness may protect against problematic smartphone use by reducing one's tendencies towards automatic and compulsive behaviors.

Purpose: We sought to test the hypothesis that trait mindfulness can mitigate the impact of risk factors on smartphone addiction in a sample of college students from a large state university in Texas.

Methods: Participants ($n = 135$, $M_{age} = 19.15$, 68% female) completed cross-sectional survey measures documenting their self-reported boredom proneness (BPS), impulsivity (short UPPS-P), technology-related anxiety (Anxiety/Dependence subscale of the MTUAS), trait mindfulness (MAAS), and smartphone addiction (SPA). This study was part of a larger study examining dysfunction associated with smartphone use.

Results: Age and gender were included as covariates. A MANCOVA indicated higher MAAS scores were significantly associated with lower levels of boredom proneness, technology-related anxiety, and smartphone addiction scores ($F(4,128) = 14.30$, $p < .01$). Next, risk factor scores, MAAS scores, and their interactions were entered into a linear regression predicting SPAI scores. Main effects were revealed for boredom proneness ($\beta = .46$, $t = 2.02$, $p < .05$) and impulsivity ($\beta = .20$, $t = 2.56$, $p < .05$), although their interactions were non-significant. However, the interaction between technology-related anxiety and MAAS scores was significant. Simple slope analyses revealed that the relationship was significant and positive for low ($\beta = 3.69$, $t = 7.70$, $p < .01$) and average ($\beta = 2.17$, $t = 2.18$, $p < .01$) MAAS scorers, but non-significant for high MAAS scorers.

Conclusions: The effect of technology-related anxiety on problematic smartphone use is conditional, and appears to diminish as one's mindfulness increases. Mindfulness may protect against risk for smartphone addiction by reducing anxiety and dependence concerns, or vice-versa. Future research should examine if problematic smartphone users benefit from mindfulness-based interventions targeting their worry and overreliance on technology.

TRACIT: THE USE OF A MODIFIED DIETARY MONITORING APP IN A HEALTHY WEIGHT INTERVENTION FOR YOUNG ADULTS

Brooke Dudley, BSc¹, Stefanie Ciszewski, M.A.², Chelsey Solar, PhD³, Lesley Lutes, PhD, R. Psych¹¹University of British Columbia - Okanagan, Kelowna, BC, Canada; ²University of British Columbia - Okanagan, Kelowna, BC, Canada; ³East Carolina University, Kelowna, BC, Canada

Young adulthood (i.e., ages 18 to 35) is associated with the most substantial amount of weight gain in a lifetime, putting young adults at risk for additional health complications. Dietary monitoring is a core component of behavioural weight loss interventions and has been shown to be the number one indicator of sustained weight loss in an adult population. However, findings are mixed for dietary monitoring in young adults, which may be due to the fact that traditional dietary monitoring tools are labour intensive and can result in considerable burden. The TRACIT app was developed based on Mozzafarrin and colleagues' (2011) landmark study, which showed that a small number of foods (15) could predict weight change over time. TRACIT only records these 15 specific foods and therefore has significant potential to decrease burden and improve accessibility, which may be useful in a young adult population. The present study is a two-armed randomized behavioural intervention that compared the efficacy of using TRACIT ($n = 17$) compared to MyFitnessPal ($n = 16$) over a 10-week evidence-based weight-management intervention in a young adult population. Participants were overweight undergraduate students ($M_{\text{age}} = 20.16[\pm 2.27]$, $M_{\text{BMI}} = 26.46 [\pm 5.40]$), primarily consisting of females (78.80%). Weight significantly decreased within groups over the intervention, $F(1, 29) = 6.66$, $p = .02$, $h^2 = .19$, but not between groups, $F(1, 29) = 0.71$, $p = .41$, $h^2 = .02$. Both TRACIT ($M = -1.29$ lbs, $SD = 2.40$) and MyFitnessPal ($M = -2.11$ lbs, $SD = 4.32$) users had similar amount of weight loss over time. Similarly, step counts increased significantly over time within groups but not between groups. There was a significant association between the type of app used and using the app everyday to track dietary intake, $\chi^2(1) = 4.50$, $p = .03$. That is, TRACIT users were 4.84 times more likely to use their app every day to monitor their diet, which may have implications for sustained adherence to dietary monitoring over time. Importantly, TRACIT improved the quality of users' diet compared to MyFitnessPal, which may be related to secondary physiological changes (e.g., decreases in systolic blood pressure for TRACIT users). Although TRACIT users found the app less time consuming, MyFitnessPal users were more likely to recommend their app to a friend looking to manage their weight. TRACIT has the potential to be a complementary adjunctive to behavioural interventions in a young adult population that reduces burden and is less time-consuming.

INTERVENTION INC: BEHAVIORAL AND BMI OUTCOMES OF A WEB-BASED TOOL TO DECREASE OBESITY RISK AMONG URBAN MINORITY YOUTH

May May Leung, PhD, RDN¹, Katrina F. Mateo, MPH, DPH candidate¹, Laura Harrison, MPH¹, Katarzyna Wyka, PhD²¹Hunter College (CUNY), New York, NY; ²CUNY Graduate School of Public Health and Health Policy, New York, NY

Background: Childhood obesity is a serious public health issue in the United States, especially among low-income, minority populations. Web-based/mHealth interventions may be an engaging approach to reach at-risk children and promote positive dietary behaviors. Intervention INC is a technology-enhanced intervention, which comprises a 6-chapter interactive nutrition comic (and related trivia questions, goal-setting, and tailored messaging), with the goal of reducing childhood obesity risk in Black/African-American (AA) and Latino preadolescents. This theory-informed, tablet-optimized intervention was iteratively developed utilizing user-centered approaches. The purpose of this study was to explore potential impact of Intervention INC on child dietary-related behaviors and anthropometric measures.

Methods: A total of 89 Black/AA and Latino children (mean age=10.4±1.0 years, 61% female, 62% Black, 42% Latino, 51% overweight or obese, and 33% annual household income < \$20,000) from East Harlem/Harlem, New York participated in a pilot two-group randomized study, comprising a 6-week intervention and a 3-month follow-up. Participants were randomly assigned to either the experimental (E) ($n=45$) group, who received Intervention INC, or the comparison (C) ($n=44$) group, who received online nutrition newsletters. Surveys measuring behaviors related to fruit, vegetable, water, sugar, and junk food intake were completed at baseline (T1), intervention mid-point (T2), intervention end (T3) and 3-month follow-up (T4). Height and weight were measured at T1 and T4 to calculate body mass index (BMI) percentiles. Data were analyzed using mixed models with repeated assessments (T1-T4), condition (E-C), and time by condition interaction.

Results: While the interactions were not statistically significant, the E group appeared to have improvements from T1 to T3 in fruit ($d=0.14$ vs. $d=-0.20$), vegetable ($d=0.43$ vs. $d=0.04$), water ($d=0.37$ vs. $d=0.15$), and sugar ($d=-0.34$ vs. $d=0.00$) intake compared to the C group. Most improvements appeared to diminish at T4. BMI percentile decreased in males within the E group ($d=0.53$ vs. $d=-0.05$) from T1 to T4.

Conclusions: Study results appear promising, however, the diminished effects in dietary behaviors observed at T4 should be noted. While an interactive nutrition comic may be a useful format to promote healthy dietary behaviors in minority children at risk for childhood obesity, a booster component should be considered to reinforce health messages upon completion of the actual intervention. Further research is also warranted to determine the efficacy of this innovative web-based health promotion tool.

ACCEPTME: EVALUATION OF A DIGITAL GAMIFIED EATING DISORDER PREVENTION PROGRAM BASED ON ACCEPTANCE AND COMMITMENT THERAPY

Maria Karekla, PhD¹¹University of Cyprus, Nicosia, Nicosia, Cyprus

Eating Disorders (ED) constitute a serious public health issue that affects predominantly women and appears typically in adolescence or early adulthood. As EDs are associated with significant adverse medical and psychological consequences, it is vital to focus on the development of successful prevention programs. Prevention programs to date have not shown great effectiveness and thus new approaches (both theoretically and technologically innovative) are needed so as to reach individuals early in the ED trajectory. This paper presents the development of a gamified prevention program (*AcceptME*) based on Acceptance and Commitment. The study used a randomized clinical trial design and investigated acceptability and effectiveness compared to a wait-list control group among high-risk for EDs young women (N= 88; Mage = 15 years). The prevention group (N= 58) completed 6 internet-based sessions targeting behavior change via helping (using ACT taught principles) a digital character in the game to overcome difficulties. Findings showed that the *AcceptME* program was perceived as helpful for dealing with body related thoughts and worries and participants particularly liked and found helpful the values and acceptance components of the program. The game storyline was reported to be engaging and aid in learning from the game experience. Repeated measures analyses of variance indicated that the *AcceptME* prevention program effectively reduced weight and shape concerns, with large resulting effect sizes (*Cohen's d*= .91) compared to wait-list controls. The gamified *AcceptME* prevention program holds promise for the prevention of EDs among young women and is ready for large-scale implementation.

A QUALITATIVE STUDY EXPLORING FACTORS INFLUENCING THE UPTAKE OF AND ENGAGEMENT WITH HEALTH AND WELLBEING SMARTPHONE APPS

Dorothy Szinay, BSc, MSc¹, Felix Naughton, PhD¹, Andy P. Jones, BSc, PhD¹, Tim Chadborn, PhD², Jamie Brown, PhD³, Olga Perski, BSc, MSc, PhD⁴

¹University of East Anglia, Norwich, England, UK; ²Public Health England, shenfield, England, UK; ³UCL, London, England, UK; ⁴University College London, London, England, UK

Background: The uptake of health and wellbeing smartphone apps is largely influenced by popularity indicators (e.g. rankings), rather than evidence-based content. Rapid disengagement is common. This study aims to explore how and why potential users 1) select and 2) engage with such apps and 3) how increased engagement could be promoted.

Methods: Semi-structured interviews and a think-aloud approach were used to allow participants to verbalise their thoughts whilst searching for a health or wellbeing app online, followed by a guided search in the UK National Health Service (NHS) 'Apps Library' and Public Health England's (PHE) 'One You' website. Recruitment took place between June and August 2019. Adults interested in using an app for behaviour change were recruited through social media. Data were analysed using the framework approach. The analysis is both inductive and deductive, with the coding framework being informed by the Theoretical Domains Framework. The results are further mapped onto the COM-B (Capability, Opportunity, Motivation - Behaviour) model. The study protocol is registered on the Open Science Framework (<https://osf.io/jrkd3/>).

Results: The following targets were identified as playing a key role in increasing the uptake of and engagement with health and wellbeing apps: 1) psychological capability (e.g. reduced cognitive load); 2) physical opportunity (e.g. low financial cost); 3) social opportunity (e.g. embedded social media); 4) automatic motivation (e.g. positive feedback). Participants believed that the promotion of evidence-based apps on NHS-related websites could be enhanced through active promotion on social media, adverts on the internet and in General Practitioner practices.

Future implications: These results can inform the development of interventions aiming to promote the uptake of and engagement with evidence-based health and wellbeing apps, providing strategic plans for the future of healthcare. The targets identified across the COM-B domains could help organisations that provide platforms for such apps to increase impact through better selection of apps.

ASSESSING INTEREST IN A DIGITAL DIABETES PREVENTION PROGRAM USING THE PATIENT PORTAL: A CASE STUDY OF THE “VAPOR TEST” APPROACH

Sara Chokshi, DrPH¹, Katharine Lawrence, MD, MPH², Sumaiya Tasneem, MPH², Devin Mann, MD, MS²¹NYU Langone School of Medicine, New York, NY; ²NYU Langone Health, New York, NY

Background: Patient/User engagement remains a persistent problem for digital behavior change (DBC). While mobile and web-based applications delivering health behavior change interventions are abundant, they suffer from low rates of adoption. Lack of uptake and sustained use threatens the promise of access and utility of these technologies for patients seeking support for healthy behavior. Strategies to assess interest in DBC tools and the upstream drivers and barriers to engagement are being developed and utilized to facilitate tool selection and application in digital health research, and can provide valuable insight for developers and researchers working with these types of interventions. The “vapor test” approach (offering an item for sale that has yet to be developed) is commonly used in the online retail industry to determine demand for new products or to test content options. Patient portals offer a rapid, low cost, low burden way to deploy the vapor test strategy to gauge or compare interest in DBC applications.

Purpose: To provide a case example of a vapor test delivered via patient portal to gauge interest in a digital diabetes prevention program (dDPP), and assess feasibility of meeting recruitment goals for a proposed research study involving the digital behavior change mobile application.

Methods: We constructed a brief online survey delivered via patient portal to assess interest in a dDPP, its desired functionalities, and potential barriers to engagement.

Findings: Of more than 6300 survey messages sent to patients fitting eligibility criteria, 15.7% (n=987) of messages were opened. Of the messages opened, 91% (n=899) contained responds indicating interest in a dDPP should it be available and prescribed by their provider. Features of most interest included easily accessible diabetes prevention education (82.9%, n=818) and diet and weight tracking (69.8%, n=689). Forty-eight percent (n=476) of respondents expressing interest identified/indicated they had no concerns with using a dDPP; for the 51.7% who reported a concern, privacy was the most cited concern (24.8%, n=245).

Conclusions: This case illustrates how a novel adaptation of the vapor test approach combined with patient portal delivery can deliver meaningful data to support engagement in downstream DBC interventions. This low burden strategy enabled our research team to gauge interest in a dDPP, assess feasibility of research study recruitment goals, and gain advance insight into patients’ perceived facilitators and barriers to engagement with DBC tools.

MOBILE APPS FOR SUICIDAL IDEATION AND BEHAVIORS

Atami Sagna DeMain, MHS, RN¹, Bo Xie, PhD¹¹The University of Texas at Austin, Austin, TX

With challenges to connect individuals with mental health services, mobile health (mHealth) apps represent means of providing mental health information and interventions. However, little is known about mHealth apps targeting suicidal ideation/behaviours. Our study explores mHealth apps for suicidal thoughts/behaviours describing key features, target populations and types of health information. We identified 60 relevant iOS and android apps. Few apps (10%) were developed by health departments and organizations (e.g SAMHSA). All apps mainly focused on self-management, symptom tracking, and social support. 85% of the apps provided health information related to psychosocial aspects, including assistance/support in dealing with suicidal thoughts. All apps targeted youth and adults but none was geared towards older adults. With suicide rates in older adults on the rise and with an increasing number of older adults owning smartphone/tablet, it is crucial to adapt suicide-related apps to older adults’ needs due to their unique symptomatology of suicidal ideation.

Learning objectives

- 1- After attending this session, participants will be able to identify mHealth app related to suicidal ideation and behaviours
- 2- After attending this session, participants will be able to describe the key functional features of the suicide related mHealth apps
- 2- After attending this session, participants will be able to summarize the different types of health information provided by suicide related apps

6:15 PM-7:30 PM

RESULTS FROM THE CHARGE STUDY: A STANDALONE TEXT MESSAGING-BASED WEIGHT LOSS INTERVENTION

Gary Bennett, PhD¹, Dori Steinberg, PhD, RD¹, John Gallis, MS², Elizabeth L. Turner, PhD², Kathryn I. Pollak, PhD², Jamiyla Bolton-Cubillan, MS³

¹Duke University, Durham, NC; ²Duke, Durham, NC; ³Duke, Raleigh, NC

Background: Innovative approaches are needed to deliver effective weight loss interventions at scale. Although there has been a proliferation of trials aimed at scaling up effective obesity interventions, none have been fully delivered via text message. The multiphase optimization strategy (MOST) can assist us in developing multicomponent interventions that consist only of active components; those that have been experimentally determined to impact the chosen outcome.

Objective: To evaluate an optimized standalone text messaging obesity intervention, Charge, using a MOST framework on changes in weight.

Methods: Using a 5x2 factorial design, participants (n=534) were randomized to one of 32 experimental conditions, consisting of a combination of five two-level text message-based intervention components: message frequency (weekly vs daily), motivational messaging (self- vs expert-generated), reminders to track goals (one vs multiple), feedback type (summary score vs individual score), and comparison unit (self vs group). All study participants received a core 6-month weight loss texting intervention that included tailored behavior change goals, interactive self-monitoring, automated feedback, and skills training videos. We used a mixed effects model to assess the main effects and interactions of all five components. To define a significant main effect or interaction, we used *a priori* effect size of 0.7 kg difference between levels of a component.

Results: At baseline, the mean (SD) participant weight was 97.1 (20.3) kg. Participants had a mean (SD) of BMI of 33.9 (6.1) kg/m² and the mean (SD) age was 42.1 (11.9) years. The sample was 73.2% non-Hispanic white, and 84.8% worked full- or part-time. The mean (SD) weight loss across all participants at 6 months was 1.8 (4.9) kg. The optimized treatment package yielded, from the statistical model, a predicted average weight loss of 2.6 kg and included the following components: texting frequency set to daily; motivational messages set to expert-generated; reminders set to one; performance comparison set to self; and feedback set to summary score.

Conclusion: Standalone approaches using optimized text messaging components can have great population-level potential on reducing obesity because they are low cost, highly scalable, and modular in nature. They can reach into broad and diverse populations that do not have stable access to other approaches frequently employed in weight loss trials.

NUDGE ME: TAILORING TEXT MESSAGES FOR PRESCRIPTION ADHERENCE THROUGH N OF 1 INTERVIEWS

Joy Waughtal, MPH¹, Sheana Bull, PhD, MPH², Phat Luong, n/a³, Lisa Sandy, MA³, Catia Chavez, MPH³, Michael Ho, MD, PhD⁴

¹mHealth Impact Lab, Colorado School of Public Health, Denver, CO; ²University of Colorado, Colorado School of Public Health, Aurora, CO; ³University of Colorado, Aurora, CO; ⁴University of Colorado School of Medicine, Aurora, CO

The increasing popularity and widespread use of mobile phones provides a great opportunity for researchers and health practitioners to find solutions that capitalize on mobile technologies to deliver more complex health behavior change interventions. Texting “nudges,” (i.e. a low intensity, easy to deliver intervention) creates a much needed opportunity to deliver mobile health at scale and generate greater impact. Nudges take advantage of the intuitive aspects of decision-making. In order to be effective nudge messages must compete with a deluge of information and distractions that phone users have on a daily basis. For nudge messages to be beneficial, they must be *engaging* so participants will not only pay attention but also act on the desired behavior change.

To develop appropriate and meaningful messages for medication adherence, we conducted N of 1 within subject interviews among persons taking cardiovascular medication. The goal of the interviews was to refine *a priori* messages informed by multiple behavior change theories and engagement approaches. Participants were patients in one of three large health care systems in the Rocky Mountain region of the U.S., including a Veteran’s Administration hospital, a large urban safety-net hospital and an urban hospital serving a mix of private and publicly insured patients. Following patient informed message design, we will incorporate nudge text messages into an automated reminder system for patients who experience a delay \geq seven days following a missed prescription refill.

A total of 35 one-on-one interviews were hosted through synchronous video conference or in person at each hospital. Participants viewed twelve screens, each with three messages and asked: what messages made the most sense, what message would you likely respond to, what is the most helpful about these messages, what do you like least about the messages, anything missing you wish was included, and any additional comments for each screen. After every five interviews messages the research team used a content analysis to adjust and revise messages. Patients resonated with messages tailored to their condition and medication, those with humor and positive reinforcement. The outcome of the N of 1 interviews is a theory and user informed message library with messages deemed engaging, a key element to ensure they are read and acted upon to impact medication adherence.

IS HEALTH FEEDBACK ENCOURAGING? DIFFERENTIAL AFFECTIVE REACTIONS TO FEEDBACK FROM CALORIE AND ACTIVITY APPS

Erin C. Standen, B.S.¹, Alexander J. Rothman, Ph.D.¹¹University of Minnesota, Minneapolis, MN

People with obesity are consistently encouraged to lose weight by creating a calorie deficit (i.e., by consuming fewer calories than they burn). To implement this strategy, people are advised to keep track of daily calorie consumption and energy expenditure; however, mobile health (mHealth) tracking can be tedious and time-consuming (Centers for Disease Control, 2018).

Although calorie-tracking and activity-tracking apps are among the most popular mHealth apps, very little is known about how they influence users' psychological experiences. Because accurate tracking requires users to interact with these apps several times per day, these apps have the potential to influence users' affect, health attitudes, or even intentions for engaging in healthy behaviors. Moreover, the types of goals generated by calorie- and activity-tracking apps are conceptually different. Calorie apps focus on avoidance goals (i.e., not exceeding a limit), whereas activity apps focus on approach goals (i.e., reaching an objective; Elliot, 1999).

A pre-registered 2 (calorie- vs. activity-tracking app) x 2 (positive vs. negative feedback) between-subjects experiment compared reactions to a simulated week of app feedback. Participants ($N = 698$) reported higher levels of negative affect when they received feedback from a calorie (vs. activity) app, regardless of feedback valence ($p's < 0.01$). They felt less encouraged, in control, and accomplished and more stressed when receiving feedback from a calorie app and found feedback from an activity app more helpful and clear ($p's < .01$). Moreover, the type of feedback affected people's differential response to the calorie and activity app. Compared to the activity app, reactions to the calorie app were much more contingent on the valence of the feedback provided ($p's < 0.01$). When feedback came from an activity app, the valence of the feedback did not matter; however, when receiving feedback from a calorie app, people reported significantly higher negative affect and significantly lower positive affect when feedback was negatively valenced. Similar patterns of results were observed for perceptions of accomplishment, encouragement, control, and stress.

Overall, these findings suggest that people experience negative feedback from a calorie-tracking app as particularly aversive. Future research should investigate strategies that lessen the "sting" of negative calorie-tracking feedback while maintaining apps' effectiveness for behavior change.

MEASURING SMOKING TOPOGRAPHY IN NATURAL SETTINGS USING NON-CONTACT PASSIVE WEARABLE SENSORS

Rawan Alharbi, n/a¹, Bonnie Spring, PhD², Nabil Alshurafa, PhD¹¹Northwestern University, Chicago, IL; ²Northwestern University Feinberg School of Medicine, CHICAGO, IL

Smoking cessation interventions measure the distal outcome of smoking relapse using biochemical methods (e.g., expired CO monitoring). While accurate, such measures are unable to detect the exact moment of smoking relapse and are unable to provide insights into smoking topography (i.e., puffing behavior, including measures of the number of puffs, puff volume, puff duration, and inter-puff interval). Currently, to measure smoking topography in natural settings, researchers use portable devices that require participants to attach the cigarette to one end of the device and smoke through a mouthpiece on the other end (e.g., CReSS Pocket) which can alter natural smoking habits. Wearable sensors, on the other hand, have shown potential in measuring human activity without direct interference with the measured behavior (e.g., accelerometer sensors embedded in smartwatches). We have developed a wearable passive device (HeatSight) that can be worn as a pendant or a pin on the chest to capture smoking topography. The wearable is equipped with a miniaturized thermal sensing array that can unobtrusively capture spatial, temporal, and thermal information around the wearer without the need for direct contact with the heat-emitting object. Recently, wrist-worn sensors combined with machine learning models have been adopted by researchers to detect smoking puffs. However, these sensors are known to be confounded by behaviors such as eating and drinking, since they too involve a hand-to-mouth gesture. Our device, on the other hand, has the potential to distinguish between these confounding activities due to the rich information that it captures. We ran a feasibility in-lab study on 5 participants who were instructed to smoke a cigarette. We were able to distinguish smoking activity from other confounding activities such as eating and drinking using machine learning models with 85% accuracy. We were also able to capture smoking topography, including start and end times of each smoking event, the time the cigarette was lit, and the start and end time of each puff. We will continue to validate HeatSight in controlled and free-living environments. In-lab, 25 participants will engage in one or more smoking sessions (using a cigarette, e-cigarette, or cigar) followed by a series of confounding activities (e.g., eating and drinking). In the free-living setting, participants will be asked to wear HeatSight with a wearable camera (to validate smoking). We will use machine learning to process data from HeatSight to detect and classify each puff. We then will report on smoking topography, including puff number, duration, inter-puff interval, and time and date of the beginning of each smoking event. We believe that HeatSight will allow researchers to capture smoking behavior independent of the form of tobacco used. Ultimately, paving the way for future timely interventions to detect and prevent smoking relapse.

PERSONAL GOAL SETTING IN DIGITAL INTERVENTION IS ASSOCIATED WITH INCREASED WEIGHT CHANGE

Lex Hurley, MPH¹, Brooke T. Nezami, PhD, MA², Karen E. Hatley, MPH³, Christopher N. Sciamanna, MD, MPH⁴, Deborah F. Tate, PhD⁵¹University of North Carolina Chapel Hill, Chapel Hill, NC; ²University of North Carolina at Chapel Hill, Chapel Hill, NC; ³UNC Chapel Hill, Chapel Hill, NC; ⁴Penn State University, Hershey Medical Center, Hershey, PA; ⁵University of North Carolina, Chapel Hill, NC

Background: Adherence to self-monitoring has been associated with better outcomes in digital interventions, and goal setting tools are common components of health interventions. However, there is scarce literature on participant-created goals and their effect on weight loss outcomes. LoseNow Physician Assisted (LNPA) was a 1 year, 3-arm cluster RCT that randomly assigned 37 primary care providers and 550 patients (72% female; 85% white; 51.4 years; BMI 35.1 kg/m²) to one of three conditions: usual care, an internet-based weight loss program alone, or the internet program with physician advice. Both internet programs included self-monitoring, behavioral lessons (including content on setting behavioral goals), resources, weekly automated feedback, and a goal-setting feature which allowed participants to create and track up to 3 goals per week.

Methods: Of participants randomized to the web interventions who completed 6-month follow-up (n=266), 260 logged into the website at least once and are analyzed here. An inductive content analysis coded goals and linear regression was applied to regress effects on weight change.

Results: On average, participants set 29.0 goals (SD=22.85) over 6 months at an average of 2.4 goals per week (SD=1.09). As a percentage of all goals set, there were more goals related to diet (41.7%) and physical activity (29.5%) than other types such as weight loss (3.2%), program adherence (10.8%), behavioral skills (5.2%), mental health (2.7%), or other (6.9%). Participants who reached clinically significant weight loss of $\geq 5\%$ (n=107) set an average of 36.0 goals (SD=25.3) over 6 months; those who lost 1–4.99% (n=89) set 28.2 goals (SD=21.4); and those who lost $< 1\%$ or gained weight (n=64) set 18.8 goals (SD=15.4). Regression analyses showed that significantly more goals were set among those who lost 1–4.99% ($p < 0.0001$) and who lost $\geq 5\%$ ($p < 0.0001$) compared to the reference group ($< 1\%$ loss). Increased utilization of the online goal-setting feature was associated with greater weight loss at 6 months ($B_1 = -0.079$, $SE=0.015$, $p < 0.0001$), and after controlling for total logins as a proxy for use of other LNPA website components ($B_1 = -0.03$, $SE=0.014$, $p=0.017$). These results indicate that greater usage of a participant-driven goal-setting component is associated with increased weight loss. Future research should directly compare weight loss programs with and without participant goal setting components to determine causality.

OUTCOMES OF PATIENT CENTERED MHEALTH MEDICAL REGIMEN PROGRAM FOR AFRICAN AMERICANS WITH UNCONTROLLED HYPERTENSION

Kinsey N. Kellam, Bachelor of Arts, Biology¹, Samantha Pairet, B.S.¹, Alison Neely, HS¹, Luke Sox, B.S.¹, Vanessa Diaz, M.D.¹, Frank Treiber, PhD¹, Jessica Chandler, PhD¹¹Medical University of South Carolina, Charleston, SC

Background: Uncontrolled hypertension (HTN) and medication nonadherence (MNA) are more prominent among African Americans (AA) compared to non-Hispanic Whites. MNA is the leading modifiable behavior to improve BP control. Using mobile health (mHealth) technology enables real-time monitoring of MA and blood pressure (BP), facilitating timely patient provider communication including, tailored reinforcement/motivational feedback to patients and quicker titration changes by providers. The purpose of the current study was to report initial findings of an ongoing 6-month randomized control efficacy mHealth trial with 6 month follow-up addressing MA and BP control among AA adults with uncontrolled HTN and poor MA.

Methods: The two-arm efficacy trial includes an experimental (Smartphone Med Adherence Stops HTN-SMASH) group and an enhanced attention control (AC) group. SMASH participants utilize a SMASH app interfaced with a Blue toothed BP monitor and Blue toothed pill cap. AC participants receive text messages including links to PDFs and brief video clips containing healthy lifestyle tips providing comparable digital contact. This report involves the first 80 AA adults, 18- 59 years old, with the sole diagnosis of uncontrolled systolic HTN and poor MA.

Results: Participants include 80 AA adults with uncontrolled HTN (average age 58.7 \pm 9.03). They were randomly assigned to either SMASH (n=40) or AC group (n= 40). At baseline, no participants had controlled systolic BP (SMASH: 143.0 vs AC: 141.0 mmHg). Resting SBPs were significantly lower in the SMASH group versus AC group at each subsequent evaluation (Month 1: 129.4 vs. 135.4; Month 3: 126.6 vs. 134.7; Month 6: 125.1 vs. 137.9 mmHg; all p-values $< .01$). Adherence levels (i.e., intake within 1.5 hours of designated times) were significantly higher in the SMASH group at 1, 3, and 6-months compared to the AC group, respectively (Month 1: 91% vs. 53%; Month 3: 89% vs. 39%; Month 6: 89% vs. 29%; all p-values $< .01$). Our smartphone enabled medical regimen self-management program may be an effective solution for the promotion of MA resulting in statistically and clinically significant reductions in SBP among AA adults with uncontrolled HTN.

LET'S TWEET ABOUT IT: A CONTENT ANALYSIS OF #HOWIFIGHTDEPRESSION TWEETS

Matthew W. Schroeder, B.S., B.A.¹, Laurie C. Groshon, B.A.¹, Jared M. Goetz, B.A.², Kelsey M. Arroyo, B.S.³, Sherry Pagoto, PhD¹¹University of Connecticut, Storrs, CT; ²University of Connecticut, Dudley, MA; ³University of Connecticut, Vernon, CT

People have taken to social media to discuss mental health issues not only in private online communities but also on public platforms including Twitter. On June 19, 2019, the hashtag #HowIFightDepression was trending on Twitter meaning it grew rapidly enough for Twitter to list it as one of the most popularly discussed hashtags of the moment. The purpose of the hashtag was for people to share how they cope with depression. The present study aimed to content analyze the tweets to determine how people discuss their depression coping behaviors. Tweets with the hashtag were pulled with a sample window from June 19, 2019 to June 23, 2019. After retweets were excluded, a total of 9616 potentially eligible tweets remained. A total of 700 tweets were randomly selected for coding. A total of 171 tweets were excluded as they were in a foreign language or cryptic. A random sample of 100 tweets was reviewed by raters to develop a coding scheme; where the raters highlighted recurring coping strategies that also had clinical value. Two raters then coded 529 tweets with 87% agreement ($\kappa=.866$). If a tweet mentioned more than one coping strategy, both were counted. Frequencies of each coping strategy were calculated. Coping strategies were then classified as potentially helpful or harmful based on whether the coping strategy was likely to improve or worsen depression from a behavioral perspective. A total of 15 coping strategies were identified, 11 of which were potentially helpful and 4 were potentially harmful. Many tweets ($n = 226$, 43%) reported more than one strategy. Of the 529 tweets, potentially helpful coping strategies included keeping a positive attitude ($n = 178$, 34%), social support seeking ($n = 130$, 25%), treatment (therapy or medication; $n = 84$, 16%), hobby ($n = 84$, 16%), being productive (e.g., goal-planning, running errands; $n = 66$, 12%), mindfulness ($n = 56$, 11%), spending time with pets/animals ($n = 46$, 9%), exercise ($n = 38$, 7%), spiritual activities ($n = 38$, 7%), using humor ($n = 17$, 3%), and using alternative medicine (e.g. supplements, vitamins; $n = 11$, 2%). Potentially harmful coping strategies included non-goal oriented sedentary activity (e.g., TV, video games; $n = 110$, $n = 21\%$), eating ($n = 42$, 8%), sleep ($n = 33$, 6%), taking recreational drugs ($n = 17$, 3%). A total of 748 coping strategies (78.7%) mentioned were potentially helpful, while 202 (21.2%) listed were potentially harmful. Many tweets ($n = 226$, 43%) reported more than one strategy. A total of 92 tweets (13%) mentioned a combination of both types of coping strategies. Results showed that most coping strategies shared in #HowIFightDepression tweets were behaviors likely to be helpful in improving depression. Given the reach of viral hashtags, social media may be a way to facilitate positive, destigmatizing conversations about depression. Further research should explore how social media can be used as a platform generate peer support for mental health problems.

ONE DROP'S DIGITAL CARE SOLUTION PRODUCES 6-MONTH A1C BENEFIT RELATIVE TO MATCHED CONTROLS

Alison Edwards, MStat¹, Chandra Y. Osborn, PhD, MPH²¹Healthagen, Chicago, IL; ²Lirio, Nashville, TN

Objective: By 2045, one in eight people will have type 2 diabetes (T2D); 48% will receive digital care. One Drop's (OD) digital care solution includes a robust app, ADA-accredited in-app coaching and Bluetooth-connected meter. An internally-conducted RCT found OD improved the 3-mo A1c of people with T2D. Sanofi sponsored a third-party prospective, matched-controlled trial to test OD's 6-mo effects on medication taking and A1c.

Methods: Participants were members of a large insurer with T2D and A1c $\geq 7\%$ naïve to OD who consented to participate between Oct 2017 and July 2018. Matched controls were members meeting study criteria one year prior to the study who did not receive OD. Controls were matched (2:1) on study enrollment month, age ± 5 yrs, gender, and drug type. Claims data assessed adherence, a central lab assessed A1c, app data assessed using OD, and surveys assessed satisfaction with OD. Descriptive statistics summarized the sample, using OD, and satisfaction. ANCOVA models, controlling for baseline adherence, A1c and other covariates, separately, tested 6-mo adherence and A1c group differences. For A1c, the interaction term was retained to examine group effects at different baseline A1c levels. Bonferroni-corrected t-tests examined effects at baseline, follow-up, and over time by group.

Results: 110 of the recruited sample ($N = 149$) were matched to 220 controls. Participants were 55.1 ± 7.4 years old, 45% female, with baseline A1c of $8.7\% \pm 1.8\%$. The OD and control group's adherence were comparable at 6 mo. For participants with a baseline A1c $\geq 8\%$, A1c was significantly lower than controls at 6 mos ($p < .05$). Overall, A1c decreased by an absolute -1.24% in the OD group and -0.37% in the control group ($p < .0001$ and $p = .01$). Of intervened participants, 87% used the app, 82% used the meter, 64% used coaching, and 77% were satisfied or very satisfied with OD.

Conclusion: OD's digital care solution had no effect on medication taking, but a substantial effect on A1c for people $\geq 8\%$. There is no optimal way to measure adherence. Multiple measures are recommended, but only claims data were used here. Adherence to insulin vs. orals differs. We were unable to tease these apart nor test insulin vs. oral adherence, separately. In other studies, OD significantly reduced carbohydrate intake and improved physical activity. Both might have driven the A1c benefit. OD's effect on A1c is consistent with other studies, and highlights OD's value for diabetes care.

SCALING OUT AN ONLINE PSYCHO-ONCOLOGY SUPPORT INTERVENTION: OUTCOMES OF THE BRECONDA IMPLEMENTATION

Kerry A. Sherman, PhD¹, Christopher J. Kilby, BPsy (Hons), MRes¹, Nicole Rankin, PhD², Elisabeth Elder, MBBS PhD², Kathryn Wells, Bachelor of Business Communications³

¹Macquarie University, Sydney, New South Wales, Australia; ²University of Sydney, Sydney, New South Wales, Australia; ³Breast Cancer Network Australia, CAMBERWELL, Victoria, Australia

Introduction: Randomised controlled trials support the efficacy of BRECONDA, an online decision support intervention for women with breast cancer considering breast reconstruction, in reducing decisional conflict and improving information satisfaction. In light of this, national level implementation (Australia) was undertaken. This study aimed to report implementation outcome data relating to multiple domains (adoption, penetration, acceptability, appropriateness, fidelity, sustainability).

Methods: At registration, users provided information about general characteristics (age, place of residence, type of user). Women facing the breast cancer surgical decision (decision-makers) also completed questions assessing decisional conflict, information satisfaction, and surgical context information. Within 2-3 months post-registration, a subset of users willing to participate in research completed a post survey assessing their use of, and responses to, the website; and for decision-makers only, decisional conflict and information satisfaction. Pre-post data were compared for decisional conflict and information satisfaction. Website usage data were obtained from the implementing organisation.

Results: Since implementation (2017), there have been 2633 registered users from 32 countries (80% Australian-based; 67% urban; 33% rural), with a steady adoption. The website has received >220,000 page hits over a 2.5 year period. Most users (86%) were the target audience of decision-makers (across a range of ages, education levels, cancer diagnostic characteristics), with an additional 11% of users being health professionals, including oncology clinicians/surgeons, breast care nurses, and psychologists/counsellors. High satisfaction with the website was evident from decision-makers, with 68% of these users spending 30 mins to 2 hours using BRECONDA. Pre-post data demonstrate acceptability and fidelity through significant reductions in decisional conflict ($d=1.12$) and improvements in information satisfaction ($d=.43$). 90% of health professionals post-survey were recommending/intending to recommend BRECONDA to patients. Sustainability is ensured through contractual agreements with the implementing organisation mandating regular reviews and content updates.

Conclusion: Taken together, these implementation outcome data are indicative of an intervention that is acceptable and appropriate for use by the target audience of women with breast cancer, as well as the broader audience of health professionals.

IMPACT OF TOBACCO CONSUMPTION AMONG CHILEAN HEALTHCARE PROVIDERS AND THEIR SMOKING CESSATION ATTITUDES

Belén Hervera, BA¹, Lisette Irrarrazabal, PhD, MPH, RN², Lilian Ferrer, PhD, MSN, RN, FAAN², Rosina Cianelli, PhD, MPH, RN, IBCLC, FAAN³

¹University of Miami, Homestead, FL; ²Pontificia Universidad Católica de Chile, Santiago, Region Metropolitana, Chile; ³University of Miami, Miami, FL

Background: Smokers are frequent hospital users, thereby, presenting a good opportunity to offer smoking cessation programs to smokers. Healthcare providers (HCP) in direct contact with patients can be the most effective at initiating tobacco cessation treatments. However, HCP's tobacco consumption and cessation related attitudes are known to affect the provision of cessation interventions. Lesser known are Latino HCP's tobacco intervention attitudes and practices. This study aimed to examine the associations between tobacco cessation attitudes (TCA), levels of consumption, and demographics among Latino HCP's.

Methods: A quantitative, correlational, cross-sectional design was used. Participants came from a larger, Chilean National Research and Development Fund in Healthcare (FONIS) investigation assessing the design and implementation of a support intervention for smoking cessation in smokers hospitalized in Chile. 66 HCP's working in a public hospital in Santiago, Chile self-reported demographics (age, gender, profession), tobacco consumption, and tobacco cessation attitudes. The tobacco cessation attitudes of HCP's were assessed with a 5-item Acceptability of Brief Counseling toward tobacco cessation scale which was modified from the Abbreviated Acceptability Rating Profile (AARP)¹, and two single item Likert-type questions regarding HCP's 1) belief that smoking is harmful for patients, and 2) belief it is their duty to aid patients quit smoking.

Results: Majority of HCP's (34 years old, 83% female, 58.5% technical nurses) did not consume tobacco (67%). Pearson's correlation revealed that greater HCP age was significantly associated with less belief that smoking is harmful for their patients ($r = -.36, p = .004$). HCP's Acceptability of Brief Counseling ($M = 22, SD = 5.5$) was positively associated with the belief that smoking is harmful for patients ($r = .306, p = .016$) and duty to help patients quit smoking ($r = .574, p = .000$).

Conclusion: Findings provide evidence that HCP's tobacco cessation attitudes are important factors to consider during cessation program implementation. Further research should focus on increasing HCP's acceptability of providing cessation care to their patients. Specifically, tailoring education and interventions by age might serve useful to address the differences in tobacco cessation attitudes which may subsequently influence their tobacco cessation practices. Further investigation of Latino HCP's tobacco cessation attitudes and practices are warranted to aid in the identification of programs that will best address their tobacco training needs.

HOW FEASIBLE IS YOUR STUDY? A CHECKLIST FOR PRACTICE-BASED RESEARCHERS

Matthew Martin, PhD, LMFT¹, Rodger S. Kessler, PhD¹¹Arizona State University, Phoenix, AZ

Practice-based research often includes important community partners with limited capacity for research participation. For example, medical and nursing staff may have little or no research training and no protected time for research; the organization lacks clear and accessible policies and procedures on IRB; or there are no established communication lines between research administration and clinical management. Researchers and community partners may enter into collaboration with assumptions that may impede the project, threaten empirical validity, or harm long-term relationships. Both parties carry assumptions into the relationship. The research team normally has the most at stake for ensuring project success. For the community partner, the project is one of many initiatives occurring in an under-resourced and complex organization and may likely be seen as a low priority and perhaps even a nuisance.

The level of awareness among researchers and community partners of potential problems in their project is not always clear. Checklists are a common feature in manufacturing industries and a growing feature in health care systems, including research. However, most practice-based checklists do not mutually favor researchers and partners, are too lengthy, or focus on responding to barriers rather than examining assumptions and adopting a proactive stance. The purpose of this pragmatic checklist is to increase the chance of collaboration success by resolving problematic assumptions.

Our checklist is based on a careful review of existing scientific literature, our own experience, and constructs from the Consolidated Framework for Implementation Research (CFIR). It includes four crucial time events: Before Signing the Memorandum of Agreement; Before Submitting to the IRB; Before Entering the Hospital or Clinic; and Before Collecting Data. Researchers can use the checklist to verify whether the relationship with the community partner is clear and to identify any potential problems.

INTERACTIVE WEBSITE FOR HEAD AND NECK CANCER PATIENTS: ADHERENCE AND COPING PROGRAM TO PREVENT DYSPHAGIA AFTER RADIATION

Eileen H. Shinn, Ph.D.¹, Jeffery McLaughlin, B.A.², Evalyne W. Kamunyo, M.H.A.³, Susan K. Peterson, PhD, MPH¹, Adam S. Garden, M.D.¹, Katrina Jensen, M.A., CCC-SLP⁴

¹The University of Texas MD Anderson Cancer Center, Houston, TX; ²Radiant Digital, Houston, TX; ³The University of Texas MD Anderson Cancer center, Houston, TX; ⁴Privia Medical Group of North Texas, Head & Neck Cancer Center of Texas: Otolaryngology & Facial Plastic Surgery Associates, Fort Worth, TX

Introduction: Pharyngeal and laryngeal cancers are highly curable; however survivors are at high risk for long-term dysphagia after radiation. To address lack of access to preventive care in community settings, we developed a responsive web-based application to help patients adhere to preventive swallowing exercises and cope with radiation side effects. We conducted an interim study analysis to determine website usage characteristics and to examine the effect size for future trials.

Methods: Pharyngeal and laryngeal cancer patients were recruited for enrollment by speech language pathologists before primary radiation and introduced to the interactive website. The program (English and Spanish) features tracking logs for preventive exercises, instructional videos, patient stories and search features. Patients' self-reported swallowing function was assessed with the MD Anderson Dysphagia Inventory (MDADI) at baseline and at 6 months. Adherence to preventive exercises was assessed during the 10 week intervention. Number of unique website visits, total duration of website exposure, and rankings of the most popular webpages were calculated. Preliminary regression models were run using adherence and MDADI as outcomes.

Results: Of the 160 enrolled, 96 had 10-week adherence data and 61 had 6-month MDADI data. The average age was 63 (SD=12.26), 49.4% were from rural counties, 44% had a high school education or lower, and 42% reported annual income of \$30,000 or less. The average number of visits was 5.49 (SD= 9.96) and the average total time spent with the website was 41.09 minutes (SD =88.48). Preliminary analyses indicated that number of unique visits to the website was independently associated with increased adherence to preventive exercises ($p=.001-.008$).

Conclusion: Our website showed significant effects in promoting adherence to swallowing exercises. However, our return visit rate showed that the platform needs improvement in navigability and usability for this older population undergoing challenging treatment in community settings with low resources.

DEMONSTRATING APPLICATIONS OF TECHNOLOGY IN PHYSICAL MEDICINE & REHABILITATION WITH CREATIVE MULTI-MEDIA MEDICAL EDUCATION

Robert Scales, Ph.D.¹, Cynthia C. Ivy, O.T.D., C.H.T.², Joshua M. Meister, n/a¹, Peter J. Pallagi, n/a¹, Joseph R. Patnaud, n/a¹, Dennis Fitz-Patrick, n/a¹, Kelly S. Vorseth, n/a¹, Skye A. Buckner Petty, n/a¹, Regis I. Fernandes, M.D.¹, Sonya E. Van Nuland, Ph.D.³

¹Mayo Clinic, Scottsdale, AZ; ²Mayo Clinic, Phoenix, AZ; ³Louisiana State University, New Orleans, LA

Background: Value-driven reimbursement will challenge clinicians to improve patient adherence and clinical outcomes with alternate methods of healthcare delivery.

Purpose: In this medical education intervention, multi-media teaching modalities were used to demonstrate motivational interviewing (MI) and clinical applications of technology in an outpatient Physical Medicine and Rehabilitation (PM&R) setting.

Methods: Eighty-three first and second year occupational therapy students (83% female) within an academic program received a 30-minute classroom presentation taught by a medical educator and completed a confidential pre and post survey to evaluate their needs, demands and attitude (0-10 Likert scale) about the PM&R workspace, the role of technology in the patient experience and the clinician's responsibility to increase patient adherence. Time series still image photography was used in combination with an interactive three-dimensional virtual tour to show the strategic design of a PM&R workspace. Video recordings of a role play between a clinician and a standardized patient living with chronic pain demonstrated an in-person clinical encounter. There were four examples of technology: (1) touchscreen display monitors to interact with the patient (2) video recording and analysis of a physical performance evaluation with the capacity to send images to the Electronic Medical Record (3) Movement Sensor Technology that quantifies objective metrics about movement and performance and (4) a Connected Health (CH) mobile device application (m-Health) that enables the clinician to monitor and prescribe treatment plans to the patient in their home. Subtitles were added to the videos to highlight key teaching points.

Results: Attitude scores significantly increased ($p < 0.001$) for the importance of the workspace in the evaluation of patients (8.1 vs 9.5, $SD=1.8$), the role of technology to enhance the patient experience (7.3 vs 9.2, $SD=2.3$) and the clinician's responsibility to increase patient adherence with a prescribed home exercise plan (7.6 vs 8.3, $SD=2.5$). None of the students were opposed to using the examples of technology in their future practice. The majority were interested in learning more about MI (98%) and clinical applications of technology (96%).

Conclusion: Creative multi-media teaching applications can provide a virtual learning experience that has the potential to enhance medical education.

MENTAL HEALTH ANTI-STIGMA DEVELOPMENT IN RESIDENCY EDUCATION

Angela Antonikowski, PhD¹

¹Albany Medical College, Albany, NY

In recent years, the ACGME has increased its focus on resident wellness and has incorporated wellness initiatives into accreditation requirements. There are, however, no specific guidelines addressing reduction of physician-focused mental health stigma in residency education despite stigma being a key barrier to seeking services. There are examples in medicine of the importance of stigma reduction for medical professionals such as that proposed in terms of obesity, serious mental illness, and HIV. Given that US residency training appears to have a negative impact on the health and wellness of trainees and associations are present among patient outcomes, and resident/physician morbidity and mortality outcomes, it is imperative that programs more effectively address mental health stigma during training.

Method: The questions were part of a larger omnibus survey conducted by the Council of Academic Family Medicine Educational Research Alliance (CERA). The methodology of the CERA Program Director Survey has previously been described in detail. The CERA steering committee evaluated questions for consistency and pre testing was conducted. Program Directors were asked about the presence of mental health anti-stigma programming and details regarding that programming. Of the PDs surveyed, 57% (n=128) report the absence of mental health anti-stigma programming. Further, 30% that did have programming (n=68) indicated the focus of programming on physician mental health. The majority of programs (52%) do not have a mental health anti-stigma program within the residency program. Further data analysis focused on program characteristics and the presence of mental health champions in programs.

Conclusions: The purpose of this study was to examine the presence of anti-stigma programming in wellness programs and the target of those programs. When examining resident wellness programs, the role of mental health stigma in the wellness and mental health of physicians is of paramount importance due to the evidence of stigma as a key barrier to residents and physicians seeking care. Given that stigma is a key barrier to care, the absence of anti-stigma programming in resident wellness and mental health programs is a curious one and may confirm the presence of stigma. Of the Program Directors who did endorse the presence of anti-stigma programming, most programs are focused on reducing mental health stigma toward patient populations. This result, while expected, speaks to a gap in wellness curricula focused on resident and physician wellness. While research suggests that physicians' reluctance to seek mental health services is, in part, due to repercussions related to seeking care when obtaining licensure, there are potentially other factors operating at the level of physician self-care, and exploring the level of stigma in help-seeking is likely one of those factors.

DIFFERENCES IN KNOWLEDGE ABOUT SICKLE CELL DISEASE AND EARLY CARRIER SCREENING BETWEEN PARENTS AND ADOLESCENTS IN SAUDI ARABIA

Mohammed Alhajji, PhD(c), MPH¹, Sarah Bauerle, Bass, Ph.D. and MPH²¹Risk Communication Lab / College of Public Health/ Temple University, Philadelphia, PA; ²Temple University College of Public Health, Philadelphia, PA

Background: Sickle cell disease (SCD) is the most common genetic disorder in Saudi Arabia. SCD is an autosomal recessive disease; a child can develop the disease only if her two parents carry the abnormal gene. But most do not know their carrier status and have poor knowledge of the disease etiology and inheritance pattern. This poses potentially serious health implications for future children. A possible preventive measure that has had success in other cultures is early carrier screening for adolescents to guide the traditional marriage arrangements (i.e., family spouse selection). However, little is known about how Saudi families would perceive such a program. This study examined knowledge of SCD and societal acceptance among parents and adolescents for a school-based SCD carrier screening program.

Methods: Parents (N=2,317) and high school students (N=763) from Alhasa municipality, where the rate of SCD is among the highest in Saudi Arabia, were surveyed through Qualtrics in 2019, using an instrument developed from focus groups with the target population. Genetic counselors and physicians reviewed the instrument for face and content validity. The instrument was pilot tested (N=10) and revised to ensure readability. Eleven-point Likert scales (ranging 0-10) asked participants to what extent they agree/disagree to statements related to SCD knowledge, attitudes towards school-based carrier screening, and willingness to participate in such a program. Independent-samples t-tests were conducted to compare these three outcomes using SPSS v24.

Results: Parents and students reported high willingness to participate (M= 9.78, SD= 0.94; M= 8.97, SD= 1.95, respectively.) However, parents reported a significantly higher score in knowledge (Cohen's d= 0.55, p < 0.000), a significantly higher score in favorable attitudes towards school-based carrier screening (Cohen's d= 0.25, p < 0.000), and a significantly higher score of willingness to participate (Cohen's d= 0.64, p < 0.000).

Conclusions: Saudi parents and adolescents are supportive of school-based SCD carrier screening for adolescents, with parents reporting more knowledge of the disease and more favorable attitudes toward early interventions, perhaps due to higher education, more familiarity with the disease in the community, and a stronger sense of responsibility. In addition, the reported high societal acceptance paves the way for policymakers in Saudi Arabia to enact and implement school-based carrier screening programs, providing families with critical information to arrange healthy marriages. Countries with similar traditions of interfamily marriages, which help perpetuate hereditary diseases, have demonstrated the feasibility and effectiveness of such programs in preventing new cases of SCD. These offer a great working model for Saudi Arabia to curb the high rates of this debilitating disease.

PERCEIVED FOOD SWAMP EXPOSURE PREDICTS SELF-REPORTED DIET QUALITY, HEALTH STATUS AND WEIGHT: IMPLICATIONS FOR PUBLIC POLICY

Kristen Cooksey Stowers, n/a¹, Qianxia Jiang, n/a², Kim M. Gans, PhD, MPH³¹University of Connecticut, Hartford, CT; ²University of Connecticut, Vernon, CT; ³UConn, Storrs, CT

Food swamps have been described as neighborhoods where unhealthy food options inundate healthier alternatives. Little is known about the effect of food retail environments on self-reported health quality, diet quality and weight status, particularly for historically marginalized groups.

The purpose of this study is to examine the relationship between food swamps exposure and self-reported health quality, diet quality, and weight status.

A national, racially/ethnically diverse sample of U.S. adults completed an online survey about the number of different food stores they have within 1 mile from their home. We then created the Retail Food Environment Index (RFEI) and modified Retail Food Environment Index (mRFEI) to measure self-reported food swamp exposure.

Predicted probabilities of self-reported health quality, diet quality, and weight status were calculated using the fitted values from the ordinal logistic regression models for each dependent variable. All regression models controlled for socio-demographic factors such as age, gender, income, education level, race, car ownership, family structure, and region, together with food swamp measured with RFEI in each model. We also explored the interaction effect between income and race in each model.

The final sample was 4,694 participants with 38.6% male, 71.3% White/Caucasian, 21.4% African American, 4.0% Hispanic, 3.3% multi-race, 42.4% single, and 48.4% low income. The mean age was 40.7 years old and 48.8% of respondents lived in an urban area, while 22.3% lived in a rural area. More than one third (35.2%) lived in food swamp areas based on RFEI and 34.3% lived in food swamp areas based on mRFEI. More than half (57.7%) of the sample had access to a vehicle. 73.0% of them were in good or above good health quality and 19.3% had high diet quality but more than half (55.4%) were overweight. Regression results showed that residents of non-food swamp areas had a higher diet quality (OR=1.265, p< .01), and self-reported health quality (OR=1.172, p< .01) than those living in food swamp areas. In addition, Black/African Americans had a lower diet quality (OR=.491, p< .001) than Whites. Individuals from middle or high-income levels had a higher quality diet (OR=1.228, p< .05) and health quality (OR=1.699, p< .001) rating and lower weight status (OR=.848, p< .05) than those with low-income levels. Multiracial individuals from middle or higher income levels tended to have higher diet quality (OR=2.588, p< .05) rating than those White individuals with low-income levels.

These findings suggest that an individual's perceptions of the built food environment may play an important role in determining diet quality, weight, and health status. Future municipal policy efforts to simultaneously promote access to healthy food and disincentivize unhealthy food retailers should maximize resident engagement during the policy development stage.

QUALITATIVE EXPLORATION OF PERCEPTIONS OF SEXUAL ASSAULT AND ASSOCIATED CONSEQUENCES AMONG LGBTQ+ COLLEGE STUDENTS

Christine L. Hackman, PhD¹, Jay Bettergarcia, PhD², Emma Wedell, BS³, Adrianna Simmons, BS¹¹California Polytechnic State University, San Luis Obispo, CA; ²California Polytechnic State University, San Luis Obispo, CA; ³College of William & Mary, Williamsburg, VA

LGBTQ+ individuals face numerous challenges related to minority stress, among them prejudice, discrimination, family disapproval, and violence, including sexual assault victimization. Research on the consequences of sexual assault victimization in LGBTQ+ communities is limited. The purpose of this qualitative study was to better understand the negative consequences of sexual assault, as well as to propose interpersonal recommendations and policy changes to improve mental and physical health support, and reporting procedures to better serve LGBTQ+ college student sexual assault survivors. Thematic analysis was utilized to identify six major themes and 20 related subthemes. The major themes included: (a) Sense of Community (b) Cisheteronormativity, (c) Consequences of Sexual Assault, (d) Conditional Disclosure of Sexual Assault, (e) Hesitance to Engage with Institutions Following Sexual Assault, and (f) Changes to Improve Institutional Support. The greater severity of sexual assault victimization consequences faced by this population, coupled with the widespread distrust of the institutions tasked with providing survivors mental and physical health treatment and criminal justice, corroborate previous research underscoring the imperative of increasing funding for, and tailoring reporting procedures and support services to the needs of LGBTQ+ college students.

GROUP AND WEB-BASED COGNITIVE BEHAVIORAL THERAPY FOR AFRICAN-AMERICANS WITH TYPE-2 DIABETES

Ronald Cornely, MPH Candidate¹, Taylor German, MPH Candidate², Anna-Leigh Powell, n/a³, Brittney Brown, n/a³, Ashley Owen, n/a³, Ambar Kulshreshtha, MD/ PhD⁴¹Emory University Rollins School of Public Health, Atlanta, GA; ²Emory University Rollins School of Public Health, Dunwoody, GA; ³Mercer University, Dunwoody, GA; ⁴Emory University Department of Family & Preventative Medicine, Dunwoody, GA

Background: African-Americans are at twice the risk of diabetes complications compared to Whites. Cognitive Behavioral Therapy (CBT) has many effective applications in patients with chronic conditions, including diabetes. Diabetes self-management that integrates education with behavioral strategies has demonstrated improved outcomes and patient satisfaction. Little is known about different approaches for effective CBT in African Americans patients with uncontrolled diabetes.

Objective: TheLIGHT (Lifestyle Intervention Guidance for a Healthier Tomorrow) is a pilot study that aims to assess whether a culturally tailored, cognitive behavior therapy (CT-CB) intervention can improve outcomes for African-American patients with poorly controlled diabetes. Our primary goal in this study is to assess the feasibility and patient perception of an in-person group and web-based CT-CB intervention in this high-risk population.

Methods: A randomized, pilot study was conducted at an Emory Clinic in Atlanta in 2019. Twenty adult African American patients with uncontrolled type-2 diabetes (HbA1C > 8 %) underwent a six-session CT-CB intervention program. Participants were randomly assigned to biweekly in-person or web-based group sessions. Participant attitudes and perceptions were evaluated via Likert-scale questionnaires after each session and focus group at the end of the intervention. MaxQDA software was used to analyze focus group data.

Results: The average age of participants was 53 years and 70% were women. The in-person and web-based interventions had a similar retention rate (80 %). Both the intervention groups rated the benefits of the intervention similar as “Strongly agree” (60%) and “Agree” (40%). The ease of incorporating the intervention into their daily activities was somewhat lower (70 %). Examples of the inductive codes from the focus group data included: knowledge, belonging, and sense of community. The deductive codes included themes such as: Culture, eating habits, and stress. Overall, participants valued the holistic approach of CT-CB as it accounted for pertinent factors in their lives such as stress management.

Conclusions: African Americans with uncontrolled diabetes favorably rated both the in-person group and web-based group CT-CB interventions. Our study provides preliminary evidence regarding the feasibility and potential efficacy of a CT-CB intervention as a useful modality for improving diabetes self-management in African Americans.

PERCEIVED SELF-EFFICACY IN LATINA IMMIGRANT MOTHERS WITH HPV VACCINATION IN THEIR 9-12-YEAR-OLD DAUGHTERS

Alexandra Khodadadi, B.A.¹, Young-il Kim, PhD², Isabel Scarinci, PhD, MPH³¹University of Alabama at Birmingham, Auburn, AL; ²University of Alabama at Birmingham, Division of Preventive Medicine, Birmingham, AL; ³University of Alabama at Birmingham, Birmingham, AL

Introduction: Human Papillomavirus (HPV) vaccination uptake remains low in the United States. The Health Belief Model (HBM) postulates that an individual's perceived risk and self-efficacy (judgement of one's self to complete an action) influence the decision to execute a preventive health behavior. Many studies have investigated factors associated with perceived risk in preventable and early detected cancers. Fewer studies have investigated the factors associated with self-efficacy.

Objectives: We examined factors associated with Latina immigrant mothers perceived self-efficacy to have their 9-12-year-old daughters vaccinated against HPV.

Methods: As part of a group-randomized trial to promote HPV vaccination, a baseline interviewer-administered survey assessing sociodemographics, knowledge and perceived risk of cervical cancer/HPV infection, self-efficacy, and intention to vaccinate their unvaccinated daughters was administered to mothers. A logistic regression was conducted to determine if self-efficacy was associated with vaccine intention when controlling for other variables. In addition, a multivariable linear regression was conducted to determine factors associated with increased self-efficacy scores.

Results: Of 316 participants, 62.9% indicated hesitancy (an answer of "don't know/not sure") to vaccinate their daughters against HPV. Mothers intending to vaccinate had higher average self-efficacy scores than those hesitant to do so (7.29 ± 1.53 v. 5.54 ± 1.42 points respectively; $p < 0.001$). Self-efficacy was strongly associated with vaccine intention when controlling for other variables ($p < 0.001$). The only significant predictor of changes in self-efficacy scores was mothers reporting "yes" or "no" to HPV awareness compared to "don't know/not sure" ($B=0.756$, $p < 0.001$; $B=0.594$, $p=0.04$).

Conclusion: Further efforts should focus on increasing awareness regarding HPV and cervical cancer to facilitate heightening perceived self-efficacy in mothers to vaccinate their daughters against HPV.

AN EXAMINATION OF FAMILIAL AND COMMUNITY SUPPORT IN LOW INCOME WOMEN'S LEVELS OF PHYSICAL ACTIVITY ADOPTION

Brianna Caicedo, BA cand¹, Guido Urizar, PhD²¹California State University Long Beach, Los Alamitos, CA; ²California State University Long Beach, Long Beach, CA

Heart disease continues to be the leading cause of death for women in the United States. Research has revealed that modifiable risk factors for heart disease, such as low levels of physical activity, are especially prevalent among low income and ethnic minority mothers due to family obligations and role demands. Few studies have examined individual and environmental factors, such as familial and communal support, in regards to low income mother's engagement in physical activity. The current study examined whether low-income Latina and non-Latina mothers differed in their physical activity levels depending on the support received from their friends, family, and community. It was hypothesized that Latina mothers who experienced more support from family or friends and a higher sense of community would engage in higher levels of physical activity compared to non-Latina mothers. Thirty low income Latina (18) and non-Latina (12) mothers participated in a three-month exercise program and completed self-report questionnaires on social support (SSFE), sense of community (SOC), and minutes of moderate-intensity physical activity (CALQ) at baseline and 3 months post-intervention. Mothers also wore a Fitbit to monitor their levels of physical activity for 3 consecutive days and participated in a focus group at 3 months post-intervention. Regression analyses revealed no significant group differences between Latina and non-Latina mothers on physical activity ($p=.07$). Additionally, support from others for exercise did not significantly affect physical activity levels ($p=.07$). Qualitative data revealed that mothers' relationships with others served as both a barrier and facilitator to physical activity. These results suggest the need to further explore possible barriers and facilitators to physical activity adoption among low income and ethnic minority mothers.

CULTURAL NORM OF SILENCE STIFLES HEALTH INFO SEEKING FOR SENSITIVE TOPICS AMONG 2ND GENERATION CHINESE AMERICAN EMERGING ADULTS

Ichhya Pant, MPH, DrPH(C)¹, Swechhya Pant, Bachelor of Arts²¹GWU School of Public Health, Arlington, VA; ²Nepali YOUth Alliance, ATLANTA, GA**Background:** Currently, there is limited data available via national surveys and through existing scientific literature for health information seeking behaviors of Chinese American emerging adults ages 18 to 29 years old.**Objectives:** To bridge this gap within existing literature, a qualitative study was conducted to understand their health information needs, preferred sources, and recommendations to improve access and availability for health information.**Methods:** We employed a phenomenological approach and conducted sixteen semi-structured in-depth interviews with Chinese American emerging adults residing in different regions of the United States between March 2017 to September 2018. Thematic analysis was conducted to identify, analyze and report patterns or themes within the data.**Results:** Family, friends, health care professionals, teachers, and the internet were preferred sources for non-sensitive health information. A culture of silent escapism was found to be the prevailing norm when confronted with sensitive health topics. Normative cultural factors inhibit health information seeking for sexual, reproductive, and mental health according to participants. Various forms of mental “escapes” were described as coping mechanisms employed to face sexual, reproductive or mental health crises. Culturally responsive, digitally accessible, private, and normatively influential multi-level public health solutions were recommendations made for making health information more accessible and salient in the Chinese American community.**Discussion:** Future studies should focus on how to mitigate the normative effect of engaging in silent escapism in response to sensitive health crises. Participant recommendations can inform the design and rationale for future public health solutions to improve accessibility and availability of sensitive health information for Chinese American emerging adults.

A LONGITUDINAL ANALYSIS OF CHILDHOOD SEXUAL ABUSE AND RISK FOR INTIMATE PARTNER VIOLENCE REVICTIMIZATION IN GAY AND BISEXUAL MEN

Danielle S. Berke, Ph.D.¹, Raymond L. Moody, M.A.², Christian Grov, PhD, MPH³, H. Jonathon Rendina, PhD, MPH⁴¹Hunter College of The City University of New York, CUNY Graduate Center, New York, NY; ²The Graduate Center of The City University of New York, New York, NY; ³CUNY Graduate School of Public Health and Health Policy, New York, NY; ⁴Hunter College and The Graduate Center, CUNY, New York, NY**Objective:** Childhood sexual abuse (CSA) has been associated with serious adverse health consequences across the life course including increased risk of exposure to intimate partner violence victimization (IPV) in adulthood. Although gay and bisexual men (GBM) may experience elevated rates of both CSA and IPV victimization, little research has examined risk factors for revictimization in this high-need population. This study examined the impact of general (i.e., emotion regulation difficulties) and sexual minority specific (i.e., internalized homophobia) risk factors on the association between CSA and IPV among GBM.**Method:** We collected longitudinal data from 943 participants as part of the *One Thousand Strong* cohort, a study of HIV-negative GBM from across the United States. Measurements included history of CSA reported at baseline, 24-month internalized homophobia and emotion regulation difficulties, and baseline and 36-month IPV. We analyzed data using longitudinal structural equation models.**Results:** For GBM who reported experiencing at least one act of IPV victimization at the 36-month assessment, CSA was significantly associated with frequency of IPV victimization for those with high, but not low levels of internalized homophobia. In contrast, CSA was only associated with frequency of IPV victimization for those with low levels of emotion regulation difficulties.**Conclusion:** These results indicate that activation of internalized homophobia following childhood sexual abuse may exacerbate risk for revictimization experiences in adulthood. Future work is needed to investigate how mitigation of this modifiable risk factor may be targeted to inform violence prevention interventions for GBM.

A COMPREHENSIVE ASSESSMENT OF WELL-BEING AMONG LATINXS AND NON-LATINX WHITE ADULTS: A PROPENSITY SCORE MATCHING STUDY.

Patricia Rodriguez Espinosa, Ph.D., M.P.H.¹, Mark Freeman, M.S.¹, Catherine A. Heaney, PhD, MPH²¹Stanford School of Medicine, Palo Alto, CA; ²Stanford University, Stanford, CA

Latinxs are soon expected to account for 30% of the US population. Few studies have examined well-being among them and most have sample or measurement limitations. Using a propensity score matching design, we examine differences in overall well-being and its subdomains among Latinxs and non-Latinx Whites (hereinafter called Whites). Data are derived from the WELL for Life initiative, a global effort aimed to accelerate the science of well-being. Using an online registry, participants (N=1,635) completed a novel and psychometrically validated well-being measure, the Stanford WELL for Life Scale (SWLS). The SWLS assesses overall well-being, and 10 domains including physical health, lifestyle behaviors, stress and resilience, financial stability, spirituality/religiosity, purpose and meaning, sense of self, experience of emotions, social connectedness, and exploration/creativity. Using a pair matching propensity score algorithm, Latinxs were matched to a sample of Whites on age, education, gender and marital status (n=556, mean age=41 years, 79% women, 42% married). Multiple regression models were then employed to evaluate group differences. No group differences were found for overall well-being ($\beta = 2.01, p = .10$). Compared to Whites, Latinxs reported higher scores on the spirituality/religiosity domain ($\beta = 1.62, p < .01$). Latinxs also reported lower scores on lifestyle behaviors ($\beta = -.24, p < .05$) compared to their matched White counterparts. Men reported more salubrious scores compared to their female counterparts in the physical health domain ($\beta = .36, p < .05$). Across models, higher levels of education -college or above- were consistently predictive of higher well-being scores. Notably, regression models that control for demographics without a formal propensity score matching resulted in more statistically significant differences. Findings point to complex similarities and differences in well-being among Latinxs and Whites. Our comprehensive well-being measure allowed us to move beyond overall comparisons and point to well-being subdomains that can be targeted for intervention or leveraged for optimizing well-being in this population. Moreover, we contribute methodological rigor and show how various approaches lead to different results, potentially contributing to mixed findings in the literature. As the Latinx population continues to grow, enhancing their health and well-being represents a key next frontier in health-related research and policy.

INTERACTION BETWEEN SELF-EFFICACY AND PERCEIVED NEIGHBORHOOD SAFETY ON BODY MASS INDEX IN AFRICAN AMERICAN ADULTS

Colby J. Kipp, B.S.¹, Mason Richardson, n/a¹, Allison Sweeney, PhD¹, Asia Brown, BS¹, Dawn K. Wilson, PhD¹¹University of South Carolina, Columbia, SC

African Americans have a high rate of obesity and comorbidities such as cardiovascular disease and diabetes. Social Cognitive Theory proposes that self-efficacy, or confidence in one's abilities, plays a central role in shaping self-regulation and motivation for maintaining a healthy weight. Although previous research has investigated how self-efficacy is associated with physical activity (PA) outcomes, little research has examined the extent to which broader environmental stressors interact with self-efficacy for exercise in understanding weight-related outcomes. A potential barrier to PA for underserved communities is perceived neighborhood safety. It was hypothesized that self-efficacy for exercise would moderate perceived neighborhood safety in predicting body mass index (BMI), such that those who have lower self-efficacy may be more susceptible to neighborhood supports for maintaining PA and a healthy weight. The present study used data from the Families Improving Together (FIT) for Weight Loss Trial. Self-efficacy was measured using the Eating and Exercise validated scale. Perceived neighborhood safety was measured using a validated subscale of the Neighborhood Environmental Walkability Scale (NEWS). BMI was measured by trained staff. Data from 241 African American adults ($M_{age} = 43.2, SD = 8.65; M_{BMI} = 37.5, SD = 8.34; 96\%$ female) that participated in Project FIT at baseline were analyzed. Regression analysis indicated that the model predicting BMI was significant ($F(8, 224) = 2.66, p < 0.01; R^2 = 0.09$). Furthermore, a significant interaction between self-efficacy and perceived neighborhood safety on BMI ($B = 1.09, SE = 0.51, p = 0.03$) was demonstrated. Among adults with high self-efficacy, neighborhood safety was not significantly related to BMI ($B = -0.04, SE = 0.73, p = 0.96$). However, as expected among adults with low self-efficacy, greater neighborhood safety was significantly associated with a lower BMI ($B = -2.21, SE = 0.77, p = 0.005$). These findings indicate that neighborhood safety is important for those with low confidence in their ability to be physically active for maintaining a healthy weight.

THE RELEVANCE OF VENUE IN RESEARCH: COMPARING RECRUITMENT STRATEGIES FOR RACIAL AND ETHNIC MINORITY YMSM IN NYC

Jesse Bradford-Rogers, MPH¹, Jonathan López-Matos, MA², Demetria Cain, PHD MPH³, Tyrel J. Starks, PhD⁴, Jessica Adams-Skinner, Ed.D. MPH⁵¹PRIDE Health Research Consortium at Hunter College, New York, NY; ²City University of New York-Graduate Center, New York, NY; ³PRIDE Health Research Consortium/Hunter College, New York, NY; ⁴Hunter College, New York, NY; ⁵BOOM!Health, Bronx, NY

Background: Overall, rates of new HIV diagnoses have decreased since 2010; however, rates among Latinx and Black/African American (AA) young (ages 25-34 years) men who have sex with men (YMSM) have increased. These racial and ethnic groups, however, are more difficult to engage in research and prevention services. Reasons could include the intergenerational impact of historically unethical research studies, frequent experiences of discrimination within the healthcare system, and greater rates of medical mistrust. Community outreach and field-based recruitment strategies have shown to be effective in recruiting ethnic and racial minority participants, yet few have compared community-based organizations (CBOs) to centralized, research-center-based screening for the same study. The current study compares recruitment strategies for racial and ethnic minority YMSM at high risk for HIV acquisition in NYC.

Methods: YMSM (ages 15-29 years) were recruited for a comparative effectiveness trial of a Motivational Interviewing (MI) based intervention to reduce substance use and sexual risk behavior. Two recruitment strategies were used: (1) field-based recruitment conducted by a local CBO delivering the intervention in the effectiveness trial and (2) online recruitment via ads and phone screening coordinated by the academic research partner in the effectiveness trial. Differences in demographics, substance use, sexual risk, and research participation were examined.

Results: The final sample consisted of 454 YMSM, most of whom identified as male (92.7%) and as a racial or ethnic minority (79.2%). The average age was 23.9 years old (SD=3.3). Compared to the research center, the CBO screened a significantly larger proportion of AA (odds ratio (OR)=7.28, p=.000) and Latinx individuals (OR=2.7, p=.000). CBO outreach efforts were more likely to reach youth who use injection drugs (OR=3.55, p=.000) and youth recently diagnosed with syphilis (OR=4.67, p<.01). Those screened by the CBO were also more likely to enroll in the study (OR=1.75, p<.05).

Conclusions: Current findings were consistent with existing literature on effective recruitment of racial and ethnic minorities. CBO recruitment was more efficient in reaching the most vulnerable YMSM. This may be attributable to the CBO's presence in the community and utilization of outreach workers who are members of the target population. This underscores the importance of relationship-building and personal contact in program implementation. Implementation research should routinely engage community partners in the development and execution of study recruitment strategies in a manner that can inform outreach and marketing efforts. This synergy may not only enhance recruitment efficiency but inform strategic marketing efforts.

INFORMATION SHARING AND TARGETED CONTENT DRIVE USE OF AN ONLINE SEXUAL HEALTH INTERVENTION FOR AFRICAN AMERICAN YOUNG ADULTS

Alicia K. Williamson, BA¹, Andrea Barbarin, PhD, JD, MS², Bettina Campbell, MSW³, Terrance R. Campbell, MA Ed, MSISM³, Marc A. Zimmerman, PhD¹, Tiffany Veinot, MLS, PhD⁴¹University of Michigan, ann arbor, MI; ²IBM Watson Health, Ann Arbor, MI; ³YOUR Center, Flint, MI; ⁴University of Michigan, Ann Arbor, MI

Objective: There is increasing interest in consumer health informatics (CHI) interventions for behavior change. However, they have varying rates of access, uptake, engagement, and effectiveness with African Americans. Therefore, we examined factors influencing uptake and engagement for a CHI intervention to prevent HIV/STIs among African American young adults. The HIV Outreach, Prevention, and Education (HOPE) eIntervention included a website, blog, Facebook, and Twitter accounts paired with face-to-face, group-based educational sessions called "HOPE Parties."

Methods: This community-based participatory research study included four waves of surveys (N=315) in which participants reported their eIntervention usage after attending HOPE parties. We gathered data on usage of the eIntervention from server logs, friends/followers and user posts. Qualitative interviews were conducted with participants (N=19) after initial surveys and website server logs indicated low uptake and engagement.

Data Analysis: We assessed uptake and engagement for each eIntervention component based on usage data and survey self-report. We then conducted a generalized linear mixed-effects model on survey data to identify predictors of eIntervention uptake. Interview transcripts were analyzed using line-by-line coding by two coders and memos were developed.

Results: Participants were majority African American, female, and in their early 20s. There were significant increases in self-reported eIntervention uptake over time (increasing from N=24 users to N=44 users), but demographic and HIV/STI-related behaviors were not significantly correlated. Instead, factors driving uptake were: desire to share HIV/STI prevention information with others, and trust in the community-based organization offering the HOPE parties. Factors driving non-uptake were: lack of time, forgetting about the eIntervention, and insufficient promotion. Factors driving initial engagement were targeted website aesthetics and content that appealed to users, but longer-term engagement was impeded by insufficiently frequent content updates.

Discussion: CHI interventions for African American young adults can leverage their desires to share information about HIV/STI prevention with others. Ensuring implementation through trusted organizations is also important, though there is a need for vigorous promotion. Visual appeal and targeted content foster initial engagement, but ongoing engagement may require continual content changes.

DO ETHNICITY AND DISEASE STAGE INTERACT IN PREDICTING QUALITY OF LIFE AND COPING CONFIDENCE IN BREAST CANCER?

Molly Ream, B.A.¹, Mollie S. Pester, BA¹, Chloe Taub, MA¹, Emily A. Walsh, B.A.¹, Erica R. Nahin, M.S.¹, Hannah Fisher, MS², Michael H. Antoni, Ph.D.³¹University of Miami, Miami, FL; ²University of Miami, Durham, NC; ³University of Miami, Coral Gables, FL

Background: Compared to non-Hispanic White (NHW) women, Hispanic women are more likely to experience reduced quality of life (QOL) following a diagnosis of breast cancer (BCa). One factor that may account for this disparity is that Hispanic women are on average diagnosed at later stages of BCa. Little is known about how ethnicity may interact with stage in predicting QOL. We hypothesized that Hispanic BCa patients at later stages of disease experience lower QOL than do NHW as a result of greater psychological and physical demands, which exceed their perceived resources and ability to cope.

Methods: Hispanic and NHW women (N=198) with newly diagnosed stage 0-III BCa in South Florida were enrolled in two randomized-controlled trials investigating different stress management interventions between 2006 and 2019. The Functional Assessment of Cancer Therapy- Breast (FACT-B) assessed QOL and the Measure of Current Status (MOCS) assessed perceived ability to cope with stressors. Stage was dichotomized as early (stages 0 and 1, $n=141$) and more advanced (stages 2 and 3, $n=57$) disease. Two-way analysis of variance examined the interaction of stage of disease and ethnicity in predicting QOL and coping confidence.

Results: Overall, 51.0% of women identified as Hispanic ($n=101$) and 49.0% identified as NHW ($n=97$). For QOL, there were significant main effects of both ethnicity ($F(1,184) = 8.03, p=.005$) and stage of disease ($F(1,184) = 9.81, p=.002$), such that Hispanic women and women at later stages of disease experienced lower QOL than NHW women and women at early stages of disease. For coping confidence, neither main effects of ethnicity ($F(1,190) = 1.32, p=.252$) nor stage of disease ($F(1,190) = 1.82, p=.179$) were significant. However, there was a significant interaction of cancer stage and ethnicity on both QOL ($F(1,184) = 4.74, p=.031$) and coping confidence ($F(1,190) = 4.11, p=.044$), indicating that Hispanic women reported larger decrements in QOL and coping confidence at later stages of disease than NHW women.

Conclusions: Hispanic women are significantly more likely to experience lower QOL and coping confidence at later stages of BCa. Providing stress management tools to Hispanic women, particularly with later stage BCa, may allow them to better cope with the increased demands of the disease and may in turn improve their QOL.

EXAMINING DIFFERENCES BETWEEN HISPANIC AND NON-HISPANIC PARENTING ON SUBSTANCE USE BEHAVIORS IN YOUTH

Katja Waldron, B.S.¹, Robert Turrisi, Ph.D.¹, Kimberly Mallett, Ph.D.¹¹Pennsylvania State University, University Park, PA

Objective: Maladaptive alcohol use and the associated negative health outcomes are major public health problems. College students are the highest risk population for maladaptive alcohol use. Parental permissiveness towards drinking has been a significant predictor of college alcohol abuse and consequences, controlling for a wide range of parent and peer influences. However, most research studying college student drinking, and associations between permissiveness and drinking, has examined samples with mainly Caucasian, non-Hispanic students. To address this gap the present study examined Hispanic ethnicity as a moderator of the association between permissiveness and college drinking outcomes using a longitudinal design. Further analyses, examined a subsample of Hispanic students to assess familismo (i.e., the importance of family on social support/identity), acculturation, and discrimination as moderators in the association between permissiveness and drinking outcomes.

Method: Students from three large and geographically diverse public universities (N=1429; 59% female; 17% Hispanic) completed measures during the fall of their first and second years. Within this sample, the Hispanic students (N=245; 73% female) were examined for the additional analyses focusing on familismo, acculturation, and discrimination. Analyses used moderated regression with bootstrapping to obtain asymmetrical 95% confidence intervals (CI).

Results: Examining the full sample, permissiveness was significantly positively associated with drinking (95% CI [0.48, 0.66]) and consequences (95% CI [0.96, 1.44]). Hispanic ethnicity significantly moderated associations between permissiveness and drinking (95% CI [-0.81, -0.43]), and permissiveness and consequences (95% CI [-1.41, -0.39]). For non-Hispanics, as permissiveness increased so did drinking and consequences. In contrast, for Hispanics the effect of permissiveness was not significantly related to drinking or consequences. The further analyses on the Hispanic subgroup revealed that discrimination significantly moderated the association between permissiveness and consequences (95% CI [0.00, 0.37]). As discrimination increased, the effect of permissiveness on consequences also increased. No other significant moderation effects were observed.

Conclusion: The research provided evidence that the positive association between permissiveness and drinking outcomes that has been widely observed in non-Hispanics was not observed for Hispanics. Within Hispanic students, as they experience more discrimination, permissiveness predicted consequences. Results emphasize the importance of examining ethnic background in studies investigating maladaptive alcohol use in college students. Ethnicity-specific contextual factors (discrimination) need to be addressed in prevention efforts.

EVALUATION OF E.A.S.Y - A GROUP DYNAMICS-BASED HEALTHY LIFESTYLE PROGRAM FOR UNDERGRAD STUDENTS W/ ETHNIC MINORITY BACKGROUNDS

Emmanuel Asenso, MPH¹, Samantha Harden, PhD, 200-RYT², Steven Trotter, MS³¹Rowan University School of Osteopathic Medicine, Clementon, NJ; ²Virginia Tech, Blacksburg, VA; ³East Carolina University, Wilmington, NC

Objective: Young adults from ethnic minority backgrounds have a higher risk and burden of chronic conditions that can be prevented and modified by a healthy lifestyle. College is a critical time within the lifespan to initiate healthier behaviors, such as increasing physical activity and fruit and vegetable intake and decreasing sugar-sweetened beverage intake. In this study, a one group, pragmatic pretest-posttest study design was used to investigate the feasibility and efficacy of a culturally sensitive, group dynamics-based intervention for ethnic minority undergrad students (EMUS).

Participants: Fifty-one EMUS were recruited from a large public university.

Methods: Participants completed baseline and post-intervention surveys. The intervention included small group GRIT™ exercise training twice a week for 8 weeks, three different educational seminars on physical activity, nutrition and self-efficacy, and activities based on group dynamics-based principles. Primary outcomes were feasibility, participant satisfaction, and physical activity and secondary outcomes were dietary behaviors. Feasibility data were analyzed by assessing the reach and adherence of the program through participation data, attendance tracking, retention, and self-report data on the level of engagement in the program. Physical activity data were analyzed using self-reported pre- and post-intervention data via the International Physical Activity Questionnaire. Dietary data were analyzed using self-report data via the Dietary Screener Questionnaire and Beverage Questionnaire-15.

Results: Participants (N = 51) were primarily female (75%), African-American (51%) or Hispanic/Latinos (41%) and underclassmen (63%; i.e., not a junior or senior). 78% of participants were retained and reported high levels of program satisfaction. No significant increase in MET-minutes from baseline to post-intervention ($p = .246$), but the change in the proportion of participants who reached the “high” levels of physical activity was significant (23% to 50%; $p = .034$). Reduction in sugar-sweetened beverages (SSB) consumption ($p = .192$) and proportion of participants consuming more than 8 fl. oz./day of SSB ($p = .66$) was not significant.

Conclusion: Results for feasibility and satisfaction of this culturally sensitive, group dynamics-based intervention were promising, but there were limitations for establishing efficacy; suggestions for future work are described. This study adds to the limited data on group-dynamics based interventions for EMUS and warrants further study with more robust study designs.

ASSOCIATIONS BETWEEN POTENTIAL PREDICTORS AND WILLINGNESS TO TAKE PREP IN MEN WHO HAVE SEX WITH MEN

Jennifer Seidman, n/a¹, Lynne Klasko-Foster, PhD², Caroline Rusch, n/a¹, Kelseanna Hollis-Hansen, MPH³¹University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY; ²Department of Psychiatry & Human Behavior, Providence, RI; ³University at Buffalo Division of Behavioral Medicine, Buffalo, NY

Background: Pre Exposure Prophylaxis (PrEP), a daily medication to reduce the risk of HIV, is biologically efficacious in men who have sex with men (MSM). Delay discounting (DD) the decision to take a smaller reward immediately over a larger reward later and probability discounting (PD) the decision to take a larger uncertain reward over a smaller assured reward are distinct measures of impulsivity associated with risky behaviors. Previous research has found that a general increasing awareness of PrEP has not influenced willingness to take the medication. In the present study, we explored associations between discounting behavior (DD and PD) and willingness to take PrEP.

Methods: MSM (N = 59, ages 18-44, 72.9% white) completed an online questionnaire including demographic variables, the perceived stress scale (PSS), DD, PD, PrEP use, willingness to take PrEP, PrEP knowledge, and risky sexual behaviors. No significant correlations were found between relevant demographic variables and the independent and dependent variables of interest, and hence those variables were not included in the model. A simultaneous linear regression was used to look at multiple hypothesized predictors of PrEP willingness, specifically PSS scores, area-under-curve (AUC) for PD and DD, the HIV Sexual Risk Behavior Scale score, and accurate PrEP knowledge.

Results: The simultaneous linear regression accounted for 27% of the variance in mean PrEP interest ($\Delta R^2 = 0.27$, $F(5,53) = 3.97$, $p < 0.01$). Probability discounting ($B = 0.37$, $t = 2.99$, $p < 0.01$) and HIV Sexual Risk Behavior scores ($B = 0.27$, $t = 2.30$, $p = 0.03$) were statistically significant predictors, while delay discounting ($B = -0.01$, $t = -0.06$, $p = 0.95$), accurate PrEP knowledge ($B = 0.11$, $t = 0.94$, $p = 0.35$), and perceived stress ($B = 0.17$, $t = 1.42$, $p = 0.16$) were not statistically significant predictors.

Conclusions: In our small cross-sectional study, those who favored the larger uncertain reward were more likely to engage in risky sexual behavior, but were also more willing to take PrEP. Thus, to the extent that PD is associated with sexual risk taking, it might hold value for both identifying individuals at risk for HIV and serve as a potential intervention target. Additionally, future studies should aim to replicate findings in a larger heterogeneous sample and to understand how impulsivity might encourage PrEP initiation and benefit MSM at increased HIV risk.

MASTERY, NOT SOCIAL SUPPORT, BUFFERS THE IMPACT OF FOOD INSECURITY ON DEPRESSIVE SYMPTOMS IN PEOPLE LIVING WITH HIV

Redd Driver, n/a¹¹University of Connecticut, Storrs, CT

The HIV epidemic in the United State is heavily concentrated among members of socially and economically disenfranchised communities. For people living with HIV (PLWH) who are living in poverty, HIV disease progression may be exacerbated by a multitude of factors including food insecurity and depression. These factors have been demonstrated to directly and indirectly adversely impact HIV-related health outcomes. To better understand and intervene on the effects of poverty and depression on HIV infection, the Stress Process Model is a useful framework, particularly as it may elucidate social resources as moderating variables as targets for intervention. One psychosocial resource that has often been studied in relation to HIV is the moderating role of social support on HIV-related health outcomes. In addition, for highly impoverished PLWH a sense of mastery as a psychological resource related to personal control and self-efficacy, may also serve as a buffer in the association between poverty-related stress and depression. In the present study we sought to examine the dual processes of social support and mastery in moderating the relationship between food insecurity and depressive symptom among PLWH. Multivariate regression analyses were performed on data collected from 180 PLWH (37% women) screened for alcohol use and who were experiencing food insecurity. We constructed a regression model to test the moderating roles of social support and mastery in the relationship between food insecurity and depression while controlling for age, alcohol use and years since diagnosed with HIV. Results indicated that one third of the sample reported experiencing extreme food insecurity as indicated by experiencing recent hunger. In bivariate analyses experiencing depressive symptoms was positively associated with food insecurity ($b = 1.54$, $SE = 0.32$, $p < .001$), and independently negatively associated with both social support ($b = -0.23$, $SE = 0.07$, $p < .001$) and mastery ($b = -0.36$, $SE = 0.07$, $p < .001$). In adjusted multivariate models, mastery ($b = 0.12$, 95% CI [0.01, 0.24], $p = .04$), but not social support ($b = 0.04$, 95% CI [-0.07, 0.14], $p > .05$), was found to moderate the relationship between food insecurity and depressive symptoms suggesting that mastery serves as a buffer to depressive symptoms over and above the influence of social support among highly impoverished food insecure PLWH. The present study demonstrates the utility of including mastery enhancing components in interventions for PLWH in an effort to improve mental health and HIV-related clinical outcomes.

THE ROLE OF RELATIONSHIP FUNCTIONING IN PREDICTING DISCUSSIONS AND UPTAKE OF PREP AMONG MEN IN SAME-SEX RELATIONSHIPS

Kendell M. Doyle, BA¹, Tyrel J. Starks, PhD²¹The Graduate Center, City University of New York, Brooklyn, NY; ²Hunter College, New York, NY

Gay and bisexual men (GBM) are disproportionately affected by HIV transmission risk. Among GBM, main partnerships account for the majority of new HIV infections. Pre-exposure prophylaxis (PrEP) is recommended for at risk populations, such as GBM in relationships. Previous research suggests that men in same-sex relationships are reluctant to discuss PrEP uptake with their main partner due to fear that such a discussion will undermine partner trust and threaten the relationship. The role of relationship functioning (RF) regarding discussions and uptake of PrEP among GBM in relationships has yet to be investigated but may provide valuable insight of interpersonal factors predicting individual level health outcomes.

Data were gathered from the baseline assessment of 59 seroconcordant-negative couples ($n_{\text{individuals}} = 118$) participating in a randomized controlled trial assessing the adjunct components of Couples HIV Testing and Counseling. Eligibility required both partners to be aged 18 or over, identified as cis-gender male, were sexually active and had a relationship length ≥ 3 months. At least one partner in each couple was 18-29 years old, reported drug use in the past 30 days, and was HIV-negative. Of these 118 individuals ($M_{\text{age}} = 26.55$, $SD = 4.78$) half identified as a racial minority (50%). The Multiple Determinants of Relationship Commitment Inventory scale was used to measure RF.

Results of an Actor Partner Interdependence Model (APIM) suggest significant partner effects between relationship functioning factors and discussions of PrEP with main partners. Partners with higher scores on MDRCI Rewards ($B = .049$; 95% CI: .005, .092; $p < .05$) and Comparisons ($B = .037$; 95% CI: .002, .073; $p < .05$) were significantly more likely to discuss PrEP with their main partner. Additionally, partners who reported more desire for alternatives to their current relationship on the MDRCI were more likely to be prescribed PrEP currently or in the past ($B = .069$; 95% CI: .000, .138; $p < .05$).

Contrary to the concerns expressed by many GBM, results suggest that PrEP communication is associated with better, not diminished, RF. Men who discussed PrEP with their partners had higher satisfaction and commitment compared to those who did not. Analyses provide some indication that high-functioning couples are able to tolerate PrEP communication successfully. These findings also suggest it is at least plausible that discussing biomedical HIV prevention may be linked to enhanced RF.

BARRIERS TO PREP UPTAKE AMONG LATINO MSM: PREP STIGMA, SEXUAL SHAME, INTERNALIZED HOMONEGATIVITY AND NEGATIVE PREP PERCEPTIONS

Jonathan López-Matos, MA¹, Stephen S. Jones, BA Mathematics², Nicola F. Tavella, MPH, CPH³, Brian Salfas, MA⁴, Ali Talan, DrPH⁵, H. Jonathon Rendina, PhD, MPH⁶

¹City University of New York-Graduate Center, New York, NY; ²RFcuny - Hunter College - PRIDE Health Consortium, NEW YORK, NY; ³PRIDE Health Research Consortium, Hunter College, CUNY, New York, NY; ⁴PRIDE Research Consortium, New York, NY; ⁵Hunter College, New York, NY; ⁶Hunter College and The Graduate Center, CUNY, New York, NY

Background: Although Pre-Exposure Prophylaxis (PrEP) has been available as a biomedical HIV prevention strategy since 2012, specific sub-groups continue to be at high risk for HIV acquisition. While PrEP can help reduce new infections, its uptake among Latino sexual minority men (LSMM) continues to be slower when compared to other populations at risk. Furthermore, previous research has found associations between negative perceptions and PrEP-related stigma (PRS) serving as barriers to uptake. Other studies have also analyzed internalized homonegativity (IH) and sexual shame (SS) as potential factors that may influence perceptions about PrEP among MSM in general. Since research with LSMM and PrEP uptake continues to be limited, this study sought to analyze the mediating effect of PRS on the association between internalized homonegativity, sexual shame and the negative perceptions about PrEP that could hinder its uptake among LSMM.

Methods: Cross-sectional data were taken from a national sample of 1,011 LSMM from across the United States. The *Internalized Homophobia Scale* was used to measure IH and the *Sexual Pride and Sexual Shame Scale* was used to measure SS. We assessed negative perceptions about PrEP using the *Decisional Balance to PrEP Use Scale* and PrEP-related stigma using the *PrEP Stigma Scale*. Data were analyzed using path analysis on Mplus and were adjusted for demographic variables, with negative perceptions about PrEP as the outcome.

Results: Average age was 23.5 years (SD=2.9) and all participants identified as Latino. After controlling for covariates, direct effects of IH and SS on the negative perceptions about PrEP remained significant (IH: $\beta = 0.13$, $p < 0.05$; SS: $\beta = 0.17$, $p < 0.05$) as well as direct effects on PRS (IH: $\beta = 0.15$, $p < 0.05$; SS: $\beta = 0.16$, $p < 0.05$). Further, a significant direct effect was observed of PRS on the negative perceptions about PrEP (PRS: $\beta = 0.23$, $p < 0.05$). Significant indirect effects were observed from IH and SS through PRS to the negative perceptions about PrEP (IH: $\beta = 0.04$, $p < 0.05$; SS: $\beta = 0.03$, $p < 0.05$).

Conclusions: These findings support the hypothesis that PrEP-related stigma may exacerbate negative perceptions, which can serve as a barrier to PrEP uptake among LSMM. Although the association of internalized homonegativity and sexual shame with negative perceptions about PrEP was significant independent of PRS as a mediator, when PRS was added, the association continued to increase. Interventions targeting PrEP uptake among LSMM may need to address individual-level barriers associated with perception and stigma related to PrEP. Future research is also needed to understand the link between internalized homonegativity, sexual shame, and PrEP-related stigma and how other cultural factors among LSMM may influence perceptions about PrEP.

PREP KNOWLEDGE, ATTITUDES, AND INTENTIONS AMONG BLACK COLLEGE MEN IN THE SOUTH

Samuella Ware, MPH, CHES¹, Yarneccia Dyson, Ph.D., MSW²

¹The University of North Carolina Greensboro, Greensboro, NC; ²UNC-Greensboro, Greensboro, NC

Most new HIV infections occur among Black men between the ages of 17-24; 52% in the southern region of the United States (U.S.). In 2012, Pre-exposure prophylaxis (PrEP), a daily HIV infection prevention pill, was approved by the Food and Drug Administration in the U.S. and in 2018 it was approved for adolescents. PrEP use and uptake have been slow, especially among Black men, with only 1% of individuals who can benefit from this prevention tool receive it. Accordingly, this study aims to examine PrEP knowledge, attitudes, and intentions of young Black college men in the South. This study is part of a larger concurrent mixed methods study conducted in 2019 that examined the sexual health needs of Black college students enrolled at five Historically Black Colleges and Universities or Minority Serving Institutions in the South. This study includes the quantitative portion which included a 70-item online survey. Those who answered questions about PrEP were included (N=108). Students were asked about their knowledge of PrEP, attitudes of PrEP as a prevention strategy, and intentions to use PrEP if they had access. Univariate, bivariate, and multivariate analyses were conducted.

Majority of our sample had not heard of PrEP (58%), however, 64% thought PrEP was a good prevention strategy, and 63% said they would use PrEP if available. Within the past 3 months, on average, students engaged in condomless vaginal sex 6 times, condomless anal sex 2 times, and had 4 partners. In a bivariate analysis, PrEP knowledge was significantly associated with age with older students were likely to have previous knowledge of PrEP. Regarding sexual orientation, those that identified as queer (gay or lesbian, bisexual, or other) were more likely to have previous PrEP knowledge. PrEP attitudes were significantly correlated to the number of sexual partners. In regression models, condomless vaginal sex was negatively associated with PrEP use intentions. Additionally, number of partners was negatively associated with PrEP attitudes. Intentions to use protective behaviors (ie. limiting partners or using condoms) was significantly positively associated with PrEP attitudes and PrEP use intentions. This shows that Black college men consider PrEP an element to their prevention toolbox but are not being informed of PrEP and additionally may have low-risk perception. More research is needed on young Black men to understand their risk perceptions and attitudes and use intentions towards PrEP.

INITIAL FEASIBILITY, ACCEPTABILITY AND USER EXPERIENCE OF A MULTI-DRUG POD-IVR: A MIXED METHODS STUDY

Melissa Guillen, BA¹, Sara Vargas, PhD¹, Rochelle K. Rosen, PhD², Lauren Dawson, BS³, Melissa L. Getz, B.A.⁴, Kelley A. Smith, MA, MPH⁵, Joseph L. Fava, Ph.D.¹, Marc M. Baum, n/a⁶, Kathleen L. Vincent, MD⁷, Kate M. Guthrie, PhD⁸

¹The Miriam Hospital, Providence, RI; ²Brown University School of Public Health, Providence, RI; ³University of Texas Medical Branch- Galveston, Galveston, TX; ⁴Centers for Behavioral and Preventive Medicine, The Miriam Hospital, Providence, RI, Sharon, MA; ⁵Centers for Behavioral & Preventive Medicine, Lincoln, RI; ⁶Oak Crest Institute of Science, Monrovia, CA; ⁷University of Texas Medical Branch, Galveston, TX; ⁸The Miriam Hospital / Brown Medical School, Providence, RI

Background: Delivering efficacious HIV/STI prevention for optimal effectiveness relies on user adherence. A dapivirine intravaginal ring (IVR) showed significant reductions in HIV incidence among adherent users. Sustained-release drug delivery devices (e.g., IVRs) are considered an important path forward to address long-term adherence.

Methods: In a pre-phase-1 trial, 10 women enrolled in serial cohorts to evaluate a pod-IVR delivering TDF-alone, TDF-FTC, and/or TDF-FTC-MVC. Six women used single and dual drug pod-IVRs; 4 used triple drug pod-IVRs – each for 7 days. Participants provided quantitative and qualitative data capturing user sensory experiences as well as acceptability, perceptibility, and adherence behaviors. The user evaluation data for each pod-IVR included sexual and reproductive health history, daily diaries, final acceptability and willingness-to-use (WTU) surveys, and qualitative in-depth interviews.

Results: We enrolled 1 Hispanic (H), 2 H White, 4 non-H White, and 3 non-H Black females. Mean age = 27.8 years (range 21-41); mean BMI = 30.8. All 10 reported they would probably/definitely recommend the pod-IVR. The majority of participants (6) reported they would probably/definitely use the pod-IVR platform for HIV prevention. However, probable use decreased with anticipated longer use times (7, 28, 90, 180 days). Confidence to insert and remove the pod-IVR was high. Users' experiences did not differ as a function of the pod-IVR delivery system itself, regardless of drug(s) delivered. Participants reported sensory and behavioral experiences that impacted their use behaviors, including insertion and removal confidence, discharge, and expulsion concerns. While experiences were not significant enough to disrupt WTU, they should be considered in developing acceptability and adherence protocols in future trials.

Conclusions: Results provide evidence that the pod-IVR device itself is well-tolerated, despite different numbers of filled pods or active drug(s). This finding holds promise both for anti-HIV pod-IVRs and, potentially, multipurpose prevention pod-IVRs that could prevent sexually transmitted infections (STIs) including HIV, and/or pregnancy. Further acceptability, perceptibility, and adherence data should continue to be explored in the context of sexual activity and menses during longer use periods (e.g., 28-day, 90-day, or 365-day ring use).

SELF ESTEEM MODERATES THE RELATIONSHIP BETWEEN ADVERSE LIFE EVENTS AND MENTAL HEALTH DIAGNOSES FOR BLACK WOMEN LIVING WITH HIV

Sannisha K. Dale, PhD¹, Sherene Saunders, BS, MPH²

¹University of Miami, Miami, FL; ²University of Miami, Pembroke Pines, FL

Background: Black women in the U.S. are more likely to be living with HIV compared to women of other racial/ethnic groups and people living with HIV are more likely to experience adverse life events (ALE) such as physical and sexual assault. High self-esteem has proven to be a protective factor and low self-esteem has been linked to mental health diagnoses such as depressive symptoms, suicidality, and posttraumatic stress disorder (PTSD). However, the existing literature is limited in the examination of how self-esteem may buffer the relationships between ALE and mental health diagnoses among Black women living with HIV (BWLWH). Among BWLWH, we investigated whether ALE predicted mental health diagnoses and whether self-esteem was a moderating/protective factor.

Method: 119 BWLWH in an HIV epicenter in the Southeastern U.S. completed self-report assessments on self-esteem (Rosenberg Self-Esteem Scale) and ALE (Life Events Checklist for DSM-5) (e.g. rape, sexual assault, physical assault, accidents, natural disaster). Women also completed a clinical interview (via Mini-International Neuropsychiatric Inventory) to diagnose current depressive disorder, PTSD, and suicidality.

Results: SPSS was used to conduct descriptive statistics and logistic regressions. Over 85% of women experienced one or more ALE and 50.4% experienced five or more ALE. There were high rates of current PTSD (54%) and current depression (28%), but a lower rate of current suicidality (10%). Higher self-esteem predicted lower likelihood of current depression (OR=.894, p=.006), PTSD (OR=.838, p=.000), and suicidality (OR=.889, p=.019). Total ALE did not predict mental health diagnoses. However, interactions between self-esteem and total ALE significantly predicted current depression (OR=.000003, p=.011) and PTSD (OR=2.7182 x 10⁻⁹, p=.000) and tended to predict suicidality (OR=2.3261x10⁻¹¹, p=.078). Further analyses indicated that higher ALE total related to higher likelihood of current PTSD only among women reporting lower self-esteem (OR=1.21, p=.04).

Conclusion: Among BWLWH, we found that self-esteem related to lower diagnoses of depression, PTSD, and suicidality, and was a protective factor between ALE and the diagnosis of PTSD. Total ALE did not directly predict diagnoses perhaps due to a ceiling effect from the high numbers of ALE among the BWLWH. Intervention efforts addressing mental health diagnoses among BWLWH should incorporate strategies to enhance self-esteem.

SEXUAL ORIENTATION AND IDENTITY DISCLOSURE: IMPLICATIONS FOR PREP EXPERIENCES AMONG BLACK MEN WHO HAVE SEX WITH MEN

Ryan Watson, PhD¹¹UConn, Storrs, CT

Background: The HIV epidemic in the United States has disproportionately burdened Black men who have sex with men (BMSM), particularly in the South. While pre-exposure prophylaxis (PrEP) has high demonstrated efficacy, uptake is low among BMSM. While we understand that stigma and health care access impacts PrEP use, health-relevant demographic characteristics have not been linked to differential uptake of PrEP. Additionally, despite great efforts in the past 5 years to make BMSM aware of and uptake PrEP, we are unsure whether or not any progress has been made.

Method: To further explore which factors are related to the abysmal uptake of PrEP among BMSM, a sample of 345 HIV-negative or unknown HIV status BMSM from Atlanta was utilized. Bivariate and multivariable logistic regression models examined the effects of sexual orientation and disclosure on PrEP awareness and use.

Results: Despite the majority of the sample reporting PrEP awareness (91%), few BMSM in our sample had ever used PrEP (10%). Bisexual BMSM experienced 0.34 (or 64% lower, 95% confidence intervals (95% CI): 0.13, 0.60) the odds of having heard of PrEP compared to their same gender loving/gay counterparts. Among all Black MSM, those who had disclosed their sexual orientations to some or all of the individuals in their networks experienced 6.7 times (95% CI: 2.28, 19.74 for out to some, 2.57, 17.42 for out to all) the odds of having heard of PrEP compared to their counterparts who had not disclosed their sexual orientation. Overall, BMSM who had disclosed their sexual orientation to some or all of the members of their networks were more aware of PrEP compared to their counterparts who reported lower levels of disclosure, but were not more likely to actually use PrEP.

Conclusions: This gap is alarming—compared to one previous 2014 study that found about 1 in 8 PrEP-aware Black MSM had used PrEP, we found with more recent data that only 1 in 9 PrEP-aware Black MSM had used PrEP. That is, we are unable to document this large gap between PrEP awareness and use has changed over the span of 5 years. This is despite concerted efforts to connect Black MSM, one of the highest risk groups for HIV acquisition, to PrEP. These findings suggest that disclosure may be a relevant characteristic to consider for PrEP awareness, but there may be more to consider in closing the awareness-uptake gap among Black MSM.

LIFE INSTABILITY AS A PREDICTOR FOR POOR HIV-RELATED HEALTH OUTCOMES AMONG A CLINIC- BASED SAMPLE OF OLDER ADULTS

Elliott R. Weinstein, MPH¹, Noelle A. Mendez, B.A.¹, Adam W. Carrico, Ph.D.¹, Deborah L. Jones, Ph.D., M.Ed¹, Steven A. Safren, Ph.D.²¹University of Miami, Miami, FL; ²University of Miami, Coral Gables, FL

Introduction: People with uncontrolled HIV have greater life instability, higher depressive symptoms, worse medication adherence, more recent substance use, less housing security, and are more likely to have been incarcerated (e.g. Wong et al., 2007; Wawrzyniak et al., 2016). Miami is the U.S. city with the highest prevalence of HIV in the U.S., and, like other parts of the U.S., there are growing numbers of older adults with HIV. We sought to examine the degree to which life instability affects HIV-related health behaviors and outcomes among older adults (50+) with HIV in the Miami area. We hypothesized that greater additive levels of life instability are associated with worse adherence to antiretroviral therapy, greater odds of having a detectable viral load, and lower CD4-cell counts.

Methods: From Apr 2017- Nov 2019, 622 patients (50 years +) in the primary public HIV clinic in Miami completed an interviewer-administered assessment (English or Spanish). An additive life instability index was created by incorporating eight relevant psychosocial variables: relationship status, working status, housing stability, presence of comorbid health conditions, incarceration (past 12 months), length of time residing in the US, binge drinking, and drug use. Adherence was calculated based on responses to the Wilson's 3-item scale validated against electronic drug monitoring (Wilson et al., 2016). Viral load (cut at ≥ 200 copies/mL for unsuppressed) and CD4 were extracted from electronic medical records. Linear and logistic regression models were used to assess hypothesized relationships.

Results: Overall, the mean level of life instability in the sample was moderate (range 0-6, $M = 2.81$, $SD = 1.08$). Each additional indicator of life instability endorsed, controlling for depression, was associated with: approximately 1.52 greater odds of having unsuppressed viral load, ($OR = 1.52$, 95% CI 1.23, 1.88, $p = .000$); 4.36 percentage points lower ART adherence (out of 100%) ($B = -4.36$, 95% CI 2.99, 5.73, $p = .000$), and a decrease of 32 CD4 cells per cubic millimeter ($B = -32.41$, 95% CI 14.71, 50.10, $p = .000$).

Conclusions: Findings show life instability influences ART adherence, viral load, and CD4-cell count among older adult patients with HIV in a region of the U.S. with an out of control HIV epidemic. Assisting older adults reduce life instability may help various components of the care continuum for this population, and consequently work toward end the epidemic targets.

INCORPORATING MOBILE HEALTH TO A COGNITIVE BEHAVIOR THERAPY: ADAPTING AN INTERVENTION FOR LATINX PEOPLE LIVING WITH HIV

Edda I. Santiago-Rodriguez, DrPH, MPH, MA¹, Andres Maiorana, MPH¹, Catherine E. Rivas, BSc², John A. Saucedo, PhD, MSc¹¹University of California, San Francisco, San Francisco, CA; ²Columbia University's Mailman School of Public Health, New York, NY

Latinx in the US are disproportionately affected by HIV. Poor access to health care, delays in HIV testing and engagement in HIV care, as well as untreated mental health issues are some of the structural barriers that influence this population. Depression has long been a barrier for engagement in care and viral suppression among people living with HIV (PLWH). Interventions using Cognitive Behavioral Therapy (CBT) have been effective in successfully treating depression among PLWH. Little is known about the effectiveness of this therapy among Latinx PLWH. We explored the cultural and linguistic needs of Latinx PLWH to better develop a treatment intervention for depression using an adaptive and mobile health approach. Qualitative semi-structured in-depth interviews were conducted with participants who identified as Latinx, HIV positive, 18 years old, English or Spanish speakers receiving HIV care at the study site clinic. Participants were also assessed through a PHQ screening and received a severity score of moderate depression or higher. We asked participants about depression, HIV treatment access and acceptability of CBT adaptation. Interviews were audio-recorded and transcribed. Thematic analysis was used to analyze data. Seventeen participants, 16 men who have sex with men and one cisgender heterosexual woman, completed the interview. Participants had experienced depression for most of their lives and reported social isolation, sadness, poor concentration and difficulties with problem-solving and coping. Most previously had sought therapy and/or psychotropic treatment. Participants were receptive to the CBT intervention. Some expressed wanting a therapist that understands their background and social context and that ideally speaks their preferred language. Participants stated that they would welcome mobile health, even if they did not use it to communicate with their medical providers. They shared that receiving a text from their therapist would mean there is someone on the other end who cares about them and would reinforce the therapeutic process. Specific suggestions for texting were to use easy to read/understand messages tailored to each individual and with adaptable frequency. Concerns about confidentiality issues were few. Overall findings suggest high acceptability of CBT using a mobile health approach among interviewed Latinx PLWH. The use of texting could be a great tool to help with engagement and completion of therapy tasks.

FORMATIVE RESEARCH AND EVALUATION OF A MOBILE ALCOHOL AND HIV PREVENTIVE INTERVENTION FOR YOUNG ADULT MEN WHO HAVE SEX WITH MEN

Robert F. Leeman, Ph.D.¹, Bonnie Rowland, B.S.², Neo Gebru, B.A., M.P.S.¹, Maria Benvenuti, M.A.¹, Robert Cook, M.D., M.P.H.¹¹University of Florida, Gainesville, FL; ²Boston University, Boston, MA

Background: HIV incidence has declined in the past decade, but certain groups continue to suffer disproportionately, including men who have sex with men (MSM), young adults, and people of color. These rates are due in part to overlapping behaviors like alcohol use that negatively affect sexual health behavior. Pre-exposure prophylaxis (PrEP) can prevent HIV, but it is underused, and often with suboptimal adherence.

Method: Thus, we undertook a two-year project to develop a multi-component mobile intervention to reduce alcohol use and prevent HIV in young adult (18-30 yrs.) MSM. The intervention has 3 parts: web-based intervention providing personalized feedback; interactive voice response (IVR) system to enhance PrEP adherence via daily assessment and weekly feedback; and open-label PrEP. The intervention was developed in 3 phases: web-based survey of the Southeastern U.S. (N=682) to provide normative data for the web-based intervention; focus groups/interviews to get input from the study population (N=17); and a small usability test where participants engaged with the IVR for 30 days (N=4).

Results: The web-based survey sample was diverse, with 49% college graduates and 47% non-White. HIV risk behavior and perceived HIV risk scale scores were high. Respondents also self-reported past-month averages of > 4 sexual partners; > 4 instances of condomless sex; and almost 3 instances of alcohol before/during sex. Past-month alcohol use was moderate, with means of 9 drinking days and just over 12 drinks per week. In the past 12-months, 70% had an HIV test. Participants were PrEP-naïve, but 89% had heard of it, with favorable attitudes, including 84% perceiving PrEP to be safe. Focus group/interview participants tended to have favorable views including a belief the intervention would enhance PrEP awareness. Participants provided feedback regarding the intervention's appearance, also noting some questions were repetitive and expressed concerns about an exercise that asks participants to write about a recent sexual encounter that may have increased HIV risk. Usability participants reported the IVR was easy to use and convenient, but had critiques about clarity. Participants had a favorable view of the continuity between feedback based on the web-based intervention and IVR.

Conclusions: Participants' feedback will be used to revise the intervention to enhance its utility to reduce alcohol use and improve sexual health in groups disproportionately affected by HIV.

INTEGRATED BEHAVIORAL HEALTH: PATIENT AND PROVIDER PERSPECTIVES FROM TWO PRIMARY CARE CLINICS

Helene Chokron Garneau, PhD¹, Ida Q. Chen, N/A¹, Heather Gotham, PhD², Kaitlin Dent, M.S.Ed., M.Phil.Ed.³, Megan R. Mahoney, MD¹, Timothy Seay-Morrison, EDD, LCSW⁴, Heather Filipowicz, MS, RD⁵, Mark McGovern, NA²

¹Stanford University, Palo Alto, CA; ²Stanford University School of Medicine, Palo Alto, CA; ³University of Northern Colorado, Fort Collins, CO; ⁴Stanford Health Care, Palo Alto, CA; ⁵Stanford Healthcare, Stanford, CA

Health care systems and providers increasingly recognize the impact of behavioral health conditions on treatment adherence, medical outcomes and costs. In response, a variety of models of providing integrated behavioral health, particularly in primary care settings, are being widely implemented. Surprisingly, few studies have examined patient and providers preferences for having behavioral health concerns addressed in primary care settings.

The purpose of this study was to: characterize patients' perceptions and preferences for integrated behavioral health services, and examine how preferences may vary by patient characteristics; and characterize providers' comfort and knowledge of behavioral health as well as time spent on patients with behavioral health needs.

Patients and primary care providers at two primary care clinics were surveyed. Patients (N=752) were asked about their beliefs and preferences for addressing behavioral health concerns. Providers (N=59) were asked about their comfort and knowledge of behavioral health as well as their perception of organizational capability to address patients' behavioral health needs.

Overall, patients reported being comfortable addressing behavioral health needs in primary care settings and considered behavioral health highly important to their overall physical health. Female gender, age, and prior treatment for mental health conditions, were each independently associated with specific preferences for addressing behavioral health concerns in primary care settings. Data pertaining to providers' comfort and knowledge of behavioral health as well as organizational capability is currently being analyzed. Preliminary results indicate that about half of providers conceptualize behavioral health as encompassing mental health, substance use, and coping with medical conditions. Providers also indicate that 10 to 30% of their daily time is spent on behavioral health. Further analyses will explore differences by study site, as well as longitudinal changes following the integration of services.

This study starts to address a gap in knowledge with regards to patient and providers preferences for addressing behavioral health concerns in primary care settings. Additional research is needed to examine individual and structural characteristics that may affect the success of efforts to integrate behavioral health services into primary care settings.

NEXT STEPS TO INTEGRATING BEHAVIORAL HEALTH: ACCEPTABILITY AND FEASIBILITY OF A HEALTH BEHAVIOR CHANGE PROGRAM IN PRIMARY CARE

Shannon M. Clark-Sienkiewicz, Ph.D.¹, Annmarie Cano, Ph.D.², Lori Lackman Zeman, PhD, ABPP³, Mark Lumley, n/a⁴, Neha P. Gothe, MA, PhD⁵

¹Arizona State University, Tempe, AZ; ²Wayne State University, Detroit, MI; ³Beaumont Health - Troy, Sterling Heights, MI; ⁴Wayne State University, Novi, MI; ⁵University of Illinois at Urbana Champaign, Urbana, IL

Integrating behavioral health into primary care settings offers an opportunity to prevent and treat chronic illness through health behavior change. Group interventions may efficiently engage multiple people in medical settings. However, the real-world experiences and logistical difficulties patients and providers experience integrating group interventions into primary care are largely unknown. The current study tested the feasibility and acceptability of a group-based, multicomponent, health behavior change program in a primary care setting. Recruitment for the program was rolling over the course of 8 months with sessions offered every week, but on alternating days/times. Of the patients who enrolled in the study (N=22), 13 attended at least one session (M=3.78 sessions) and completed 5- and 10-week follow-up surveys assessing their satisfaction with the group and barriers to attending. Overall, patients rated the program as satisfactory. They appreciated the rolling recruitment and frequency of sessions offered; however, they reported logistical barriers to attendance (i.e., transportation and time). Regarding intervention components, patients preferred concrete guided meditations, given that mindfulness was new to many patients, and they preferred walking, strength training, and yoga to other forms of physical activity. Health care providers who practiced in the clinic where the intervention took place were also surveyed at study completion; 21 of the 56 providers (37.5%) responded and shared their satisfaction, referral rate, and perceived integration of the program into their practice. Health care providers reported they were less satisfied with the referral process and integration of the program. Seven providers (33.3%) responded that they never referred a patient to the group, or at most, patients were referred 2-3 times per month. Providers offered several suggestions for improving integration: with notable caveats. The use of motivational techniques during recruitment as well as ways to increase provider participation are needed to improve feasibility. Results from this study will better inform health care providers and researchers who are working to address dissemination and implementation of health behavior change programs in primary care settings.

USING TECHNOLOGY TO IMPROVE IDENTIFICATION AND MANAGEMENT OF ADOLESCENT SUBSTANCE USE IN PEDIATRIC PRIMARY CARE

Juliet C. Yonek, PhD, MPH¹¹University of California San Francisco, San Francisco, CA

Background: Adolescent substance use is often under-identified and undetected, leading to increased risk for development of substance use disorders. Screening, Brief Intervention, and Referral to Treatment (SBIRT) is a widely recommended approach to early detection and intervention, but uptake has been slow in pediatric primary care (PPC) settings. Reasons may include provider discomfort discussing stigmatizing topics with youth, time constraints, and limited knowledge and self-efficacy in addressing adolescent substance use.

Objective: To understand how technologies including digital health (e.g., tablets, cell phones) and electronic medical records (EMR) can facilitate implementation of SBIRT in PPC settings serving vulnerable youth.

Methods: Qualitative semi-structured interviews were conducted with a convenience sample of 12 clinic staff members (pediatricians, nurse practitioners, and behavioral health clinicians) from a safety-net PPC clinic in San Francisco. Participants discussed challenges to screening and addressing adolescent substance use, and perspectives on how technology could help overcome these challenges. Coded interview transcripts were analyzed inductively to ascertain themes.

Results: The most frequently reported challenges were a lack of time to screen for substance use problems during adolescent well-care visits and limited knowledge regarding what to do for youth who screen positive. Technology-based solutions to overcoming these challenges included: (1) Using mobile phone or tablets to administer screeners and educational information about substance use to adolescents prior to their visit; (2) Integrating screening results into the EMR so that they are available at the point of care; (3) Having an EMR-based decision support tool that accurately determines the appropriate level of intervention based on screening results; and (4) Providing up-to-date information on local referral resources in the EMR or other Web-based systems.

Conclusions: Findings support the potential suitability and potential benefits of using technology to facilitate SBIRT implementation in PPCs serving vulnerable youth.

TREATMENT OF PATIENTS WITH CHRONIC PAIN AT RISK FOR SUICIDE: ROOM FOR INNOVATIVE APPROACHES

Alexandria Brunkow, B.S.¹, Phoebe Long, B.A.², Darren Winograd, M.A.², Margeaux Cannon, BA², Justin M. Kimber, M.A.³, Lisa McAndrew, Ph.D.²¹University at Albany, Albany, NY; ²University at Albany, SUNY, Albany, NY; ³University at Albany, SUNY, Williamsville, NY

Background: People with chronic pain (PWCP) are at least twice as likely to die by suicide than the general population (Racine, 2018). Existing suicide prevention efforts have focused on screening and referring these individuals to mental health to ensure that this high-risk population receive suicide prevention (SP) treatment. However, only about 5% of PWCPs follow-up on referrals (Edmond, Moore, Dorflinger et al., 2018). Further, PWCP who die by suicide are more likely to see a primary care provider (PCP; 75%) than mental health provider (MHP; 30%) in the past year (Edmond, Moore, Dorflinger et al., 2018, Luoma, Martin & Pearson, 2002), suggesting opportunities to deliver SP treatments in medical settings for this high-risk population. The goal of this study was to understand where and from whom PWCPs at risk for suicide want to receive SP treatments.

Methods: We conducted a national survey of 1090 PWCPs who were feeling hopeless. We asked about their suicidal thoughts and behaviors in their lifetime and in the past year. Additionally, we asked where and from whom they would be interested in receiving treatments for their hopelessness.

Results: PWCPs who were feeling hopeless (n=1090) were most interested in receiving treatment in a mental health setting (71%), a primary care setting (68%), and remotely by computer or app (67%). These individuals are interested in receiving treatment from a mental health (74%) or medical (69%) provider. Those at highest risk for suicide (i.e., previous attempt(s); n=92) were more likely to be interested in receiving treatment in a mental health setting (75%) than those at moderate risk (i.e., suicidal ideation but no prior attempts; n=284; 67%). Higher risk and moderate risk individuals were equally likely to be interested in receiving treatment in a primary care setting (68%, & 69%) or remotely via computer or app (67%, & 66%).

Conclusions: Overall, PWCPs at risk for suicide are most interested in receiving treatments in primary care. They are open to receiving this treatment from either mental health or medical providers. A small proportion of this population at highest risk for suicide are open to receiving treatment in mental health. These findings suggest opportunities to continue to screen and refer, but also to integrate SP treatment into medical settings to reduce suicide risk for this high-risk population. Future research should develop and test integrative approaches to addressing suicidality among PWCPs.

EXPLORING ILLNESS PERCEPTION AND ITS ASSOCIATION WITH DEPRESSION SYMPTOMS IN A DIVERSE SAMPLE OF PEOPLE WITH EPILEPSY

Sugandha Gupta, MA¹, Seth Margolis, Ph.D.², Arthur C. Grant, MD, PhD³, Jeffrey S. Gonzalez, Ph.D.⁴, Luba Nakhutina, Ph.D.³¹The Graduate Center, City University of New York, New York, NY; ²Alpert Medical School of Brown University, Providence, RI; ³SUNY Downstate Medical Center, Brooklyn, NY; ⁴Ferkau Graduate School of Psychology, Bronx, NY

Background: Epilepsy has been linked to negative mental health outcomes, including depression. The Common Sense Model of Self-Regulation purports that coping with chronic illness is shaped by illness perceptions, which in turn influences emotional outcomes. We explore illness perceptions and their association with depression symptoms in a diverse sample of people with epilepsy (PWE).

Methods: Sixty PWE (*M* Age = 41.8; 61.7% female; 78% Black/African or Caribbean American) completed self-report measures of epilepsy illness perceptions (IPQ-R) and depression (BDI-II, NDDIE). Average illness duration was 20.8 years (*SD* = 14.5).

Results: Approximately one-fourth of participants met criteria for moderate to severe depression on the BDI-II (25.0%; *M* = 11.8, *SD* = 9.5) and were above the cut-off on the NDDIE (26.7%; *M* = 11.7, *SD* = 3.5). When asked to rate potential causes of their illness, participants indicated stress/worry, family problems/worries, and one's own emotional state as the three most important causes, i.e., those with the highest means. T-tests revealed that participants who met criteria for moderate to severe depression on the BDI-II more strongly endorsed these causes, compared to participants who endorsed minimal to mild symptoms ($p < 0.01$). Similarly, participants who were above the NDDIE cut-off more strongly endorsed stress/worry ($p < 0.05$) and family problems/worries ($p < 0.01$) as causes, compared to those below the NDDIE cut-off. Negative emotional representations of epilepsy significantly correlated with beliefs that epilepsy is chronic ($r = 0.40$, $p < 0.01$) and has negative consequences ($r = 0.44$, $p < 0.01$), and that epilepsy is hard to comprehend ($r = 0.49$, $p < 0.01$). Multiple regression analyses indicated that these illness perceptions predicted higher levels of depression symptoms on the BDI-II ($p < 0.01$, $R^2 = 0.26$) and the NDDIE ($p < 0.01$, $R^2 = 0.25$).

Discussion: Self-reported depression symptoms were prevalent in this diverse sample of PWE and were significantly associated with negative illness perceptions. Behavioral interventions promoting a better understanding about epilepsy and that take patients' illness-related beliefs into account may help individuals challenge ineffective perceptions and improve psychological outcomes.

ACCREDITED SOCIAL HEALTH ACTIVIST (ASHA) SUPPORT AND ANTENATAL ANXIETY AMONG PREGNANT WOMEN IN MYSORE, INDIA

Nivedita L. Bhushan, PhD, MA¹, Karl Krupp, MSc, PhD², Poornima Jaykrishna, n/a³, Kavitha Ravi, n/a³, Anisa Khan, M.Sc⁴, Sandra Kiplagat, BA, MS⁵, Vijaya Srinivas, M B B S⁶, Purnima Madhivanan, MBBS, MPH, PhD⁷¹University of North Carolina at Chapel Hill, Chapel Hill, NC; ²University of Arizona, Tucson, AZ; ³Public Health Research Institute of India, Mysuru, Karnataka, India; ⁴Public Health Research Institute of India (PHRII), Mysore, Karnataka, India; ⁵Florida International University, Miami, FL; ⁶Public Health Research Institute of India, Mysore, Karnataka, India; ⁷Mel & Enid Zuckerman College of Public Health, The University of Arizona, Tucson, Tucson, AZ

Background: In India, antenatal depression and anxiety prevalence estimates range from 6% to 48% and a recent national mental health survey reported a treatment gap of 85% across the country for common mental health disorders. Social support has been found to be strongly associated with mental wellbeing. However, most studies in the country have examined the impact of support from partners and family members rather than peers, community members, or health care providers. Understanding the impact of non-family member support, particularly from Accredited Social Health Activists (ASHA), has the potential to inform the development of future interventions for antenatal depression and anxiety.

Methods: Cross-sectional data were analyzed from the Saving Children, Improving Lives project, a quasi-experimental study conducted among rural, pregnant women in the Mysore district of Karnataka, India from 2011-2014. Generalized linear models with a log link and binomial distribution were used to estimate adjusted risk ratios (aRRs) and corresponding 95% confidence intervals for the relationship between ASHA social support and antenatal anxiety. Antenatal anxiety was measured using a subscale of the Edinburgh Postnatal Depression Scale.

Results: The sample consisted of 480 pregnant women who were primarily in their second trimester (52%) and experiencing their first pregnancy (65%). Reported antenatal anxiety prevalence was 27% (95% CI: 0.23, 0.31). Participants who were more frequently visited by ASHAs at home (aRR: 0.90; 95% CI: 0.76, 0.98) and participants who were more frequently accompanied by ASHAs to their antenatal care visits (aRR: 0.86, 95% CI: 0.78, 0.95) were less likely to report antenatal anxiety. Effect modification results suggest that ASHA home visits were protective for the most vulnerable women (primigravida and those experiencing husband or husband's family perpetrated intimate partner violence) and ASHA accompaniment to antenatal care visits were equally protective for all women.

Conclusions: ASHAs are valued for their contribution towards maternal health education and linking women of reproductive age and their children to health-care services. Our findings additionally suggest the important role ASHAs play in providing psychosocial support to pregnant women, particularly those who are most vulnerable to experiencing antenatal anxiety.

EXAMINING DIFFERENCES IN ANXIETY SENSITIVITY AND EMOTION REGULATION AMONG ADULTS WITH ASTHMA AND COPD

Patric J. Leukel, B.A.¹, Ann-Marie K. Rosland, M.D., M.S.², Aaron A. Lee, Ph.D.³¹University of Mississippi, University, MS; ²VA Pittsburgh Healthcare System, Pittsburgh, PA; ³University of Mississippi, Oxford, MS

Introduction: Anxiety sensitivity and difficulties with emotion regulation are common risk factors for anxiety and depression which have been linked with worse respiratory symptom control among patients with COPD and asthma. Patients with asthma and patients with COPD often experience similar respiratory symptoms (e.g., dyspnea, acute symptom exacerbations) and have similar treatment regimens. However, to date no studies have compared anxiety sensitivity and difficulties with emotion regulation among adults with asthma, COPD, or comorbid asthma and COPD.

Methods: Respondents were recruited from a large national online panel of adults with chronic respiratory conditions. The sample included adults with current asthma ($n = 230$), COPD ($n = 321$), or comorbid asthma and COPD ($n = 217$). Anxiety sensitivity was measured using the Anxiety Sensitivity Index-3. Emotion regulation was measured using the 36-item Difficulties with Emotion Regulation Scale. Differences in ASI-3 and DERS scores were tested using one-way Welch ANOVAs. Games-Howell post-hoc tests were used to compare mean ASI-3 and DERS scores among respiratory conditions.

Results: There were significant differences in ASI-3 ($F[2, 716] = 17.28, p < .001$) and DERS ($F[2, 716] = 12.37, p < .001$) scores among respiratory conditions. Compared to adults with COPD only, ASI-3 scores were significantly higher among adults with asthma only ($M_{diff} = 9.36, SE = 2.38, p < .001$) and with comorbid asthma and COPD ($M_{diff} = 9.98, SE = 2.42, p < .001$). ASI-3 scores did not differ significantly between adults with asthma vs. comorbid asthma and COPD ($M_{diff} = -0.63, SE = 2.82, p = .973$). Similarly, compared to adults with COPD only, DERS scores were significantly higher among adults with asthma only ($M_{diff} = 5.94, SE = 1.47, p < .001$) and among adults with comorbid asthma and COPD ($M_{diff} = -8.53, SE = 1.60, p < .001$). ASI-3 scores did not differ significantly between adults with asthma vs. adult with comorbid asthma and COPD ($M_{diff} = -2.59, SE = 1.80, p = .332$).

Conclusion: Asthma is uniquely associated with heightened anxiety sensitivity and greater difficulties with emotion regulation compared to COPD. Comorbid COPD is not associated with greater anxiety sensitivity or difficulties with emotion regulation among adults with asthma. Adults with asthma have higher levels of these common, treatable, psychological vulnerabilities which may place them at greater risk for mental health conditions and associated negative respiratory disease related outcomes.

USE OF THE PHQ-9 TO PREDICT RECOVERY OF FUNCTIONAL INDEPENDENCE DURING ACUTE REHABILITATION, POST-SCI

Ted Allaire, M.S.¹, Andria Norman, PhD², Summar Reslan, PhD, ABPP-CN²¹Eastern Michigan University, Ypsilanti, MI; ²Rehabilitation Institute of Michigan, Detroit, MI

Background: Depression disproportionately impacts individuals living with spinal cord injury (SCI) and has been associated with many adverse functional outcomes. Accordingly, it is crucial that healthcare providers possess the necessary tools to accurately identify depression in this population. Findings from previous studies have failed to fully support the unidimensionality of a commonly used depression measure (i.e., Patient Health Questionnaire-9; PHQ-9) within the SCI population. Rather, factor analytic findings have more robustly supported the existence of oblique somatic and non-somatic factors, with scores on the non-somatic factor, but not the somatic factor, during acute rehabilitation predicting long-term psychosocial outcomes after SCI.

Method: In this study, we examined the association between PHQ-9 derived variables (i.e., total score, somatic factor, non-somatic factor) and rehabilitation gains (i.e., Functional Independence Measure [FIM] Motor Gain) made by a sample of 32 adults living with SCI during acute rehabilitation. Salient covariates were controlled for across statistical analyses (i.e., length of stay, race, sex, age, neurologic level of injury).

Results: Results of linear regression indicated that the initial model containing PHQ-9 total score did not yield a significant effect on FIM Motor Gain ($F = 1.97, p > .05$). In a subsequent model, we examined the effects of the PHQ-9 somatic and non-somatic subfactors on FIM Motor Gain. Results of this latter analysis indicated that the overall model significantly predicted FIM Motor Gain ($F = 2.67, p < .05$), with scores on the PHQ-9 somatic factor ($\beta = -0.35, p < .05$), but not the non-somatic factor ($\beta = .25, p > .05$), significantly contributing to overall model fit.

Conclusion: Greater endorsement of somatic distress, but not non-somatic distress, on the PHQ-9 by individuals living with SCI during participation in acute rehabilitation was associated with diminished recovery of functional independence by time of discharge. The disparate impact of these two factors on FIM Motor Gain lends additional support for the two-factor conceptualization of distress captured by the PHQ-9 within this clinical population.

CLINICIAN REPORTED CHALLENGES IN THE CREATION OF ACTION PLANS

Elena Agapie, MS¹, Cynthia Thompson, NA², Jessica G. Carr, n/a¹, Dawn Ferguson, MA¹, Gary Hsieh, PhD¹, Sean A. Munson, PhD¹, Patricia Arian, PhD³

¹University of Washington, Seattle, WA; ²University of Washington, Renton, WA; ³University of Washington Medical Center, Seattle, WA

Background: A critical component of evidence-based behavioral treatment for mental health problems is the creation of action plans that clients implement between sessions. Implementation of these plans is closely tied to clinical outcomes. However, adherence to action plans is poor. Researchers suspect it can be due to the clinician's skill in collaboratively creating action plans and in using complex treatments.

Purpose: Human Centered Design (HCD) has the potential to address challenges clinicians face through identifying usability problems of an intervention. In this preliminary study, we employed HCD to understand clinician challenges in delivering the treatment steps for creating action plans.

Methods: We interviewed 7 certified clinicians about their experiences delivering Problem Solving Therapy and Engage treatments to clients with late life depression. Both treatments include identifying a problem and goal, and creating an action plan to meet that goal. The clinicians participated in a randomized trial evaluating their use of these treatments. To inform the interview, we drew insights from 8 therapy recordings of 5 clinicians in the trial. We identified emerging themes through qualitative coding.

Results: Clinician challenges vary with different clients. Identifying and scoping problems and goals was difficult when clients experienced complex or poorly specified problems, for which a solution was hard to anticipate, such as relationship issues. When generating alternative solutions and assessing their feasibility, clinicians were heavily involved in assisting some clients. This made clinicians tired, and concerned about patronizing clients when offering their own ideas. Generating the week's activity plan was seen as easier, because the client was able to lead this step. Clinicians were hopeful about client progress and anticipated reviewing the activity plan in the next session, but were frustrated when clients repeatedly did not complete plans. Additional challenges include the cognitive burden of delivering structured treatments, such as boredom, and poor interactions with clients.

Conclusion: This study is the first step in potentially redesigning behavioral treatment to better support implementation of action plans. Results suggest that therapists need more support in addressing complex or seemingly unsolvable problems. Additionally, the structured approach to action plans may need to be loosened to reduce implementation burdens.

EMOTION REGULATION AND ANXIETY SENSITIVITY AMONG ADULTS WITH ASTHMA AND COPD: LINKS WITH SYMPTOMS AND ACUTE MEDICAL SERVICE USE

Aaron A. Lee, Ph.D.¹, Patric J. Leukel, B.A.², Ann-Marie K. Rosland, M.D., M.S.³

¹University of Mississippi, Oxford, MS; ²University of Mississippi, University, MS; ³VA Pittsburgh Healthcare System, Pittsburgh, PA

Introduction: Individuals with chronic respiratory conditions (i.e., asthma and COPD) have higher risk of mental health conditions such as depression and anxiety. Patients with depression and anxiety often experience heightened anxiety sensitivity and greater difficulties with emotion regulation. Among adults with chronic respiratory disease, anxiety sensitivity and emotion dysregulation have been linked with poorer respiratory symptom control. The purpose of this study was to examine the associations of emotion regulation and anxiety sensitivity with frequency of acute symptom exacerbations and use of acute medical care (e.g., ER visits and hospitalizations) among adults with chronic respiratory conditions.

Methods: We surveyed 710 adults with asthma and/or COPD recruited from a large national web-based panel of adults with chronic respiratory disease. Predictors included: emotion regulation, measured using the Difficulties in Emotion Regulation Scale (DERS); and anxiety sensitivity, measured using the Anxiety Sensitivity Index-3 (ASI-3). Dependent variables included self-reported frequency of acute respiratory exacerbations, emergency department (ER) visits, and hospitalizations during the prior 12-months. Logistic regression models were used to test the relationship of DERS and ASI-3 scores with each outcome, controlling for respondents' current depression and anxiety symptoms (measured using the Patient Health Questionnaire 4), current smoking status, and primary care use in the past 12-months.

Results: Each ten-point increase in DERS score (range: 36 to 180) was associated with an approximately 20% increase in likelihood of an acute symptom exacerbation (AOR=1.19, 95%CI: [1.12, 1.28], $p < .001$), ER visit (AOR=1.20, 95%CI: [1.11, 1.29], $p < .001$), or hospitalization (AOR=1.18, 95%CI: [1.08, 1.28], $p < .001$) during the prior 12-months. Each ten-point increase in ASI-3 score (range: 0 to 72) was associated with a 62% increase in the odds of an acute symptom exacerbation (AOR=1.62, 95%CI: [1.43, 1.83], $p < .001$) 47% increase in the odds of an ER visit (AOR=1.47, 95%CI: [1.31, 1.66], $p < .001$) and 41% increase in odds of hospitalization (AOR=1.41, 95%CI: [1.23, 1.60], $p < .001$) during the prior 12-months.

Conclusion: Greater difficulties with emotion regulation and higher anxiety sensitivity are strongly associated with the greater odds of acute symptom exacerbation and costly acute medical care use among adults with chronic respiratory disease, above and beyond variance attributable of depression, anxiety, smoking, and primary care use. Existing evidenced based interventions for reducing anxiety sensitivity and improving emotion regulation may help to improve symptom control and reduce use of acute medical service among patients with chronic respiratory conditions.

GENERATIVITY AS MEDIATOR IN THE RELATIONSHIP BETWEEN GAY COMMUNITY ATTACHMENT AND REDUCED DEPRESSION AMONG GAY AND BISEXUAL MEN

Brian Salfas, MA¹, Nicola F. Tavella, MPH, CPH², Ali Talan, DrPH³, H. Jonathon Rendina, PhD, MPH⁴

¹PRIDE Research Consortium, New York, NY; ²PRIDE Health Research Consortium, Hunter College, CUNY, New York, NY; ³Hunter College, New York, NY; ⁴Hunter College and The Graduate Center, CUNY, New York, NY

Generativity as mediator in the relationship between gay community attachment and reduced depression among gay and bisexual men

Brian Salfas, MA Nicola Tavella, MPH, CPH Ali Talan, DrPH

Jonathon Rendina, PhD, MPH

Background: Generativity has been shown to positively impact mental health and overall well-being. This construct is often examined in the context of parenting and embeddedness in conventional family structures. Some qualitative research on sexual and gender minority populations has instead linked generativity to other forms of social and community attachment. We examined quantitative data on generativity, gay community attachment, and depression to test for significant associations among these factors in a population of sexual minority men (SMM).

Methods: We administered measures of demographics, the Loyola Generativity Scale (LGS), the Gay Community Attachment (GCA) Scale and the CES-D, a measure of depressive symptoms to 10,663 SMM. We ran a series of Pearson correlations to determine which demographic factors were significantly associated with the LGS and CES-D. We then ran a series of regressions adjusting for these potential confounding factors, to test a mediation model wherein generativity mediates the relationship between gay community attachment and scores on the CES-D.

Results: Age, race/ethnicity, employment, income, educational attainment, and sexual identity were correlated with CES-D scores. Being older, non-white, employed, having higher income, a college degree, and raising a child were associated with higher generativity. Higher GCA ($\beta = -0.22, p < 0.00$) and generativity ($\beta = -0.46, p < 0.00$) were independently associated with lower depression. GCA also predicted generativity ($\beta = 0.30, p < 0.00$). In a combined model, both GCA ($\beta = -0.09, p < 0.00$) and generativity ($\beta = -0.44, p < 0.00$) predicted lower depression; however the effect of GCA decreased from the single-factor model. The model supports partial mediation of the relationship between GCA and depression through generativity.

Conclusions: Gay community attachment and generativity are important factors affecting mental health in GBM. Evidence of generativity mediating the relationship between GCA and depression supports the hypothesis that attachment to the community may be central to attainment of generativity among GBM and the connection between GCA and generativity partially accounts for the positive effect of GCA on mental health in this population.

PRENATAL INTERVENTION REDUCES POSTPARTUM DEPRESSIVE SYMPTOMS FOR WOMEN WITH OVERWEIGHT BUT NOT OBESITY

Krista S. Leonard, MS¹, Abigail M. Pauley, M.S.², Emily E. Hohman, PhD³, Katherine M. McNitt, BS, RD⁴, Penghong Guo, Ph.D.⁴, Daniel E. Rivera, PhD⁵, Jennifer S. Savage, PhD⁶, Danielle Symons Downs, PhD⁷

¹The Pennsylvania State University, State College, PA; ²The Pennsylvania State University, Bellefonte, PA; ³Pennsylvania State University, University Park, PA; ⁴Arizona State University, Mesa, AZ; ⁵Arizona State University, Tempe, AZ; ⁶Penn State University, University Park, PA; ⁷The Pennsylvania State University, University Park, PA

Pre-pregnancy overweight/obesity and high gestational weight gain (GWG) are recognized risk factors for postpartum depression. However, research examining the impact of prenatal behavioral interventions on postpartum depression is scant. The purpose of this exploratory secondary analysis was to examine whether women differed in postpartum depressive symptoms by GWG intervention assignment (intervention vs. control) and weight status (overweight vs. obese). Pregnant women with overweight or obesity (N=31) participated in Healthy Mom Zone, an individually-tailored, adaptive intervention to regulate GWG. Women were randomized to an intervention (n=15) or control group (n=16) from ~9-36 weeks gestation. Women completed the Edinburgh Postnatal Depression Scale at the 6-week postpartum study visit to assess postpartum depressive symptoms (PDS). Available data during postpartum reduced the sample to N=21 (n=10 intervention, overweight=7, obese=3; n=11 control, overweight=5, obese=6). A 2 X 2 factorial design was used to examine main effects and interactions in 6-week PDS by intervention assignment and weight status groups. Monthly prenatal depressive symptoms were included as a covariate; significance was set at $p < 0.10$ as appropriate for exploratory analyses. The main effect for intervention assignment [intervention (Mean=6.1) vs. control (Mean=7.1)] on 6-week PDS was not significant ($p > 0.10$). There was a main effect for weight status such that women with overweight (Mean=4.78) had lower 6-week PDS compared to women with obesity (Mean=8.37; $p=0.09$). There was an interaction ($p=0.09$) between intervention assignment and weight status such that for women with overweight, intervention women (Mean=2.6) had lower 6-week PDS compared to control women (Mean=6.9). There was no significant effect for women with obesity. These exploratory findings suggest that an individually-tailored, adaptive intervention aiming to regulate GWG may protect against PDS among women with overweight. Future research is needed to replicate these findings and further understand why similar effects were not observed among women with obesity.

RELIGIOSITY EFFECTS ON SUICIDE RATES AND ATTITUDES TOWARD SUICIDE: A LARGE-SCALE INTERNATIONAL ANALYSIS

Jesus Saiz, n/a¹, Elena Ayllón-Alonso, n/a², Iván Sánchez-Iglesias, n/a², Deepak Chopra, n/a³, Paul J. Mills, n/a⁴¹Complutense University of Madrid, Madrid, Catalonia, Spain; ²Complutense University of Madrid, Madrid, Cantabria, Spain; ³UC San Diego, La Jolla, CA; ⁴UCSD, La Jolla, CA

Each year, more than 800000 people of all ages commit suicide, accounting for 56% of all world violent deaths. This is a global tragedy, higher in figures than the mortality caused by war and homicides. The majority of all suicides (75%) occur in low and middle-income countries (WHO, 2014). Suicide is a complex phenomenon, the explanation of which brings together social and cultural factors as well as individual and environmental elements. In a cohort of 74399 participants from 47 countries, this study examined suicide rates and attitudes towards suicide considering five indicators for religiosity (Value of God, Value of Religion, Religious self-description, Prayer frequency, and Frequency of attendance to religious services), subjective well-being (Happiness, Health perception and Freedom of choice and control over own life) and sociodemographic and environmental variables (Rural population, Unemployment, Human Development Index (HDI), Education, Social class, Incomes and Hours of sunshine per year). We extracted data from the Wave-6 (2011-2014) data set of the World Values Survey (Inglehart et al., 2014); the Global Health Observatory data repository (2018); United Nations Development program (2018); the World Meteorological Organization (2018); the World Bank (2018); and the International Labour Organization (2018) data bank. Suicide rate correlated with: Value of God ($r=-.67, p<.001$), Value of Religion ($r=-.58, p<.001$), Prayer frequency ($r=-.47, p<.01$), HDI ($r=.450, p<.01$), Sunshine ($r=-.43, p<.01$), Religious self-description ($r=-.43, p<.01$), Attitude towards suicide ($r=.41, p<.01$), and Attendance to religious services ($r=-.359, p<.05$). Attitude towards suicide correlated with: Value of God ($r=-.65, p<.001$), Value of Religion ($r=-.57, p<.001$), HDI ($r=.51, p<.001$), Religious self-description ($r=-.45, p<.01$), Prayer frequency ($r=-.42, p<.01$), Suicide rate ($r=.41, p<.01$), Rural population ($r=-.38, p<.01$), and Attendance to religious services ($r=-.28, p<.05$). In multiple regression analyses, Value of God ($b=-.59, p<.001$) was the only predictor for suicide rates, explaining 35.1% of the variance. For attitude towards suicide, Value of God ($b=-.68, p<.001$) as well as Subjective state of health ($b=-.31, p<.01$) were found as predictors, explaining together 47% of the variance. The findings open again the paradox of high rates of suicide in modern societies and emphasize the importance of considering religiosity in prevention and attention programs to suicidal behavior.

PERCEPTIONS OF TELEHEALTH USE AMONG UNDERSERVED ADOLESCENTS AND YOUNG ADULTS

Natalia Gatdula, MPH¹, Mayra Rascon, MPH², Mara Bird, PhD³, Lea Ann Gomez, n/a¹, Cathleen M. Deckers, EdD, RN, MSN, CHSE⁴, Christine Costa, DNP, APRN, PMHNP-BC⁴¹California State University Long Beach, Long Beach, CA; ²Center for Latino Community Health / California State University Long Beach, Long Beach, CA; ³Center for Latino Community Health, Evaluation and Leadership Training, Long Beach, CA; ⁴California State University Long Beach School of Nursing, Long Beach, CA

Background: One in five youth ages 12 – 18 lives with significant mental health challenges. Half of the adult diagnosable mental health conditions are symptomatic by age 14 and 75% by age 24. However, less than 20% receive mental health services. Technology provides the opportunity to increase access to healthcare by using interactive videoconferencing that allows clinicians and patients to connect in different locations.

Objective: To assess the perceptions of underserved minority young people (ages 13-24) regarding the use of telehealth as an avenue to address mental health needs.

Methods: Six focus groups were conducted as part of a needs assessment to inform the development of a pilot mental health telehealth training program to addresses the clinical training needs of psychiatric mental health nurse practitioner (PMHNP) students; and identify the mental health needs of underserved minorities in Los Angeles County (LAC) and Orange County (OC). Eligibility criteria included: 1) Hispanic/Latino or other underserved minority population as identified by partner organizations; 2) 13-25 years old; and, 3) resident of LAC or OC. Additionally, participants were required to have enough English communication to understand and complete the survey and focus group activities. A total of 59 people between the ages of 13 and 23 from LAC or OC participated in the focus groups.

Results: A little less than half of the participants (47%) reported being confident/very confident in using a telephone or computer for two-way health services, 25% reported not confident/not confident at all, and 27% reported being neutral. Overall, there were mixed feelings among all participants about their level of comfort in using technology to talk to someone for mental health related issues. While some participants acknowledged the value in using technology, many mentioned issues of distrust, privacy, and security in addition to the loss of empathy and personal connection with the mental health practitioner.

Conclusion: Although the use of technology was hypothesized as a viable tool to reach underserved minority youth and young adults to address the shortage of mental health services, challenges lie ahead to address the issues of privacy and trust with the use of technology. In addition, a hybrid approach (in-person/telehealth) may be necessary to allow participants and mental health practitioners to build trust and address the perceptions of loss of personal relationship and empathy.

PROMOTING ATTACHMENT SECURITY AND BIOPSYCHOSOCIAL OUTCOMES THROUGH EMOTIONALLY-FOCUSED MENTORING

Atina Manvelian, M.A.¹, David Sbarra, Ph.D.¹¹University of Arizona, Tucson, AZ

Our early life experiences give rise to attachment orientations—ways of thinking, feeling, and relating to others (Bowlby, 1969). Ranking high on attachment insecurity is characterized by emotional instability and maladaptive behavioral patterns. Attachment insecurity is a transdiagnostic marker of risk that leaves people vulnerable to experience adverse mental, social, and physical health outcomes (Ein-Dor, Viglin, & Doron, 2016). Attachment theory is an established framework of human development that identifies *emotion dysregulation* as the root cause of this distress. Approximately 30-40% of people are insecurely attached; however, many psychological interventions don't focus on enhancing attachment security. Based on the NIH Stage Model of Intervention Development, the current proposal fills this gap by using feasibility and acceptability data to pilot test a novel intervention program, called Emotionally-Focused Mentoring (EFM). EFM targets emotion regulation capacities in insecurely attached adolescents (N = 60) using a creative attachment-based approach. This innovative program provides mentees (i.e., insecurely attached first-year college students) with a warm and trained mentor (i.e., a securely attached upperclassmen trained in basic principles of Emotionally-Focused Therapy) for five weeks. Mentorship begins during the stressful transition to college with the aim of enhancing adaptive emotion regulation strategies and attachment security during this high-risk developmental window of time. To track change over time, mentees will provide self-report data on three occasions over the course of 5 weeks to assess changes in emotion regulation skills, mental health outcomes (i.e., loneliness, depression, anxiety) and health behaviors (i.e., alcohol consumption, cigarette smoking). Multilevel modeling will be used to assess how changes in emotion regulation, mental health outcomes, and health behaviors are associated with one another. By pilot testing Emotionally Focused Mentoring, I hope to create a low-cost and sustainable way to improve emotion regulatory capacities, attachment security, and biopsychosocial outcomes for at-risk adolescents.

HOW DO SUBJECTIVE HEALTH LITERACY MEASURES WORK IN YOUNG ADULTS? SPECIFYING “ONLINE” OR “PAPER-BASED” FORMS IMPACTS RESULTS

Mary C. Politi, PhD¹, Courtney M. Goodwin, MPH¹, Kimberly Kaphingst, ScD², Angela Fagerlin, PhD², Xuechen Wang, MS², Lindsay N. Fuzzell, PhD³, Sydney Philpott-Streiff, MPH⁴¹Washington University in St Louis, School of Medicine, St Louis, MO;²University of Utah, Salt Lake City, UT; ³Moffitt Cancer Center, Tampa, FL;⁴Centene Corporation, St Louis, MO

Purpose: Health literacy refers to the ability to access, understand and use information to make health decisions. Measuring health literacy is challenging; there is no gold standard measure. The Single Item Literacy Screener (SILS) and Subjective Literacy Screener (SLS) ask people to self-report ability to understand health information and complete medical forms. However, they were developed over 10 years ago, before common use of electronic health records and forms. This study explored how well the SILS and SLS perform among young adults and whether specifying “online” or “paper-based” wording impacted measure performance.

Methods: Participants were recruited from an online survey company. Eligible individuals (18-35, English speaking, US residents) were randomized to: 1) original SILS and SLS, 2) modified SILS and SLS, adding “paper-based” to describe health information and forms; or 3) modified SILS and SLS, adding “online” to describe health information and forms. We examined how these measures related to validated measures including: e-Health Literacy scale (eHEALS), subjective numeracy scale (SNS), objective numeracy scale (ONS), and knowledge after reading a short passage.

Results: 1342 participants were recruited; 848 correctly responded to attention checks and were retained in analyses. Mean age was 26; 66.4% were white, 14.3% were black, 19.3% were another or mixed race. Most (61.7%) had at least 1 health condition. The original SILS performed reasonably, relating to knowledge (p=0.003), eHEALS (p=0.04) and ONS (p< 0.001) but not SNS (p=0.44). When adding “paper-based,” though, SILS did not relate to either knowledge (p=0.25) or SNS (p=0.35). When adding “online,” SILS better differentiated between adequate and limited health literacy, relating to knowledge (p< 0.001), eHEALS (p< 0.001), ONS (p=0.002) and SNS (p=0.03). The original SLS performed well and related to knowledge (p< 0.001), eHEALS (p< 0.001), ONS (p< 0.001), and SNS (p< 0.001). When adding “paper-based,” though, the SLS related to knowledge (p=0.03) and eHEALS (p< 0.001) but not ONS (p=0.13) or SNS (p=0.33). When adding “online,” the SLS related to knowledge (p< 0.001), eHEALS (p< 0.001) SNS (p=0.03) but not ONS (p=0.06).

Conclusion: Young adults might interpret subjective health literacy measures differently when prompted to think about electronic or paper-based information and forms. Researchers should consider clearer instructions or modified wording when using these measures in this population

PERCEIVED MENTAL FATIGUE: MEASUREMENT VALIDATION IN TWO STUDIES OF ADULTS WITH CHRONIC COGNITIVE COMPLAINTS

Imani Canton, B.S.¹, Adam P. Taggart, MSc², Madhura Phansikar, MA³, Daniel Palac, PhD⁴, Jason D. Cohen, Ph.D⁵, Sean P. Mullen, PhD²¹University of Illinois at Urbana-Champaign, Champaign, IL; ²University of Illinois at Urbana-Champaign, Urbana, IL; ³University of Illinois, Urbana-Champaign, Urbana, IL; ⁴Exponent, Urbana, IL; ⁵Washington University in St. Louis, St. Louis, MO

Mental fatigue may be defined by cognitive “slowness” or actual impaired performance as a function of cognitive load (degree of personal and/or situational stress). Mullen and colleagues (2019) developed a novel, unidimensional *Perceived Mental Fatigue Questionnaire* (PMFQ; 7-item Likert scale, e.g., “My thinking requires effort,” 1 = Not at all to 5 = Very true) which has shown strong psychometric attributes. The purpose of this study was to validate the PMFQ in two samples experiencing fatigue and cognitive complaints, namely breast cancer survivors (BCS) and individuals with post-concussion symptoms (PCS). Each sample participated in a feasibility study of aerobic exercise training paired with either mindful relaxation (study 1: BCS) or cognitive stimulation (study 2: PCS) relative to unimodal interventions. A battery of established psychosocial questionnaires assessing fatigue, mindfulness, anxiety, depression, memory, and the PMFQ was administered at multiple time points during the 1-week BCS study and 1-month PCS study. Data herein were collapsed across groups for all analyses. In study 1, the total PMFQ score was significantly ($p < .05$) positively correlated with the *Brief Fatigue Inventory* at baseline ($r = .58$) and the *Piper Fatigue Scale* at session 1 through 3 at pre-intervention (r 's = .63, .77, .73) and post-intervention (r 's = .50, .74, .59), as well the *Activation Deactivation Adjective Checklist* subscales at pre-intervention (range of correlations: *tired* = -.57 to -.44; *energy* = -.55 to -.29) and post-session (r range: *tired* = -.55 to -.42; *energy* = -.50 to -.24). PMFQ was also positively associated with *Frequency of Forgetfulness* total score ($r = .44$) at baseline. One-week test-retest reliability = .58. In study 2, PMFQ negatively correlated with the *Mindfulness Attention and Awareness Scale* at baseline ($r = -.57$) and 1-month follow-up ($r = -.46$). Baseline and follow-up PMFQ correlations with *Hospitalized Anxiety and Depression Scale* were also consistent for depression ($r = .53, .56$), but less so for anxiety ($r = .28, .53$). Two of three subscales of the *Multifactorial Memory Scale* were negatively correlated with PMFQ at baseline and follow-up i.e., contentment with memory ($r = -.39, -.48$) and memory ability ($r = -.31, -.52$). Memory strategy-use was unrelated with PMFQ across time. One-month test-retest reliability = .61. These results offer further evidence of the PMFQ's construct, convergent, and discriminant validity, and its psychometric consistency over time. Furthermore, the PMFQ may prove valuable to healthcare providers in the development and monitoring of individualized treatment plans for patients with mental fatigue and cognitive complaints.

REACTIVITY TO ECOLOGICAL MOMENTARY ASSESSMENT OF AFFECTIVE STATES AMONG CURRENTLY AND FORMERLY HOMELESS YOUNG ADULTS

Sara Semborski, LCSW¹, Eldin Dzubur, PhD¹, Harmony R. Rhoades, PhD², Benjamin F. Henwood, PhD, MSW¹, Danielle R. Madden, PhD¹¹University of Southern California, Los Angeles, CA; ²University of Southern California, SAN DIEGO, CA

Background: Ecological momentary assessment (EMA) is thought to yield both feasibility and acceptability among marginalized groups, such as homeless and formerly homeless young adults, as a method to capture and understand context and correlates of health behaviors. However, the day-to-day life experience of those who have experienced homelessness is unique, and it is not known how the introduction of an intensive longitudinal data collection protocol may affect this population, particularly regarding self-report as self-reflectivity of a behavior may in fact alter the behavior. This study examined reactivity to EMA through use of pre- and post-tests for symptomatology of anxiety and depression among currently and formerly homeless young adults, as well as individual EMA compliance rates (i.e., how many prompts were completed).

Methods: Data come from a study of HIV risk among young adults who have experienced homelessness. 236 young adults ages 18-27 were recruited from drop-in centers or housing programs located in Los Angeles between 2017 and 2019. EMA prompting occurred over a 7-day period and asked about risk behaviors and affective states every two hours. Multilevel modeling was used to assess the impact of EMA compliance on depression (PHQ-9) and anxiety (GAD-7) scores from baseline to follow-up. All models controlled for age, gender, sexual orientation, race, and housing status.

Results: Both anxiety and depression scores decreased from baseline to follow-up ($\beta = -1.77$, $p < 0.001$; $\beta = -1.10$, $p = 0.03$, respectively). However, no significant effects for EMA compliance were detected for either anxiety or depression thus, the decrease in symptomatology was not associated with compliance.

Discussion: While it is true that results indicate improvement in anxiety and depression symptomatology from baseline to follow-up, no significant emotional reactivity was detected in terms of anxiety and depression symptoms based on EMA compliance. Decreases in symptomatology scores do indicate a change between baseline and follow-up, therefore future studies should consider the potential reactivity to EMA beyond compliance, as there may be elements associated with EMA other than the number of prompts completed. In this case, symptomatology decreased during the study, but it is unclear why participation resulted in improvement. Results have implications for the continued development of EMA use with marginalized groups.

HEALTH PERCEPTIONS OF CANNABIS: A QUALITATIVE ANALYSIS

Mitchell C. Myers, n/a¹, Renee E. Magnan, PhD², Benjamin O. Ladd, Ph.D.²¹Washington State University, Washougal, WA; ²Washington State University Vancouver, Vancouver, WA

Information on the health effects of cannabis use is often based on anecdotal experience rather than empirical investigation. This could be a double-edged sword: on one hand, misinformation about the health claims of cannabis may abound, while on the other hand, anecdotal evidence can lend a broader understanding of a complex phenomenon. To get a more comprehensive understanding of perceptions about the health benefits and risks of cannabis use, Magnan and colleagues (2019) surveyed 408 participants (72% lifetime users) from a psychology subject pool consisting of 21 true or false questions of potential positive and negative health effects. The most commonly endorsed positive consequences included pain relief (95.3%) and stress management (84.8%) while the most commonly endorsed negative consequences included impaired decision-making (88%) and impaired driving (87.5%). The current investigation is a qualitative extension of this work based on open-ended responses to a prompt to add additional health effects of cannabis use not included in the pre-established list of outcomes. Of the 1765 items provided by participants, the majority ($f = 880$, 50%) were categorized as similar to items already on the inventory. The remaining 885 responses were reviewed and categorized into items reflecting novel content. A number of additional content areas emerged related to perceived health effects of cannabis, suggesting that beliefs about effects of cannabis varies across individuals. The most frequent additional effect reported was that cannabis can be used to increase appetite/cause weight gain ($f = 122$); other commonly reported effects included makes you feel relaxed ($f = 97$) and makes you feel paranoid ($f = 43$). Endorsement of any of these perceived consequences did not significantly differ based on lifetime use (χ^2 s ranged from .21-.57, $ps = .48-.65$) or past-month use (χ^2 s = .31-1.06, $ps = .30-.58$). Further examination of these data as well as replication among different samples for a better understanding of health perceptions of cannabis use will inform future lines of empirical inquiry and health messaging efforts to inform about the positive and negative effects of cannabis.

MEASURING OUTCOMES IN AN OUTPATIENT PEDIATRIC BEHAVIORAL PAIN MANAGEMENT SERVICE

Anne M. Lynch-Jordan, PhD¹, Shalonda Slater, PhD¹, Naomi Joffe, PhD¹¹Cincinnati Children's Hospital Medical Center, Cincinnati, OH

Background: Psychological interventions are an integral part of pain management for children and adults. Creating systems that routinely collect patient-reported outcomes (PROs) and develop metrics of treatment success is important at a patient and systems level. The outpatient behavioral pain management program in a large children's hospital integrated evidence-based PRO measures (functional disability, pain coping efficacy and pain intensity) for youth receiving treatment for chronic pain. Using composite responder outcomes, the program established classification criteria for "positive treatment response" to assess the program's intervention success. This was tracked across psychology providers to capture the success of the system overall.

Purpose: The purpose of this study was to report program effectiveness over the last 10 years regarding 1) reliably administering key PRO measures and 2) maintaining an average of 75% or better of patients achieving a "positive treatment response" at the end of treatment across providers.

Methods: PRO measures were completed electronically by patients presenting for psychological treatment of chronic pain and saved to flowsheets in the electronic medical record (EMR). Data were extracted and aggregated at a summary level regarding 1) number of visits in which one of the key PRO measures (Functional Disability Inventory--FDI) was administered and 2) number of patients meeting the criteria for "positive treatment response" following psychological treatment for chronic pain (25% reduction in FDI, 30% decrease in average pain intensity, and/or a score of ≥ 10 on pain coping efficacy).

Results: Data were collected for 121 consecutive months from September 2009 to August 2019 with 18,583 patient encounters for psychology assessment/treatment. The FDI was collected at 91.3% of these visits. Of the 118 months of collected post-treatment data, 1486 patients completed a prescribed course of treatment (which was documented by the provider in the EMR), with 82.2% having a "positive treatment response". Across psychology providers, the program showed a positive treatment response of 75% or better for 84 of 118 months (71.2%).

Conclusion: Reliable systems for collecting PROs can be established, are sustainable, and allow for tracking individual treatment success as well as system-wide progress. They can be valuable for both understanding and improving service delivery for pediatric patients with chronic pain.

INCONSISTENCIES WHEN MEASURING MOTIVATION TO COMPLY: EXPLORING A CONSTRUCT THAT HAS BEEN MIS-DEFINED AND OPERATIONALIZED

Paul Branscum, PhD, RD¹¹Miami University, Oxford, OH

The Theory of Planned Behavior (TPB) is widely used in research and practice. Although there is a great deal of evidence that shows valid and reliable methods of evaluating the psychosocial constructs within the TPB, motivation to comply (mtc) has remained problematic, in that it has not typically contributed to the understanding of how subjective norms are determined. In Fishbein and Ajzen's 1975 book, "Belief, attitude, intention, and behavior" they noted mtc was the "least developed" construct in the model, and while their suggestions for operationalizing and measuring mtc were only tentative, they also conceded that a problem was researchers could interpret the meaning of the construct in different ways. In their 2010 follow up book "Predicting and Changing Behavior", they noted this again and called for new approaches or alternative measures to the construct. The nature of mtc stems from its interaction with normative beliefs for understanding how one forms their subjective norm pertaining to a behavior. Normative beliefs are beliefs one has about important referents (individuals or groups) who want/do not want an individual to perform a behavior, and motivation to comply centers on the motivation one has to act in the way those important referents desire. To understand the extent to how mtc has been operationalized and measured in the literature, we first conducted a systematic review utilizing multiple data bases (i.e. medline, ERIC) with the key words 'Motivation to Comply'. Overall, we found 93 manuscripts, of which 27 measured mtc. Of these studies, only 55% measured mtc as 'one's motivation to comply with a referent's wishes' (i.e. In general, I want to do what my parents think I should do), while other studies measured mtc as some other psychosocial construct such as attitudes (My husband's approval for taking oral contraceptives would be important for me). In a follow-up study, we used a valid and reliable survey to evaluate the TPB constructs for sleep behaviors, and developed alternative measures to mtc such as attitudes to comply, and normative pressure to comply. When interacting with measures of normative beliefs across 3 referents (parents, friends, and professors), attitudes to comply appeared to slightly outperform measures of mtc when measuring their association with generalized subjective norms. Results from this study point to the need for standardization in the definition and measurement of the mtc construct.

INTERVENTION MEDIATORS OF OUTCOMES FOLLOWING LATENT PERIODS: AN APPLICATION TO WEIGHT LOSS

Kara L. Gavin, PhD¹, Yongman Kim, PhD², Corrine I. Voils, PhD¹, Felix Elwert, PhD¹¹University of Wisconsin, Madison, WI; ²University of Missouri, Columbia, MO

Background: Behavioral interventions have shown benefit for helping people maintain weight loss. Mediation analyses could shed light on mechanisms and inform intervention refinement. Many statistical approaches have been applied to mediation analyses, sometimes without consideration of the assumptions required by mediation theorems. In the context of a successful weight loss maintenance intervention, we discuss which assumptions—beyond the usual assumptions (VanderWeele 2015)—are necessary to justify causal mediation analysis with latent periods between measurement time points, i.e. when a continuous-time process is measured in discrete steps.

Methods: Secondary analysis was conducted using data from a randomized controlled trial (N=222) comparing a weight loss maintenance intervention to usual care in Veterans. Weight and self-reported satisfaction with outcomes, social support, and recovery and maintenance self-efficacy were self-reported at randomization and at 14, 26, 42, and 56 weeks. The primary outcome of weight change at 56 weeks showed a small benefit of the intervention (estimated treatment difference 1.6 kg, 95% CI: 0.1, 3.1). Statistical models examined causal mediation of the intervention effect by psychosocial constructs (satisfaction with outcomes, social support, and self-efficacy) under alternative assumptions about (a) latent periods between measurements and (b) complete mediation by observed measures of caloric intake and energy expenditure.

Results: Our statistical analyses indicated that causal-mediation effects of psychosocial constructs can be estimated despite latent periods when measured dietary intake and energy expenditure fully mediate the intervention effect. Statistical models found no statistically significant evidence for mediation by psychosocial constructs measured at week 26 (estimated indirect effect by all mediators kg, 95% CI: -1.878, 0.570).

Conclusions: Findings illustrated that when complete mediators are measured in at least one period, latent periods in a continuous time process can be handled in causal mediation analysis. However, in this case of psychosocial mediators of a weight loss maintenance intervention trial, no statistically significant mediation effect was detected. This work highlights the precarious nature of mediation in behavioral medicine and the strong assumptions required to accept statistical results. Future work should incorporate features to warrant the assumptions needed for causal mediation into the study design.

WORKING CONDITIONS ARE KEY TO “WHOLE HEALTH”: AN ANALYSIS OF FOCUS GROUP DISCUSSIONS WITH VETERANS AFFAIRS EMPLOYEES

Eve M. Nagler, ScD, MPH¹¹Dana–Farber Cancer Institute, Boston, MA

Background: The Veteran's Health Administration (VA) “whole health” strategy focuses on what matters most to the whole person for both veterans and employees. A growing body of literature indicates both employee health and the quality of health care they provide are affected by working conditions, including physical, organizational and psychosocial factors at work. More information is needed about working conditions at the VA to design improvements that will benefit VA employees and ultimately, more effectively fulfill the VA mission of improving the health and well-being of America's veterans. To identify working conditions that mattered most to VA staff, we conducted focus groups with employees to better understand the positive and negative aspects of their work environment.

Methods: Two investigators from Harvard Center for Work, Health & Wellbeing and one VA investigator conducted 9 focus groups (1 leadership, 2 supervisor and 6 front-line employees) to discuss working conditions in one VA healthcare facility. We transcribed audio recordings of these focus groups and performed content analysis of the transcripts using NVivo software. Emergent themes were confirmed through independent analysis by two investigators. Exemplar quotes were selected for each emergent theme.

Results: Fifty-five staff members participated in 9 focus groups of 5-9 participants per group. Employees generally agreed that serving veterans and the mission were the most positive aspects of their job. Many felt the VA did a good job at providing educational benefits and career development opportunities. Some commented on the sense of community created by co-workers, and appreciated having flexible schedules, supportive supervisors, and leadership support in the form of policies and reporting mechanisms that listen to employee concerns. Conversely, some participants raised concerns about stressful working conditions, such as mandated overtime and being assigned collateral duties. Across all groups, employees highlighted staffing shortages and hiring challenges as a cause of negative employee morale. Employees also discussed health hazards related to the physical environment, not taking breaks, and staff safety concerns by dealing with agitated patients.

Conclusions: Actions to enhance and improve working conditions at the VA may pay dividends in achieving the whole health strategy as well as improve the health of the veterans they serve.

PERCEIVED AND ACTUAL SOCIAL SUPPORT ON FACEBOOK: A MIXED METHODS STUDY OF MILITARY VETERANS

Alan R. Teo, M.D., M.S.¹¹VA Portland Health Care System, Portland, OR

Background: The perceived availability of social support in time of need is known to be strongly associated with physical and mental health. However, less is known about the influence of actual social support or social support that is exchanged through social media platforms. The aims of this study were to: a) characterize military veterans' perceived and actual social support received on Facebook, and b)

determine whether exchange of social support on Facebook is associated with lower risk of psychiatric disorders or suicidality.

Methods: We used an explanatory sequential mixed methods design (quantitative analysis of survey, followed by qualitative analysis of Facebook posts). United States military veterans who served after September 2001 and responded to an ad on Facebook completed an anonymous online survey (n=587), a subgroup of whom provided access to their user activity on Facebook (n=19). Social support was quantitatively measured using a scale assessing perceived social support on Facebook, and qualitatively assessed using content analysis of Facebook activity. Risk for psychiatric problems was assessed with reliable and valid screening tools for major depression (PHQ-2), PTSD (PC-PTSD), alcohol use disorder (AUDIT-C), and suicidality (DSI-SS).

Results: Self-reported use of Facebook or other social media platforms for social support was low. Perceived social support on Facebook was associated with reduced risk of screening positive for major depression (AOR=.969, SE=.016, p=.045) and suicidality (AOR=.957, SE=.017, p=.012), but not associated with symptoms of PTSD or alcohol use disorder. For each one-point increase on a 12-point subscale of received social support on Facebook, there was an estimated 9% decreased odds of current suicidal ideation (p=.023). Content analysis revealed that actual social support on Facebook consisted of both received and given social support. Imbalance in participants' actual social support (“low received, high given” or “low given, high received,”) was associated with screening positive for any psychiatric disorder (p=0.03)

Conclusions: Lack of perceived social support and imbalance in the exchange of actual social support on Facebook may both be indicators of risk of active psychiatric symptoms among post-9/11 era military veterans in the United States.

ADVERSE CHILDHOOD EXPERIENCES IN VETERANS SEEKING WEIGHT MANAGEMENT SERVICES

Alison G. Marsh, B.A.¹, Jennifer L. Snow, MSc², Robin M. Masheb, PhD³¹VA Connecticut Healthcare System, Wakefield, MA; ²Dept. of Veterans Affairs, West Haven, CT; ³Yale School of Medicine/VA CT Healthcare System, North Haven, CT

Adverse childhood experiences (ACEs) drastically increase risk for a wide range of mental illness and health problems, including outcomes related to weight management. The present study aimed to examine the prevalence of ACEs and to explore potential relationships between these experiences and measures of weight and health in a sample of weight loss seeking Veterans. Participants were 224 Veterans (mean age 59.9 (0.86), mean Body Mass Index (BMI) 35.27 (0.41), 85.71% male, 63.59% white) receiving care at VA Connecticut Healthcare System (VACHS) who attended an orientation session of VA's behavioral weight management program, MOVE!. Participants completed a packet including demographics, a measure of Adverse Childhood Experiences, the Weight Control Strategies Scale (WCSS), the Godin Leisure-Time Exercise Questionnaire (Godin), the European Quality of Life Screener (EuroQoL-5D) and a weight-specific measure of quality of life. 87.9% Veterans completed the ACE Survey, and 68.5% of completers endorsed any ACE. The average number of reported ACEs was 2.2 (SD: 0.18), with 44.7% reporting more than one type. The most frequently reported ACE was parental separation (37.2%), followed by household substance abuse (33.3%), emotional abuse (27.6%), physical abuse (24.5%), emotional neglect (23.0%), and household mental illness (19.7%). Women were more likely to report any ACE and reported significantly more ACEs compared to males, (81.5% v. 66.5% and 4.0 v. 1.9, respectively). There was no difference in BMI, highest adult BMI, race, education, or disability status between those who reported any ACEs and those who did not. In regression models accounting for differences by gender, ACE was predictive of physical activity ($r^2 = 0.04$, $p = 0.014$) and several quality of life measures, including QoL measured dimensionally, ($r^2 = 0.05$, $p = 0.004$), QoL measured with a visual analog scale (0-100) ($r^2 = 0.04$, $p = 0.012$), and weight specific QoL ($r^2 = 0.13$, $p < 0.001$). BMI and weight control strategies were not associated with ACEs. More than two-thirds of Veterans seeking weight management services through VACHS reported at least one ACE with close to half of those reporting more than one type of ACE. Female Veterans were more likely to report ACEs than male Veterans. In the context of treating Veterans in weight management services, ACEs may have more important implications for exercise interventions and quality of life outcomes than for dietary interventions and weight outcomes.

NATIONAL INSTITUTES OF HEALTH FUNDED ADHERENCE RELATED MULTILEVEL RESEARCH

Natasha R. Burse, MS, DrPH(c)¹, Karen C. Lee, MD MPH², David Clark, DrPH³, Erica S. Breslau, Ph.D., M.P.H.⁴, Janet S. de Moor, PhD, MPH⁵¹Penn State College of Medicine, Hershey, PA; ²National Institutes of Health/ Eunice Kennedy Shriver National Institute of Child Health and Human Development, Bethesda, MD; ³National Institutes of Health/National Center for Complementary & Integrative Health (NCCIH), Bethesda, MD; ⁴National Institutes of Health/National Cancer Institute, Rockville, MD; ⁵National Cancer Institute, Rockville, MD

Background: Poor adherence to treatment and prevention regimens is prevalent across chronic conditions and patient populations. There is limited evidence and understanding of how to improve adherence to many treatment and prevention behaviors. Descriptive and intervention research may address adherence determinants at one or more levels of social ecologic influence (patient, caregiver/family, provider and/or healthcare system, and community levels).

Purpose: This project examines the National Institutes of Health (NIH) grant portfolio of adherence related multilevel research to identify scientific gaps and inform future funding opportunities.

Methods: The Query, View, Report (QVR) system was used to identify grants funded by the NIH from 10/1/2016-5/30/2019. Eligible grants were identified using adherence related search terms from the NIH Research, Condition, and Disease Categorization thesaurus. The analysis consisted of screening titles, abstracts, and specific aims to confirm eligibility, abstracting key variables from each grant, synthesizing research findings and describing scientific gaps. Information about the grant mechanism and funding were abstracted directly from QVR. Manual data abstraction captured additional information about the adherence behaviors under study, design and methodology.

Results: Of the 196 grants identified, 18 grants were excluded because the focus was not on human behavior or interaction with the healthcare system. Eligible grants were funded by Institutes across NIH, including the NIMH (17%), NIDA (12%), NHLBI (12%), and NCI (9%). Grants focused most frequently on HIV (40%), heart diseases (10%), and cancer (8%). Most grants examined adherence to prescribed medication (84%), followed by health behavior recommendations (3%). The most common measures of adherence were self-report (34%), Medication Event Monitoring Systems (MEMS) (17%), and pharmacy records or the electronic health record (13% respectively). Most grants included interventions (84%), followed by observational studies (11%). Almost half of the studies included multilevel assessments of adherence determinants (47%), whereas less than half were multilevel interventions (21%).

Conclusions/Implications: There is a need for more multilevel interventions to understand how to improve adherence behaviors, identify the determinants of adherence at each level, and the most effective strategies to improve adherence behaviors. There are multiple methods and new innovative approaches (e.g. drug levels in hair samples) to assess adherence. The findings from this project will inform new research priorities and funding opportunities at NIH to support research to improve adherence behaviors.

CHANGING PERCEPTIONS AND EFFICACY OF GENERIC MEDICINES BY INCREASING TRUST: AN INTERVENTION STUDY

Maria Kleinstäuber, n/a¹, Sarah Colgan, n/a², Keith Petrie, n/a²¹University of Otago, Dunedin, Otago, New Zealand; ²University of Auckland, Auckland, Auckland, New Zealand

Objectives: Generic medicines have been associated with less efficacy and more side effects compared to innovator products. The central aim of the current study was to examine if perceptions, pain relief and side effects of generic medicines can be changed with two different types of educational video interventions.

Methods: Participants with frequent tension headaches in an average fortnight were randomly assigned to watching a video explaining either the process of approval and release of generic medicines (release process-video: n=34), similarities between innovator and generic drugs (similarity-video: n=35) or types and epidemiology of headaches (control-video: n=34). After watching the video, participants took in a randomised order an innovator and a generic pain medication to treat their next consecutive headaches. Perceptions of medicines, pain severity, and side effects were measured.

Results: Mixed-effect ANOVAs showed that only after watching the release-process video participants perceived generics as more safe and of higher quality. The preference of taking a generic compared to an innovator medication increased significantly only in the similarity-video group. Trust in generics increased in both experimental groups compared to the control group. Independent of the type of video, the innovator product induced a higher pain relief than the generic medication. The educational intervention had no effect on the medication's side effects.

Discussion: Results of this study show that educational video interventions can change individuals' perceptions of and trust in generic drugs. The videos used in this study however could not counteract the unspecific effect of the label "generic" on pain relief.

KNOWLEDGE AND AWARENESS OF FOOD-ENERGY-WATER NEXUS: A DRIVER OF FOOD WASTE BEHAVIORAL CHANGE

Adenike Opejin, n/a¹, Maricarmen Vizcaino, PhD², Andrew Berardy, PhD², Christopher Wharton, PhD²¹Arizona State University, TEMPE, AZ; ²Arizona State University, Phoenix, AZ

Introduction: The Food-Energy-Water (FEW) Nexus represents a scientific and technical sustainability-related construct meant to conceptualize the interrelations of systems critical to food production. Research related to FEW has gained in popularity across multiple disciplines; even so, little research has to date explored awareness of and knowledge about the nexus among the public. This research may be vital to pursue given the environmental pressures these systems face which, in part, are related to individuals' behavioral and consumer choices. Although studies have often demonstrated that awareness alone is unlikely to influence individuals' food- and other health- or sustainability-related behaviors, emphasizing the environmental consequences of target behaviors could trigger biospheric values that motivate consideration of pro-environmental or health behaviors. The purpose of the present study was to examine associations between knowledge and awareness of the FEW nexus and food waste-related behaviors among Arizona residents participating in a household food waste reduction study.

Methods: Sixty-five adults, self-identified as the primary food purchasers in their home, were included in this cross-sectional analysis. Participants completed a survey that asked about current food waste behavior, knowledge about the FEW nexus in Arizona, awareness about the FEW nexus generally, and theoretically based behavior change constructs (i.e., perceived behavioral control, intentions, norms, and attitudes). Spearman correlation analyses were used to explore associations between variables under study. Significance was set at $\alpha < 0.05$.

Results: Awareness and knowledge were not associated with food waste behavior. Awareness, but not knowledge, was significantly associated with perceived behavioral control ($r = .31, p = .02$), intentions ($r = .29, p = .03$), norms ($r = .36, p < .01$), and attitudes ($r = .35, p < .01$).

Discussion: Our results suggest that educating people about the interrelated nature of food, energy, and water systems could be a useful tool in supporting factors associated with food waste behavior. Future research should include larger sample sizes as well as educational interventions to reduce food waste in the home with an emphasis on the FEW nexus.

EARLY QUALITATIVE FINDINGS TO INFORM A NOVEL MULTICOMPONENT BEHAVIORAL INTERVENTION IN MIDLIFE ADULTS: BE SMART

Jennie L. Turner, MS, CHES¹, Dana Burnejko, n/a², Talia Brookstein-Burke, n/a³, Greg Dominick, PhD¹¹University of Delaware, Newark, DE; ²University of Delaware, 19711, DE; ³University of Delaware, Oak Park, IL

Background: Physical inactivity and poor sleep exacerbates cardiovascular disease (CVD) risk, with nearly one-third of preventable CVD deaths occurring before age 65. As midlife adults (50-64 years) are at an increased risk for CVD, it is imperative that prevention strategies target key behaviors known to facilitate the development and early onset of CVD. Here we describe early results of an ongoing qualitative study among midlife adults to inform a comprehensive, cloud-based, physical activity (PA) and sleep intervention called **Bio-behavioral Systems to Motivate And Reinforce Heart Health (Be SMART)**.

Methods: Study-eligible participants attended a semi-structured, moderator-led focus group or interview to elicit feedback on their value of PA and sleep as health behaviors, use/familiarity of mobile and wearable technology and proposed intervention procedures. Data were transcribed verbatim and thematically analyzed. Four project staff independently and iteratively coded transcripts. Participants also completed a self-report survey onsite. Data collection for this study is ongoing.

Results: Participants (N=8) were primarily female (62.5%) with at least some college/two year degree (n=7) and most were in the contemplation stage of PA change (n=6). Overall, participants were obese and hypertensive (mean BMI=33.1; resting BP=148/92) and most (n=7) reported using a wearable device to track their PA and/or sleep in the past 6 months. To date, 38 themes have been identified. Themes commonly reported included, PA/sleep challenges, activity tracker use, reaction to Fitbit wear criteria, and Be SMART feedback process. Responses to the proposed Be SMART study procedures were overall positive, with one participant stating, "I think it's great to be in on something that can actually help focus and tailor something to be helpful to many people."

Conclusion: Although preliminary, early study findings suggest that midlife adults experience various challenges to PA and sleep, are comfortable using mobile/wearable technology, and are receptive to the proposed Be SMART intervention procedures. Additional qualitative data will enable a more robust analysis of midlife adult perceptions and results will provide greater insight into this high-risk population allowing for a more personalized approach to behavioral medicine.

EFFECTS OF TAI CHI EASY ON BODY FAT PERCENTAGE, SLEEP QUALITY, AND EMOTIONAL EATING IN MIDLIFE AND OLDER WOMEN

Dara James, MS¹, Ann Sebre, EdD, CMT-P¹, Bronwynne C. Evans, PhD, RN¹, Linda Larkey, PhD¹, Kimberley Goldsmith, PhD¹Arizona State University, Phoenix, AZ

Background/Purpose: Approximately 30% of the female adult population in the United States is obese (BMI > 30 kg/m²), which is a key risk factor for cardiometabolic diseases, neurocognitive disorders, diabetes, certain types of cancer, and deleterious psychosocial outcomes (i.e., anxiety, depression). Preliminary evidence demonstrates that Meditative Movement (MM) practices (combining breath focus, body movement, and a meditative state) such as Tai Chi and Qigong may improve body composition and associated behavioral factors (i.e., sleep quality, diet quality). The purpose of this single group pilot study was to evaluate the change in body fat percentage, sleep quality, and emotional eating in a group of midlife/older women after an 8-week standardized Tai Chi Easy (TCE) intervention.

Methods: Women age 45-75 were screened for ability to engage in low-intensity gentle movement. The TCE intervention (combining Tai Chi and Qigong) was delivered for 8-weeks (30 minutes per week) with certified practice leaders; on average participants attended 5 classes. Participants were encouraged to practice most days per week at home with take-home practice materials. Pre- and post-intervention data collection included self-report psychometric measures (i.e., sleep quality, eating behaviors), body weight and body composition.

Results: The majority of participants (N = 51) (M age = 53.7) were white (80.4%) and had attended four years of college or more (70.6%). Body fat percentage (Tanita scale), sleep quality (Pittsburg Sleep Quality Index: PSQI), and emotional eating (Three Factor Eating Questionnaire-Revised 18: TFEQ-R18) were assessed and tested for change from pre- to post-intervention using paired sample t-tests. Change in body fat percentage did not reach statistical significance; however, change in PSQI (sleep quality) was significant ($p = .04$) and change in one factor of the TFEQ-R18, emotional eating, approached significance ($p = .07$).

Conclusion: Participation in an 8-week low-intensity exercise program, TCE, showed significant differences in sleep quality and a trend towards significance in emotional eating (less reporting of the maladaptive behavior in response to negative emotions). Further evaluation with larger sample sizes are needed for examining factors associated with body composition changes in response to MM practices such as Tai Chi and Qigong.

LIFESTYLE MODIFICATION AND WEIGHT LOSS TO REDUCE BREATHLESSNESS IN COPD

Kara Dupuy-McCauley, M.D.¹, Maria Benzo, M.D.², Matthew M. Clark, Prof. LP PhD³, Roberto P. Benzo, M.D.¹¹Mayo Clinic, Rochester, MN; ²Mayo Clinic, rochester, MN; ³Department of Psychiatry & Psychology / Obesity, Bariatric Surgery & Eating Disord. Program, Mayo Clinic, Rochester, MN

Chronic Obstructive Pulmonary Disease (COPD), one of the most prevalent respiratory conditions worldwide, subjects with coexisting obesity have worse breathlessness, worse quality of life, more frequent exacerbations and more healthcare utilization than their non-obese counterparts. In obese COPD patients with optimal medical management, weight loss can be an effective method to reduce breathlessness; however there is a knowledge gap regarding feasible interventions. Our study aimed to define the feasibility and acceptability of a weight loss intervention to decrease breathlessness through lifestyle modification in patients with significant obesity and COPD.

Methods: The study was IRB-approved (IRB: 18-001832) and registered with clinicaltrials.gov (NCT: 03836547). Patients were recruited from our pulmonary outpatient practice. Inclusion criteria were age over 17 years, BMI > 34, dyspnea of Medical Research Council class II or greater, and diagnosis of chronic lung disease.

Our 8-week intervention included the Weight Watchers online program, a Garmin® wristband and a Bluetooth smart scale for weigh-ins at home and weekly telephonic motivational interviewing based health coaching for goal setting. Outcomes included weight, BMI, percent body fat, and skeletal muscle mass with the InBody770, the Mindful Eating Questionnaire (MEQ), and disease-specific quality of life measured by the Chronic Respiratory Questionnaire (CRQ).

Results: We recruited 14 Caucasian subjects, mostly female (86%) and married (80%). Mean age was 67. Mean weight was 263.4lbs with a mean BMI of 43.2. Average weight loss of 3.5% of their baseline weight (SD 2.2%, $p=0.0001$), and a mean BMI decrease of 1.5kg/m² (SD 0.8 kg/m², $p<0.0001$), percent of body fat went down an average of 1.8% (SD 1.9%, $p=0.0072$). The MEQ summary increased 0.2 (SD 0.3, $p=0.0208$). All CRQ domains improved: Dyspnea 0.7 (SD 1.1, $p=0.0460$), Fatigue 0.9 (SD 0.8, $p=0.0015$), Emotions 0.6 (SD 0.9, $p=0.0283$), Mastery 0.9 (SD 1.0, $p=0.0053$).

Discussion: This intervention is feasible and likely effective to produce weight loss and increase the quality of life measures including dyspnea, in obese people with chronic lung disease. Increasing self-awareness through monitoring food, checking daily steps, and measuring weight, could explain the success of our intervention and also the weekly health coaching to set goals and maintain motivation for change. The improvement in CRQ indicates the clinical relevance of the intervention with regard to increasing quality of life. While the small sample size and homogenous participant demographics are a limitation of the study, we reached statistical and clinical significance in the relevant outcomes measured.

This intervention may represent a scientific and clinical opportunity to improve breathlessness in highly symptomatic and obese patients with COPD.

REWARD PROCESSING, EXECUTIVE FUNCTION, AND PHYSICAL ACTIVITY IN A PILOT TEXT-DELIVERED INTERVENTION FOR OBES ADOLESCENTS

Caroline Cummings, MA¹, Amy Hughes Lansing, Ph.D.¹, Catherine Stanger, Ph.D.²¹University of Nevada, Reno, Reno, NV; ²Dartmouth College, Lebanon, NH

Objective: This study examines changes in reward processing and executive function across a pilot text-delivered intervention to increase physical activity in overweight and obese adolescents. Behavioral economic incentives for physical activity in the context of daily and weekly goal setting and monitoring may improve reward processing and executive function by training self-monitoring and goal-setting skills, modifying reward expectation contingencies and via physiological pathways linking increased physical activity and enhanced cognitive function. It was hypothesized that adolescents who evidenced greater increases in physical activity would experience greater improvements in reward processing and executive function.

Methods: Adolescents (N=27) aged 13 to 18, with a body mass index at or above 90th percentile participated in a 12-week text-delivered behavioral economic incentive intervention to increase physical activity. At baseline and 12-week follow-up, teens completed measures of self-control, physical activity and appetitive cognitive processing, and a behavioral measure of delay discounting. Parents reported on their teen's executive function problems. Teens also wore a Fitbit watch to track daily vigorous and moderate physical activity.

Results: Improvements in adolescent self-control were associated with increased adolescent and accelerometer reported vigorous physical activity ($r=.56$, $p=.003$; $r=.38$, $p=.062$, respectively). Further, improvements in delay discounting performance were associated with adolescent-reported increases in walking ($r=.64$, $p=.007$) and overall physical activity ($r=.54$, $p=.03$). Also, improved cognitive processing in the presence of food was associated with increased adolescent-reported vigorous physical activity ($r=.54$, $p=.005$), and overall physical activity ($r=.41$, $p=.036$). Last, parent-reported improvements in adolescent task initiation were also associated with increased overall accelerometer reported physical activity ($r=.49$, $p=.014$) and decreased body weight ($r=.41$, $p=.04$).

Conclusion: Interventions using text-delivered incentives to encourage increased self-monitoring and goal-setting for additively increased and sustained physical activity might improve reward processing and executive function in overweight and obese adolescents. Further research in larger randomized controlled studies is needed to elucidate the direction of the causal relationship between these biobehavioral and cognitive processes in adolescence.

THE ASSOCIATION BETWEEN PHYSICAL ACTIVITY AND CALORIE INTAKE DURING BEHAVIORAL WEIGHT LOSS TREATMENT

Stephanie G. Kerrigan, PhD¹, Rebecca J. Crochiere, B.A.², Stephanie Manasse, Ph.D.², Meghan L. Butryn, PhD², Evan M. Forman, PhD²¹Yale School of Medicine, New Haven, CT; ²Drexel University, Philadelphia, PA

Standard behavioral treatments for weight loss prescribe a combination of reduced energy intake (EI) and increased energy expenditure through physical activity (PA). Relationships between PA and EI are complex and poorly understood, often yielding equivocal findings (e.g., whether PA increases or decreases hunger). Critically, the free-living within-day association between PA and EI is rarely evaluated and the effect of this association on weight loss has not been explored. The present study utilized data from a 12-week behavioral weight loss program where the PA goal was 30 minutes/day and the calorie goal was individualized based on standard calorie-deficit prescriptions. Participants wore a commercially-available wrist-worn activity monitor and self-monitored EI daily. The difference from an individual's calorie goal was calculated for each day (i.e., positive numbers indicated that EI exceeded the calorie goal). A linear mixed-model was conducted predicting difference from calorie goal. Fixed effects for between- and within-subject (BS and WS) PA, individual calorie goal, and day of the intervention and random effects for intercept and WS PA were included. The random effects estimates for slope (i.e., the association between difference from calorie goal and WS PA) were generated. These values were then correlated with weight loss at post-treatment. Trend-level WS ($p = .09$) effects indicated that, on average, lower PA than an individual's own average was associated with greater overeating on the same day. However, there was considerable variability in the association between PA and calorie difference, including some individuals for whom the effect was opposite. This individual effect was correlated with weight loss ($r = -.28, p < .05$), indicating that individuals with more negative associations between PA and eating (i.e., increased PA is associated with decreased calorie intake) lost more weight during treatment. Results suggest that PA has a small average association with concurrent EI. Interestingly, the individual-level associations for each person were related to weight loss. This may mean that individuals who experience greater appetitive control with PA may have better success with standard recommendations for weight control. Alternatively, it may be that maintaining lower EI increases the likelihood of PA engagement on that day. Future research should investigate the temporal effects of PA and EI during behavioral weight loss.

EXAMINING GENDER DIFFERENCES IN YOUNG MEN AND WOMEN'S GOALS FOR A TECHNOLOGY-DRIVEN WEIGHT LOSS INTERVENTION

Jean M. Reading, MA¹, Melissa M. Crane, PhD², Jessica G. LaRose, Ph.D.³¹Virginia Commonwealth University School of Medicine, Richmond, VA;²Rush University Medical Center, CHICAGO, IL; ³VCU School of Medicine, Richmond, VA

Background: Emerging adults (EA) are at high risk for weight gain and obesity yet are underrepresented in behavioral weight loss (BWL) programs and fare worse than their older counterparts when they join these programs. Further, even within BWL programs adapted specifically for this population, young men are particularly challenging to recruit, representing less than 20% of samples in recent trials. One hypothesis for the poor recruitment of men is that men's goals for a weight loss program are not described in recruitment messages for these studies. Understanding whether men and women's personal goals for participating in a weight loss program could be a key way to tailor recruitment messaging. As such, the objective of this study is to compare young men and women's personal goals for a BWL program.

Methods: Participants (N=382; 21.9 + 1.2 years; 83% female; BMI=33.5 + 4.9 kg/m²) were recruited for a technology-driven weight loss intervention adapted for this age group. At baseline, participants ranked their top 3 personal goals from a list of 15 areas in which they wanted to see change during the program. The most commonly reported areas (n=8) were coded as yes or no if the goal was ranked as one of their top 3. Chi-square tests were conducted to compare men and women on the most commonly reported goals for the program; using Bonferroni correction to adjust for multiple comparisons ($p < .006$).

Results: Overall, the most commonly reported areas for wanting to change in the program were: weight (62.7%), physical fitness (43.7%), body fat percentage (25.7%), body shape (25.1%), energy level (24.1%), clothing size (19.6%), confidence (18.8%), and self-esteem (18.0%). Weight was the most commonly ranked as a top goal (43.5%), followed by physical fitness (11.3%) and body fat percentage (8.9%). No significant differences were found between men and women for personal goals.

Conclusion: Emerging adults have a desire to lose weight and body fat, as well as improve physical fitness when it comes to personal goals for a weight loss program. While there were no gender differences in goals for a weight loss program, this could be due to enrollment of a treatment seeking sample. Coupled with differential enrollment of young men, it is possible the results may not be representative of non-treatment seeking young men. More research is needed to understand potential gender differences in goals for a weight loss program to improve recruitment messaging targeting young men.

THE RELATION OF INTRINSIC MOTIVATION TO TREATMENT RESPONSE ACROSS BEHAVIORAL WEIGHT LOSS INTERVENTIONS OF VARYING INTENSITY

Michael Berry, B.Sc.¹, Evan M. Forman, PhD¹¹Drexel University, Philadelphia, PA

Outcomes of behavioral weight loss programs are highly variable, with approximately 25% of participants failing to achieve clinically significant weight loss even after receiving frequent and intensive treatment. While outcomes generally improve with greater intervention intensity (i.e., more direct clinical support and accountability), many participants receive minimal benefit from higher levels of care. However, the individual differences determining participant need for high vs. low-intensity treatment are not well-studied. One important potential factor is intrinsic motivation, which is negatively associated with weight loss treatment adherence and outcome. Although such evidence might suggest that motivation is more important for success in interventions providing low accountability (i.e., low-intensity), little research to date has examined whether intrinsic motivation differentially predicts weight loss success between interventions of varying intensity.

The present study examined the relationship between baseline intrinsic motivation (TSRQ) and weight loss outcome across two completed behavioral weight loss intervention studies, one high in intensity and the other low. Both interventions targeted weight loss among participants with overweight or obesity. The high-intensity intervention ($N=186$) examined the effects of two group-based behavioral weight loss treatments, and the low-intensity intervention ($N=105$) examined the effects of a 75-minute psychoeducational workshop designed to reduce intake of foods with added sugars plus at-home computerized neurocognitive trainings. For both trials, imputed weight losses were coded as a binary variable such that a weight loss of 2% at Week 9 was considered a successful outcome. Results indicated that as expected, more participants reached 2% weight loss in the high-intensity (83.7%) relative to the low-intensity program (53.3%), whereas intrinsic motivation did not predict treatment response when examined across trials ($\chi^2 = 1.0$, $OR = 0.9$, $p = 0.32$). However, intervention type interacted with baseline intrinsic motivation to predict successful outcome ($\chi^2 = 5.6$, $OR = 2.7$, $p = 0.02$) such that the effect of intrinsic motivation on treatment response was greater in the high-intensity relative to the low-intensity condition. Specifically, in the high-intensity intervention, motivation scores were 5.1% greater in treatment responders relative to non-responders. These findings, while surprising, could relate to the fact that higher-intensity interventions require greater effort, and therefore motivation, to comply with intervention requirements and thereby benefit from treatment. The results further suggest that individuals low in intrinsic motivation may be better-suited to low-intensity interventions, where they may receive similar benefits to high-intensity interventions at a reduced cost.

WEIGHT STATUS VARIES IN GIRLS BORN IN AND OUTSIDE THE US

Daniella Marchetti, MS¹, Mary Kate Barnes, M.S.², Patrice G. Saab, PhD³¹University of Miami, miami, FL; ²University of Miami, West Palm Beach, FL;³University of Miami, Coral Gables, FL

Introduction: Although many immigrants come from low socioeconomic status backgrounds, there is widespread evidence that most immigrants have better than expected health outcomes compared to their US born peers. Their “protection”, however, often dissipates as they acculturate and adopt maladaptive lifestyle practices related to eating habits, physical activity, and screen time. The purpose of this study was to investigate whether rates of overweight/obesity varied as a function of birthplace (inside or outside the US) in a group of ethnically diverse preadolescent and early adolescent girls.

Methods: The participants were 375 middle school aged girls ($M = 11.8$ years). Approximately 92% had an ethnic minority

Background: Body mass index was calculated after measuring height and weight. Approximately 57% of the girls were slightly underweight or normal weight, while 43% were overweight or obese. Birthplace was determined by their parents' response to the item “Country where your child was born.” Response options were coded as US born or non-US born. Approximately 76% of the girls were US born. Girls were asked about sports team participation, days in the last week they were physically active for at least 60 minutes, and time they spent on a computer outside of school. Parents were also asked about their child's eating habits.

Results: Chi-square tests of independence showed that there were differences in weight status based on birthplace ($\chi^2(1, N = 354) = 7.71$, $p = .006$). Among the US born girls, 52.8% were underweight or normal weight, while 47.2% were overweight or obese. Among the non-US born girls, 69.7% were underweight or normal weight, while 30.3% were overweight or obese. As such, rates of overweight/obesity were 1.5 times higher among girls born in the US compared to the girls born outside the US. Although non-US born girls participated in significantly more organized physical activities than girls born in the US ($p=.01$), there were no group differences in self-reported physical activity, screen time, or eating habits ($p > .05$). On average, the girls reported spending 2.4 hours on the computer away from school, being active for 60 minutes 5 days a week, and as having good to very good eating habits.

Conclusion: The findings suggest that more engagement in organized sports may be health protective for immigrant girls. While the mechanism remains unclear, it is possible that being part of a team provides benefits associated with social support and belongingness. Further research is warranted to examine other possible lifestyle and sociocultural factors that support healthy weight status. A better understanding of the protections afforded by immigrant status is needed to inform interventions targeting weight maintenance and management efforts for all girls.

ASSOCIATIONS OF PERCEIVED STRESS WITH DIETARY AND WEIGHT RELATED OUTCOMES IN AFRICAN-AMERICAN ADOLESCENTS

Mary Quattlebaum, B.A.¹, Allison Sweeney, PhD¹, Haylee Loncar, Psychology, MA¹, Dawn K. Wilson, PhD¹¹University of South Carolina, Columbia, SC

Limited data suggests that dietary restraint may impact eating behaviors in response to stress, such that adolescents with low dietary restraint and high stress levels may reduce their energy intake. Conversely, some studies suggest that higher adiposity may be linked to increased energy intake under high-stress. Prior studies on stress and eating behaviors, however, are limited in African American (AA) youth and have failed to account for curvilinear relationships between stress levels and dietary intake. The current study expands on previous literature by examining the associations between body mass index (zBMI), kcals, fat intake, and fruit/vegetable intake across stress levels among AA adolescents in the Families Improving Together (FIT) for Weight Loss trial. A total of 126 overweight AA adolescents (66.7% female; *M* age 12.83±1.74 yrs; *M* BMI %ile 96.65±4.13) provided baseline data from the FIT for Weight Loss trial. Adolescents completed the Cohen Perceived Stress Scale to assess stress levels, which were then categorized into low- (1 SD below the mean), medium- (mean), and high-stress groups (1 SD above the mean). Random 24-hour dietary recalls were completed on two weekdays and one weekend day to determine average kcals, fat intake, and fruit/vegetable intake. Height and weight were measured by trained staff. A MANOVA analysis demonstrated a significant overall effect of stress on dietary outcomes and zBMI ($F(8, 242)=2.02, p<0.05$). Follow-up univariate tests revealed significant effects of stress on kcals ($F(2, 123)=6.84, p<0.01$) and fat intake ($F(2, 123)=5.98, p<0.02$). Post-hoc tests indicated significant differences in kcals and fat intake, with greater intake among the medium-stress group as compared to the low-stress ($p<0.02$, for both) or high-stress group ($p<0.02$ for both). These findings are among the first to indicate a curvilinear effect of stress on dietary outcomes in AA adolescents. High-stress was associated with reduced energy intake, which is consistent with some, but not all, related studies. Future studies should assess curvilinear relationships between stress levels and dietary intake to expand our understanding of how to best address stress, eating and weight outcomes in underserved AA adolescents.

EFFECTS OF A PILOT GUIDED IMAGERY INTERVENTION ON TEMPORAL DISCOUNTING AND FOOD DEMAND AMONG OVERWEIGHT AND OBESE ADULTS

Sara J. Sagui-Henson, PhD¹, Laura E. Martin, Ph.D.², Austin S. Baldwin, PhD³, Nina Cooperman, PsyD⁴, Angelos Kassianos, PhD⁵, Noreen Mdege, BPharm(Hons), MPH, PhD, PGCAP⁶, Elisa M. Trucco, PhD⁷, Sara M. Levens, PhD⁸

¹University of California, San Francisco, San Francisco, CA; ²University of Kansas Medical Center - Hoglund Brain Imaging Center, Kansas City, KS; ³Southern Methodist University, Dallas, TX; ⁴Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ; ⁵UCL, London, England, UK; ⁶University of York, York, England, UK; ⁷Florida International University, Miami, FL; ⁸University of North Carolina at Charlotte, Charlotte, NC

Background: Unhealthy dietary choices contribute to negative health outcomes, such as cancer and cardiometabolic diseases. To promote healthy food choice, interventions should target both the regulation and reward mechanisms that guide eating behavior. Episodic future thinking (EFT)—imagining personal experiences that might occur in one's future—may strengthen regulatory mechanisms by reducing unhealthy food choice and temporal discounting (i.e., valuing smaller immediate rewards over larger future rewards). Further, positive affect (PosA) related to healthy food may enhance the rewarding effects of healthy eating and strengthen the impact of EFT-anchored programs. Despite their potential synergistic effects, these processes have not been examined together. We conducted a factorial, randomized, controlled pilot intervention to test the independent and interactive effects of EFT and PosA on temporal discounting, food choice, and food demand among overweight and obese adults.

Method: Using a 2 (EFT: yes, no) x 2 (PosA: yes, no) design, we randomized 153 participants with a BMI >25 kg/m² (*M* age=31.3 years; *M* BMI=32.5; 70% female) to one of four guided imagery interventions. Participants completed surveys, then a temporal discounting task and a food demand task, which assessed food demand breakpoint (first price at which consumption was zero) and demand intensity (how much someone will consume at the price of \$0.01) for healthy and unhealthy food. Then participants listened to a brief guided imagery intervention. EFT conditions guided participants to think of a future where they have made healthy food choices. PosA conditions guided thoughts of positive feelings surrounding fruits and vegetables. Afterward, participants again completed the temporal discounting and food demand tasks, as well as a behavioral food choice task. A between-subject univariate ANOVA was conducted on all outcome indices.

Results: We found a main effect of EFT condition on unhealthy food demand for both breakpoint ($F(1, 146) = 5.448, p=.02$) and intensity ($F(1, 146) = 4.655, p=.03$). We also found a main effect of EFT condition on healthy behavioral food choices ($F(1, 152) = 6.821, p=.01$). There were no significant effects of EFT or PosA condition on temporal discounting or healthy food demand, and no interactions were significant.

Conclusions: Our findings indicate that listening to EFT guided imagery focused on visualizing future healthful choices results in a devaluation of unhealthy food and an increase in healthy food preference in the lab. Guided imagery to enhance positive associations with healthy food did not influence indices of decision-making or eating behavior. This suggests that EFT guided imagery can be targeted to address cognitive processes surrounding healthful behavior. Future research should explore scalability and dosing, and replicate findings with food decision-making outside the lab.

EVALUATION OF THE VARYING EFFECTS OF “COMPETITIVE” FOOD AND BEVERAGE POLICY ON OBESITY AMONG UNDER-STUDIED MINORITY STUDENTS

Mika Matsuzaki, PhD¹, Emma V. Sanchez-Vaznaugh, ScD, MPH², Maria E. Acosta, MPH³, Brisa N. Sanchez, PhD⁴¹SFSU, Seattle, WA; ²San Francisco State University, San Francisco, CA; ³San Francisco State University, Alameda, CA; ⁴Drexel University, Philadelphia, PA

Background and Purpose: It is currently unknown whether California's competitive food and beverage policies (CF&B policies) were effective in reducing high prevalence of overweight/obesity among severely understudied subgroups who have high rates of obesity and chronic diseases: Pacific Islander (PI) and American Indian/Alaskan Native (AI/AN) children.

Objective: To investigate the associations between CF&B policies and overweight/obesity status among PI and AI/AN school children in California.

Methods: Using a quasi-experimental design, prevalence trends of overweight/obesity were compared between the periods of before and after CF&B enactment in California among 5th and 7th grade PI, Filipino, AI/AN and White students.

Results: Among both boys and girls, obesity was significantly increasing in the period before the California CF&B policies (2002-2005) for 5th and 7th grade White, PI and AI/AN students. In the period after policy implementation (2006-2012), there was evidence of decline in obesity prevalence among White boys in both grades, controlling for student-level variables (age, race/ethnicity, physical fitness), school factors (enrollment, and racial/ethnic composition of students within schools and percent of eligible students for free or reduced price meals), school-neighborhood socioeconomic characteristics (annual median household income and percent of residents 25 years or older who completed a sixteen or more years of education) and district-level percent of students eligible for free or reduced price meals. The rate of increase in obesity prevalence declined significantly after the policies were adopted, for AI/AN girls and boys and PI girls in both grades and PI boys in 5th grade.

Conclusions: Our study findings point to substantial differences in the association between CF&B policies and obesity by race/ethnicity. Differential effects of the CF&B policy suggest that there is a need to further assess factors contributing to these differences and to implement additional obesity prevention strategies targeting high risk subpopulations such as PI and AI/AN.

6:15 PM-7:30 PM

RACISM AND SOURCES OF STRESS ASSOCIATED WITH BMI

Megan Tsutakawa, BA¹, Shima Esmaeili, BS¹, Chris Costanza, BS¹, Luci Martin, Ph.D.¹¹University of La Verne, La Verne, CA

Body mass index (BMI) is a known predictor of mortality, with acute physiological as well as psychological causes and implications. Race and sex differences in BMI may help to explain health disparities in the US. The perception of stress and the frequency of stressors has also been associated with mortality. The connection between stress and BMI has been investigated in relation to altered or unrestrained eating patterns, but has rarely been examined in a cultural or racial context. The current study examined multiple sources of stress (daily hassles, perceived stress, racism, sexism and acculturative stress) and their associations with BMI ($M=26.56$, $SD=6.58$) in a sample of 246 university students (mean age = 21.81, $SD = 4.37$; 72% female; 47% Latinx) through an online self-report survey. Using categorical guidelines provided by the Centers for Disease Control and Prevention, 49% of the sample was classified as overweight or obese. Among participants of color ($n = 171$; 50% overweight/obese), daily hassles ($r = .19$, $p = .01$), frequency of racist events ($r = .18$, $p = .02$), stress associated with racist events ($r = .21$, $p = .006$) and acculturative stress ($r = .17$, $p = .03$) were associated with BMI, and remained after adjusting for age and income. Among female participants of color ($n = 119$; 49% overweight/obese), daily hassles ($r = .22$, $p = .02$) was associated with BMI, though perceived stress ($r = .25$, $p = .009$), hassles ($r = .28$, $p = .003$) and acculturative stress ($r = .20$, $p = .04$) were associated with BMI when adjusted for age and income. Frequency of sexist events and stress associated with sexist events were not associated with BMI. Among male participants of color ($n = 52$; 54% overweight/obese), frequency of racist events ($r = .39$, $p = .005$), stress associated with racist events ($r = .43$, $p = .002$) and acculturative stress ($r = .43$, $p = .002$) were associated with BMI, and remained after adjusting for age and income. BMI was not associated with exercise or fruit/vegetable intake, but was associated with less hours of sleep for participants of color ($r = -.16$, $p = .04$). Future weight management interventions should integrate measures to assess for racial and cultural factors that could contribute to a heightened experience of stress in overweight populations.

6:15 PM-7:30 PM

THE IMPACT OF WEIGHT SUPPRESSION AND DIETARY RESTRAINT ON OUTCOMES IN AN EATING DISORDER AND OBESITY PREVENTION TRIAL

Christine C. Call, M.S.¹, Laura D'Adamo, B.A.¹, Meghan L. Butryn, PhD², Eric Stice, PhD³¹Drexel University Center for Weight, Eating, and Lifestyle Science, Philadelphia, PA; ²Drexel University, Philadelphia, PA; ³Stanford University, Eugene, OR

Emerging adults are at heightened risk for excess weight gain and eating disorder (ED) pathology. Two prevention programs that focused on small, sustainable changes to eating and physical activity (one with the addition of cognitive dissonance induction) reduced both weight gain and increases in ED pathology (Stice et al., 2018). However, a subset of participants had suboptimal outcomes, necessitating research on factors that influence outcome. Weight suppression (WS; the difference between highest lifetime weight and current weight) and dietary restraint (the cognitive effort to limit food intake) predict weight gain and ED pathology in community and clinical samples, but WS has not been examined in weight gain/ED prevention programs and the limited findings on restraint in this context are mixed. This study tested the hypothesis that WS and dietary restraint would each interact with condition to predict greater weight gain and increases in ED pathology.

Participants ($N=364$) aged 17-23 years with BMIs of 18-30 kg/m² enrolled in an RCT comparing two weight gain/ED prevention programs and an educational video control reported on weight history and dietary restraint (Dutch Restrained Eating Scale) at baseline. Weight and ED symptoms (Eating Disorder Diagnostic Interview) were assessed at baseline, 6-weeks (post-intervention), 6-months, 1-year, and 2-years.

WS and dietary restraint did not interact with condition, so conditions were collapsed for subsequent analyses. In the overall sample, WS, but not dietary restraint, predicted higher weight at 1-year ($p=.03$) and, at trend-level, 2-years ($p=.08$). At 1-year, mean weight gain was 4.1 lb for those in the top quartile of WS (WS >12.5 lb) and 1.0 lb for those in the bottom quartile (WS < 2.2 lb). Dietary restraint, but not WS, predicted greater ED pathology at 6-weeks, 6-months, and 1-year ($p's < .05$). At 1-year, ED symptoms increased by 27% in the top quartile (restraint >3.3) and 18% in the bottom quartile (restraint < 2.0).

High dietary restraint predicted increases in ED pathology while high WS predicted weight gain, demonstrating that these processes may differentially relate to suboptimal outcomes in emerging adults seeking weight gain and ED prevention programs. To improve the efficacy of prevention programs, future research should explore the mechanisms through which these factors impact outcome and identify treatment strategies for individuals presenting with these characteristics.

EFFECTS OF CHANGES IN NEIGHBORHOOD OBESOGENIC ENVIRONMENTS ON BODY WEIGHT BY MOVER STATUS: THE MULTIETHNIC COHORT STUDY

Lilian G. Perez, PhD, MPH¹, Juan Yang, PhD, MPH², Lynne R. Wilkens, DrPH, MS³, Scarlett Gomez, PhD, MPH², Loic Le Marchand, MD, PhD⁴, Iona Cheng, PhD, MPH², Salma Shariff-Marco, PhD, MPH²¹National Cancer Institute, Rockville, MD; ²Department of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA; ³Biostatistics Shared Resource, University of Hawaii Cancer Center, Honolulu, HI; ⁴University of Hawaii Cancer Center, Honolulu, HI

Introduction: Neighborhood environments can change via residential relocation or changes to one's present neighborhood, potentially influencing obesity risk through lifestyle behavior change. However, the effects of neighborhood environmental changes on body weight by mover status (mover or non-mover) are unknown. Thus, this study investigated the longitudinal associations of neighborhood environmental changes with weight change by mover status among a multiethnic adult sample.

Methods: We used baseline and 10-year follow-up data from 32,530 adults (aged 45-75 years at baseline) from the Multiethnic Cohort Study, who resided in California. Questionnaires assessed socio-demographics, health, behaviors, and self-reported weight. Geocoded residential addresses were assigned scores for five block group-level composite neighborhood factors, including 4 obesogenic environment factors (mixed-land development, unhealthy food environment, parks density, and urbanicity) and socioeconomic status (nSES). Sex-stratified mixed-effects models examined associations between change in each neighborhood factor (decrease, no change, increase) and annual rate of weight change by mover status. Models accounted for person and block group-level clustering and controlled for baseline individual-level covariates and time between surveys.

Results: Over the 10-year follow-up period, the average annual rate of weight gain was higher for movers (men: 0.11 lbs/yr; women: 0.36 lbs/yr) than non-movers (men: 0.08 lbs/yr; women: 0.18 lbs/yr). Among women, those who moved to a neighborhood with a higher unhealthy food environment gained 0.17 lbs fewer/yr than those who moved to a neighborhood with a similar food environment as their baseline neighborhood ($p=0.004$). Women non-movers whose unhealthy food environment increased gained 0.10 lbs fewer/yr than those who experienced no change ($p=0.02$). Among men, non-movers whose nSES increased gained 0.09 lbs fewer/yr than those who experienced no change ($p=0.05$). There was no significant effect of nSES on weight among men movers.

Discussion: Findings suggest that the effects of neighborhood change on weight vary by mover status and sex. Our study shows that women's weight may be more sensitive to changes in available food amenities following residential relocation. Men's weight appeared to be less sensitive to environmental changes following residential relocation. These findings in women, if confirmed, would warrant implementation of environmental interventions to prevent obesity.

INCREASED 2ND TRIMESTER PHYSICAL ACTIVITY MAY REGULATE RESTING METABOLISM AND WEIGHT GAIN IN WOMEN WITH OVERWEIGHT

Krista S. Leonard, MS¹, Abigail M. Pauley, M.S.², Emily E. Hohman, PhD³, Daniel E. Rivera, PhD⁴, Jennifer S. Savage, PhD⁵, Danielle Symons Downs, PhD⁶¹The Pennsylvania State University, State College, PA; ²The Pennsylvania State University, Bellefonte, PA; ³Pennsylvania State University, University Park, PA; ⁴Arizona State University, Tempe, AZ; ⁵Penn State University, University Park, PA; ⁶The Pennsylvania State University, University Park, PA

While studies show that RMR is higher in later pregnancy compared to pre-pregnancy, scant research has examined variation in RMR throughout pregnancy. The 2nd trimester is marked by rapid gestational weight gain (GWG) and fetal growth, which may increase RMR; however, the rate of change in RMR remains unclear. In addition, little research has examined modifiable factors of RMR variation, such as physical activity (PA) and energy intake (EI), which in turn, regulate GWG. These secondary analyses characterize change in RMR during the 2nd trimester and examine whether change in RMR is associated with PA, EI, and meeting GWG guidelines. Pregnant women with overweight/obesity ($N=18$) completed weekly mHealth assessments of PA (wrist-worn monitor), GWG (Wi-Fi scale), and RMR (mobile indirect calorimetry) during the 2nd trimester (T2) as part of a larger longitudinal study. EI was estimated with back calculation based on PA, weight, and RMR. Change scores for T2 PA, EI, and GWG were calculated as: week 27-week 14. Women (56%; $n=10$) were categorized as “fluctuating” RMR if their RMR increased and decreased throughout T2 and as “linear” RMR (44% $n=8$) if their RMR only increased or decreased. Women were also categorized as meeting (33%; $n=6$) or exceeding (67%; $n=12$) weekly IOM GWG guidelines (overweight: 14 weeks*0.6lbs/week; obese: 14 weeks*0.5lbs/week). One-way ANOVAs revealed women with linear RMR increased in PA ($M=41.6\text{kcal/day}$) while women with fluctuating RMR decreased ($M=-42.8\text{kcal/day}$; $p=0.03$) throughout T2. There was no significant difference in EI between RMR groups ($p=0.88$). In women with linear RMR, 38% met GWG guidelines while 62% exceeded. In women with fluctuating RMR, 30% met GWG guidelines while 70% exceeded (chi-square NS). Women with linear RMR had increased PA and a slightly higher proportion gaining within the GWG guidelines compared to women with fluctuating RMR suggesting that further research is needed to examine within-person variation in RMR as a potential modifiable factor of GWG.

FAMILY CHECK-UP 4 HEALTH IMPROVES CHILD AND PARENT HEALTH BEHAVIORS: RESULTS OF A RANDOMIZED PEDIATRIC WEIGHT MANAGEMENT TRIAL

J.D. Smith, PhD¹, Cady Berkel, PhD², Kevin Grimm, PhD³¹Northwestern University Feinberg School of Medicine, Chicago, IL; ²REACH Institute, Arizona State University, Tempe, AZ; ³Arizona State University, Tempe, AZ

Introduction: Implementing effective family-based programs in pediatric primary care to prevent excess weight gain in childhood is a critical goal set forth by the US Preventive Services Task Force. Most children access a primary care provider annually, caregivers are present and they look to pediatricians for advice on children's health. This poster presents the effects of the first randomized trial of the individually-tailored Family Check-Up 4 Health (FCU4Health), an adaptation of the evidence-based Family Check-Up program to specifically address pediatric obesity in primary care.

Method: A randomized hybrid type II Implementation-effectiveness trial was conducted in partnership with a large hospital-based outpatient clinic and four Federally Qualified Health Centers, all of whom served primarily low-income, Mexican-origin families. Families with children age 6-12 years and BMI ($\geq 85^{\text{th}}$ percentile) were recruited both during visits with their pediatrician or over the phone by a recruiter after identification via EMR query. Families completed surveys, an interaction task, and were weighed using a portable electronic body composition scale and measured using a stadiometer. Families were then randomized to services as usual ($n=99$) or to FCU4Health ($n=141$). FCU4Health was delivered as an integrated service in the clinic or via referral to an external behavioral health provider who met with the family in their home or at a community site. Intention-to-treat analyses were conducted using latent growth curve models in Mplus to test for group differences in child and caregiver behavioral and anthropometric variables, as well as family health routines, after 6-months of intervention and 6-months of follow-up.

Results: Randomization to the FCU4Health was associated with significant effects on the child's physical activity (Cohen's $d=.40$), eating behaviors ($d=.22$), food choices ($d=.20$), and hours of sleep per night ($d=.18$). Effects were also found on improving family mealtime routines ($d=.31$) and caregiver health behaviors ($d=.28$). All analyses controlled for baseline levels and BMI, gender, age, and ethnicity (of the child or caregiver depending on outcome). No significant group differences were found for child or caregiver anthropometric measures.

Conclusions: Implementing the FCU4Health in coordination with pediatric primary care shows promise for improving health behaviors that are associated with obesity in childhood. The effect sizes are likely to be conservative given that 80% of families offered the FCU4Health received any services and there was wide variation in the amount of total service hours. Thus, accounting for engagement and dose are warranted. Further, longer-term follow-up might be needed to detect intervention effects on weight and body composition given the findings of previous research using family-based interventions like the FCU4Health.

INCLUSION OF MINORITIES AND LOW-SES INDIVIDUALS IN MINDFULNESS-BASED INTERVENTIONS FOR WEIGHT LOSS: A SYSTEMATIC REVIEW

Charlayne A. Scarlett, M.P.H.¹, Courtney L. Strosnider, M.S.², Jackie Luong, n/a³, Ashli A. Owen-Smith, Ph.D., S.M.⁴, Kathryn M. Ross, Ph.D., M.P.H.¹, Claire A. Spears, Ph.D.⁴

¹University of Florida, Gainesville, FL; ²Georgia State University, MARIETTA, GA; ³Georgia State University, Marietta, GA; ⁴Georgia State University, Atlanta, GA

Background: Obesity is a leading cause of preventable death in the United States. Moreover, serious health disparities exist such that certain groups are at elevated risk for obesity and associated health consequences. For example, the prevalence of obesity is higher among Hispanics and African Americans/blacks compared to non-Hispanic whites; among lesbian and bisexual women compared to heterosexual women; and among individuals of low socioeconomic status (SES) compared to those with higher SES. A growing body of research supports mindfulness-based interventions for treating obesity. Recent reviews concluded that racial/ethnic minorities and low-SES populations have not been sufficiently included in clinical trials of mindfulness interventions addressing stress and depression. However, the extent to which priority populations have been included in mindfulness interventions for weight loss is unclear.

Method: Following PRISMA guidelines, we conducted a systematic review (searching Google Scholar, PubMed, PsycINFO, Scopus and Web of Science) to assess the extent to which groups that are most detrimentally impacted by obesity have been included in research investigating mindfulness-based interventions for weight loss. Studies were included if they were published in a peer-reviewed journal, described interventions that used mindfulness to target obesity or associated risk factors (e.g., diet, exercise, etc.) and were conducted in the U.S.

Results: Twenty-seven studies met inclusion criteria. Of these, 26 reported the proportion of participants by race/ethnicity. Across these 26 studies, 69.5% of participants were white, 20.4% were African American/black, and 3.8% were Hispanic (vs. 76.5%, 13.4% and 18.3% in the U.S. overall, respectively). Seven studies (26%) included no African-American/black and 12 (44%) included no Hispanic participants. Only one study reported sexual orientation; this study was designed to determine the efficacy of an intervention specifically for lesbian and bisexual women. Among the 13 studies that reported education level, 59.6% of participants had a college degree or more. In the four studies that reported annual household income using comparable ordinal scales, 49.7% of participants reported income of \$50,000-\$100,000, and 23.5% reported income above \$100,000. The six other studies reporting on income also indicated relatively high income levels. Over 88% of participants in the six studies that reported employment status were employed.

Conclusion: Overall, Hispanic adults and people with lower education levels were especially underrepresented in studies of mindfulness interventions for obesity. Efforts are urgently needed to include more diverse participants (particularly those from priority populations who are at disproportionate risk for adverse health consequences of obesity) in clinical trials of mindfulness interventions.

LONG-TERM EHR-MEASURED WEIGHT CHANGES FOLLOWING A RANDOMIZED CONTROLLED TRIAL OF A WEIGHT LOSS MAINTENANCE INTERVENTION

Corrine I. Voils, PhD¹, Kara L. Gavin, PhD¹, William S. Yancy, MD², Janet Grubber, PhD³, Maren K. Olsen, PhD²

¹University of Wisconsin, Madison, WI; ²Duke University, Durham, NC; ³Durham Veterans Affairs Medical Center, Durham, NC

Background: Long-term effects of weight management interventions have rarely been documented due to lack of availability of weight measures. Weight is recorded in the electronic health record (EHR) at most medical visits, providing data for long-term analyses. Additionally, the Veterans Administration (VA) national EHR allows for all weights collected at medical visits to be obtained provided they occurred within the VA. We used EHR-recorded weight to examine long-term weight outcomes two years following completion of randomized controlled trial (RCT) of a weight loss maintenance intervention.

Methods: MAINTAIN was an RCT comparing a primarily telephone-delivered weight loss maintenance intervention (n=110) to usual care (n=112) in veterans with obesity who had lost ≥ 4 kg in a 16-week weight loss program. The RCT primary outcome of study-measured weight change 56 weeks following randomization showed a small benefit of the intervention such that those in the intervention group regained less weight (-1.6 kg; 95% CI: -0.1, -3.1) during the intervention phase than the control group. Weight at the 56-week time point served as baseline for the current analyses. EHR weights were obtained for two years following baseline. Mixed-effects models with quadratic time were fit to estimate between-arm differences in weight change.

Results: Estimated weight at trial completion was 109.7 kg for usual care and 106.8 kg for intervention; estimated difference of -2.9 kg (95% CI: -8.8, 3.0). One year post-trial completion, estimated mean weight among usual care participants was 111.4 kg and intervention participants was 108.6 kg, estimated difference -2.8 kg (95%CI: -8.6, 3.0). Two years following trial completion, estimated mean weight among usual care participants was 111.5 kg and intervention participants was 108.0 kg, estimated difference -3.4 kg (95%CI: -9.3, 2.4 kg).

Conclusions: The VA EHR was an effective tool in tracking weight changes two years following conclusion of an RCT. This work highlights the importance of identifying methods to obtain long-term weight outcomes to better understand the effectiveness of weight loss maintenance interventions. More work is needed improve and monitor long-term weight loss.

GETTING A HEAD START ON OVERWEIGHT AND OBESITY IN PRESCHOOL-AGED CHILDREN

Carina Hansen, n/a¹, Abbie Jo Madson, n/a¹, Loren Toussaint, Ph. D.¹, Antonela Miccoli, MD², Brian Lynch, M.D.², Latasha Smith, PhD¹¹Luther College, Decorah, IA; ²Mayo Clinic, Rochester, MN

The current study assessed the impact of a regional food and fitness initiative on body mass index (BMI) of preschoolers enrolled in the Northeast Iowa Head Start program. Head Start is a federal preschool program committed to promoting school readiness, overall health and wellness of children, and supportive parenting skills in child development. This study was done in collaboration with Head Start, a medical center, a college, and a regional food and fitness initiative. The initiative has run for seven years and has grown in depth and reach each year. As such, although benefits to BMI were expected in all students, it was expected that children experiencing the program in more recent years may benefit more than those experiencing the program in the earlier years. Additionally, the role of sex was examined as an important factor in BMI changes. Participants (N=1,205) were Head Start preschoolers who attended for two years between 2012-2019, and had sex and their BMI data recorded by date of measurement. Results revealed a year 1 (M=16.74, SD=2.14) to year 2 (M=16.58, SD=2.07) decrease in BMI for all students that approached statistical significance ($t=1.90$, $p=.06$, $d=0.08$). Analyses that examined the years of program deployment showed that exposure to the initiative in the early years did not differ from exposure to the initiative in later years of the program in terms of its effectiveness in reducing BMI gains ($F=1.52$, $p=.18$). Examining changes in BMI across the two years by sex revealed a statistically significant moderating effect of sex ($F=6.83$, $p=.009$) wherein a significant decrease in BMI for females from year 1 (M=16.71, SD=2.35) to year 2 (M=16.41, SD=2.16) was observed ($t=2.005$, $p=.046$, $d=.15$), but the same decrease for males from year 1 (M=16.76, SD=1.943) to year 2 (M=16.73, SD=1.986) was half the size and not statistically significant ($t=0.37$, $p=.71$, $d=0.08$). In conclusion, the food and fitness initiative showed some promise of effectiveness in reducing gains in BMI in preschool aged Head Start students. However, the results indicate that while the initiative is having a positive impact on girls' BMI, it is not having a similarly beneficial impact on boys' BMI. This raises several questions regarding food and fitness initiative content, boys' socialization, and family characteristics of boys' homes. Future research should examine how the initiative can be equally effective for both sexes.

EXTENDED CARE FOR OBESITY MANAGEMENT: EFFECTS OF MATCHING PARTICIPANTS TO THEIR TREATMENT PREFERENCE FOR FOLLOW-UP CARE

Meena N. Shankar, MS, RD, CCRC¹, Vivian Bauman, MS¹, Andrea N. Brockmann, M.A.¹, Umelo A. Ugwoaba, B.S.¹, Charlayne A. Scarlett, M.P.H.¹, Abraham Eastman, M.S.¹, Brittney N. Dixon, M.P.H.¹, Kathryn M. Ross, Ph.D., M.P.H.¹, Michael Perri, PhD²¹University of Florida, Gainesville, FL; ²University of Florida, College of Public Health and Health Professions, Gainesville, FL

Introduction: Following behavioral treatment for obesity, participants commonly regain weight. Providing extended care via phone or email may reduce weight regain; however, it is unknown whether matching the mode of extended care (i.e., phone vs. email) to a participant's preference may improve weight-loss maintenance.

Methods: The study included 72 adults with obesity (female = 86%, non-Hispanic white = 68%; ($M \pm SD$) age = 54.9 ± 9.4 years; BMI = 36.4 ± 3.8 kg/m²) who participated in a 4-month behavioral weight-loss intervention followed by random assignment to a 12-month extended-care program consisting of 18 contacts delivered by phone or email. Prior to randomization, participants were asked to specify their preference for extended care via phone or email. Participants in both the email and phone conditions received written modules describing strategies to enhance weight-loss maintenance. Participants in the phone condition also had the opportunity to call into a group or individual phone session with a weight-loss interventionist to discuss the treatment modules and problem solve any obstacles to maintenance. Thus, a 2 (phone vs. email contact) X 2 (preferred vs. nonpreferred modality) factorial design was used to assess the effects of extended-care modality and participant preference, and their interaction, on weight change during the 12 months following initial weight-loss treatment.

Results: Overall weight loss following initial treatment was 8.6 ± 4.5 kg. An ANOVA on weight changes during the 12-month extended-care period indicated a significant main effect for treatment modality ($p = .01$), such that participants assigned to extended care delivered by phone demonstrated less weight regain than those in the email condition ($M_s \pm SEs = 0.3 \pm 0.9$ kg vs. 4.0 ± 1.2 kg, respectively). There was not a significant main effect for treatment preference ($p = .48$). Moreover, there was not a significant difference in weight regain for participants assigned to their preferred vs. nonpreferred treatment modality (1.6 ± 1.1 kg vs. 2.7 ± 1.0 kg, respectively, $p = .48$).

Conclusion: Collectively, these findings indicate that providing extended care via phone contact produces greater maintenance of weight loss than email contact, even among those participants who express a clear preference for extended care via email.

COGNITION MEDIATES THE EFFECTS OF PAIN ON LOWER EXTREMITY FUNCTION IN OLDER ADULTS

Hannah Pakray, M.A.¹, Elizabeth K. Seng, Ph.D.², Roe Holtzer, Ph.D.³¹Yeshiva University, New York, NY; ²Ferkauf Graduate School/Yeshiva University, Bronx, NY; ³Albert Einstein College of Medicine/ Yeshiva University, Bronx, NY

Objective: Pain is prevalent in aging and is commonly associated with deficits in physical function. Persistent pain has been associated with decrements in performance on measures of overall cognitive function. Normal aging is also known to result in gradual declines in cognition and physical function. As such, older adults who experience persistent pain are particularly vulnerable to the development of physical and functional disabilities. Beyond its direct effects on cognitive and physical function, pain can also affect physical function via its impact on cognition. However, further research is needed to identify which aspects of physical function are most reliant on this indirect effect. An improved understanding of the mediating role of general cognition on the relationship between pain status and physical function in older adults could help to reduce their risk of recurrent falls. The current study examined the mediating effect of overall cognitive function on the association between pain status and physical function. We hypothesized that individuals who reported ongoing pain and exhibited poor general cognition would be more likely to report greater physical dysfunction.

Participants and Methods: Participants (n= 383) consisted of non-demented, community-dwelling older adults (mean age= 76ys; %female= 55) who were assessed within a single clinic visit. Pain status and physical function were assessed by self-report using the Medical Outcomes Study Pain Severity Scale (MOS-PSS) and the Late-Life Function and Disability Instrument (LLFDI), respectively. Overall cognitive function was assessed using the Total Index Score of the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS).

Results: Separate mediation analyses were conducted for the following physical outcomes: basic lower extremity function, advanced lower extremity function, and upper extremity function. Cognition was found to mediate the association between pain and basic lower extremity function. Step 1 of the mediation model revealed a significant negative association between pain and basic lower extremity function ($\beta = -0.199$, $p < .001$). Step 2 showed a significant positive association between pain and cognition ($\beta = 0.105$, $p < .05$). Step 3 showed a significant positive association between cognition and self-reported lower extremity function when controlling for pain ($\beta = 0.229$, $p < .001$). Step 4 revealed that in the presence of cognition, pain was a significant predictor of lower extremity function ($\beta = -0.224$, $p < .001$), demonstrating a partial mediation effect. Separate mediation models that considered upper extremity function and advanced lower extremity function as distinct outcomes did not yield significant results.

Conclusions: General cognition mediated the relationship between pain and lower extremity function in a sample of community-residing older adults.

THE EFFECTS OF ADDICTION ON CHRONIC MIGRAINE TREATMENT OUTCOMES

Sarah Martin, MS¹, Dallas Robinson, M.S.², Amy Wachholtz, PhD, MDiv, MS³, Amrita Bhowmick, MBA, MPH⁴¹University of Colorado Denver, Centennial, CO; ²University of Colorado Denver, Wheat Ridge, CO; ³University of Colorado Denver, Denver, CO; ⁴Health Union, LLC, Chapel Hill, NC

Introduction: Dual disorder research has emphasized the importance of integrated, individualized care for comorbid substance use disorder and mental illness. However, a lack of research has addressed whether a similar standard of specialized care is needed for the co-occurrence of substance use disorder and a physical disability, such as chronic pain. With a high prevalence of substance use disorder in the chronic pain population, it is important for clinicians to recognize the effects of this comorbidity on treatment outcomes. The purpose of the current study was to examine the relationship between co-occurring substance use disorder and chronic migraine treatment outcomes.

Method: As a part of a larger study, 4502 participants with chronic migraine completed an array of self-report questionnaires related to health and treatment experiences. Chi-square tests of independence were performed to assess the relation between co-occurring substance use disorder and migraine treatment outcomes in the chronic migraine population.

Results: Chi-square tests of independence revealed that individuals with comorbid substance use disorder were more likely than those with chronic migraine alone to experience less migraines after learning how to avoid specific triggers ($\chi^2(1, N = 4502) = 4.195$, $p < .05$). The presence of co-occurring substance use disorder did not significantly associate with any other treatment outcomes.

Discussion: The results suggest that individuals with co-occurring substance use disorder and chronic migraine benefit from interventions that incorporate trigger avoidance training. To ensure optimal treatment outcomes, clinicians must assess for co-occurring substance use disorder when constructing treatment plans for chronic migraine patients. Future research should attempt to develop and test a migraine treatment protocol for patients with comorbid substance use disorder. Furthermore, additional research is needed to explore whether the presence of co-occurring chronic migraine also effects addiction treatment outcomes.

Learning Objectives

1. At the conclusion of this presentation the audience will be able to identify the impact of co-occurring substance use disorder on chronic migraine treatment outcomes.
2. This presentation will help the audience develop more effective treatment plans for patients with comorbid substance use disorder and chronic migraine.

ETHNICITY INFLUENCES PAIN, PERIOD: ETHNIC DISPARITIES IN MENSTRUAL PAIN AND ATTITUDES

Kezia Shirkey, PhD¹, Katelyn Truex, BA in Psychology², Sarah Lindner, n/a³¹North Park University, Department of Psychology, Chicago, IL; ²Park Nicollet, Woodland, MN; ³Chicago school of professional psychology, Chicago, IL

Studies show significant differences in menstrual attitudes between women in the U.S. and those in other countries (Hoerster et al., 2008; Marván et al., 2006). However, little literature discusses ethnic differences in menstrual pain and attitudes within the U.S. (Hollingshead et al, 2016).

We surveyed 106 Latina (N=47) and Caucasian (N=59) female college students (18-27 yo). Measures included the Abdominal Pain Index (API) for dysmenorrhea, Body Appreciation Scale (BAS), Beliefs and Attitudes Toward Menstruation questionnaire (BATM), and religiosity items.

Consistent with literature in other pain domains (Campbell, 2012; Finkelstein & Eye, 1990; Marván et al., 2006), Latinas reported significantly greater pain intensity ($t(101) = 3.585, p = .001$), and a higher peak pain ($t(101) = 2.362, p = .020$). Interestingly, Latinas average pain was more intense than Caucasians' peak pain, on average. However, Latinas reported shorter duration of pain on the days they experienced menstrual pain ($t(101) = -2.02, p = .030$), though a trend to experience pain about a half day longer ($t(100) = 1.883, p = .063$). There were no significant differences between cycle length or period duration. When entered into a regression controlling for age, body appreciation, and religiosity in the first step, ethnicity was the only significant predictor of summary pain scale ($\beta = -.233, p = .041, \Delta R^2 = .043$), days in pain ($\beta = -.240, p = .032, \Delta R^2 = .049$), and remained a significant predictor (with BAS and religious activities) of peak pain ($\beta = -.273, p = .011, \Delta R^2 = .064$), and pain intensity ($\beta = -.424, p < .001, \Delta R^2 = .153$).

Beyond pain, Latinas endorsed behavioral pre/proscriptions while menstruating (e.g. not carrying heavy things, drinking tea) significantly more than Caucasians ($t(83.677) = 4.704, p < .001$). Latinas showed a trend both toward being more annoyed by their period ($t(102) = 1.818, p = .072$), yet a higher appreciation for their body ($t(101) = 1.781, p = .078$) than Caucasians; it is possible that these analyses were underpowered and would become significant with larger sample sizes. As consistent with prior literature, our sample showed Latinas were significantly more likely to report using pads ($t(100.74) = 4.922, p < .001$) and less likely to use tampons ($t(101) = -4.388, p < .001$) than Caucasians.

This study extends prior pain disparity research by examining ethnic differences and menstrual pain. Differences in pain may be due to cultural differences in pain expression, increased sensitization from systematic prejudice, medical provider skepticism, differences in coping, or neurobiological differences (Campbell, 2012). While Latinas report more pain and more behavioral prescriptions, they also trend toward greater bodily appreciation; further research should expand on these findings to best serve the diversity within women's health and understand possible cultural resilience to pain experiences.

COGNITIVE, AFFECTIVE, AND NEUROENDOCRINE CORRELATES OF PAIN TRAJECTORIES IN SURVIVORS OF RECENT INTERPERSONAL VIOLENCE

Edward W. Lannon, MA¹, Burel R. Goodin, PhD², Uma Rao, MBBS³, Matthew C. Morris, PhD⁴¹University of Mississippi Medical Center, Ridgeland, MS; ²The University of Alabama at Birmingham (UAB), Department of Psychology, Birmingham, AL; ³University of California, Irvine, Irvine, CA; ⁴University of Mississippi Medical Center, Department of Psychiatry and Human Behavior, Jackson, MS

Interpersonal violence (IPV) is a major public health concern. Women are at high risk for IPV exposure, which, in turn, is associated with negative health outcomes including chronic pain. The mechanisms contributing to this increased risk are not well understood. Cognitive (e.g., catastrophizing), affective (e.g., depressive and posttraumatic stress [PTS] symptoms), and neuroendocrine (e.g., stress response system alterations) factors have been implicated in the development of chronic pain and may account, in part, for the IPV-Pain association. Three multilevel models were conducted to examine within-person relations between daily pain outcomes (i.e., McGill Pain Questionnaire short form, sensory and affective pain; PROMIS Pain Interference short form) and potential correlates of change (i.e., pain catastrophizing, depressive symptoms, PTS symptom severity, and diurnal salivary cortisol secretion). 47 young adult women completed assessments within three months of an IPV incident and at 1-, 3-, and 6-month follow-ups. Multilevel models examined predictors of pain outcome trajectories (i.e., predictor X time interactions), controlling for age and race. Pain catastrophizing interacted with time to predict both affective pain ($\beta = -.15, p = .033$) and pain interference ($\beta = -.37, p = .043$). Simple slopes revealed that women reporting *higher catastrophizing* had higher affective pain and pain interference at baseline; whereas affective pain decreased significantly over time, pain interference remained stable. Women reporting *lower catastrophizing* had low and stable affective pain but showed increases in pain interference. Depressive symptoms interacted with time to predict affective pain ($\beta = .27, p = .004$). Women reporting *higher depressive symptoms* exhibited higher affective pain at baseline and increases in affective pain over time, whereas women with *lower depressive symptoms* exhibited lower affective pain at baseline and decreases in affective pain over time. Neither PTS severity nor diurnal cortisol secretion were associated with pain or interference trajectories. No cognitive, affective, or neuroendocrine factors were associated with sensory pain. The present findings highlight the importance of psychological variables in the relationship between IPV and daily pain and suggest the possibility that psychological interventions targeting depression and pain catastrophizing could prevent pain onset and maintenance in IPV survivors.

PAIN SELF-MANAGEMENT IN TEENS RECEIVING AN OPIOID FOR ACUTE PAIN: ASSOCIATIONS WITH PARENTAL SUBSTANCE USE AND MONITORING.

Corrin Murphy, BS¹, Kira Beck, n/a¹, Tara G. Chowdhury, PhD¹, Katrina Cordts, PhD², Amy Holley, PhD¹, Sarah Feldstein Ewing, PhD¹, Anna Wilson, PhD¹¹Oregon Health and Science University, Portland, OR; ²University of Nebraska Medical Center, Omaha, NE

Objective: Opioid misuse is a significant public health concern impacting adolescents. In contrast to other substances of abuse, teens are largely introduced to opioids through non-drug seeking behaviors, predominantly legitimate prescriptions. Further, little is known about substance use outcomes in these teens. The objectives here were to examine: 1) sex differences in pain and medication use in a sample of teens with opioid prescriptions for pain and 2) associations between pain, medication use, and parental substance use/monitoring.

Methods: Participants include 69 teens, (14-18 years; $M = 15.9$) from a larger longitudinal study. Participants completed 4-10 daily diaries within 10 days of receiving their prescription opioid, on prescription and over the counter (OTC) pain medication use, and pain self-management techniques. Teens also reported on perceptions of their parents' substance use, and the Parental Monitoring Questionnaire (PMQ) subscales: monitoring, solicitation, parental control, child disclosure). T-tests examined sex differences in pain and medication use; bivariate correlations examined associations between pain, medication use, and parental variables.

Results: Average pain intensity across diary days was 41.9, (0-100 NRS), with females reporting higher pain than males; $t(48) = -2.06, p = .04$. Diaries capturing the first day of this window reflected 16.9% of teens still using their prescription opioids, while 81.5% had transitioned off of their prescription opioids to OTC use. Opioid use, OTC use, parent substance use and PMQ scores did not differ by sex. Females reported using significantly more pain self-management techniques (e.g. distraction, ice, heat) than males, $t(63) = -3.12, p = .003$. There were no associations between opioid use and PMQ scores or perceived parental substance use. OTC use was correlated with two subscales of the PMQ (control $r = .38, p = .03$; disclosure; $r = .40, p = .02$). Teens reporting more substance use by their mothers reported lower PMQ monitoring ($r = -.26, p = .046$). There was no correlation between PMQ scores and paternal substance use.

Conclusions: By the initiation of the daily diary period, a majority of the youths prescribed opioids for acute pain had successfully transitioned from opioids to OTC use. A smaller, but relevant proportion of teens were still on the opioids; it is this subset of teens who we must continue to evaluate to see if/how they transition off of narcotic medication. We found some sex and family differences that may be relevant to informing how acute pain experiences are a potential entry point for encouraging non-pharmaceutical pain management behaviors in teens.

PAIN ANXIETY SYMPTOMS SCALE – 20: MEASUREMENT INVARIANCE ACROSS RACE/ETHNICITY AND SEX

Andrew H. Rogers, M.A.¹, Matthew W. Gallagher, Ph.D.¹, Michael J. Zvolensky, Ph.D.¹¹University of Houston, Houston, TX

Chronic pain affects a significant proportion of the population in the United States, causing significant disability. According to the fear-avoidance model of chronic pain, a number of psychological factors serve to maintain and exacerbate pain experience. Pain-related anxiety, or fear of pain and pain-related sensations, is one candidate mechanism that serves to maintain chronic pain. Well-validated self-report measures, including the Pain-Anxiety Symptoms Scale-20 (PASS-20), have been designed to measure pain-related anxiety, and psychometric studies have shown that this scale has good reliability, convergent, and divergent validity. Yet, to date, no work has examined measurement invariance, or how the PASS-20, may measure pain-related anxiety across race/ethnicity and sex. Given that research has shown racial and sex differences in the experience of pain, it is also possible that these differences may extend to the measurement of pain-related anxiety. Therefore, the current study explored measurement invariance of the PASS-20 across race/ethnicity and sex among 3,445 college students ($M_{age} = 21.49, SD = 4.24, 73.7\%$ female; 33.5% Hispanic, 29.3% Asian/Pacific Islander, 22.4% White, 14.8% Black/African American). Results showed that the PASS-20 showed configural and weak invariance across all race/ethnicity and sex comparisons, suggesting that the general factor structure and factor loadings for each item were invariant across race/ethnicity and sex. However, for strong invariance, there were mixed results. Hispanic compared to African American showed strong invariance, Hispanic-White, Asian-African American, and White-African American showed partial strong invariance, and Asian-White, Hispanic-Asian, and Male-Female showed no strong invariance. These results begin to shed light on differences in the measurement of pain-related anxiety across race/ethnicity and sex, and may suggest that a better understanding of the nuances of measurement of this construct may be important for treatment development.

THE EFFECT OF A BIOMEDICAL EXPLANATION ON UNCERTAINTY AND UNPLEASANTNESS OF PAIN

Eleanor Ghanbari, BA¹, Jena Tronieri, Ph.D.², Andrew Ward, Ph.D.³¹University of Pennsylvania Center for Weight and Eating Disorders, Philadelphia, PA; ²University of Pennsylvania, Center for Weight and Eating Disorders, Philadelphia, PA; ³Swarthmore College, Swarthmore, PA

Ambiguous pain without a precise, identifiable source is associated with distress and impairment, and unexplained somatic symptoms account for half of all physician visits. A previous study found that patients sought a convincing explanation for their unexplained symptoms from their physician more than a medical intervention. Two studies evaluated whether a biomedical explanation for ambiguous pain would reduce uncertainty and whether the explanation would alter the pain experience itself. In Study 1, participants were first asked to imagine unexplained pain in a specific area of their body. They rated how certain they were about the exact cause of their pain, as well as the intensity and painfulness of their symptoms, on 7-point Likert-type scales. Participants then were randomly assigned to either a biomedical or generic explanation. They were asked to imagine that their doctor explained that their pain was caused by “specific neural receptors in the injured tissue sending signals to the pain processing centers of the brain” (biomedical explanation); or by “the body’s response to the situation it is in” (generic explanation). Participants then repeated certainty and symptom ratings. The biomedical explanation resulted in larger increases in certainty about the exact cause of their symptoms ($M_D = 1.36$, $SE=0.31$) than the generic explanation ($M_D = -0.06$, $SE=0.31$), $p = .004$. There was no difference in intensity or painfulness of symptoms. In Study 2, the generic explanation was replaced with a less detailed biomedical explanation: “the body’s response to the source of the injury”. Study 2 also added an additional primary outcome: the overall unpleasantness of the experience taking into account participants’ certainty about the cause of their symptoms. In this study, there was no difference between the original biomedical explanation ($M_D = 0.88$, $SE=0.30$) and the less detailed explanation ($M_D = 1.05$, $SE=0.30$) in change in certainty, suggesting that a biomedical explanation was sufficient to reduce uncertainty regardless of the level of detail. In addition, participants given the more detailed biomedical explanation rated the overall experience as more unpleasant, $p = .03$. Together, our findings suggest that a biomedically-oriented explanation may reduce uncertainty about the source of pain symptoms, but it does not affect the experience of pain and the overall experience may become more unpleasant.

ASSESSING THE RELATIONSHIP BETWEEN PERCEIVED LOCI OF CONTROL AND PATIENT OUTLOOK ON MIGRAINES

Caitlin A. Kienzler, BS¹, Dustin Goerlitz, BA¹, Amrita Bhowmick, MBA, MPH², Amy Wachholtz, PhD, MDiv, MS¹¹University of Colorado Denver, Denver, CO; ²Health Union, LLC, Chapel Hill, NC

Introduction: Research examining perceived loci of control and quality of life (QOL) in migraine patients has shown relationships between internal loci of control (migraine self-management) and QOL, as well as between external loci of control (perception of physician treatment) and QOL (Grinberg & Seng, 2017). One essential aspect of QOL includes an individual’s perceptions/outlook of their position in life (Megari, 2013). We conducted this study to assess the associations between a patient’s perceived loci of control and their personal outlook on their life with migraines.

Method: 4,502 U.S. adult migraine participants completed the 2015 Migraine.com survey. 2 tests of independence were performed to assess the associations between personal migraine outlook and perceived loci of control. Migraine outlook was assessed by endorsement of positive and/or negative words associated with the participant and/or their life with migraines. Perceived loci of control ratings were assessed across multiple questions using a 7-point Likert scale. Demographic factors, including age, gender, race/ethnicity, and socioeconomic status (SES) were also assessed.

Results: 2 tests of independence on migraine outlook showed a significant relationship with both external ($2(18) = 117.3$, $p < .05$, $\phi = 0.2$) and internal ($2(18) = 182.6$, $p < .05$, $\phi = 0.2$) loci of control. Additional 2 tests showed non-significant relationships between migraine outlook and age ($2(47) = 57.2$, $p=ns$), and migraine outlook and gender ($2(1) = 0.6$, $p=ns$). Significant relationships were found between migraine outlook and race/ethnicity ($2(6) = 15.0$, $p < .05$, $\phi = 0.1$), and migraine outlook and SES ($2(4) = 21.2$, $p < .05$, $\phi = 0.1$).

Discussion: Migraine outlook showed a relationship with feelings of internal and external loci of control, as well as with race/ethnicity and SES, though effect sizes were small. Future research should examine other possible factors impacting both migraine patients’ perceived loci of control and their quality of life. Expanding the current literature on these two domains may provide useful direction for creating targeted interventions to improve patient outcomes and quality of life.

ATTENTION TO PAIN IN CHILDREN WITH CHRONIC PAIN: A CHILD VERSION OF THE PAIN VIGILANCE AND AWARENESS QUESTIONNAIRE (PVAQ-C)

Lauren C. Heathcote, PhD¹, Laura E. Simons, PhD²¹Stanford University Medical School, Palo Alto, CA; ²Stanford University School of Medicine, Palo Alto, CA

Background/Purpose: Pain is evolutionarily primed to capture and hold attention, urging behavior to escape. In the case of chronic pain, repeated attentional interruption from pain can exacerbate pain-related catastrophizing, drive fear and avoidance behaviors, and fuel disability. Accordingly, attentional processes have become intervention targets for chronic pain disorders, including via self-management, cognitive-behavioral therapies, and computerized attentional (re)training. Despite its demonstrated importance in adult samples, and application of these treatments to children with chronic pain, there are currently no validated tools to capture self-reported attention to pain in children.

Methods: The goals of this study were to adapt the Pain Vigilance and Awareness Questionnaire (PVAQ) for use in a child sample, to preliminary examine its psychometric properties, and to assess its utility over and above a measure of general attentional capacities. We adapted the language of the original PVAQ to be more easily understood by children as young as 8 years, maintaining the overall structure and content of the original measure. In a sample of 160 children (8-18 years) recruited from chronic pain clinics across two hospital sites, we examined the factor structure, internal consistency, and criterion validity of the PVAQ-C.

Results: Like the original adult measure, the PVAQ-C demonstrated excellent internal consistency ($\alpha = .92$) and moderate-to-strong criterion validity. That is, children who reported greater attention to pain also reported greater pain catastrophizing ($r = .532, p < .001$), fear of pain ($r = .467, p < .001$), avoidance of activities ($r = .439, p < .001$), and poorer physical functioning ($r = .448, p < .001$). Pain-related attention remained a significant predictor of the child's physical functioning while controlling for demographic variables (age and gender) and the child's level of catastrophizing, fears, and avoidance behaviors, indicating the utility of this newer construct in addition to established pediatric pain measures. In addition, pain-related attention significantly predicted child outcomes independent of the child's general attention control capacities, indicating added value of a pain-specific versus a general measure of attention. Unlike the adult measure, exploratory factor analysis indicated that a one-factor solution was the best fit to the data, explaining 45.9% of the variance ($\chi^2 p < .001$).

Conclusions: The PVAQ-C shows strong indices of internal reliability and criterion validity and can be used to assess children's pain-related attention in research studies and in the clinic. Further examination of its test-retest reliability and sensitivity to change will be important to consider for use in studies examining mechanisms of treatment effects in children with chronic pain.

EXAMINING ASSESSMENTS OF PAIN-RELATED FEAR AND ANXIETY

Cecelia I. Nelson, n/a¹, Casey D. Wright, MS¹, Jonathan W. Nauser, MS¹, Richard T. Gross, PhD¹, Daniel W. McNeil, PhD¹¹West Virginia University, Morgantown, WV

Rationale: The burden of chronic pain is significant at both an individual and a systemic level in terms of its cost and impact. Indeed, chronic pain patients face a number of challenges, both physiological and psychological in nature. Psychological factors, including anxiety, fear, and avoidance, are associated with individual pain experiences and are thereby important to measure and treat in tandem with the nociceptive components of pain. The assessment of pain and its psychological comorbidities, however, remains complex. The aim of the current study was to examine the overall associative properties of the most common measures of anxiety and fear associated with pain, to determine how similar or different they are, in order to further research and treatment of chronic pain and associated conditions.

Method: Participants ($n = 72$) were patients (M age = 54.6, $SD = 11.3$; 50.7% female) recruited from the West Virginia University pain clinic who were being treated for chronic pain. The mean reported pain duration was 14.5 years ($SD = 11.6$), with 43.7% of patients reporting issues related to back pain. Patients completed a battery of questionnaires about their pain experience and associated psychological factors. Among the questionnaires were the Fear of Pain Questionnaire-9 (FPQ-9), the Pain Anxiety Symptoms Scale short form (PASS-20), and the Tampa Scale for Kinesophobia (TSK). To examine the relations among the three aforementioned instruments, Pearson correlational analyses were performed on the scale total scores as well as the subscales.

Results: The TSK total score was associated with the PASS total score ($r = .48, p < .001$), and all subscale scores of the PASS. The TSK total score was unrelated to the FPQ-9 total score ($r = .15, p = .36$), or any FPQ-9 subscale scores. The FPQ-9 total score was moderately associated with the PASS total score ($r = .30, p < .05$), and the PASS physiological anxiety subscale ($r = .31, p < .05$).

Conclusion: While each instrument examined here is designed to assess a different component of pain-related fear and anxiety, similarities exist between participants' TSK and PASS scores. The FPQ-9, however, may be measuring a unique and general component of pain-related anxiety fear that is more associated with physiological anxiety, but less related to fear of movement or reinjury.

Significance: The results of this study contribute to the general understanding of each of the instruments examined. Additional research is needed to understand how patients' scores on these questionnaires may differentially and uniquely impact their treatment needs. It is possible that psychological treatment may look different for those with a broader fear of pain, versus a specific fear of the pain associated with movement/reinjury.

MEDITATION COMBINED WITH BRAIN STIMULATION FOR CLINICAL PAIN SEVERITY IN OLDER ADULTS WITH KNEE OSTEOARTHRITIS

Hyochol Ahn, Ph.D., MSN, MS-ECE, MS-CTS, APRN, ANP-BC¹, Lindsey Park, B.S.¹, Setor Sorkpor, MSN¹, Hongyu Miao, Ph.D.¹¹University of Texas Health Science Center at Houston, Houston, TX

Introduction: Knee osteoarthritis (OA) is one of the most common causes of pain in older adults. Recent evidence suggests that knee OA pain is characterized by alterations in central pain processing in the brain. Two nonpharmacological pain treatments, transcranial direct current stimulation (tDCS) and mindfulness-based meditation (MBM), have been shown to improve pain-related brain function in older adults with knee OA. However, no studies have examined whether tDCS combined with MBM can reduce clinical pain in older adults with knee OA. Thus, the purpose of this study was to examine the preliminary efficacy of tDCS combined with MBM in older adults with knee OA.

Methods: Thirty participants 50-85 years old with symptomatic knee OA were randomly assigned to receive either 10 daily sessions of 2 mA tDCS combined with active MBM for 20 minutes (n=15) or sham tDCS combined with sham MBM (n=15). Ten daily sessions of 2mA tDCS with the anode electrode over the primary motor cortex and with the cathode electrode over the supraorbital region was applied daily for 2 weeks (Monday to Friday) via the Soterix 1x1 tDCS mini-CT Stimulator (Soterix Medical Inc., NY). For sham tDCS, the electrodes were placed in the identical positions as for active stimulation, but the stimulator delivered no electrical current except a 30-second ramp-up/down period at the beginning and the end to mimic somatosensory perception of active tDCS. Also, participants practiced MBM simultaneously with tDCS by a guided meditation recording through earphones on a CD player. The recording instructed participants to close their eyes, connect to the openness of one's mind, and mindfully maintain and deepen the connection through breathing with more openness and awareness. For sham MBM, the recording instructed participants to relax and take deep breaths every three minutes without the specific mindfulness-based instructions. Clinical pain severity was measured by asking participants to rate their average knee pain over the past 24 hours via Numeric Rating Scale (NRS) from 0 (no pain) to 100 (worst pain imaginable). We also evaluated the presence and severity of possible side effects of treatment at the end of each session.

Results: Participants had a mean age of 59 years (SD = 7 years), and 60% were female. The average decrease in the NRS score was 24.67 ± 12.88 in the active group and only 3.33 ± 10.63 in the sham group (Cohen's D = 1.81, $P < 0.0001$). In addition, no participants complained about serious adverse events.

Discussion/Conclusion: We demonstrated that tDCS combined with MBM significantly reduced clinical pain severity in older adults with knee OA without any serious adverse events. Future studies with larger samples and longer-term follow-up evaluations are needed to validate and extend these findings.

DEMOGRAPHIC PREDICTORS OF ENGAGEMENT IN AN INTERNET-BASED CBT PROGRAM FOR VETERANS WITH CHRONIC LOW BACK PAIN

Chelsey Solar, Ph.D.¹, Allison Halat, n/a¹, Haseena Rajeevan, Ph.D.², David Williams, Ph.D.³, Sarah Krein, Ph.D., RN⁴, Alicia Heapy, PhD⁵, Matthew Bair, M.D.⁶, Robert Kerns, Ph.D.⁷, Diana M. Higgins, PhD⁸

¹VA Boston Healthcare System, Boston, MA; ²Yale School of Medicine, New Haven, CT; ³University of Michigan Medical School, Ann Arbor, MI; ⁴VA Ann Arbor Center for Clinical Management Research, Ann Arbor, MI; ⁵VA Connecticut Healthcare System, West Haven, CT; ⁶VA Center for Health Information and Communication, Indianapolis, IN; ⁷Yale School of Medicine, West Haven, CT; ⁸VA Boston Healthcare System, Jamaica Plain, MA

Introduction: Internet-based interventions for chronic pain have demonstrated efficacy and may address access barriers to pain care. One recently published pilot trial demonstrated feasibility and preliminary efficacy of a cognitive behavioral Internet-delivered self-management intervention for veterans with chronic low back, named Pain EASE. The objective of this study was to examine race, gender, and age as predictors of engagement in Pain EASE.

Methods: Participants were veterans enrolled in a 10 week trial of a self-directed, internet-based cognitive behavioral intervention for chronic low back pain (i.e., the Pain EASE program). Pain EASE includes a self-assessment, 10 pain coping skills training modules, tools for monitoring pain intensity, sleep quality, and activity, and links to additional resources. Participants received 10 weekly check-in phone calls with study staff to collect some data elements. Engagement variables examined were: number of days logged in, modules accessed, use of self-monitoring tools, and number of completed check-in phone calls. Descriptive statistics, t-tests, nonparametric statistics, and linear regression were used to describe the study sample and engagement and to examine demographic predictors of engagement.

Results: 57 veterans (93% male, 61% White, mean age = 54) were included in analyses. Because the engagement variables were not normally distributed, medians were used for sample description and analyses. Veterans logged into the program for a median of 3 days total, accessed a median of 3/10 modules, and used self-monitoring tools a median of 0 days, overall. Non-white participants compared to White participants logged into the program on fewer days ($Mdn = 1$ vs $Mdn = 3$, $p = 0.01$), accessed fewer modules ($Mdn = 1$ vs $Mdn = 2$, $p < 0.01$) and were less likely to self-monitor ($Mdn = 0$ vs $Mdn = 1$, $p < 0.01$). Veterans completed an average of 5/10 calls (normally-distributed data). There was no significant difference between Non-White and White veterans in number of completed phone check-ins ($M = 5.11$ vs. $M = 5.81$, $p = 0.46$). Linear regression revealed significant positive relationships between age and number of days logged in ($F(1,55) = 7.12$, $p = 0.01$, $R^2 = 0.12$) and between age and number of modules accessed ($F(1,55) = 4.80$, $p = 0.03$, $R^2 = 0.08$). Age was not significantly related to other engagement variables. Gender was not significantly related to any of the engagement variables.

Conclusions: Non-white veterans with chronic pain demonstrated significantly less engagement with the Pain EASE program than White veterans. Older age was significantly related to increased engagement. Results were consistent with research on engagement in internet-based programs for other health problems, although data for pain programs are limited. The findings encourage further modification of Pain EASE to be more appealing to younger and racial/ethnic minority veterans.

EXAMINING INSOMNIA, PAIN SEVERITY, AND COPING STRATEGIES IN ETHNIC/RACIAL GROUPS WITH/AT RISK FOR KNEE OSTEOARTHRITIS.

Cesar Gonzalez, M.A.¹, Daniel A. Kusko, B.A.², Tyler Huang, n/a¹, Kimberly Sibille, PhD³, Roger Fillingim, PhD³, Burel R. Goodin, PhD¹¹The University of Alabama at Birmingham (UAB), Department of Psychology, Birmingham, AL; ²The University of Alabama at Birmingham, Birmingham, AL; ³Pain Research and Intervention Center of Excellence, University of Florida, Gainesville, FL

Background: Knee osteoarthritis (OA) is a degenerative, debilitating condition affecting functional mobility, pain, and quality of life. Factors contributing to health outcomes in knee OA populations include poor sleep quality and pain coping strategies. Cross-sectional studies have demonstrated significant associations among poor sleep quality and higher OA-related pain severity and fatigue; however, the extent to which associations among knee pain, sleep, and coping differ across ethnic/race groups remains unclear. The overall aim of this study was to examine associations among knee pain severity, insomnia severity, and pain coping strategies in non-Hispanic Black and non-Hispanic White adults with/at risk for knee OA. We hypothesized that (1) (NHB) participants would report greater insomnia, pain severity, and catastrophizing compared to NHW participants, and (2) the magnitude of correlations among pain, insomnia and pain coping would be different between ethnic/race groups.

Methods: We conducted a cross-sectional study of adults with/at risk for knee OA using community and clinic-based recruitment from two study sites both in the Southeastern United States. All participants (N = 188) provided sociodemographic data prior to completing the following validated measures: WOMAC, Insomnia Severity Index, Coping Strategies Questionnaire, and PROMIS-Anxiety and Depression.

Results: Mean age was 58 years; 37% were men and 63% women; 52% were NHB and 48% NHW. In an adjusted model controlling for anxiety, depression, and sleep medication use, results revealed that NHB reported significantly greater insomnia ($p = .015$), pain severity ($p < .001$), and catastrophizing ($p = .03$) than NHW. For both ethnic/race groups, greater insomnia severity was significantly associated with greater pain severity ($p < .001$) and catastrophizing ($p < .001$) but was not significantly associated with any adaptive coping strategies. The association between insomnia severity and catastrophizing was significantly stronger for NHW compared to NHB ($p = .03$).

Discussion: Previous literature has suggested that up to 81% of knee OA patients experience symptoms of problematic sleep, including insomnia. Results of this study suggest that NHB adults with/at risk for knee OA may be particularly vulnerable to experiencing greater insomnia and pain severity. Evidence-based behavioral pain management interventions that also address sleep may be beneficial for NHB adults with knee pain associated with OA.

EXAMINING THE MODERATING EFFECTS OF CANNABIS USE ON PHYSICAL ACTIVITY AND MOOD IN INDIVIDUALS WITH CHRONIC PAIN.

Maria Moylan, B.S.¹, Jessica Fales, Ph.D.¹¹Washington State University-Vancouver, Vancouver, WA

Objective: Recently there has been growing research and public interest in the health risks and benefits of cannabis use, including its links to physical functioning and mood. The aim of this study was to explore links between physical activity, cannabis use, and positive affect among a sample of young adult recreational cannabis users with chronic pain. We expected that greater participation in physical activity would be associated with more positive affect, but that increased frequency of cannabis use would act as a moderator reducing the significance of the relationship.

Methods: Participants (ages 18-29, 63% female) included 90 community-dwelling young adult cannabis users with chronic pain (defined as moderate or higher intensity pain of at least 3 months duration). All participants completed a set of questionnaires assessing their pain, levels of physical activity, mood state, and frequency of cannabis use. Bootstrap moderation models were conducted using the PROCESS macro.

Results: The vast majority of the sample (83%) reported using cannabis at least once per day and approximately half (53%) reported that their chronic pain was associated with significant activity limitations. Pain locations were predominantly musculoskeletal, though the vast majority of participants reported pain in across multiple locations and body regions. Within the total sample, higher physical activity was positively associated with positive mood ($r = .36$, $p < .001$), and frequency of cannabis use moderated this relationship ($b = -.0009$, 95% CI $[-.0016, -.0002]$, $t = -2.57$, $p = .01$). Positive mood was significantly related to physical activity when cannabis use was low and at the mean value ($p < .001$) but not at high levels of cannabis use ($p = .21$).

Conclusions and future directions: Participating in leisure physical activity is associated with positive mood in those with chronic pain; however, and this relationship may be dampened by more frequent cannabis use. Further investigation is warranted to determine whether and how cannabis affects physical activity and mood in young adults with and without chronic pain. Physical activity is an important component of treatment for young people in pain, and there may be a transactional relationship between engagement in physical activity and positive mood. If frequent cannabis use dampens that relationship, users with pain may be less likely to engage in physical activity over time. This remains to be tested.

BODY MASS AND ANXIETY SENSITIVITY PREDICT PERCEIVED EXERTION DURING EXERCISE AMONG INDIVIDUALS WITH OBESITY

Jacob D. Landers, M.A.¹, Jocelyn D. Shoemaker, M.A., M.P.H.², Brian C. Focht, PhD², Charles F. Emery, PhD³¹The Ohio State University, Dublin, OH; ²The Ohio State University, Columbus, OH; ³Ohio State University, Columbus, OH

Background: Regular physical exercise is important for individuals attempting weight loss, but some individuals with obesity are less likely to engage in exercise. Anxiety sensitivity (AS; i.e., fear of experiencing anxiety and its associated symptoms) is associated with higher ratings of perceived exertion (RPE) during acute exercise among treatment-seeking smokers. This study was designed to determine the extent to which BMI and AS predict RPE during exercise among individuals with obesity.

Methods: Forty-five individuals with obesity attempting to lose weight (mean age = 44.6±14.7 years; mean BMI = 39.2±6.2; 8 males) participated in two sessions (i.e. exercise and rest) approximately one week apart. Order of sessions was randomly assigned. During the exercise session, participants exercised on a treadmill for twenty minutes at moderate intensity; and during the rest session, participants read quietly for twenty minutes. Participants provided RPE at four-minute intervals during both sessions. Participants also completed the Anxiety Sensitivity Index – 3 (ASI-3), and had height and weight measured to calculate BMI. Residualized peak RPE scores represented the difference between peak RPE and predicted peak RPE during both exercise and reading sessions. Hierarchical regression analyses were performed predicting peak RPE scores in the exercise condition, controlling for peak RPE during reading. It was hypothesized that higher BMI and greater AS would predict higher peak RPE during exercise.

Results: Main effects were observed for BMI and AS, with higher BMI ($\beta = .89$, $p = .002$) and greater AS ($\beta = 3.21$, $p = .007$) associated with higher RPE during exercise. Also, there was a significant interaction of BMI and AS ($\beta = -3.27$, $p = .007$), but surprisingly, higher BMI and greater AS predicted lower peak RPE during exercise.

Conclusions: Lower RPE in the presence of higher BMI and greater AS may reflect reduced sensitivity to exertion during exercise among individuals with extreme obesity. However, lower BMI with greater AS was associated with higher RPE during exercise. Because heightened RPE may impair efforts to increase physical activity, individuals with less extreme obesity and greater AS may benefit from skills to help improve tolerance of exercise-related exertion.

THE EFFECTS OF AN URBAN FOREST HEALTH INTERVENTION PROGRAM ON PHYSICAL ACTIVITY AMONG ADOLESCENTS

Riki Tesler, PhD on Health Promotion¹¹Ariel University, Tel Aviv, Tel Aviv, Israel

Background: At-risk adolescents have been defined as youth who are or might be in physical, mental, or emotional danger. An Urban Forest Health Intervention Program (UFHIP) was formed at a center for at-risk adolescents in Israel, in order to promote physical activity and reduce risky behavior.

Objective: To evaluate the intervention's effect on physical activity, smoking, alcohol consumption, psychosomatic symptoms, and life satisfaction.

Methods: From 2015 to 2016, at-risk youth were nonrandomly selected to participate in the UFHIP. Questionnaires were administered to both intervention and control groups before and after the intervention. Univariate and multivariable analyses evaluated the intervention's effect.

Results: The study participants ($n=53$) showed 0.81 more sessions per week of 60 min of physical activity than did the control group ($n = 23$; $p = 0.003$). Among the intervention group, smoking frequency reduced from a mean of 2.60 ($SD = 1.30$) to 1.72 ($SD = 1.08$), whereas that in the control group increased from 3.17 (1.03) to 3.39 (1.03). In both groups, there was a reduction in alcohol consumption, with a greater change among intervention participants: -1.08 ($SD = 1.30$), compared with -0.09 ($SD = 1.79$) in the control group.

Conclusions: Findings indicate that the environmental intervention was efficacious in increasing physical activity and reducing risky behaviors among youth. The effectiveness of this intervention among larger samples is warranted in future prospective studies.

Keywords: urban forest; at-risk youth; risky behavior; physical activity; intervention; psychosomatic symptoms; life satisfaction

THE ELECTRONIC COMMUNITY PARK AUDIT (ECPAT) SYSTEM: A STAKEHOLDER VALUE ASSESSMENT OF PARK RESOURCE TECHNOLOGY

Gina Besenyi, MPH, PhD¹, Benjamin Schooley, PhD, MBA², Shirelle Hallum, PhD student², Sonja Wilhelm Stanis, PhD³, Sara Wilcox, PhD², Andrew T. Kaczynski, PhD²

¹Kansas State University, Manhattan, KS; ²University of South Carolina, Columbia, SC; ³University of Missouri, Columbia, MO

Parks are key physical activity (PA) behavior settings that confer numerous health benefits. However, maximizing this potential requires an accurate understanding of the current state of parks, and tools to connect stakeholders with these important public health resources. The purposes of this study were to describe a unique National Institutes of Health Small Business Technology Transfer (STTR)-funded collaboration of a small business and multiple public and academic partners to develop innovative technologies for improving and promoting community park resources, and report findings from a stakeholder value assessment of the resulting electronic Community Park Audit Tool (eCPAT) System with expert end users. Researchers from multiple disciplines partnered with a technology company (EnQ) to develop the eCPAT System, a comprehensive set of mobile technologies for collecting, sharing, managing, and promoting park information. The eCPAT System consists of a park audit mobile application, secure server and database, public searchable website with map-based visualization of park information, and client-facing web interface to view, modify, and export data. Guided by researchers, stakeholder assessment data of the eCPAT System were collected in Summer 2019 by a technology consulting firm. Diverse end users (e.g., PA researchers, parks and recreation professionals; n=9) were interviewed via phone to assess technology needs, preferences, barriers, and product value. The majority expressed a need for eCPAT technology in the commercial marketplace, with importance placed on collecting and reporting park data to demonstrate funding needs, track improvements, allocate resources, and share with policymakers. Preferences included mobile data collection, report generating, benchmarking against other agencies, customizing questions, and integration of eCPAT with other technologies. Challenges included staff training, merging datasets, and lack of funding for park initiatives. The eCPAT System represents strategic partnerships from diverse sectors to provide valid and innovative tools for PA and health promotion. End users found value in the eCPAT System stating that data allow them to compete for funds and justify expenditures. Results inform ongoing efforts to advance park PA resources. Future steps include integration of eCPAT in park prescriptions initiatives, real estate decision-making, ongoing research studies, and citizen-science efforts to advance the value of parks in promoting PA and public health.

THE SELF-AS-DOER IDENTITY: PREDICTING PHYSICAL ACTIVITY ABOVE AND BEYOND SOCIAL COGNITIVE AND SELF-DETERMINATION THEORIES

Amanda M. Brouwer, Ph.D.¹, Abigail Benventuo, n/a¹, Danielle Langworthy, n/a², Elizabeth Schmitt, n/a¹

¹Winona State University, Winona, MN; ²Winona State University, Winona, MN

Introduction: Physical activity (PA) is associated with many benefits including reduced disease risk, better sleep, and improved mental and physical health. Yet only 53.3% of adults are meeting the recommended guidelines for PA (CDC, 2018). Psychosocial interventions based on theoretical models like the social cognitive theory (SCT) and self-determination theory (e.g., intrinsic and controlled motivation) have had success in predicting PA, but some variability in the degree to which PA is adopted and maintained still exists. A recently developed construct, the self-as-doer identity, may provide additional insight. The self-as-doer identity is a motivational identity which describes an individual in terms of identification with *doing* a behavior. The self-as-doer has been found to predict PA, but whether it can predict PA beyond existing theories is yet untested. Therefore, it was hypothesized that the self-as-doer identity would predict both moderate and vigorous PA above and beyond variables from SCT and self-determination theories.

Methods: Sixty undergraduates ($M_{age}=20.66$, $SD=3.87$) completed a survey assessing physical activity, self-regulation, outcome expectancies, self-efficacy, motivation, and self-as-doer identity. A hierarchical linear regression model was conducted to determine if self-as-doer identity predicted moderate and vigorous PA above and beyond SCT and self-determination variables.

Results: Self-as-doer identity predicted an additional 4.4% of the variance in vigorous PA over and above the SCT variables and control and intrinsic motivation, ($\Delta R^2=.044$, $F(1,47)=5.90$, $p=.02$). It was not, however, a predictor of moderate PA ($\Delta R^2=.02$, $F(1,47)=1.77$, $p=.19$).

Discussion: The self-as-doer identity contributes unique variance in PA behaviors, especially vigorous PA, and may serve as an additional intervention for promoting the enactment and maintenance of PA behaviors. The self-as-doer identity did not predict moderate PA behaviors (e.g., brisk walking). It may be that moderate PA behaviors have fewer barriers to overcome and may not require the additional motivation provided by the doer identity to enact. The universal nature of the self-as-doer identity makes it easily translatable to other health behaviors like healthy eating, but more research is needed to determine these relationships as well as the causal effects of the doer identity on health behaviors.

PARENT PHYSICAL ACTIVITY IS NOT RELATED TO PHYSICAL ACTIVITY OF ADOLESCENTS WITH INTELLECTUAL AND DEVELOPMENTAL DISABILITIES.

Lauren Ptomey, PhD¹, Anna M. Gorczyca, PhD¹, Joseph Sherman, MS¹, Richard A. Washburn, PhD¹, Joseph Donnelly, EdD¹

¹University of Kansas Medical Center, Kansas City, KS

Background: Levels of moderate-to-vigorous physical activity (MVPA) are low in both typically developing adolescents and adolescents with intellectual and developmental disabilities (IDD). Intervention strategies are needed to increase MVPA in adolescents with IDD. Interventions to increase MVPA by targeting parental MVPA have been the subject of an increasing body of research. In typically developing adolescents, accelerometer derived measures of physical activity have found that parents' MVPA predicts MVPA of their children. However, this relationship has never been examined in adolescents with IDD, who have unique barriers to MVPA. The purpose of this analysis was to examine the relationship between parental and adolescent MVPA in adolescents with IDD.

Methods: To assess physical activity levels, adolescents (ages 10-21) with IDD and a parent were instructed to wear an ActiGraph Model GT3+ (ActiGraph LLC, Pensacola, FL) for 7 consecutive days. Accelerometer data was collected in 1-min epochs with a minimum of 8 hours constituting a valid monitored day. Participants with less than 3 valid days were excluded from the accelerometer data analysis. The average number of minutes/day in MVPA were calculated using a custom software program developed by our group. The Freedson intensity cut-points were used in individuals >18 years of age and the Troiano intensity cut-points were used for individuals ≤ 18 years of age.

Results: Accelerometer data was collected from 53 adolescents with IDD (~16 yrs of age, 53% female) and a parent (~48 yrs of age, 93% female). Thirty-nine adolescents and 42 parents had at least 3 valid days and were included in our analysis. Adolescents obtained 22.2 ± 25.4 minutes of MVPA per day and parents obtained 13.7 ± 13.8 minutes of MVPA per day. There was no significant correlation between parent and adolescent MVPA ($r=0.112$, $p=0.5138$). Additionally, age ($p=0.137$), sex ($p=0.940$), and parent's employment status ($p=0.926$) were not associated with the relationship between parent and adolescent MVPA.

Discussion: Adolescents with IDD obtained 37% of the recommended 60 minutes of MVPA per day. These low levels of MVPA adds to the evidence that interventions in adolescents with IDD are warranted. Unlike the typically developing population, parental MVPA does not appear to predict MVPA in adolescents with IDD. Thus, physical activity interventions should target adolescents with IDD themselves, and not just the parent.

DIFFERENCES IN RESISTANCE TRAINING AND PERCEIVED BARRIERS TO PHYSICAL ACTIVITY AMONG LGBTQ AND NON-LGBTQ COLLEGE STUDENTS

Ginny M. Frederick, M.S.¹, Isaura M. Castillo-Hernández, M.Sc.¹, Ewan Williams, MSc, MPT¹, Anneliese Singh, PhD², Ellen M. Evans, PhD¹

¹University of Georgia, Athens, GA; ²University of Georgia, Avondale Estates, GA

Purpose: Health disparities in rates of chronic disease exist for adult members of the lesbian, gay, bisexual, transgender, and queer (LGBTQ) community across the lifespan. Lifestyle health behaviors, including engaging in sufficient physical activity (PA) and exercise (EX), are known to prevent chronic diseases, especially if adopted earlier in life; however, little is known about PA/EX behaviors in the LGBTQ population. Thus, the aim of this study was to compare PA/EX behaviors, and related perceived benefits and barriers, in LGBTQ and non-LGBTQ college student cohorts.

Methods: Self-identified LGBTQ ($n = 54$; 19.7 ± 1.4 yo) and non-LGBTQ college students ($n = 286$; 20.2 ± 1.3 yo) completed online surveys: a) Exercise Benefits and Barriers Scale (EBBS) and b) International Physical Activity Questionnaire (IPAQ) with subsequent MET-min/wk and days of resistance training (RT) scores being calculated. T-tests were used to compare PA levels and EBBS scores of LGBTQ and non-LGBTQ students.

Results: Regarding PA, there were no differences in MET-min/wk for LGBTQ and non-LGBTQ students (2376.5 ± 1626.8 vs. 2722.8 ± 1610.5 ; $p = 0.149$); however, LGBTQ students reported significantly fewer days of RT than non-LGBTQ students (1.5 ± 1.9 vs 2.1 ± 2.0 , respectively; $p = 0.047$). Total EBBS scores were 4.4% lower among LGBTQ students while Barriers scale scores were 12.8% higher than non-LGBTQ students ($p = 0.005$ and $p < 0.001$, respectively), indicating less positive perceptions of, and higher perceived barriers to PA in this group. Further, compared to non-LGBTQ students, LGBTQ students reported higher perceived barriers scores on the Exercise Milieu, Time Expenditure, and Physical Exertion sub-scales of the EBBS ($p < 0.001$; $p = 0.012$; and $p = 0.012$, respectively), suggesting these as areas of particular concern.

Conclusion: College student members of the LGBTQ community report more barriers to PA/EX than their non-LGBTQ counterparts. This research highlights the presence of unique needs of college-aged LGBTQ individuals for promotion of PA/EX by addressing such barriers. Further research may be necessary to fully understand the context of these barriers and inform program development toward the end of increased participation in PA/EX, specifically RT, among LGBTQ college students.

WOMEN'S ACTIVE LIVING FOR KOREANS PILOT STUDY USING MOBILE TECHNOLOGIES TO PROMOTE PHYSICAL ACTIVITY AND SOCIAL NETWORKING

JiWon Choi, PhD, RN¹, Juhyun Cho, BS², Nah-Mee Shin, PhD³, Jane Jih, MD, MPH, MAS⁴, Janice Y. Tsoh, PhD¹¹University of California, San Francisco, San Francisco, CA; ²UCSF, Berkeley, CA; ³Korea University, Seoul, Seoul-t'ukpyolsi, Korea; ⁴UCSF, San Francisco, CA

Background: The risk of metabolic syndrome has significantly increased among Korean Americans (KAs) due to the adoption of unhealthy westernized lifestyle habits. Lifestyle modification including regular physical activity (PA) reduces the risk of metabolic syndrome, but little research has been done among KAs. In addition, lack of physical activity is prevalent among KAs, especially, women. Thus, a lifestyle program called Women's Active Living for Koreans (WALK) was developed and tested in a pilot randomized controlled trial with 40 physically inactive KA women in the San Francisco Bay Area. The purpose of the study was to examine the feasibility and acceptability of WALK.

Methods: A community advisory board (CAB) was formed of 8 KA women with diverse backgrounds who represent different community organizations. The CAB provided feedback on study procedures and recruitment strategies before the trial started, and on study findings at the conclusion of the trial. Participant inclusion criteria were: 1) self-identified KA women; 2) sedentary lifestyle at work and/or during leisure time defined by the Stanford Brief Physical Activity Survey; 3) 40-69 years old; 4) intention to be physically active defined by the Physical Activity Stages of Change; and 5) having a smartphone compatible with KakaoTalk, a popular mobile messaging application among Koreans. Forty women (mean age=48.4 ± 6.3 years) were randomized to one of two groups, WALK-plus and WALK-regular. Both conditions included an in-person session, handout regarding metabolic syndrome and its management, weekly challenge sheets, and an accelerometer (Fitbit Zip). Only women assigned to the WALK-plus group were invited to a closed online community via NAVER BAND, a popular social media app among Koreans and posted comments on the research team's and other participants' posts and encouraged other to increase PA.

Results: All WALK-plus group women joined closed online communities and nearly everyone (95%) posted at least once during the 4-week study period. Thirty-seven women (93%) completed the post-test visit. More than 3 in 4 (78%) used Fitbit at least 70% of the time for 4 weeks. Majority of women (90%) of the WALK-plus group (n=20) reported that BAND-related activities were helpful in increasing their PA. Thirty-nine women completed the usability questions and all of them responded that the WALK program was helpful in increasing PA and they would recommend it to other women like them. All women reported having an in-person meeting and use of Fitbit helpful.

Conclusion: Overall, the WALK program was feasible and acceptable among KA women. Most of the WALK-plus participants were highly engaged in online social networking despite of the moderate assignments requested for the participants. We should investigate how to build online social networks among KA women and what components should be included to form online communities to promote PA.

A SYSTEMATIC REVIEW OF THE RELATIONSHIPS BETWEEN PHYSICAL ACTIVITY AND SLEEP IN YOUTH

Christine W. St. Laurent, MPH, PhD¹, Katrina Rodheim, BA¹, Rebecca Spencer, PhD¹¹University of Massachusetts Amherst, Amherst, MA

Background: In adults, higher levels of physical activity are associated with better sleep outcomes, and more or better quality of sleep is associated with higher levels of physical activity. However, there is not yet a consensus of the influence of sleep on physical activity outcomes or physical activity on sleep outcomes in childhood.

Purpose: The aim of this systematic review was to examine the relationships between physical activity and sleep in children and adolescents.

Methods: A systematic literature search was conducted with a predefined list of keywords in PubMed, PsycINFO, and Web of Science for articles published between January 1, 1980 and July 15, 2019. Articles were included if participants were under 18 years, published in English, and used an observational (cross-sectional, cohort, and case-control) or experimental (acute bout or intervention) study design. Articles were excluded if participants were mostly or only adults, primarily a clinical population (e.g., diagnosed sleep or cardiometabolic disorders), or the study design was a case study or case series report. The GRADE framework was used to assess study quality.

Results: A total of 111 studies (conducted in 36 countries), from 99 articles met the inclusion criteria. Fifty-eight out of the 111 studies examined physical activity or fitness exposures with sleep outcomes (n = 37 cross-sectional, 4 longitudinal, 1 acute bout experimental, and 16 intervention experimental). Among the 58 studies with sleep outcomes, 16, 23, 16, and 3 reported favorable, mixed, null, and negative findings, respectively. Fifty-three studies examined sleep exposures with physical activity or fitness outcomes (n = 32 cross-sectional, 4 longitudinal, 4 acute bout experimental, and 13 intervention experimental). Among the 53/111 studies on physical activity and fitness outcomes, 14, 20, and 19 reported favorable, mixed, and null findings, respectively. Most studies included preadolescents (n = 56) and adolescents (n = 60), while fewer included infants (n = 5), toddlers (n = 8), and preschoolers (n = 22). Across study designs and outcomes, quality of evidence ranged from very low to high.

Conclusions: Although there is some evidence of interactive relationships between sleep and physical activity in youth, the high prevalence of mixed and null results could be related to study limitations. Additional higher quality studies and more studies in early childhood are needed.

“WE’RE ALL IN THE SAME BOAT TOGETHER”: EXPLORING QUALITY PARTICIPATION IN DRAGON BOAT TEAMS FOR BREAST CANCER SURVIVORS

Angela Fong, PhD¹, Hailey Saxton, BSc.², Kaitlyn D. Kauffeldt, MSc¹, Catherine Sabiston, PhD³, Jennifer Tomasone, PhD¹¹Queen’s University, Kingston, ON, Canada; ²Queen’s University, Seneca Falls, NY; ³University of Toronto, Toronto, ON, Canada

Dragon boat is suitable for breast cancer survivors as it is associated with increased social support and wellbeing and offers an opportunity for increase physical activity (PA; quantity participation). However, quality participation experiences in PA have yet to be explored systematically in breast cancer survivors. Quality participation is one’s subjective perceptions and experiences in PA. A conceptual framework to promote a quality experience has been developed in the parasport context. The framework identified elements (i.e., autonomy, belongingness, challenge, engagement, mastery and meaning) and conditions (i.e., physical environment, within the activity and social environment) to foster quality participation. While there is evidence to suggest that dragon boat may offer a quality experience, a systematic approach exploring it is needed.

Purpose: (a) to explore strategies that are used to foster elements of quality participation in dragon boat teams for breast cancer survivors and (b) to understand the context in which these strategies are implemented within these teams (i.e., conditions).

Methods: The study used a sequential mixed-methods study design with an online questionnaire followed by a structured interview. Coaches and team leaders ($N=11$; collectively “leaders”), were recruited from seven dragon boat programs for breast cancer survivors in Ontario, Canada. Transcripts were inductively thematically analyzed and then deductively mapped onto the quality participation framework. A constructivist paradigm was adopted to acknowledge multiple realities within the different dragon boat teams.

Results: Several strategies mapped onto the original framework; however, definitions were revised to suit the current context. Leaders fostered quality participation through challenge, mastery, and the social and physical environments. Some strategies included creating friendly competition, using social media to celebrate success and mentorship opportunities. Strategies that did not map onto the framework, included dragon boat providing an opportunity to feel validated, to be in nature (physical environment) and aspects of the sport specifically related to breast cancer (within the activity).

Discussion: Through leaders’ experiences, a clearer understanding of the quality participation framework within the breast cancer context has developed. Future research can explore and test strategies identified from the study for consistency and relative importance.

24-HOUR MOVEMENT BEHAVIORS: DYNAMICS OF SLEEP, SEDENTARY BEHAVIOR AND MVPA ON SCHOOL VS. NON-SCHOOL DAYS.

Bridget Armstrong, PhD¹, Michael Beets, M.Ed, MPH, PhD¹, Keith Brazendale, PhD², Brie Turner-McGrievy, PhD, MS, RD¹, Russell Pate, PhD¹, Alberto Maydeu-Olivares, Ph.D.¹, Brian Saelens, Ph.D.³, Shawn Youngstedt, PhD⁴, R G. Weaver, Ph.D.¹¹University of South Carolina, Columbia, SC; ²University of Central Florida, Orlando, FL; ³University of Washington / Seattle Children’s Research Institute, Seattle, WA; ⁴ASU, Phoenix, AZ

Background: Sleep, physical activity and sedentary behavior exist on an interdependent 24-hour movement continuum that mutually influences health. Studies examining movement behaviors on school days compared to non-school days have often examined these behaviors separately, ignoring their interrelated nature (i.e. MVPA accounting for sleep/sedentary) and dynamics (i.e. the impact of previous day behavior on current behavior). Neglecting components of the movement continuum such as sleep and sedentary time, and the interrelated dynamics within-individuals, limits our ability to optimize the health benefits of movement behaviors. This study examines the impact of school day (v. non-school day) on behaviors across the movement continuum.

Methods: Time series data from Fitbits (Charge-2) were collected from 196 children over 6,642 days as part of a larger school-based study. The sample was 53% female, 5-10yrs; zBMI $M = 0.75$ ($SD = 1.2$). Dynamic Structural Equation Modeling was used to simultaneously examine the effects of school on 24-hour movement behaviors (sleep, sedentary behavior and MVPA) accounting for previous day’s behavior.

Results: Within participant analysis showed that on a school day, any given child generally (1) slept less ($\beta = -.17$, 95%CI $-.21$ to $-.13$), (2) was less sedentary ($\beta = -.05$, 95%CI $-.09$ to $-.02$), and (3) did not have a significant change in MVPA ($\beta = -.05$, 95%CI $-.11$ to $.00$) compared to their own behavior on a non-school day. Between participant analysis showed that children with higher zBMI experienced a relatively larger decrease in sedentary behavior on their school days ($\beta = -.41$, 95%CI $-.64$ to $-.13$). Compared to more active children, children with lower overall levels of MVPA accumulated more MVPA on their school days compared to their non-school days ($\beta = -.41$, 95%CI $-.64$ to $-.13$).

Conclusions: Movement patterns among school age children differ on school v. non-school days. The magnitude of the associations between school day and movement behaviors is related to average MVPA and zBMI. The finding that, on school days, children with higher zBMI had an ever greater reduction in sedentary behavior (compared to kids with lower zBMI), and children who were less active compared to their peers accumulated more MVPA on school days, may indicate that the regulated and consistent (i.e., structured) environment afforded by school is most beneficial for children at the highest risk for overweight or obesity.

SENIOR CENTER DIRECTORS' PERCEPTIONS OF THE SUSTAINABILITY OF BAILAMOS™ DANCE PROGRAM

Guilherme M. Balbim, MS¹, Martha G. Garcia, n/a², Susan Aguiñaga, PhD³, Priscilla Vásquez, PhD, MPH⁴, Isabela G. Marques, PhD⁵, Jacqueline Guzman, MS³, David X. Marquez, PhD, FGSA, FACSM, FSBM¹

¹University of Illinois at Chicago, Chicago, IL; ²Department of Kinesiology and Nutrition, University of Illinois at Chicago, MONTGOMERY, IL; ³University of Illinois at Urbana-Champaign, Urbana, IL; ⁴University of California San Diego, San Diego, CA; ⁵University of Victoria, Victoria, BC, Canada

Prior research indicates the need for community-based physical activity (PA) programs for older Latino adults. Older Latinos participate in less leisure-time PA compared to non-Latino Whites and Blacks. Addressing barriers to the sustainability of PA programs might increase PA access. We aimed to identify and describe the perceived positive and negative aspects and the sustainability factors of the BAILAMOS™ dance program.

Methods: BAILAMOS™ was implemented in 12 centers (senior, community, and church-based) in the Chicago area. Participants were 333 older Latinos (≥ 55 years old) randomized to the BAILAMOS™ (n = 166) or health education (n = 167) group. BAILAMOS™ participants attended twice a week dance classes (merengue, bachata, cha-cha-cha, and salsa) in a four-month adoption phase led by a professional dance instructor and a four-month maintenance phase. Participants were trained by the instructor to lead the classes in the four-month maintenance phase. After maintenance, we conducted semi-structured interviews with senior center directors at one-month post-maintenance completion (n=10), and six-month post-maintenance completion (n=9). Two directors at one- and three at six-month post-maintenance had schedule conflicts or declined to participate. Questions focused on sustainability, positive, and negative aspects of the program. Interviews were audio-recorded, transcribed, and analyzed using a thematic analysis approach.

Results: At one-month post-maintenance, seven centers had ongoing peer-led dance classes as a result of BAILAMOS™. At six-month post-maintenance, five centers had ongoing peer-led dance classes. Findings from the interviews indicated that sustainability factors at one- and six-month post-maintenance included: effective instruction, available and convenient environment, interest/enjoyment, social interaction, and perceived benefits. Key factors for program discontinuation included: competing activities, undesirable weather, and lack of leadership. Positive aspects of BAILAMOS™ included: age- and culturally-relevant activity, enjoyable PA, and social interaction. Negative aspects included: lack of instruction and participant disinterest over time.

Conclusions: Offering instructor-led, age- and culturally-relevant PA were pivotal to create a sustainable program for older Latinos. These findings can help researchers and community centers design and offer sustainable programs to improve older Latinos' overall health.

MODERATING EFFECTS OF SOCIAL SUPPORT AND STRESS ON PHYSICAL ACTIVITY IN AFRICAN-AMERICAN WOMEN

Asia Brown, BS¹, Dawn K. Wilson, PhD¹, Allison Sweeney, PhD¹

¹University of South Carolina, Columbia, SC

In the US, African-American women participate in less physical activity (PA), have higher rates of chronic disease, and report higher perceived chronic stress relative to other race and sex demographic groups. Lack of adherence to a PA routine may be associated with high levels of perceived stress. Thus, the purpose of the present study was to test a stress buffering hypothesis on PA engagement in African American women. The stress buffering hypothesis purports that the presence of social support should buffer the negative effects of stress, but only under high stress conditions. The current study examined a moderating relationship of perceived stress and perceived social support on moderate-to-vigorous physical activity (MVPA) in African-American women. Based on the stress-buffering hypothesis, the current study tested the hypothesis that social support would buffer the negative effects of perceived stress on MVPA under high, but not low, stress conditions. Participants were 114 female African-American caregivers with a mean age of 44.60 years (SD=8.45) and an average BMI of 37.96 (SD=8.11) enrolled in the Families Improving Together for Weight Loss Trial. The Perceived Stress Scale (PSS) was used to assess caregiver perceived stress and has demonstrated validity in African-Americans. The Multidimensional Scale of Perceived Social Support (MSPSS) was used to assess social support and has demonstrated validity in African-Americans. Average daily minutes of MVPA was assessed via 7-day accelerometers estimates. A hierarchical linear regression, controlling for demographic data, was significant and explained a significant portion of the variance in MVPA ($R^2 = 0.27$, $F(8, 118) = 5.23$, $p < 0.001$). The stress-by-social support interaction term in the model ($\beta = 0.28$, $p < 0.001$) demonstrated significant effects and indicated that perceived stress and perceived social support have a moderating effect on MVPA. Simple slope analyses showed that under low stress, social support was not significantly associated with MVPA ($t = -1.97$, $SE = 0.11$, $p = 0.06$), however, under high levels of stress, social support was positively associated with MVPA ($t = 2.12$, $SE = 0.15$, $p = 0.03$). Findings highlight the importance of integrating constructs of stress and social support into future intervention programs for African American women.

PREDICTORS OF PHYSICAL ACTIVITY IN CANCER SURVIVORS: META-ANALYSIS AND META-ANALYTIC STRUCTURAL EQUATION MODELING OF STUDIES

Rachel Hirshey, PhD¹, Ashley L. Bryant, PhD, RN², Catherine Macek, BSN, RN³, Claudio Battaglini, PhD, FACS⁴, Shelia Santacroce, RN, PhD⁵, Kerry S. Courneya, PhD⁶, Jennifer Walker, MSIS⁷, Aya Avishai, B.S.⁴, Pachal Sheeran, MA, PhD⁸

¹University of North Carolina at Chapel Hill, Durham, NC; ²The University of North Carolina at Chapel Hill, DURHAM, NC; ³Nicklaus Children's Hospital, Miami, FL; ⁴University of North Carolina at Chapel Hill, Chapel Hill, NC; ⁵UNC-Chapel Hill, Chapel Hill, NC; ⁶University of Alberta, Edmonton, AB, Canada; ⁷Health Sciences Library, University of North Carolina, Chapel Hill, NC; ⁸UNC Chapel Hill, Chapel Hill, NC

Objective: The purpose of this project is to understand psychosocial predictors of physical activity among cancer survivors. Through meta-analyses and meta-analytic structural equation modeling, the following is presented: (1) quantification of associations between psychosocial predictors and physical activity, (2) a model of how psychosocial predictors combine to influence physical activity, and (3) an exploration of study, demographic, and clinical characteristics that moderate associations.

Methods: This project was registered in Prospero and conducted according to PRISMA guidelines. Systematic literature searches were conducted by a medical librarian in PubMed, Web of Science, Embase, SportDiscus, PsycInfo, and CINAHL. Search terms for psychosocial constructs, physical activity, cancer, and longitudinal design were used. Initial search yielding 2,431 records were reviewed for inclusion. Those that used a longitudinal, observational design, included a sample of cancer survivors, and measured both a psychosocial predictor at baseline and physical activity at a later time-point were retained. A final 25 studies ($N = 5,897$) met inclusion criteria and were retained for inclusion. Two researchers independently abstracted data for analyses. Random effects meta-analyses and meta-analytic structural equation modeling were conducted.

Results: Most studies included survivors of breast cancer, who had completed curative treatment or samples including both participants who had completed and were receiving treatment. Eight psychosocial predictors of physical activity were identified including intentions, self-efficacy, attitudes, affective attitudes, instrumental attitudes, injunctive norms, descriptive norms, social support and past behavior. In bivariate analyses, self-efficacy and intentions ($r_+ = 0.26$, $r_+ = 0.33$, respectively) were the strongest predictors of physical activity. Attitudes, injunctive norms, self-efficacy, intentions, and physical activity ($k = 22$, $N = 4,385$) are included in the structural equation models. All specified paths are significant. The self-efficacy-physical association relation was moderated by sample age. The intention-behavior relation was moderated by BMI. No other moderation effects were observed.

Conclusion: These findings can be used to design physical activity interventions for cancer survivors. Results indicate that strengthening intentions and enhancing self-efficacy are likely to be effective. Further, interventions may be strengthened by testing volitional strategies such as self-monitoring and implementation intentions.

EARLY MULTISPORT PARTICIPATION IN YOUNG ADULTS: A PATH ANALYSIS OF POTENTIAL HEALTH BENEFITS

Jonathan North, n/a¹, Daniel Palac, PhD², Sean P. Mullen, PhD³

¹University of Illinois at Urbana-Champaign, Monticello, IL; ²Exponent, Urbana, IL; ³University of Illinois at Urbana-Champaign, Urbana, IL

Approximately 60 million children play organized sports in the U.S. Evidence is growing that early specialization in sport is associated with injury, burnout, and disengagement from physical activity. These statistics are alarming, as continued patterns of inactivity are associated with poor health in adulthood. However, the benefits of multisport participation are not well established and children who are considered “gifted athletes” could be less susceptible to injury, have higher motivation, or play more sports. The purpose of this cross-sectional study was to test a novel theoretical model that multisport participation contributes to greater rates of physical activity through less physical dysfunction and more use of physical activity regulation strategies. To test this hypothesis, 894 adults ($M_{age} = 21.01 \pm 2.35$; 52% female) completed an online survey assessing demographic information, number of organized sports played between ages 3-18, physical activity (*Godin Leisure-time Exercise Questionnaire* (GLTEQ)), *Physical Activity Self-Regulation Questionnaire* (PASR), *Hospitalized Anxiety and Depression Scale*, *Multifactorial Memory Questionnaire* (memory mistakes subscale), concussion history and functional difficulties in walking and lifting. A path model was tested using Mplus (version 8.1) such that GLTEQ was regressed on demographics, concussion history, perceptions of mental health and memory, physical function, sport achievement, number of sports played and PASR, with all indirect effects specified between outcomes and #sports. The model fit the data ($\chi^2 = 3.566$ ($df=2$) $p > .05$, CFI = 0.993, RMSEA = .030, SRMR = .007) and the pattern of significant pathways supported the hypothesis. The direct effect of #sports on GLTEQ was not significant ($p = .054$), yet significant indirect pathways via physical dysfunction and PASR, and via PASR, were found. Despite #sports showing a low positive association with concussion, #sports was negatively associated with memory mistakes, and not associated with depressive symptoms. The findings suggest that greater number of sports played from ages 3-18, the better one's self-reported physical & cognitive health, and engagement in physical activity and self-regulatory strategies to maintain it (regardless of demographics and “talent” via achievement). The cross-sectional design of this study precludes any causal inferences, but results are promising. Further research on multisport effects is warranted.

DAILY MINDFULNESS AND ITS RELATIONSHIP TO DAILY PHYSICAL ACTIVITY

Adam D. Harris, MA¹¹University of Colorado Denver, Clinical Health Psychology PhD Program, Denver, CO

Existing cross-sectional and intervention research has demonstrated a link between trait mindfulness and physical activity between persons, as well as associations between state mindfulness and various affective and self-regulatory mechanisms within persons, but to date, there have been no studies exploring the within-person relationship between mindfulness and health behaviors on a day-to-day basis. This study investigated the relationship between daily mindfulness and daily physical activity, using a novel conceptualization of mindfulness that draws from both trait and state theories. Participants ($n=157$) were undergraduate college students who completed an 11-day daily diary protocol. Results demonstrated day-to-day within-person fluctuations in mindfulness, as well as a moderate correlation between daily mindfulness and trait mindfulness. Individuals exercised more on days in which their daily mindfulness was higher (approximately 12 minutes additional moderate-to-strenuous physical activity for each 1-point increase on a 4-point mindfulness scale), and this association was stronger among individuals who exercise regularly. Potential mechanisms are discussed which draw on extant mindfulness/health behaviors, trait/state, and exercise/attentional strategies research. Future directions for the development of mindfulness measures that can more accurately predict changes in health behaviors are also discussed. Health behaviors require day-to-day maintenance, and therefore gaining an understanding of the relationship between day-to-day fluctuations in health behaviors and mindfulness will help to inform the development of future mindfulness-based health behavior interventions.

CHANGES IN PHYSICAL ACTIVITY FOLLOWING A SEDENTARY INTERVENTION IN BREAST CANCER SURVIVORS (PLAN TO STAND)

Jessica Gorzelitz, MS¹, Diana Kellum, MS², Amye J. Tevaarwerk, MD³, Mary Sesto, PT, PhD⁴, Ronald Gangnon, PhD⁴, Lisa Cadmus-Bertram, Ph.D.⁵¹University of Wisconsin-Madison, Madison, WI; ²Profile by Sanford, Rapid City, SD; ³University of Wisconsin, Madison, Madison, WI; ⁴University of Wisconsin, Madison, WI; ⁵University of Wisconsin - Madison, Madison, WI

Background: Strategies for reducing sedentary behavior include breaking up sedentary time and reducing total volume of sedentary activity. Reducing sedentary behavior can lead to compensatory behaviors including standing more, doing more activity or sleeping more. The purpose of this investigation was to analyze the accelerometer-measured physical activity for breast cancer survivors in a trial of reducing sedentary behavior, focusing on light and moderate-vigorous physical activity (MVPA) intensities.

Methods: This randomized controlled trial ($n = 60$) had three groups including a (1) reducing total volume of sedentary time using a standing desk, (2) re-patterning sedentary times by breaking up long periods of sitting, and (3) no-treatment control. Physical activity (PA) was measured via Actigraph wGT3x-BT accelerometer at baseline and after 8 weeks of intervention. PA was analyzed in SAS 9.4 using linear mixed effect modeling to account for repeated measures.

Results: On average, participants were $57.0 (\pm 7.8)$ years of age, with mean BMI of $29.6 (\pm 9.7)$ kg/m² at baseline. Mean time since diagnosis was $4.5 (\pm 3.7)$ years. Participants in the three groups did not differ with respect to key demographic or clinical characteristics. Ninety-five percent of participants completed accelerometer wear. Baseline to 8-week change in weekly minutes of MVPA was -35.6 ± 18.8 in Group 1, 10.6 ± 18.7 in Group 2, and 12.1 ± 24.2 in Group 3. Light-intensity activity changed by -75.8 ± 45.7 , -5.8 ± 33.5 , and -33.3 ± 25.0 , respectively. While the changes were not statistically significant, the effect sizes (compared to the control group) for MVPA in group 1 was 0.23, compared to -0.12 in group 2. The effect size for light PA in group 1 was 0.21, and for light PA in group 2 the effect size was -0.0.

Conclusions: The focus of this intervention was reducing sedentary behavior, and as a manipulation check compensatory light or moderate-vigorous physical activity changes were not observed in these breast cancer survivors. Participants in this study were very active, completing more than the federally recommended levels of physical activity at both measurement points. The intervention did not target physical activity, thus these results are expected. To increase physical activity, the intervention needs to focus on that behavior. Standing time and sleeping time was recorded and additional analyses will include changes in those behaviors as well.

CHANGES IN SLEEP QUALITY AMONG CANCER SURVIVORS FOLLOWING A CLINICALLY IMPLEMENTED EXERCISE PROGRAM

Mary Hidde, MS¹, Ryan Marker, PT, PhD², Heather J. Leach, PhD³¹Colorado State University, Fort Collins, CO; ²University of Colorado Anschutz Medical Campus, Aurora, CO; ³Colorado State University, Fort Collins, CO

Purpose: Many cancer survivors report poor sleep quality during and following treatment(s). Exercise may improve sleep, but changes in sleep quality following a clinically implemented cancer exercise program, or the impact of change in physical fitness on sleep quality is not well understood. This study examined changes in sleep quality among cancer survivors following a 12-week exercise program, and associations of these changes with fitness responses.

Methods: The BfitBwell exercise program consists of supervised combined aerobic and resistance exercise sessions, 2x week for 1-hour, for individuals undergoing or within 6-months of cancer treatment. Sleep quality was self-reported using the following questions: How often do you awaken during the night [1 (never) – 5 (> 2 times/night)]? During the past 4-weeks, how would you rate your sleep quality [1 (very poor) – 5 (very good)]? Fitness was assessed by grip strength and the 6-minute walk test (6MWT). Wilcoxon Signed-Rank tests were conducted separately for each sleep question to examine changes in participants' categorical responses from pre- to post-program. Participants were classified as did or did not achieve clinically meaningful improvements in grip strength (≥ 67.98 kg) or 6MWT (≥ 30.5 m). Changes in sleep responses were compared between these two groups.

Results: N=36 completed pre- and post-program measures of sleep and fitness (MAge = 52.7 ± 13.0 years, MBMI = 25.8 ± 5.2 kg/m², 38.9% breast cancer). At pre-, 47.3% reported awakening at least once per night and 25% rated their sleep as poor or very poor. From pre- to post-, there was no change in the number of participants who reported how often they awoke during the night ($p=.523$), or how they rated their sleep quality ($p=.847$). Among participants who increased grip strength by ≥ 67.98 kg (N=8), 87% rated sleep quality as "good" post-program, compared to 75% at baseline ($p=.059$).

Conclusion: Sleep quality may improve for those who achieve a clinically relevant increase in grip strength following an exercise program. Limitations were a small sample size, self-report measure of sleep, and low prevalence of sleep disturbance at baseline. Future studies should use objective measures of sleep, ensure compliance to exercise programming in order to elicit changes in fitness outcomes, and target cancer survivors who report poor sleep quality at baseline.

INFLUENCE OF WEEKEND SITTING TIME AND MODERATE-VIGOROUS ACTIVITY IN PREDICTING CARDIOVASCULAR FITNESS AMONG COLLEGE STUDENTS

Emily Erlenbach, BS¹, Samuel Streeter, BS², Neha P. Gothe, MA, PhD²¹University of Illinois at Urbana-Champaign, Champaign, IL; ²University of Illinois at Urbana-Champaign, Urbana, IL

Background: Cardiorespiratory fitness (CRF) is an important predictor of morbidity and mortality across the lifespan. Physical activity, especially at moderate-to-vigorous intensities (MVPA), is a key predictor of CRF. However, the role of sedentary time (ST) in influencing CRF as well as overall health and wellbeing, regardless of MVPA is gaining importance in exercise research. College-aged students are particularly vulnerable to ST with the use of internet and technology in their leisure time in addition to spending significant periods of time seated in their classrooms. The purpose of this cross-sectional study was to examine the independent associations of ST and weekly MVPA on CRF among college students.

Methods: Ninety-five university students (Females=47, Mean age = 19.96 ± 0.933) completed an online survey consisting of demographics, CRF questionnaire, Godin-Shephard leisure-time physical activity questionnaire, and a sitting time questionnaire, which assessed estimated CRF (CRFest), physical activity levels, and domain specific weekday and weekend ST, respectively. Pearson correlations and multiple linear regression analyses were used to determine individual associations and contributions of self-report MVPA and weekday and weekend ST on CRFest.

Results: Partial correlations (controlling for sex) were calculated between CRFest, weekly MVPA, and different weekday and weekend sedentary activities. CRFest was significantly correlated with weekend ST ($r = -0.26$, $p < 0.05$) and weekly MVPA ($r = 0.35$, $p < 0.05$) which were included as predictors. The multiple linear regression explained 46.8% of the variance in CRFest ($F(3,91) = 28.55$, $p < 0.001$). Weekend ST was an independent significant predictor of CRFest ($\beta = -0.16$, $p < 0.05$), over and above weekly MVPA ($\beta = 0.25$, $p < 0.05$) and sex ($\beta = 0.64$, $p < 0.0005$). Lower levels of ST, higher levels of MVPA and being a male were associated with higher CRFest levels.

Discussion: Our results highlight the role of ST, specifically weekend leisure sitting time in influencing CRF. Given that weekends are often less structured than weekdays for college students, the leisure-time behaviors they engage in appear to be important contributors to their CRF. Health interventions to improve CRF in college students should not only take an umbrella approach to increase MVPA or overall lifestyle PA but could be more effective by specifically targeting weekend leisure sitting time in this population.

6:15 PM-7:30 PM

MEASURING ‘PARTNER INVESTMENT IN PHYSICAL ACTIVITY’ AMONG CANCER SURVIVORS AND THEIR ROMANTIC PARTNERS

Gillian Lloyd, MA¹, Krista W. Ranby, PhD¹¹University of Colorado Denver, Denver, CO

Introduction: The quality of support individuals receive from romantic relationships is one of the strongest predictors of positive illness coping and health behavior change. However, few measures capture how couples view the responsibility of managing their own and their partner's health, which may be crucial to understanding how partners view support behaviors. Because physical activity is recommended for cancer survivors to reduce the side effects of treatment and cancer recurrence, this research explored the reliability and utility of the Partner Investment in Physical Activity scale among couples coping with cancer.

Methods: This research was part of a larger study exploring cancer survivors and their romantic partners' interest in individual and couples-based exercise. Both survivors (n=209) and partners (n=155) individually completed an online survey. On the 18-item Partner Investment in Physical Activity scale, participants indicated whether they are invested in their partner's physical activity (9 items) and whether they perceive their partner to be invested in their own physical activity (9 items) from 1 (strongly disagree) to 6 (strongly agree).

Results: The 18-item Partner Investment in Physical Activity scale demonstrated good reliability in survivors ($\alpha=0.93$) and partners ($\alpha=0.92$), and it was significantly correlated with relationship satisfaction (survivors: $r=0.50$, $p<0.01$, partners: $r=0.48$, $p<0.01$), partner support for exercise (survivors: $r=0.78$, $p<0.01$, partners: $r=0.72$, $p<0.01$), and participants perceived importance of engaging in regular physical activity together (survivors: $r=0.29$, $p<0.01$, partners: $r=0.43$, $p<0.01$). Regarding the two 9-item subscales, participants' investment in their partner (survivors: $M=4.4$, $SD=0.96$; partners: $M=4.5$, $SD=0.93$) was significantly higher than their perceived partners' investment in themselves (survivors: $M=3.9$, $SD=1.18$, partners: $M=4.2$, $SD=1.1$) (survivors: $t(208)=7.2$, $p<.01$, partners: $t(154)=3.7$, $p<0.01$).

Conclusion: The Partner Investment in Physical Activity scale demonstrated good reliability and utility among cancer survivors and their romantic partners. Future research should continue to validate this scale in more specific types of cancer couples (e.g., specific cancer sites, relationship types (married), dual survivor couples) and further elucidate this scale's content validity compared to similar measures (e.g., communal coping).

PROMOTING STRENGTH TRAINING AMONG BABY BOOMERS: MESSAGE FRAMING EFFECTS ON MOTIVATION AND BEHAVIOR

Emily L. Mailey, PhD¹, Rebecca Gasper, MPH¹, Deirdre Dlugonski, PhD², Gina Besenyi, MPH, PhD¹¹Kansas State University, Manhattan, KS; ²University of Kentucky, Lexington, KY

When done regularly, strength training can help older adults build muscle mass, preserve bone density, and maintain function and independence as they age. However, only 14% of adults over age 50 report engaging in strength training at least twice per week. Exercise messages about why and how older adults should engage in strength training could influence their perceptions of, and participation in the behavior. Thus, the purpose of this study was to determine whether manipulating message frames accompanying a brief home-based strength training workout would have an effect on Baby Boomers' exercise motivation or behavior. Participants (N=308) were recruited online and randomly assigned to one of four message conditions: Easy Intrinsic, Hard Intrinsic, Easy Extrinsic, or Hard Extrinsic. Immediately after completing baseline measures of motivation (Exercise Self-Regulation Questionnaire) and exercise (IPAQ – short form), participants received the recommended strength training workout and corresponding motivational message (e.g., 8 Quick and Simple Exercises to Feel Refreshed and Energized Today! [Easy Intrinsic Condition]). The strength training exercises were designed to be suitable for adults aged 50-70 of varying activity levels to complete at home. Two weeks later, 213 participants completed follow-up measures of motivation and exercise. Of these, 70% reported that they had completed the recommended workout at least once. An ANCOVA revealed a significant group effect for introjected ($F=2.90$, $p=.04$) and external regulation ($F=4.05$, $p=.008$), which were higher at follow-up among participants exposed to an extrinsic message relative to an intrinsic message. Strength training ($Z=-5.95$, $p<.001$) and moderate activity ($Z=-3.23$, $p=.001$) increased in the full sample, but these changes were comparable across groups. These results suggest message framing may have a short-term impact on Baby Boomers' exercise motivation, such that emphasizing extrinsic goals (i.e., weight loss and appearance) may contribute to controlled motivation. Highlighting intrinsic goals related to feeling good may be a more effective approach, but continued exposure to exercise messages may be needed to have a sustained impact on motivation and behavior. Future studies should explore strategies for refining and delivering effective, evidence-based physical activity messages in contexts such as healthcare, health coaching, and worksite wellness.

TESTING THE WEISS-HARTER-MODEL: PHYSICAL ACTIVITY, SELF-ESTEEM, ENJOYMENT, AND SOCIAL SUPPORT IN CHILDREN AND ADOLESCENTS

Darko Jekauc, n/a¹, Carina Mnich, BA², Claudia Niessner, n/a², Kathrin Wunsch, n/a², Claudio Nigg, PhD², Janina Krell-Roesch, n/a², Alexander Woll, Professor³¹Karlsruhe Institut of Technology, Karlsruhe, Baden-Wurttemberg, Germany;²Karlsruhe Institute of Technology, Karlsruhe, Baden-Wurttemberg, Germany;³Karlsruher Institut of Technology, Karlsruhe, Baden-Wurttemberg, Germany

Background: Several theories have been established to explain physical activity (PA) participation. However, many of these theories might not be applicable to adolescent PA behavior as they require a high level of cognitive reflection. Weiss suggests a model for youth which is based on the theoretical concept of Harter, focusing on self-esteem within social, emotional, and developmental aspects to explain behavior. The aim of this study was to test the original and social support focused alternative version of the Weiss-Harter-model, and to cross-validate the findings in two separate studies.

Methods: Data from two cross-sectional studies was retrieved and the models tested using structural equation modeling. Participants aged 11-17 years were recruited from a school (Study 1: N=182) and from the German MoMo study (Study 2: N=2,274). They filled in questionnaires about perceived competence, social support, self-esteem, PA enjoyment, and minutes of moderate-vigorous PA (MVPA).

Results: None of the studies showed a good model fit for the original model (Study 1: CFI=.870, RMSEA .118 [90% CI .081-.158], $\chi^2 = 38.7$, $p < .01$; Study 2: CFI=.871, RMSEA .148 [90% CI .140-.155], $\chi^2 = 1112.6$, $p < .01$), explaining only 12% and 17% of MVPA variance, respectively. The alternative model which added the direct paths of social support to MVPA and PA enjoyment had a very good model fit for both Study 1 (CFI=1.000, RMSEA .000 [90% CI .000-.031], $\chi^2 = 4.8$, $p > .05$) and Study 2 (CFI=.990, RMSEA .043 [90% CI .035-.051], $\chi^2 = 103.7$, $p < .01$). The addition of these paths led to changes in effect size and directions of other path coefficients, with self-esteem having a small to meaningless impact on MVPA. The revised models accounted for 38% and 42% explained variance in MVPA, respectively.

Discussion: The prominent role of self-esteem in the original model could not be confirmed. Instead, the results emphasize the role of social support for PA and PA enjoyment, which is in line with current research. Interventions to increase adolescent PA levels should thus focus more on components of social support instead of self-esteem. Future studies are needed to examine the interplay between social support, PA enjoyment and perceived competence as PA determinants.

PHYSICAL ACTIVITY, SEASONALITY, AND WEATHER: A SCOPING REVIEW OF RESEARCH WITH DEVICE-BASED MEASURES OF PHYSICAL ACTIVITY

Taylor B. Turrissi, Doctoral Student | Department of Kinesiology | Penn State University¹, Ashley B. West, MS², Kelsey M. Bittel, BS², Scherezade K. Mama, DrPH³, Sahar Hojjatinia, n/a², Sarah Hojjatinia, n/a¹, Constantino Lagoa, n/a⁴, David E. Conroy, PhD³¹Penn State University, State College, PA; ²The Pennsylvania State University, State College, PA; ³The Pennsylvania State University, University Park, PA; ⁴The Pennsylvania State University, University park, PA

Background: Weather is a naturally occurring dynamic construct that has demonstrated both positive and negative associations with physical activity (PA). Weather conditions can facilitate or inhibit physical activity, and thus represent potential tailoring variables for context-sensitive, just-in-time PA interventions. This scoping review examines associations between weather and device-based measures of physical activity since the last review 12 years ago.

Methods: PubMed was searched from January 1, 2006 until December 31, 2019. A total of 558 unique articles were identified. Articles were included if physical activity was measured using a device (e.g., ActiGraph, StepWatch) and the results reported an association between physical activity and either seasonality or specific weather indices (e.g., cloud cover, temperature, precipitation, humidity, photoperiod, wind speed). Following title and abstract review, three coders independently assessed 93 full text articles for eligibility. Data were extracted from 67 articles.

Results: Most articles included an international (versus US-only) sample (80%), studied adults (55%), utilized research-grade accelerometers to measure physical activity (59%), and measured seasonality instead of specific weather indices (51%). A subset of studies (20%) investigated physical activity for individuals with chronic obstructive pulmonary disease, obesity, osteoarthritis, and type 2 diabetes. Physical activity measures focused on volume (daily step count [46%], total activity counts [16%], total energy expenditure [4%]) and intensity-specific duration (36%). Physical activity was consistently lower in winter compared to spring, summer, or autumn. Studies consistently reported that physical activity had (a) positive associations with temperature (with some studies reporting a quadratic association indicating reduced activity during excessive heat) and photoperiod, and (b) negative associations with precipitation, cloud cover, humidity and wind speed.

Conclusions: Some weather conditions were consistently more conducive to physical activity than others, with positive associations between device-based measurements of physical activity, temperature and photoperiod consistently documented in diverse populations around the globe. Other conditions, such as cloud cover, precipitation and wind, may inhibit physical activity. Weather is a potential tailoring variable for context-sensitive, just-in-time physical activity interventions.

INCREASING PRESCHOOLERS' PHYSICAL ACTIVITY VIA A MOBILE APP GAME

Nan Zeng, n/a¹, Susan Johnson, n/a², Barbara Chamberlin, n/a³, Morgan McCloskey, n/a¹, Mackenzie Ferrante, n/a¹, Savannah Hobbs, n/a¹, Nooreem Mena, n/a¹, Laura Bellows, n/a¹

¹Colorado State University, Fort Collins, CO; ²University of Colorado Anschutz Medical Campus, Aurora, CO; ³New Mexico State University, Las Cruces, NM

Background: Children today are being raised in technology-rich environments. Paralleling this is the noted increase in sedentary screen-time and decline in physical activity (PA) levels among young children. Applying emerging technology to promote PA, therefore, has generated substantial public interest. This study aimed to investigate the feasibility of employing a culturally tailored mobile app (Jungle Gym) to encourage PA among preschool children in rural Head Start and preschool centers.

Methods: Preschool children ($N = 11$, girls = 6, $X_{age} = 54.07 \pm 3.15$ months, $X_{BMIz} = 0.54 \pm 1.08$), were recruited from child workshop for Healthy Environments feasibility study (HEROs). Children were instructed to play (1) mobile app (Jungle Gym) (7 minutes), (2) obstacle course (10 minutes), and (3) motor skills (MS) building (10 minutes) activities. PA levels were captured by ActiGraph GT9X accelerometers attached to the right hip. The percentage of time spent in moderate-to-vigorous PA (MVPA%) for each activity was calculated as the dependent variable. Repeated-measures ANOVA was performed to evaluate differences in MVPA% among the three activities.

Results: Descriptive statistics showed that preschool children spent most MVPA% in MS building ($84.15\% \pm 15.82\%$), followed by mobile app ($81.04\% \pm 18.04\%$) and obstacle course ($59.10\% \pm 16.89\%$). Repeated-measures ANOVA indicated a significant difference in MVPA% among three activities, ($F(2,20) = 8.61$, $p = 0.002$). Pairwise comparisons revealed that MVPA% in obstacle course was significantly lower than mobile app (mean difference [MD]: -21.94 , 95% confidence interval [CI]: -35.68 to -8.21 , $p = 0.003$), and MS building (MD: -25.06 , 95% CI: -11.32 to -38.80 , $p = 0.001$). No significant difference was noted between mobile app and MS building (MD: 3.12 , 95% CI: -10.62 to 16.85 , $p = 0.641$), indicating these two activities may trigger equivalent MVPA.

Conclusions: Our findings suggest that a culturally tailored mobile app (Jungle Gym) is able to prompt a considerable proportion of MVPA which is comparable to traditional physical education, supporting the feasibility of increasing preschoolers' PA via mobile apps. Such apps may also be used as an alternative at home to encourage PA and decrease sedentary behaviors when other activity equipment or outdoor opportunities are absent. More research is warranted on the impact of the app over time (i.e. repeated usage) and in different settings (i.e. home and classroom environments).

SEIZING THE MOMENT: PRELIMINARY RESULTS OF COMPLIANCE TO ECOLOGICAL MOMENTARY ASSESSMENT FROM THE ADAPT STUDY

Pallavi Dutta, BSc¹, Matthew Kwan, PhD²

¹McMaster University, Innisfil, ON, Canada; ²McMaster University, Hamilton, ON, Canada

Background: The transition from late adolescence to emerging adulthood represents a major life transition, often associated with significant declines in physical activity behaviours (Bray & Born 2004; Kwan et al., 2012). Current knowledge of these behaviours, however, is largely based on cross-sectional or infrequent longitudinal designs, and is limited in its understanding of contextual and intra-individual factors impacting physical activity during this transitional time. Ecological Momentary Assessment (EMA) is an intensive data capture method that can address these limitations (Shiffman et al., 2008), and is made easier through recent advancements in smartphone technology and widespread use. While compliance has been strong among some populations (e.g., Dunton et al., 2011; Maher et al., 2018), compliance among youth is in question (Bedard et al., 2017). The purpose of the current study was to examine the compliance to EMA prompts in high school students.

Methods: The current sample included 166 grade 11 students (Mage=15.76, 57 females) from one large school board in Southern Ontario. Participants were asked to wear accelerometers and complete 6 EMA prompts on their smartphones each day, for a 7-day study period. Each prompt included a very brief questionnaire assessing context, acute feeling states, and motivations to be physically active.

Results: On average, participants responded to 16.98 (SD +/- 7.56) of the prompts, with response to prompts ranging from 1 to 34. When data from 19 non-participants (< 7 prompts/week) was removed, the mean response increased to 18.55 (SD +/- 6.60). It should also be noted that there was variability in compliance based on when the EMA prompts were sent, with the early morning prompts having the lowest compliance (43%) while the afternoon or evening prompts ranged in compliance from 54% - 60%.

Conclusions: Findings suggest that the compliance in this adolescent cohort is lower in comparison to other EMA studies of younger children and older adults. Although it may be that the youth population, in general, may be less motivated to respond to EMA prompts, raising some questions about the validity of the data, these results may be more reflective of EMA research using community-based sampling approaches. More research is required to understand the potential factors related to EMA response patterning among the youth population.

PATTERNS OF INDIVIDUAL LEVEL IMPLEMENTATION IN A WORK-PLACE HEALTH AND WELL-BEING PROGRAM

Ashlee Davis, M.S.¹, Sarah A. Appleton, n/a², Ryan Sweigart, n/a¹, Rebecca Ellis, PhD³¹Georgia State University, Atlanta, GA; ²Georgia State University, DECATUR, GA; ³Georgia State University, Department of Kinesiology and Health, Atlanta, GA

Objectives: Desire2Move (D2M) is an annual peer support health and well-being program that encourages physical activity (PA) participation among university employees. Previous program evaluations of D2M assessed implementation at the organizational level, but not at the individual level. Therefore, the purpose of this study was to examine patterns of individual level implementation (non-compliance) during years 5 and 6 of D2M.

Methods: During the 8-week program, D2M participants recorded minutes of PA using the *MapMyFitness* mobile app or website. Student liaisons tallied individual PA minutes on Monday for PA logged the previous Monday to Sunday. Participants who did not report any minutes of PA during a program week were non-compliant. Frequencies, means, standard deviations, and independent *t*-tests examined patterns of non-compliance.

Results: During year 5, 207 employees participated in D2M, and 118 (57.0%; $M = 7.75$, $SD = 4.67$) were non-compliant at least one time. Of those, 34.0% were non-compliant one week, 20.3% were non-compliant two weeks, and 62.7% were non-compliant three weeks or more. During year six, 286 employees participated in D2M, and 150 (52.5%; $M = 15.00$, $SD = 5.65$), were non-compliant at least one time. Of those, 34.0% were non-compliant one week, 15.3% were non-compliant two weeks, and 50.7% were non-compliant three or more weeks. For both program cycles, the number of non-compliant participants increased from week 1 to week 8 ($\text{Range}_{\text{yearfive}} = 32 - 79$; $\text{Range}_{\text{yearsix}} = 36 - 94$). The number of non-complaint participants between years was not significantly different $t(7) = -0.74$, $p = 0.469$.

Conclusion: Over half of D2M participants were non-compliant at least one time during the 8-week program. To improve program effectiveness, we need to understand implementation at the individual level. Future research should identify techniques, such as targeted and tailored messages to non-compliant participants, to improve program implementation.

ADVERSE CHILDHOOD EXPERIENCES, COPING AND QUALITY OF LIFE IN MENTAL HEALTH PROVIDERS

Eve DePascale, B.S.¹, Bree Gidner, M.S.¹, Luci Martin, Ph.D.¹, Julee La Mott, Psy.D.¹¹University of La Verne, La Verne, CA

Endorsing a personal history of adverse childhood experiences may increase a provider's risk of developing negative physical and psychological outcomes. Mental health providers are often required to work nights and weekends in order to accommodate the needs of their clients and are at risk of being overextended. Understanding ways in which coping strategies may mitigate these negative experiences may improve health and well-being of providers and improve quality of care for their clients. The purpose of this study was to examine adverse childhood experiences and the moderating role of coping on quality of life among mental health providers. Mental health providers ($N = 371$; 94.1% female; Mean age = 47.12) were surveyed regarding their coping strategies, history of adverse childhood experiences, and quality of life experienced. The ethnic diversity of the sample was as follows: 88.4% White/European American/Not Hispanic, 4.6% Hispanic/Latino, 2.4% Black/African American, 2.2% Bi-Racial/Mixed, 1.4% Asian/Asian American, and 1.1% "Other". Approximately 32% of the sample reported working more than 40 hours per week. Results indicated that providers who endorsed a history of adverse childhood experiences (82.5% of the sample) endorsed a poorer quality of life than those who did not have a history ($t = -3.00$, $p = .003$). Hierarchical multiple regression analysis revealed that adverse childhood experiences, coping and interactions among adverse childhood experiences and coping significantly predicted quality of life (Adj. $R^2 = .46$, $F(29, 339) = 11.64$, $p < .001$). Adverse childhood experiences were no longer a significant predictor of quality of life when coping strategies were added to the model (Adj. $R^2 = .43$, $F(15, 353) = 19.84$, $p < .001$). Substance use ($t = -2.00$, $p = .046$), behavioral disengagement ($t = -5.83$, $p < .001$), planning ($t = -2.38$, $p = .018$), self-blame ($t = -5.90$, $p < .001$) and self-distraction ($t = -3.09$, $p = .002$) were negatively associated with quality of life, while emotional support ($t = 3.98$, $p < .001$) was positively associated with quality of life. Both substance use and denial moderated the relationship between adverse childhood experiences and quality of life. The findings of this study highlight the prevalence of adverse childhood experiences in mental health providers, the impact these experiences likely have on quality of life and the importance of coping strategies that may assist in managing psychological and physical health outcomes. Regardless of the mental health provider's background, it is imperative that all mental health providers begin establishing self-care routines early on in their careers. Though coping and self-care are discussed conceptually, there are limited resources for mental health providers that ensure that they are taking the time to care for themselves throughout both graduate school and their professional careers.

MINDFULNESS FACETS PREDICT QUALITY OF LIFE AND SLEEP QUALITY VIA DISTRESSES IN CANCER PATIENTS: MODERATED MEDIATION ANALYSIS

Rainbow T.H. Ho, PhD, REAT, BC-DMT, AThR, RSMT/E, CGP, CMA¹, Ted C.T. Fong, PhD²¹Centre on Behavioral Health, The University of Hong Kong, Hong Kong, N/A, Hong Kong; ²Centre on Behavioral Health, Hong Kong, N/A, Hong Kong

Introduction: Patients with colorectal cancer are at elevated risks of physical and emotional distresses which could lead to sleep disturbance and impaired functioning. Identifying mindfulness facets that can predict distresses and functional outcomes is of clinical relevance. The objective of this study was to examine the temporal associations among mindfulness facets, physical and emotional distresses, and functional outcomes.

Research Design: A total of 127 Chinese patients with colorectal cancer participated in this longitudinal survey. The participants completed the Five Facet Mindfulness Questionnaire, Memorial Symptom Assessment Scale, Perceived Stress Scale, Hospital Anxiety and Depression Scale, Pittsburgh Sleep Quality Index, and SF-12 Health Survey. Moderated mediation analyses were performed under Bayesian estimation on the direct and indirect effects of mindfulness facets on quality of life and sleep disturbance via physical and emotional distresses, using acting with awareness as a moderator.

Results: There were no significant direct effects from the mindfulness facets to functional outcomes. Awareness and nonreacting showed significant and positive indirect effects on physical and mental SF-12 via physical and emotional distresses, respectively. Awareness, nonjudging, and nonreacting showed significant and negative indirect effects on sleep disturbance via emotional distress. The indirect effects of nonreacting on the functional outcomes increased as a function of awareness.

Conclusions: This longitudinal study demonstrates significant indirect effects from mindfulness facets to functional outcomes via physical and emotional distresses. Nonreacting could play a stronger protective role in improving sleep disturbance and functioning among patients with greater awareness.

Acknowledgments: This work was supported by the General Research Fund of the Hong Kong Research Grants Council (GRF/HKU 17611615). We would like to express our thanks to Dr. Adrian Wan and Mr. Joshua Yau and other colleagues of the Centre on Behavioral Health for their help in study coordination and the participants for joining this study.

NON-MONOSEXUALITY AS A FACTOR IN INCREASED PREVALENCE OF SEXUAL RISK BEHAVIOR

Nicola F. Tavella, MPH, CPH¹, Brian Salfas, MA², Jesse Bradford-Rogers, MPH³, Ali Talan, DrPH⁴, H. Jonathon Rendina, PhD, MPH⁵¹PRIDE Health Research Consortium, Hunter College, CUNY, New York, NY; ²PRIDE Research Consortium, New York, NY; ³PRIDE Health Research Consortium at Hunter College, New York, NY; ⁴Hunter College, New York, NY; ⁵Hunter College and The Graduate Center, CUNY, New York, NY

Background: As researchers explore the complexities of human sexuality, a lack of behavioral sexual health research persists concerning differences between monosexual and non-monosexual men and the conflation of these groups as “men who have sex with men” (MSM). Researchers have begun investigating these differences, finding that men who have sex with men and women (MSMW) report higher rates of sex work, more sex with partners of different or unknown HIV status, and more male sexual partners. We sought to determine whether non-monosexuality influenced engagement in greater sexual risk among a national cohort of sexual and gender minority (SGM) men.

Methods: Cross-sectional data were collected from a national sample of 10,663 SGM men in the United States. Participants estimated not only numbers of male and female casual sex partners, but also the kinds of sexual behavior including insertive and/or receptive sex, anal and/or vaginal sex, and the HIV statuses of both male and female casual sex partners. Data were analyzed using Pearson Chi-Square and independent-samples t-tests.

Results: The average ages for MSM ($M = 32.48$) and MSMW ($M = 34.83$) were significantly different ($t = -5.12, p = 0.000$). Among MSM, 24.3% identified as Hispanic/Latino, 10.7% as Black/African American, and 51.5% as White. Among MSMW, 23.2% identified as Hispanic/Latino, 14.0% as Black/African American, and 51.2% as White. MSMW reported significantly more male casual partners compared to MSM ($M_{MSMW} = 10.16, M_{MSM} = 6.89, t = -8.34, p = 0.000$). MSMW also reported significantly more condomless anal sex with male partners of different/unknown HIV status compared to MSM ($M_{MSMW} = 3.32, M_{MSM} = 2.20, t = -2.84, p = 0.000$). Finally, MSMW were significantly more likely to engage in sex work, with 27.7% of MSMW exchanging sex for goods compared to 19.4% MSM ($X^2 = 13.44, p = 0.000$).

Conclusions: While much research conflates MSM and MSMW under monikers like “MSM” and “LGBT samples,” data suggest this overlooks key differences between groups based on one’s monosexuality. Analysis of these data support the hypothesis that people who engage in non-monosexual sex are more likely to engage in riskier health behaviors. These groups would benefit from research informed by a more nuanced understanding of sexuality not defined by the presence of male sex partners. Non-monosexual people engage with health behaviors in different ways, and therefore deserve research that acknowledges these differences.

THE MODERATING ROLE OF SEXUAL ORIENTATION IN THE ASSOCIATION BETWEEN RELIGIOSITY AND SEXUAL HEALTH AMONG COLLEGE STUDENTS

Kalina M. Lamb, MA¹, Carlee K. Conner, n/a², Sarah S. Dermody, PhD¹¹Oregon State University, Corvallis, OR; ²Counseling and Psychology Services at Oregon State University, Corvallis, OR

Objective: Past research has shown that religiosity can impact sexual behaviors of youth. No known studies have examined the relationship between religiosity and sexual behavior in sexual minority (e.g., gay, lesbian, bisexual) youth. As many world religions promote doctrines that include negative views toward sexual minorities, it is unclear if religiosity would impact sexual minority sexual behaviors in the same way as heterosexual individuals.

Methods: College/university students across Oregon (N = 1213) completed an online cross-sectional survey. The sample included four sexual orientation subgroups: straight (reference group; N = 992); gay/lesbian (N = 29); bi/pansexual (N = 153); and unsure (N = 39). Religiosity was assessed using the 15-item Centrality of Religiosity Scale (M = 2.44, range 1-5). Using logistic models in PROCESS, sexual orientation was examined as a moderator of the relations between religiosity and the occurrence (yes vs no) of four sexual behaviors in the past 6 months: sexual activity, birth control use during sex, sexual activity under the influence, and testing positive for an STI. Covariates were age and natal sex.

Results: There was a significant association of religiosity with all outcomes for the straight subgroup: greater religiosity scores were associated with reduced odds of sexual activity (OR = .68, $p < .001$), birth control use (OR = .65, $p < .001$), sex under the influence (OR = .76, $p < .001$), and testing positive for an STI (OR = .63, $p = .02$). Gay/lesbian identity moderated the religiosity association ($p < .05$) such that religiosity was even more protective for gay/lesbian identity for sex under the influence (OR = .68). Bi/pansexual identity was also a moderator ($p < .05$), such that religiosity was relatively less protective for sexual activity (OR = 1.38) and sex under the influence (OR = 1.29), but more protective for birth control use (OR = 1.13).

Conclusions: Sexual orientation moderated the association between religiosity and sexual activity, birth control use, and sex under the influence, but not STI risk. Differences were found when comparing straight individuals to gay/lesbian and bi/pansexual individuals, but not unsure individuals. Also, the current study confirms past research that identifies religiosity as a protective factor for a number of sexual health outcomes excluding birth control use, but suggests that this may be primarily among straight individuals.

UTILIZING A FACTORIAL EXPERIMENTAL DESIGN IN A RANDOMIZED CONTROLLED TRIAL TO EVALUATE AN ONLINE SEXUAL HEALTH INTERVENTION

Jeffrey J. Milroy, DrPH, MPH¹, Samuella Ware, MPH, CHES¹, Alicia M. Miller, BSc¹, Shemeka Thorpe, MS¹, Amanda E. Tanner, PhD, MPH¹, David L. Wyrick, PhD, MPH¹, Kate Guastafarro, PhD, MPH², Linda Collins, PhD²¹The University of North Carolina Greensboro, Greensboro, NC; ²Pennsylvania State University, University Park, PA

Alcohol use is often implicated in the sexual behaviors that increase college students' sexually transmitted infection (STI) risk. Accordingly, we developed and are currently evaluating a highly efficient online intervention, *itMatters*, to address the intersection of alcohol and sexual behaviors. *itMatters* was designed using the Multiphase Optimization Strategy (MOST), an engineering-inspired framework for creating optimized interventions in three phases: Preparation, Optimization, and Evaluation. Based on our conceptual model, we developed a 5-component intervention that was piloted and revised during two optimization trials. Based on these results, we moved forward with evaluating our optimized treatment package. A 2-arm randomized controlled trial (RCT) for intervention evaluation was originally proposed, however, one of the four participating institutions required students to complete sexual violence prevention education. Therefore, we adapted an existing sexual violence prevention module for inclusion in the RCT. This presented three challenges for RCT implementation: (1) evaluation of *itMatters* required a no-treatment control; (2) randomization at the individual (student) level with a no-treatment control arm posed contamination issues; and (3) potential interaction of sexual violence programming with *itMatters* sexual health. To address some of these issues, our approach includes a two-by-two factorial RCT design with placebos (e.g., sleep and mental health) for control students. Other challenges will be addressed analytically at the conclusion of the RCT. The factorial design enables us to speak to the effectiveness of *itMatters*, effectiveness of the not-previously-evaluated sexual violence prevention module on its own, and the effectiveness of sexual violence prevention and *itMatters* together. Because *itMatters* takes a sex-positive approach, simply adding the sexual violence prevention module to the intervention introduced a concern that its inclusion could dilute sex-positive messaging. This process highlights the flexibility needed to implement online health promotion interventions that meet students' needs, acknowledge institutional requirements, and are scientifically rigorous. This also highlights the benefits of utilizing a factorial design in an RCT for intervention development and evaluation.

THE MEDIATING EFFECT OF SUBSTANCE USE ON THE RELATIONSHIP BETWEEN DEPRESSION AND HOURS OF SLEEP

Yu-Ping Chang, PhD, RN, FGSA, FIAAN, FAAN¹, Young Sik Seo, PhD(c)²¹University at Buffalo School of Nursing, The State University of New York, Buffalo, NY; ²University at Buffalo School of Nursing, The State University of New York, Buffalo, NY

Background: Depression, substance use, and insufficient sleep are prevalent health issues among U.S. high school students, in part due to academic related stress and their use of technology. There is a known link between depression and insufficient sleep, yet, little evidence is currently available regarding how substance use may play a role in the relationship. This study aimed to examine the mediating effect of substance use on the association between depression and insufficient sleep among high school students.

Methods: This study used the 2017 Youth Risk Behavior Surveillance System data collected by the Center for Disease Control and Prevention with the intent to assess the conditions, changes, and co-occurrence of health behaviors among U.S. high school students. Student race, sex, age, and hours of watching TV/playing video games per day were used as covariates. Descriptive statistics and correlations were examined in relation to the distributions, multi-collinearity, and associations of the variables used in this study. Then, mediation analysis using Hayes Process macro v.3.1 was run to investigate whether the relationship between student depression (feeling sad or hopeless) and hours of sleep on school nights would be mediated through student substance use (current uses of cigarette, electronic cigarette, cigar, alcohol, and marijuana).

Results: A total of 10,970 high school students with complete data were included in the study. Depression was negatively associated with hours of sleep, but was positively related to substance use after controlling for race/ethnicity, sex, age, and hours of watching TV/playing video games per day. Likewise, substance use was negatively associated with hours of sleep on school nights ($r = -.12, p < .01$). There was no multi-collinearity issue identified. Mediation analysis indicated that substance use served as a significant mediator in the relationship between depression and hours of sleep ($ab = -.03$, Bootstrapped SE = .01, Bias-corrected Bootstrap Confidence Interval [CI] [-.05, -.02]). Specifically, being depressed was associated with increased substance use ($a = .27, SE = .02, CI [.24, .31]$), which in turn led to decreased hours of sleep ($b = -.13, SE = .02, CI [-.17, -.09]$).

Conclusions and Implications: In summary, the U.S. high school students who were depressed had fewer hours of sleep on school nights than those who were not depressed. More importantly, being depressed increased the students' likelihood of using various types of substances, which in turn led them to sleep fewer hours on school nights. Our findings provide insight regarding the association between depression, sleep, and substance use. These findings indicate a need to develop interventions aimed at addressing multiple co-existing behaviors within this population. Finally, integration of a behavioral health component into school-based health education programs is needed.

ROLE OF ADULT ATTACHMENT AND INTIMACY IN SLEEP IN COLORECTAL CANCER PATIENTS AND SPOUSAL CAREGIVERS

Amanda Ting, MS¹, Jamie Zeitzer, PhD², Kaitlin Hahn, n/a¹, Patricia Pedreira, B.S.¹, Youngmee Kim, PhD¹¹University of Miami, Coral Gables, FL; ²Stanford University, Palo Alto, CA

Close relationships and intimacy foster emotional comfort and feelings of safety, which are optimal for sleep. Sleep disturbance is a prominent concern among adult cancer patients and their spousal caregivers. Less known is the extent to which general attachment orientation and daily variation of intimacy are associated with patients and caregivers' own daily sleep efficiency and sleep quality, which this study investigated.

Newly and recently diagnosed colorectal cancer patients ($n = 48$, $M = 55.5$ years old, 40% female) and their heterosexual spouses ($M = 55.1$ years old) individually completed the Consensus Sleep Diary and three intimacy items regarding feeling cared for, validated, and understood by one's partner, daily across 14 consecutive days, from which sleep efficiency (SE: 0 – 100%) and sleep quality (SQ: 1 – 5) were derived. Attachment orientations (MAQ: security, avoidance, and anxiety) with the partner was self-reported once.

Good SE and fair SQ were reported by patients (SE = 89% and SQ = 3.61) and caregivers (SE = 89% and SQ = 3.51). Multilevel modeling separately predicting SE and SQ revealed that among patients, SE was not associated with general attachment orientations or daily intimacy; and better SQ was associated with greater intimacy on the same day ($B = 1.31, p < .048$). Among caregivers, worse SE was associated with greater general attachment security ($B = -.17, p < .014$), greater general attachment avoidance ($B = -.30, p < .001$), and greater daily intimacy ($B = -.23, p < .001$), although the impact of daily intimacy augmented by general attachment security ($B = 0.04, p < .010$) and general attachment avoidance ($B = 0.07, p < .001$). Better overall SQ in caregivers was associated with general attachment avoidance ($B = 1.22, p < .028$). Caregivers' better SQ related to greater intimacy on the same day ($B = 1.38, p < .018$), though the impact of daily intimacy attenuated by general attachment avoidance ($B = -.046, p < .001$) but intensified by general attachment anxiety ($B = 0.24, p < .011$).

Findings provide preliminary evidence highlighting that both stable relational characteristics and daily interpersonal factors play substantial roles in distinct aspects of sleep for cancer caregivers but not for patients around the time of diagnosis. Further investigation of daily psychosocial and medical characteristics attributable to sleep disturbance is crucial for understanding discrete contributors to sleep in cancer patients and their caregivers.

SCREEN TIME, SLEEP, AND ACTIVITY LEVEL FOR COLLEGE STUDENTS IN HAWAII

Cheyne Y. Nakamura, n/a¹, Tracy Trevorrow, Ph.D.¹¹Chaminade University, Honolulu, HI

Screen time has been associated with poor sleep and inactivity, obesity, anxiety and depression. Most studies focus on the effect of screen time on children and adolescence. This study hypothesized that screen time would correlate with reduced total sleep time (TST), delayed sleep onset, reduced physical activity and greater BMI in college students. Participants included 191 undergraduate students (8.5% of the student body) of a small Honolulu university. The faculty were solicited to allow the survey to be administered in their classrooms. The Report of Undergraduate Screen Time (RUST) was developed by the senior author and consisted of items regarding demographics, BMI, type of screen use, anxiety regarding screen availability and dependency on screen use. The Godin-Shephard Physical Activity Questionnaire and questions from the Pittsburgh Sleep Quality Index (PSQI) were also administered. Pearson correlations and student t-tests examined the association of screen use by demographics, type of screen use, anxiety and dependency on screen devices and measures of sleep and activity. Participants reported being engaged in screen time for most of their waking day and significantly more than their time asleep. Weekend use ($M = 13.15$ hours/day) was greater than weekdays ($M = 11.64$ hours/day) ($t(127) = 25.71, p < .01$). Male students reported greater use of screen time for gaming ($t(30) = 4.6, p < .01$), while female students reported more social media use ($t(130) = 2.60, p < .01$). Anxiety levels regarding screen availability and dependency on screen devices were high and significantly correlated ($r(185) = .464, p < .01$). No significant associations were found between screen time and TST, sleep onset time, BMI, activity level, anxiety or dependency regarding screen use. Gender differences in gaming and use of social media are consistent with psycho-evolutionary theory regarding gender roles. The lack of association between screen time and measures of sleep, physical activity, and BMI was surprising and may reflect the ubiquitous use of screen time across all groups. Our study was limited in its reliance on self-report and that the psychometric properties of the RUST have yet to be established.

6:15 PM-7:30 PM

IMPLICATIONS OF CHRONODISRUPTION ON PHYSICAL AND MENTAL HEALTH IN COLLEGE STUDENTS

Alexandra K. Gremp, n/a¹, Laura Nicholson, MA², Amy M. Bohnert, Ph.D.³, Amy Egbert, M.A.¹¹Loyola University Chicago, Chicago, IL; ²Loyola University Chicago, Forest Park, IL; ³Loyola University Chicago, Evanston, IL

Chronodisruption (CD) is characterized by discrepancies between biologically preferred sleep-wake schedules and socially enforced schedules (Erren et al., 2009). CD has been linked to depression (Keller et al., 2016) and health risks (Erren et al., 2009). College students may be prone to CD, as they transition to a less structured setting and alternating class start times (Dills & Hernandez-Julian, 2008). The current study will measure CD by analyzing discrepancies between preferred and actual waketimes and consider links between developmental and environmental factors (e.g., year in school and residential status) and CD, as well as how CD relates to mental and physical health among a sample of college students.

Participants were recruited from a mid-sized urban university ($n = 402$, 80.5% female), and reported on age, gender, residential status, year in school, BMI, and symptoms of anxiety and depression. Actual waketimes were reported using a daily diary and preferred waketimes were reported using an item from the Morningness-Eveningness Questionnaire (MEQ). A novel index of waketime discrepancy was calculated by categorizing actual and preferred waketimes based on six MEQ classifications (e.g., 5:00-6:29 A.M.) and taking the difference between categories. Scores ranged from 0-4, and higher scores indicate a greater degree of CD.

More than half (64%) of participants reported a discrepancy between actual and preferred waketimes. Linear regressions demonstrated nonsignificant relations between degree of CD and year in school, anxiety, and BMI. Linear regressions revealed a significant positive relation between degree of CD and depression ($p < .01$). ANOVAs indicated greater degrees of CD among students living with a parent or guardian ($M = 1.04$) compared to those living in residential halls ($M = .78$; $F(3,391) = 3.57, p < .05$). The average weekday waketime of students living with a parent was significantly earlier ($M = 7.81$) than that of students living in residential halls ($M = 8.55$) or off-campus apartments ($M = 8.27$) ($F(2,395) = 22.4, p < .01$). Additional analyses will be conducted to see if CD is more prevalent among those with an evening versus morning preference as assessed by the MEQ.

Results suggest that college students living at home may experience higher levels of CD, influenced by earlier weekday waketimes. While these results are cross-sectional, they suggest that encouraging students to adhere to consistent waketimes may be associated with better mental health.

PILOT STUDY OF A NOVEL APPROACH MANAGEMENT OF SLEEP ASSOCIATED PROBLEMS IN BREAST CANCER PATIENTS (MOSAIC) DURING CHEMOTHERAPY

Oxana Palesh, PHD, MPH¹, Natalie Solomon, PsyD², Elisa Hofmeister, n/a¹, jo Booil, n/a³, Erin L. Cassidy-Eagle, n/a¹, Pasquale F. Innominato, PHD, MD⁴, Sophie Fisher, BS¹, Hanyang Shen, n/a¹, Shelli Kesler, n/a⁵

¹Stanford University, Stanford, CA; ²PGSP- Stanford Consortium, Palo Alto, CA; ³Stanford University, Palo Alto, CA; ⁴North Wales Cancer Center, bangor, Wales, UK; ⁵University of Texas at Austin, Austin, TX

Objectives: This pilot RCT was conducted to assess the preliminary effects of Brief Behavioral Therapy for Cancer-Related Insomnia (BBT-CI) in comparison to a sleep hygiene pamphlet control, and to assess moderators of treatment effect in breast cancer patients undergoing chemotherapy.

Methods: Of 74 participants recruited, 37 were randomized to BBT-CI and 37 were randomized to the control condition. Trained staff members delivered the intervention during chemotherapy treatments to reduce burden on the patients. Insomnia was assessed with the Insomnia Severity Index (ISI), anxiety was assessed with the Spielberger State-Trait Anxiety Inventory (STAI), symptom burden was assessed with the Symptom Inventory (SI), and study staff recorded previous treatments and surgeries received by patients.

Results: Patients randomized to BBT-CI showed significantly greater improvements in their ISI scores than the sleep hygiene group. Additionally, several treatment moderators were identified. The effect of BBT-CI was greater among individuals with lower baseline state-trait anxiety, with previous surgery for cancer, and with higher baseline somatic symptom severity.

Conclusions: BBT-CI shows preliminary efficacy compared to the sleep hygiene handout on insomnia in cancer patients undergoing chemotherapy. A large phase III RCT needs to be conducted to replicate the preliminary findings.

SELF-REPORTED SYMPTOMS IN SUPPORT OF A NEWLY PROPOSED SLEEP DISORDER: TRAUMA-ASSOCIATED SLEEP DISORDER

John T. Freeman, Ph.D.¹, Raha F. Sabet, n/a², Vincent Mysliwiec, MD³, Christi S. Ulmer, PhD, DBSM⁴

¹Durham VA Healthcare System, Durham, NC; ²Durham VAMC, Durham, NC; ³Mysliwiec Medical Consulting, San Antonio, TX; ⁴Duke University Medical Center, Durham, NC

Introduction: Disruptive nocturnal behaviors such as dream reenactment have been observed following exposure to trauma. This has resulted in the proposal of a new parasomnia diagnosis, Trauma-Associated Sleep Disorder (TASD), in order to describe the clinical features of these cases and differentiate them from other parasomnias like REM Sleep Behavior Disorder (RBD). The purpose of the current project was to establish the relationship between self-reported symptoms consistent with TASD and combat exposure, trauma exposure, and PTSD.

Methods: Data was collected as part of the Veterans Affairs VISN-6 MIRECC Post-Deployment Mental Health (PDMH) Registry. The PDMH is a multisite study of military personnel who have served since September 11, 2001. A sample of 3876 active duty military and veterans completed a battery of measures, including the Pittsburgh Sleep Quality Index-Addendum (PSQI-A), Structured Clinical Interview for DSM-IV TR Axis I Disorders (SCID), Combat Exposure Scale (CES), and Traumatic Life Events Questionnaire (TLEQ). Key TASD criteria (e.g. trouble sleeping because of episodes of “acting out” dreams, and trouble sleeping because of memories or nightmares of a trauma) were examined using PSQI-A items to assess the association between PTSD and TASD.

Results: Among individuals with a current PTSD diagnosis, 30.9% endorsed symptoms consistent with TASD, compared to only 3.1% of those without PTSD (χ^2 (2, N = 3661) = 556.4, $p < .001$). TASD symptoms were significantly associated with serving in a warzone (χ^2 (1, N = 3858) = 49.4, $p < .001$), firing a weapon (χ^2 (1, N = 3858) = 140.2, $p < .001$), and being fired upon (χ^2 (1, N=3858) = 61.2, $p < .001$). TASD self-report was also significantly associated with depression, suicidality, combat exposure, and trauma exposure (all p 's < .001). Individuals who endorsed symptoms consistent with TASD were significantly younger ($M = 36.85 \pm 9.79$ years old) than those who did not ($M = 38.14 \pm 10.48$ years old) ($F = 6.017$, $p = .014$).

Discussion: In contrast to RBD, which occurs primarily in older males, the symptoms reported in our cohort of younger veterans and active duty military are more consistent with TASD and lend additional support to this newly proposed sleep disorder. Symptoms which may be frequently characterized as RBD, such as dream reenactment, are consistently more common among individuals with trauma diagnosis and history relative to those without. More research is needed to better understand TASD and whether behavioral sleep interventions may be beneficial in reducing their adverse impact on sleep quality.

BITTEN BY THE SYSTEM THAT CARED FOR THEM: THE IMPACT OF HEALTHCARE INSTITUTIONAL BETRAYAL ON PATIENTS' HEALTH BEHAVIOR

Fallon Richie, BA¹, Emma Lathan, MS², Candice Selwyn, PhD², Jennifer Langhinrichsen-Rohling, PhD³¹University of North Carolina at Charlotte, Concord, NC; ²University of South Alabama, Mobile, AL; ³University of North Carolina at Charlotte, Charlotte, NC

Institutional betrayal, a type of betrayal trauma that occurs when an individual's existing trust in and/or dependency on an institution is broken, has been linked to numerous negative health outcomes (Smith & Freyd, 2014). A healthcare organization may engage in behavior consistent with institutional betrayal by failing to respond supportively to patients' traumatic experiences, creating an environment in which reporting concerns is difficult, or minimizing a traumatic experience. Institutional betrayal in healthcare organizations may further traumatize patients and/or reduce trust in the healthcare system and individual providers. BITTEN (Lewis, Langhinrichsen-Rohling, Selwyn, & Lathan, 2019), a newly proposed applied theoretical model of trauma-informed healthcare, emphasizes the importance of considering the impact of institutional betrayal and trauma history on patients' trust of healthcare providers and subsequent health-related expectations and needs. The purpose of the present study was to test the BITTEN model of trauma-informed healthcare by examining the degree to which institutional betrayal and trust in provider predicted patient health behaviors in a sample of undergraduate students (N= 100; 63% White, 25% Black/African American; 81% female; mean age = 19.7 years). Regression analyses revealed main effects of institutional betrayal ($B = -.71$, $p < .05$) and trust in provider ($B = -.31$, $p < .05$) on patient health behaviors as well as an interaction effect between institutional betrayal and trust in provider on health behaviors ($B = .02$, $p < .05$); the overall model accounted for 16% of the variance in health behaviors, $F(3, 82) = 5.27$, $p < .01$. Specifically, participants who endorsed institutional betrayal and low provider trust engaged in more potentially detrimental health behaviors (i.e., withholding relevant medical information from providers and delaying seeking needed medical treatment). Importantly, those with high levels of resilience were more likely to trust their providers, $r = .32$, $p < .01$. Taken together, these results suggest that for patients who have a history of institutional betrayal, mistrust in their healthcare providers may play a large role in their subsequent health behaviors, potentially impacting adherence to medication and recommended behavioral interventions. Thus, facilitating the development of patients' resiliency may buffer against the negative effects of institutional betrayal on provider trust and subsequent health behaviors. Ultimately, this study demonstrates that the behaviors of the healthcare system as a whole, in addition to those of individual providers, may serve to facilitate or disrupt patient trust and subsequent health behaviors.

THE MEDIATING ROLE OF ANXIETY AND DEPRESSION IN THE RELATION BETWEEN NEIGHBORHOOD INCIVILITIES AND HEALTH OUTCOMES IN LATINOS

Natalia I. Heredia, PhD, MPH¹, Tianlin Xu, MPH², MinJae Lee, PhD³, Lorna McNeill, PhD, MPH⁴, Belinda Reininger, DrPH⁵¹The University of Texas MD Anderson Cancer Center, Houston, TX; ²University of Texas Health Science Center at Houston, Houston, TX; ³McGovern Medical School, UTHealth, Houston, TX; ⁴MD Anderson Cancer Center, Pearland, TX; ⁵UT Health School of Public Health, Harlingen, TX

Hispanic adults on the Texas-Mexico border have very high rates of metabolic conditions. Though neighborhoods may exert an influence on health, there is limited evidence that neighborhood environment is directly associated with metabolic conditions. However, neighborhood incivilities, such as crime, traffic or stray dogs, may be experienced as stress and manifested as depression or anxiety. The purpose of this study is to assess the relation of neighborhood incivilities with type 2 diabetes, metabolic syndrome, and a marker of chronic inflammation (c-reactive protein; CRP) and determine if depression and/or anxiety mediate the association. Participants were part of a randomized control trial. Adults were randomly-selected from a Hispanic cohort on the Texas-Mexico border. Through questionnaires, we assessed various neighborhood incivilities (Physical Activity Neighborhood Environment Survey), anxiety (Zung Self-Rating Anxiety Scale), and depression (CES-D). We use lab values to determine Type 2 diabetes, metabolic syndrome, and CRP. We evaluated associations between neighborhood environment and various health outcomes using univariable and multivariable mixed-effect model that accounts for within-subjects correlations. We also conducted a series of path analyses via structural equation models to determine the direct and indirect effects of neighborhood incivilities on mental and physical health outcomes. Participants (n=495) were mostly females (69.4%), without insurance (66.4%) and completed 8th grade (69%). After controlling for covariates, traffic (AOR=1.7, 95%CI 1.2-2.4, $p < 0.001$), crime (AOR=1.7, 95%CI 1.2-2.3, $p < 0.01$), and stray dogs (AOR=1.8, 95%CI 1.3-2.5, $p < 0.01$) were all significantly positively associated with anxiety, while only traffic was associated with depression (AOR=1.7, 95%CI 1.2-2.3, $p < 0.001$). Depression was associated with both type 2 diabetes (AOR=1.75, 95%CI 1.08-2.83, $p=.02$) and metabolic syndrome (AOR=1.72, 95%CI 1.21-2.43, $p < 0.05$). Anxiety was similarly associated with type 2 diabetes (AOR=2.01, 95%CI 1.24-3.25, $p < .001$) and metabolic syndrome (AOR=1.87, 95%CI 1.33-2.63, $p < .001$). We found that both stray dogs and traffic were associated with CRP via the indirect path of both depression and anxiety, while crime was associated with CRP via the indirect path of anxiety only. Our results indicate that while there is not a statistically significant direct effect of various neighborhood incivilities on metabolic conditions and inflammation, certain neighborhood incivilities may impact these health outcomes through depression and anxiety.

RELATIONSHIP BETWEEN ECONOMIC INSTABILITY AND READINESS FOR BEHAVIOR CHANGE AMONG LATINX HYPERTENSIVE PATIENTS

Abhiruchi Chaulagain, n/a¹, Karina Fing Castro, BS², Alondra Salazar, BS³, Brett Cervantes, BS⁴, Sergio Gago Masague, PhD⁵, Dara Sorkin, PhD⁶, David Kilgore, MD⁶, John Billimek, PhD⁶

¹University of California, Irvine, Buena Park, CA; ²University of California, Irvine, Long Beach, CA; ³University of California, Irvine, Santa Ana, CA; ⁴University of California, Irvine, Anaheim, CA; ⁵University of California, Irvine (UCI), Irvine, CA; ⁶University of California, Irvine, Irvine, CA

Behavior change is pivotal in the management of hypertension. Despite efforts to develop behavioral interventions for blood pressure (BP) control, patients—especially in low-income communities—face difficulty successfully implementing behavior change strategies. This study examines how acute economic stressors (food insecurity and financial distress) may impede low-income hypertensive patients from adopting lifestyle changes to control their BP.

In preparation for a clinical trial examining a health education intervention to increase adoption of BP lowering strategies in Latinx adults with uncontrolled hypertension, we administered a baseline questionnaire to patients at a federally qualified health center in southern California. Previously validated instruments like the USDA two-item food insecurity screening measure, the InCharge Financial Distress/Financial Well-Being Scale, and an adapted version of the Leonard Stages of Change questionnaire were used to assess food insecurity, financial distress, and the willingness for behavior change, respectively. Proportion of individuals contemplating or planning behavior change in the domains of diet, physical activity and medication adherence were compared between food secure vs. insecure, and low vs. high financial distress groups using Fisher's exact test.

Mean (\pm SD) age of the participants was 61.1 \pm 10.5. Of the participants (n=101), 72 (71%) were female, 81 (80%) were Latinx, and 79 (78%) reported household income < \$20,000 per year. Roughly 31% reported food insecurity and 71% reported high financial distress. Overall, 53 (52.5%) of the participants were contemplating and 25 (24.8%) were planning to initiate a new strategy to improve their diet. Likewise, 57 (57.6%) were contemplating and 17 (17.2%) planning to increase physical activity while 39 (39.0%) were contemplating and 21 (21.0%) planning to work to improve medication adherence. Food insecurity was associated with higher rates of contemplation (74.2% vs. 42.9%) but lower rates of planning (12.9% vs. 30.0%; $p = 0.016$) for dietary changes, but was not associated with readiness to make other changes. Similar patterns were observed for financial distress.

Among low-income, Latinx adults with uncontrolled hypertension, contemplation was more common than planning for several behavior changes for BP control. Readiness to adopt changes in diet was significantly lower in those facing acute economic stressors compared to other low-income adults.

COMMUNICATION AND PERCEPTIONS OF ENVIRONMENTAL INFLUENCES ON RESPIRATORY SYMPTOMS IN PATIENTS WITH ASTHMA AND COPD

Shivani Parikh, n/a¹, Kelly Henderson, MPH², Rahul Gondalia, PhD, MPH², Leanne Kaye, PhD, MPH, RD², Esther Rummelink, PhD neuroscience², Alesha Thompson, MPH³, Meredith Barrett, PhD²

¹Propeller Health, Palo Alto, CA; ²Propeller Health, San Francisco, CA; ³Council of State and Territorial Epidemiologists (CSTE), Atlanta, GA

Introduction: Environmental exposures like air pollution may play an important role in asthma and chronic obstructive pulmonary disease (COPD) morbidity. Despite public health efforts to educate at-risk communities, knowledge gaps still remain. Thus, we sought to understand: 1) perceived impact of environmental exposures on symptoms, 2) preferred information resources for environmental exposures like air pollution and pollen, and 3) whether responses varied by education or income among patients with asthma or COPD.

Methods: Users of a smartphone app (Propeller Health, WI) were invited to complete a brief electronic survey. Eligible patients had a self-reported history of asthma or COPD, were ≥ 18 years, and had been active on the app in the previous 60 days. Electronic consent was obtained from all enrolled patients. The survey consisted of 21 and 17 closed-ended questions for asthma and COPD, respectively. We conducted descriptive analyses, as well as chi-square tests to evaluate outcomes by education (\leq vs. $>$ some college) and annual household income ($<$ vs. \geq \$50,000).

Results: We analyzed data from 698 respondents (500 patients with asthma (mean age (SD) 37.8 (12.3)), 82% female, 59% some college or less, 47% income $<$ \$50k) and 198 patients with COPD (mean age (SD) 60.3 (9.1)), 62% female, 83% some college or less, 68% income $<$ \$50k). Patients perceived that pollen (93% for asthma vs. 86% for COPD), mold (89% vs. 85%), second-hand smoke (89% vs. 83%), and air pollution (84% for both) made their symptoms worse. Up to 47% of patients did not know that NO₂, O₃, SO₂ and PM were pollutants. Patients sought information about changes in air pollution through smartphone apps (66% for asthma vs. 63% for COPD) and televised programs (42% vs. 57%). Similarly, patients used apps (66% for asthma vs. 55% for COPD) and television (37% vs. 57%) to learn about daily pollen status. Few significant differences were identified by education or income.

Discussion: Patients with asthma and COPD perceived that environmental factors were related to their symptoms and sought out information about daily changes in air pollution and pollen via apps and televised programs. Further research is needed to understand perceptions of pollen influence among COPD patients, given that there is no known allergic phenotype in COPD. Largely, communication preferences did not differ by education level or income, suggesting that these information sources are accessible to a broad audience.

DISTRIBUTOR AGREEMENTS AND THE LOCATION AND
BRANDING OF UNHEALTHY PRODUCTS WITHIN FOOD STORES

Petrona Gregorio-Pascual, MA¹, Erika I. Romero, BS², Lukar Thornton, PhD³, Joel Gittelsohn, PhD⁴, Melissa N. Laska, PhD, RD⁵, Heather D'Angelo, PhD, MHS⁶, Kurt M. Ribisl, PhD⁷, Guadalupe X. Ayala, MA, PhD, MPH⁸

¹San Diego State University/ UC San Diego, Fallbrook, CA; ²San Diego State University School of Public Health, Murrieta, CA; ³Deakin University, Burwood, Victoria, Australia; ⁴Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ⁵University of Minnesota, Minneapolis, MN; ⁶University of Wisconsin-Madison Carbone Cancer Center, Madison, WI; ⁷UNC Gillings of Global Public Health, Chapel Hill, NC; ⁸San Diego State University, SAN DIEGO, CA

The food store environment refers to the availability, cost, placement and promotion of foods and beverages within a store. Marketing research has found that more energy dense, nutrient poor (i.e., unhealthy) products are placed at the point-of-sale to influence people's purchasing. Brand familiarity and availability also impact purchase decisions; thus, it is important to examine presence, placement, and branding of unhealthy products in food stores and how these relate to distributor agreements of unhealthy foods and beverages. This study examined the presence and branding of five product categories (e.g., sweet snacks, savory snacks, confectionary, frozen treats, and sugary beverages) in five in-store locations (e.g., front and back endcaps (of store aisles), cash registers, and other displays) as a function of distributor agreement type: formal (i.e., written contract) versus informal (i.e., verbal agreement or handshake). This cross-sectional study involved a single semi-structured interview with owners/managers and collection of store audit data in 72 small stores located in 4 major metropolitan US cities: Baltimore, MD; Durham, NC; Minneapolis/St. Paul, MN; and San Diego, CA. The audit protocol we used assessed the (a) presence (1) or absence (0), and (b) branding (yes=1, no=0) of five product categories by location: front and back endcaps, at the cash register(s), and other displays (e.g. coolers). Distributor agreement type was assessed through owner/manager report. Independent samples t-tests were conducted on SPSS to compare the mean percent of presence/branding of each product category by distributor agreement type. A higher percent of stores had savory snacks available at front endcaps when the stores had formal ($M = 66.9\%$, $SD = 32.8\%$) versus informal agreements ($M = 48.2\%$, $SD = 30.9\%$, $p < .04$). Moreover, a higher percent of stores had sugary beverages available at cash registers when the stores had informal ($M = 42.4\%$, $SD = 45.9\%$) versus formal agreements ($M = 18.2\%$, $SD = 39.2\%$, $p = .049$). Also, there was a higher percent of stores had sugary beverages available at other displays when the stores had informal ($M = 65.4\%$, $SD = 20.6\%$) versus formal ($M = 52.8\%$, $SD = 23.1\%$) agreements ($p < .04$). No other relationships were statistically significant by distributor agreement type ($p > .05$). Distributor agreements exist in small food stores and these agreements appear to play a role in the presence, placement and the branding of some but not all unhealthy foods and beverages. Understanding how agreements influence presence, placement and branding throughout the store is important due to the ubiquity of small food stores in low income communities, and their importance as a source of food and beverages.

THE ASSOCIATIONS BETWEEN PERCEIVED AND OBJECTIVELY
MEASURED AIR QUALITY AMONG VULNERABLE AGING ADULTS
IN SAN FRANCISCO BAY AREA

Jenna Hua, RD, MPH, PhD¹, Edmund Seto, PhD², Ines Campero, BA³, Dulce Garcia, N/A¹, Elena Austin, ScD², Ching-Hsuan Huang, n/a², Monica Done, Masters of Science⁴, Isela Blanco-Velazquez, BS⁵, Fernando Fierros, N/A⁶, Nancy Carmona, MPH², Abby C. King, PhD⁷

¹Stanford Prevention Research Center, Palo Alto, CA; ²University of Washington, Seattle, WA; ³Stanford University School of Medicine, Palo Alto, CA; ⁴University of California, Los Angeles, San Jose, CA; ⁵Stanford Medicine, Palo Alto, CA; ⁶Stanford University, Santa Clara, CA; ⁷Stanford University School of Medicine, Stanford, CA

Air pollution is a major public health issue that disproportionately affects marginalized populations. Most studies rely on sparse data from air monitoring networks rather than more precise cohort locations, and few have examined the linkages between perceived air quality, and behavior. Our study examined the relationships between perceived and objectively measured air quality in a cohort of marginalized seniors using adapted Air Quality Perception Scale (AQP) and locally measured, next-generation low-cost air quality monitor data.

As part of the NIH-funded physical activity intervention, *Steps for Change*, that focuses on vulnerable aging adults residing in affordable housing sites in San Francisco Bay Area, 14 low-cost particle monitors (Edimax Airbox AI-1001W V2, Santa Clara, CA) were deployed at 7 sites (2 monitors per site) over a 1-month period. PM_{2.5} and PM₁₀ concentrations were collected at each site at 6-minute intervals. Two monitors were collocated at each site in order to provide more reliable monitoring of PM concentrations. A total of 121 participants (83.5% female, mean age of 70.6 years old) answered the 25-question AQP. Associations between each AQP question and mean PM_{2.5} and PM₁₀ concentrations were evaluated.

Generally, the PM concentrations from the two monitors at each site were found to be positively correlated with each other. Average PM_{2.5} and PM₁₀ among sites ranged between 4.4 to 14.9 µg/m³ and 6.7 to 26.9 µg/m³, respectively. AQP questions with the greatest associations with PM_{2.5} were those that concerned nose irritation, difficulty breathing, airing out of homes, and avoiding opening windows. For PM₁₀, three AQP questions with the greatest associations included closing shutters and blinds at home, avoiding opening windows and feeling the need to wash hands or face. Differences in perceptions were consistent with larger PM₁₀ sized particles contributing to visible, dirty dust in homes, while smaller PM_{2.5} sized particles, which can travel deeper into the lungs, being related to perceived respiratory issues.

These findings suggest that some air quality perceptions of older adults are corroborated by objective PM measurements. While this is among the first studies to use low-cost sensors to systematically measure local air quality in and around older adult affordable housing sites, further research is needed to ascertain whether these perceptions alter willingness to engage in physical activity.

RELIGIOSITY/SPIRITUALITY AND CARDIOVASCULAR HEALTH: THE AMERICAN HEART ASSOCIATION LIFE'S SIMPLE 7 IN AFRICAN-AMERICANS

LaPrincess Brewer, MD, MPH¹, Janice Bowie, PhD², Joshua Slusser, BS³, Christopher Scott, MS³, Lisa Cooper, MD, MPH⁴, Sharonne Hayes, MD¹, Christi A. Patten, PhD¹, Mario Sims, PhD, MS⁵

¹Mayo Clinic College of Medicine, Rochester, MN; ²Johns Hopkins Bloomberg School of Public Health, Baltimore, MD; ³Mayo Clinic, Rochester, MN; ⁴Johns Hopkins School of Medicine, Baltimore, MD; ⁵University of Mississippi Medical Center, Rochester, MN

Introduction: African Americans (AAs) have a low prevalence of ideal cardiovascular health (CVH) (by the American Heart Association Life's Simple 7-LS7) placing them at a disproportionately high risk for CVD. Religiosity and spirituality (R/S), major coping mechanisms in the lives of AAs, have been associated with their health behaviors; however, little research has studied their effects on CVH. We examined the relationship between multiple R/S measures and CVH as assessed by the LS7 components (physical activity [PA], diet, smoking, body mass index [BMI], blood pressure [BP], cholesterol, glucose) and LS7 composite score classified as poor, intermediate and ideal in AAs.

Hypothesis: Greater levels of R/S are positively and independently associated with achieving intermediate/ideal levels of LS7 components and LS7 composite score.

Methods: Using data from the Jackson Heart Study, we examined associations of multiple domains of religiosity (religious attendance, private prayer, religious coping) and spirituality (theistic, non-theistic) with LS7 components and LS7 composite score among AAs. Multivariable logistic regression assessed the odds of achieving intermediate/ideal levels of CVH adjusted for socio-demographic, behavioral, and biomedical factors.

Results: Participants (N=2,967) were on average 54 (SD=12.3) years of age; 66% were women. Participants reported high religiosity (81% organized religion) and spirituality (Daily Spiritual Experiences Score 29.2 (4.7) [Range 6, 36]). Higher *religious attendance* was associated with increased odds (odds ratio [OR] 95% confidence interval-CI) of achieving intermediate/ideal levels for BP, PA, smoking, diet and LS7 composite score (OR [95% CI]: 1.12 [1.01-1.24]; 1.16 [1.06-1.26]; 1.50 [1.34-1.68]; 1.10 [1.01-1.20]; 1.15 [1.06-1.26], respectively). *Private prayer* was associated with increased odds of achieving intermediate/ideal levels for smoking and diet (OR [95% CI]: 1.24 [1.12-1.39]; 1.12 [1.03-1.22] respectively). *Religious coping* was associated with increased odds of achieving intermediate/ideal levels for PA, smoking, diet and LS7 (OR [95% CI]: 1.18 [1.08-1.28]; 1.32 [1.18-1.48]; 1.10 [1.01, 1.20]; 1.14 [1.04-1.24], respectively). *Theistic spirituality* was associated with increased odds of achieving intermediate/ideal levels for smoking (OR [95% CI]: 1.27 [1.13-1.43]). *Non-theistic spirituality* was associated with increased odds of achieving intermediate/ideal levels for PA, smoking, diet and LS7 (OR: 1.15 [1.06-1.25]; 1.38 [1.23, 1.55], respectively).

Conclusion: Our study suggests that AAs with higher R/S are more likely to achieve ideal CVH across multiple LS7 components. Promotion and reinforcement of R/S through lifestyle interventions could reduce overall cardiometabolic risk for CVD in this group.

LONGITUDINAL EFFECTS OF FOOD INSECURITY ON MEN'S PERPETRATION OF PARTNER VIOLENCE IN SOUTH AFRICA

Abigail M. Hatcher, PhD¹, Torsten Neilands, PhD², Dumisani Rebombo, n/a³, Sheri D. WEISER, n/a⁴, Nicola Christofides, PhD⁵

¹University the Witwatersrand, JOHANNESBURG, Gauteng, South Africa; ²University of California, San Francisco, San Francisco, CA; ³Sonke Gender Justice, Johannesburg, Gauteng, South Africa; ⁴University of California, San Francisco, CA; ⁵University of the Witwatersrand, Johannesburg, Gauteng, South Africa

Introduction: Intimate partner violence (IPV) is a leading cause of morbidity and mortality globally, with one in three women experiencing it in their lifetime. Although poverty is widely viewed as a structural driver of IPV, few studies have examined how changes in poverty influence men's IPV perpetration. One sensitive marker of poverty is food security, or the ability of households to obtain adequate nutrition. Food security is associated with IPV perpetration in two published cross-sectional studies, yet it is unclear whether this is a longitudinal relationship.

Methods: We followed a cohort of 2,479 men living in a peri-urban settlement near Johannesburg, South Africa from 2016-2018. Using self-completed audio-assisted questionnaires, men responded at baseline, 12 months, and 24 months to questions around current food security, childhood conditions, and IPV perpetration. We used cross-lagged dynamic panel modeling to assess whether food insecurity changes influenced men's IPV perpetration over time.

Results: A majority (54.4%) of men reported perpetrating IPV at baseline, but this proportion reduced over time (47.1% and 36.0% reported IPV perpetration at midline and endline, respectively). Roughly half (51.2%) of participants reported food insecurity at baseline, and this stayed consistent at midline and endline (50.3% and 55.9%, respectively). Food insecurity was higher among those men perpetrating IPV (58.3%) than among those who used no violence (42.3%, $p < 0.001$). In a cross-lagged dynamic panel model, food insecurity predicted men's use of IPV one year later, with each one-point increase in food insecurity associated with a 20% increase in IPV intensity. This longitudinal association persisted in a final model controlling for housing status (as another indicator of socio-economic status), men's exposure to childhood abuse (as a time invariant predictor), and potential bidirectionality (IPV leading to food security status). There was no evidence to suggest that IPV perpetration led to later food insecurity. In the final model, food insecurity was associated with a small, but significant, longitudinal impact on men's IPV use (standardized coefficient=0.10, $p=0.035$) and the model fit indices were strong (RMSEA=0.016, CFI=0.998).

Conclusions: Food insecurity had small but persistent longitudinal effects on men's perpetration of IPV in a peri-urban settlement in South Africa. Addressing IPV perpetration will require examination of broader structural challenges, such as livelihoods and food security, particularly in settings with endemic poverty. Future interventions should consider food security and livelihood strategies to improve health outcomes for both women and men.

PREDICTORS OF KIDNEY TRANSPLANT EVALUATION CLINIC ATTENDANCE

C. Graham Ford, MS¹, Yuridia Leyva, MS², Yiliang Zhu, PhD³, Emilee J. Crowell, BA⁴, Chethan Puttarajappa, MD, MS⁵, Mary Amanda Dew, PhD⁴, Mark Unruh, MD, MS³, Yue-Harn Ng, MD⁶, Larissa Myaskovsky, PhD⁷

¹University of New Mexico, Albuquerque, NM; ²University of New Mexico Health Sciences Center, Albuquerque, NM; ³University of New Mexico School of Medicine, Albuquerque, NM; ⁴University of Pittsburgh, Pittsburgh, PA; ⁵University of Pittsburgh, SEWICKLEY, PA; ⁶University of New Mexico, Albuquerque, NM; ⁷Center for Healthcare Equity in Kidney Disease, UNM HSC, Albuquerque, NM

Introduction: Clinic non-attendance is a significant healthcare challenge which is associated with worse health outcomes for patients and increased burden for clinic staff and healthcare providers. During a clinical trial testing a streamlined kidney transplant evaluation (KTE) approach (completing all testing on the same day as the KTE versus the standard approach of testing that spans weeks to months), we examined whether ambivalence about receiving a transplant and other psychosocial factors predict KTE clinic non-attendance.

Methods: All patients completed an interview before their first scheduled KTE, including transplant ambivalence (i.e., “worry that transplant will do more harm than good”, rated from 1=lower to 6=greater worry), demographics (e.g., income, education), medical factors (e.g., duration of dialysis, having an identified living donor), and psychosocial factors (e.g., social support, depression). We used logistic regression analysis to determine the unique relationship between transplant ambivalence and KTE clinic non-attendance, controlling for demographic, medical, and psychosocial covariates. Variables were examined for multicollinearity before proceeding.

Results: Our sample (N=1,119) was 37% female, median age 59.4 years (IQR=49.2-67.5), 45% had income < \$25,000, 47% were ≤ high school graduate, 48% were married, and 44% had public insurance. Of note, 142 (13%) never attended a KTE clinic appointment. Adjusted multivariable modeling showed that the transplant ambivalence question (worry that transplant will do more harm than good) significantly predicted KTE non-attendance: for every 1 point increase on the item, the odds of KTE non-attendance increased by 19% (OR= 1.19; p=.05; 95% CI =1.00-1.43). Two medical factors approached statistical significance: patients without an identified living donor had higher odds of KTE non-attendance than patients having an identified living donor (OR= 1.64; p=.08; CI=.94-2.87); and patients on dialysis also had higher odds of KTE non-attendance than patients who had never been on dialysis (OR≥2.19; p=.08; 95% CI 1.08-4.46). No other variables approached significance in the adjusted model.

Conclusions: Prospectively assessing for ambivalence about kidney transplant may help identify patients who would benefit from additional support from the clinic team throughout the kidney transplant referral and evaluation process (e.g., outreach to emphasize the importance of transplant). Future research is needed to validate the use of a one-item measure to predict clinic attendance and subsequent interventions. Adding a single question regarding ambivalence during clinic scheduling may be a cost-effective and simple innovation to help address a difficult healthcare challenge.

SOCIAL ISOLATION, SOCIAL SUPPORT, AND TREATMENT DELAYS IN BREAST CANCER PATIENTS IN AN INTEGRATED HEALTH CARE SYSTEM

Candace Kroenke, ScD, MPH¹, Anita Stewart, PhD², Marilyn L. Kwan, PhD³, Scarlett Gomez, PhD, MPH⁴, Isaac J. Ergas, MPH³, Janise M. Roh, MSW, MPH³, Tatjana Kolevska, MD⁵, Marion Lee, PhD⁶, Lawrence Kushi, ScD¹

¹Kaiser Permanente Northern California, Division of Research, Oakland, CA; ²University of California San Francisco, San Francisco, CA; ³Kaiser Permanente Division of Research, Oakland, CA; ⁴University of California, San Francisco, San Francisco, CA; ⁵Kaiser Permanente, Vallejo, CA; ⁶University of California San Francisco, San Francisco, IN

Purpose: Women diagnosed with breast cancer with greater social support have better survival but it is unclear whether this might be due in part to suboptimal treatment. We evaluated associations of social support and delays to initial surgery or to adjuvant chemotherapy in a breast cancer cohort from Kaiser Permanente Northern California (KPNC).

Methods: This study included 4,056 women from the Pathways Study diagnosed from 2005-2013 with stages I-IV breast cancer, had surgery within the first year after diagnosis, and responded to questions about social ties, personal support using the Medical Outcomes Study Social Support survey, and clinician support from the Interpersonal Processes of Care survey approximately two months following diagnosis. Level of social integration was computed from a published index of social ties. The analysis of chemotherapy delays included a subset of patients who also received adjuvant chemotherapy (N=1,721) and excluded women with neoadjuvant chemotherapy. Time to surgery was defined from the date of diagnosis to the date of definitive surgery in the KPNC Cancer Registry. Time to chemotherapy was defined from the date of diagnosis or definitive surgery to the date of chemotherapy initiation. We used logistic regression to evaluate associations with >30 day delays to surgery and >90 day (from diagnosis) or >60 day (from surgery) delays to chemotherapy and linear regression to evaluate associations with continuous outcomes.

Results: Twenty-five percent had surgery delays and 18% had chemotherapy delays (26% from the date of surgery) from time of diagnosis. Women in the lowest tertile of personal social support were more likely to have surgery (OR=1.35, 95% CI: 1.11-1.63, p-continuous=0.003) and chemotherapy (OR=1.49, 95% CI: 1.08-2.04, p-continuous=0.04) delays compared to women in the highest tertile. Women who reported low clinician support were also more likely to have surgery (OR=1.28, 95% CI: 1.06-1.55, p-continuous=0.0006) but not chemotherapy (p-continuous=0.73) delays compared to women with high clinician support. We noted suggestive but nonsignificant associations of social isolation with delays. However, women in the lowest tertiles of personal social support, clinician social support, and social integration had a nearly two-fold (OR=1.96, 95% CI: 1.30-2.95) higher likelihood of surgery delays (p-value, test for three-way interaction=0.08). Associations with chemotherapy delays from the time of diagnosis were qualitatively similar to associations with surgery delays but we noted no significant associations with chemotherapy delays when delays were measured from the date of surgery.

Conclusions: Women with low levels of social support had greater delays to surgery and chemotherapy, the latter due to surgery delays. It is important to identify patients with low support and provide support needed to ensure timely care.

EXPLORING THE RELATIONSHIP BETWEEN DIABETES, STRESS, AND SELF-MANAGEMENT TO INFORM CHRONIC DISEASE PRODUCT DEVELOPMENT

Jessica S. Yu, Ph.D.¹, Tong Xu, Master², Bobbie A. James, MStat³, Wei Lu, PhD⁴, Julia Hoffman, PsyD⁵¹Livongo, San Ramon, CA; ²Livongo Health Inc, Sunnyvale, CA; ³Livongo Health, Mountain View, CA; ⁴Livongo, Mountain View, CA; ⁵Livongo Health, San Jose, CA

Background: Research has shown that among people with diabetes mellitus (DM), those who have difficulty coping with stress are less likely to engage in self-management behaviors and more likely to exhibit poor glycemic control and be at risk for diabetes complications.

Objective: To explore the relationship between stress and sequelae of DM among adults enrolled in a digital DM program (Livongo), in order to inform intervention and product development. Livongo provides enrolled members with a cellular-connected blood glucose (BG) meter, glucose test supplies, and digital one-on-one coaching.

Methods: The study included 3263 members, under age 65, with DM who had access to Livongo between June 2015 and August 2018. Data were collected over 24 months. Data collected at enrollment included demographics, HbA1c, duration of illness, diabetes distress (measured by DM Distress Scale), diabetes empowerment (measured by DM Empowerment Scale), and insulin use. Data collected over the 24 months included behavioral health (BH) diagnosis, BH utilization, and BG readings with self-reported stress. Members were grouped based on presence of self-reported stress and BH diagnosis/utilization. Analysis of variance (ANOVA) was used to compare continuous variables across groups, and Chi-Square test was used for categorical data comparisons.

Results: 1808 members (55%) endorsed stress at the time of at least 1 BG reading; of these, 940 (52%) also had at least 1 BH diagnosis/intervention. Members who reported stress, compared to those who did not, had greater diabetes distress (2.6 ± 1.25 v. 2.1 ± 1.11 , $p < 0.001$), lower diabetes empowerment (3.8 ± 0.79 v. 3.9 ± 0.79 , $p < 0.001$), higher insulin usage (35.1% v. 28.9% , $p < 0.001$), and poorer glycemic control throughout the study (ratio of BG readings > 180 mg/dL = 0.25 ± 0.25 v. 0.21 ± 0.26 , $p < 0.001$). Members who reported stress and had at least 1 BH diagnosis/intervention, compared to those who did not, had higher body mass index (34.7 ± 7.67 v. 32.8 ± 7.36 , $p < 0.001$) and duration of illness (9.0 ± 8.6 years v. 8.2 ± 7.86 , $p = 0.007$).

Conclusion: Stress is common among people with DM and associated with greater diabetes distress, poorer glycemic control, and worse physical health regardless of the co-occurrence of a BH condition. Digital products that focus on the whole person and integrate stress management tools, BH support, and chronic disease treatment have the promise to improve disease-specific and psychosocial outcomes.

EXAMINING ON- AND OFF-DUTY STRESS AND TIREDNESS IN FIREFIGHTERS USING ECOLOGICAL MOMENTARY ASSESSMENT

Jimikaye B. Courtney, M.S.¹, Josiane Broussard, PhD¹, Tiffany Lipsey, M. Ed.¹, Barry Braun, PhD¹, Kimberly Henry, PhD¹, Tracy Nelson, MPH, PhD¹, Kaigang Li, PhD¹¹Colorado State University, Fort Collins, CO

Firefighters are at high risk for developing cardiovascular disease (CVD), with CVD accounting for 45% of on-duty deaths in firefighters. Psychological stressors and sleep disturbances may be mechanisms involved in this increased CVD risk among firefighters. However, few studies have captured acute stress or tiredness levels or dynamic changes in stress and tiredness in a real world setting in firefighters, limiting our ability to examine relationships between stress, sleep and CVD risk. Therefore, we conducted a pilot study using ecological momentary assessment (EMA) to characterize the relationship between acute stress and tiredness in firefighters on- and off-duty. A convenience sample of 42 (38 male, 4 female; age range: 21–61 years) full-time, career Colorado firefighters completed three, eight-day periods of EMA assessments via personal smartphones. Firefighters were sent seven surveys, at random, between 8AM and 9PM on each day of EMA assessments. EMA surveys assessed current duty status (on- or off-) and stress and tiredness on a 0–100 visual analogue scale. Mixed-effects location scale models were used to examine between-subject (B-S) and within-subject (W-S) effects of duty status on acute stress and tiredness, and heterogeneity in the mean and variability of stress and tiredness. Effects of sex, age, race/ethnicity, years in the fire service, and shift type (24 or 48 hour shifts) were examined. Model fit was tested using log likelihood difference tests and analyses were completed using the MIXREGLS program which provides estimates for mixed-effects location scale models. Firefighters demonstrated significant heterogeneity in mean stress ($\mu=0.82$, $p < .001$) and stress variability ($\omega=0.81$, $p < .001$). Stress was significantly increased on-duty ($b=5.12$, $p < .001$), as was B-S variance in stress ($\alpha=0.56$, $p < .001$). There were no B-S effects of shift type on variance in stress. There were no W-S effects of duty status or shift type on variance in stress. Firefighters demonstrated significant heterogeneity in mean tiredness ($\mu=0.52$, $p < .001$) and tiredness variability ($\omega=0.65$, $p < .001$). Being on-duty ($b=1.58$, $p=.004$) and being female ($b=14.22$, $p=.007$) significantly increased tiredness. There were no B-S effects of duty status, sex, or years in the fire service on variance in tiredness. There were significant W-S effects of being on-duty ($\tau=-0.24$, $p < .001$) and serving more than the average number of years in the fire service ($\tau=-0.03$, $p=.032$) on variance in tiredness. Our findings indicate being on-duty increases acute stress and tiredness in firefighters. Serving more years in the fire service decreased W-S variability in tiredness, suggesting firefighters with more years of experience may become accustomed to the effects of firefighting on tiredness, thus demonstrating lesser variability in W-S tiredness compared to firefighters with fewer years in the fire service.

STRESSORS FOR RETURNING CITIZENS LIVING WITH HIV AND SUBSTANCE USE PROBLEMS: A MIXED METHODS ANALYSIS

Alexandra Wimberly, PhD¹, Orrin D. Ware, MSW, MPH², Alicia T. Bazell, n/a³, Erica Sibinga, MD, MHS⁴¹University of Maryland School of Social Work, Baltimore, MD; ²University of Maryland, Baltimore, MD; ³University of Maryland, School of Social Work, Columbia, MD; ⁴Johns Hopkins School of Medicine, Baltimore, MD

Background: People in reentry from prison or jail (returning citizens) experience high rates of substance use disorders and HIV. During reentry, a period known to be challenging, there are high rates of return to substance use and difficulties adhering to antiretroviral therapy (ART). To better understand this challenging period, this mixed methods analysis asks: What are the leading sources of stress among a sample of returning citizens living with HIV and substance use problems? Answering this question can inform stress-management interventions.

Methods: The 75 participants were largely male (68%), African American (78%), and had an average age of 44. Fifty-eight semi-structured qualitative interviews were completed. Interviews sought to identify stressors experienced during reentry. Transcribed interviews were analyzed in NVivo, guided by a qualitative descriptive methodology. Thematic analysis was used to identify themes. Analysis of demographics was conducted to provide a more complete picture of variables that impact stress. A multiple regression analysis assessed whether age, substance use, length of time since last incarceration, length of time living with HIV, length of previous incarceration, adherence to ART and substance use treatment involvement predicted self-reported stress on the Perceived Stress Scale.

Results: Qualitative analysis found that living with HIV was a stressor due to confronting one's mortality, carving out a new identity, and difficulties establishing relationships. Adhering to ART was an additional stressor because it was a reminder of one's status and could reveal one's status to others. While people realized the necessity of disclosing their HIV status in the context of intimate relationships, it was difficult to do, and some forewent initiating partnerships due to fear of rejection and public exposure. Quantitative analysis revealed a significant regression equation ($R^2=0.23$, $F(7, 60)=2.58$, $p<.05$), with the longer a person had been in the community since release from prison or jail ($b=-0.02$, $P<.01$) and the longer a person had been living with HIV ($b=-0.30$, $p<.05$) each predicting less stress.

Conclusions and Implications: This sample of returning citizens living with HIV and substance use problems experienced stress related to living with HIV, which interfered with establishing relationships. While it was recognized that ART was important for survival, taking these medications was stressful because it was a reminder of one's status. It may be that participants had not had the time or support to accept and cope with their HIV status, an idea supported by the finding that people who had been in the community and/or were living with HIV longer had less stress. These findings highlight the need for supportive services in reentry regarding coping with living with HIV.

GENDER DIFFERENCES IN POST-TRAUMATIC STRESS, MINDFULNESS, AND COPING IN CAREGIVERS OF NEUROCRITICAL CARE PATIENT

Melissa V. Gates, BA¹, Ethan G. Lester, PhD², Ann Lin, BS³, Emma Meyers, BA⁴, Danielle Salgueiro, BSN, RN⁵, Tara M. Tehan, RN⁵, Jonathan Rosand, MD⁵, Ana-Maria Vranceanu, PhD⁶¹Massachusetts General Hospital, South Boston, MA; ²Massachusetts General Hospital, Boston, MA; ³Albany Medical College, Boston, MA; ⁴Harvard Medical School, Boston, MA; ⁵Massachusetts General Hospital - Department of Neurology, Boston, MA; ⁶Massachusetts General Hospital/Harvard Medical School, Boston, MA

Background/Objective: Informal caregivers (i.e., friends and family providing the bulk of support) of neurosciences intensive care unit (Neuro-ICU) patients are at a heightened risk for developing chronic post-traumatic stress (PTS). While resiliency factors show promise in protecting against chronic PTS development, the effect that resiliency factors and caregiver gender have on PTS at hospitalization and overtime has not been explored. This prospective study examined main effects and interactions of resiliency and gender on the trajectory of PTS symptom severity at three timepoints (baseline at hospitalization, 3, and 6 months post-discharge).

Methods: Caregivers ($N=96$; X biologically female; mostly White, well-educated, and coupled) were enrolled from a major northeastern academic medical center. Caregivers reported sociodemographic variables, resiliency factors (mindfulness, self-efficacy, intimate care, preparedness for caregiving, and coping) and PTS symptom severity in the hospital (baseline), and PTS symptom severity (only) post-discharge (3 and 6 months).

Results: Baseline PTS was predictive of higher PTS symptom severity at 3 and 6 months. Caregivers with high (vs. low; median split = low < 34; high ≥ 34) levels of mindfulness, coping (low < 32; high ≥ 32), and self-efficacy (low < 88.67; high ≥ 88.67) had lower PTS symptoms at baseline (i.e., $p=0.003$, $p=0.002$, $p=0.005$, respectively). No additional main effects for caregiver gender or resiliency were found at 3 or 6 months. A significant interaction between mindfulness and gender, as well as intimate care and gender were seen for PTS at 3 and 6 months. At 3 months, we found a significant interaction of mindfulness and caregiver gender onto PTS, $F(1, 71)=4.68$, $p<0.03$, $\eta^2=0.06$, with males high in mindfulness having lower PTS symptom severity ($M=26.15$, $SE=2.34$) compared to females with high mindfulness ($M=33.24$, $SE=1.95$), $F(1, 71)=5.80$, $p<0.019$, $\eta^2=.076$. Males low in mindfulness had higher PTS symptom severity ($M=29.73$, $SE=2.39$) than females low in mindfulness ($M=27.85$, $SE=1.89$), $F(1, 71)=.372$, $p<.544$, $\eta^2=0.005$. Furthermore, we found a significant interaction between intimate care and caregiver gender on PTS at 6 months $F(1, 66)=4.69$, $p<0.034$, $\eta^2=0.066$, with male caregivers with high intimate care reporting low levels of PTS symptom severity ($M=24.49$, $SE=2.31$), as compared to female caregivers ($M=32.25$, $SE=1.85$), ($M=32.25$, $SE=1.85$), $F(1, 66)=4.35$, $p<0.041$, $\eta^2=0.062$.

Conclusions: Findings highlight the importance of assessing and addressing PTS in caregivers of patients hospitalized in the Neuro-ICU. Interventions focused on teaching resiliency skills before the patients get discharged may be able to prevent chronic PTS in caregivers. Males may particularly benefit from interventions focused on increasing mindfulness and intimate care.
